- Building a 4D Application

## Copyrights and Legal notices

---

# Preface

4D has its own programming language. This built-in language, consisting of more than 1000 commands, makes 4D a powerful development tool for database applications on desktop computers. You can use the 4D language for many different tasks—from performing simple calculations to creating complex custom user interfaces. For example, you can:

- Programmatically access any of the record management editors (order by, query, and so on),
- Create and print complex reports and labels with the information from the database,
- Communicate with other devices,
- Manage documents,
- Import and export data between 4D databases and other applications,
- Incorporate procedures written in other languages into the 4D programming language.

The flexibility and power of the 4D programming language make it the ideal tool for all levels of users and developers to accomplish a complete range of information management tasks. Novice users can quickly perform calculations. Experienced users without programming experience can customize their databases. Experienced developers can use this powerful programming language to add sophisticated features and capabilities to their databases, including file transfer and communications. Developers with programming experience in other languages can add their own commands to the 4D language.

The 4D programming language is expanded when any of the 4D modules are added to the application. Each module includes language commands that are specific to the capabilities they provide.

## About the Manuals

The manuals described here provide a guide to the features of both 4D and 4D Server. The only exception is the 4D Server Reference, which describes features exclusive to 4D Server.

- The Language Reference is a guide to using the 4D language. Use this manual to learn how to customize your database by incorporating 4D commands and functions.
- The Design Reference provides detailed descriptions of the editors and tools available in this environment.
- The Self-training manual leads you through example lessons in which you create and use a 4D database. These examples provide hands-on experience and help you become familiar with the concepts and features of 4D and 4D Server.
- The 4D Server Reference, which is included only in the 4D Server package, is a guide to managing multi-user databases with 4D Server.

## About this Manual

This manual describes the 4D language. It assumes that you are familiar with terms such as table, field, and form. Before you read this manual, you should:

- Use the Self-training manual to work through the database example.
- Begin creating your own databases, referring to the Design Reference manual when necessary.
- Increase your knowledge by studying that numerous demo and example databases that are available on the 4D Web site (*http://www.4d.com*).

## Writing conventions

In this manual, several writing conventions are used:

- Following the example of the 4D Method editor, commands are written in all caps using special characters, e.g.: **CLOSE DOCUMENT**. Functions (commands that return a value) start with a capital letter and continue in lower case, e.g.: **Change string**.
- In the command syntax, the { } characters (braces) indicate optional parameters. For example, **SET DEFAULT CENTURY (century{; pivotYear})** means that the *pivotYear* parameter may be omitted when calling the command.

- In the command syntax, the | character indicates an alternative. For example, **Table (tableNum | aPtr)** indicates that the function accepts either a table number or a pointer as parameter.
- In certain examples in this documentation, a line of code may be continued onto the following line(s) due to lack of space. However, you should type these examples as a single line of code without using carriage returns.

## Where to go from here?

If you are reading this manual for the first time, read the **Introduction** section.

# Introduction

This topic introduces you to the 4D programming language. The following topics are discussed:

- What the language is and what it can do for you,
- How you will use methods,
- How to develop an application with 4D.

These topics are covered here in general terms; they are covered in greater detail in other sections.

## What is a Language?

The 4D language is not very different from the spoken language we use every day. It is a form of communication used to express ideas, inform, and instruct. Like a spoken language, 4D has its own vocabulary, grammar, and syntax; you use it to tell 4D how to manage your database and data.

You do not need to know everything in the language in order to work effectively with 4D. In order to speak, you do not need to know the entire English language; in fact, you can have a small vocabulary and still be quite eloquent. The 4D language is much the same—you only need to know a small part of the language to become productive, and you can learn the rest as the need arises.

## Why Use a Language?

At first it may seem that there is little need for a programming language in 4D. In the Design environment, 4D provides flexible tools that require no programming to perform a wide variety of data management tasks. Fundamental tasks, such as data entry, queries, sorting, and reporting are handled with ease. In fact, many extra capabilities are available, such as data validation, data entry aids, graphing, and label generation.

Then why do we need a 4D language? Here are some of its uses:

- Automate repetitive tasks: These tasks include data modification, generation of complex reports, and unattended completion of long series of operations.
- Control the user interface: You can manage windows and menus, and control forms and interface objects.
- Perform sophisticated data management: These tasks include transaction processing, complex data validation, multi-user management, sets, and named selection operations.
- Control the computer: You can control serial port communications, document management, and error management.
- Create applications: You can create easy-to-use, customized databases that run in the Application environment.
- Add functionality to the built-in 4D Web Services: Create dynamic HTML pages in addition to those automatically translated from forms by 4D.

The language lets you take complete control over the design and operation of your database. 4D provides powerful “generic” editors, but the language lets you customize your database to whatever degree you require.

## Taking Control of Your Data

The 4D language lets you take complete control of your data in a powerful and elegant manner. The language is easy enough for a beginner, and sophisticated enough for an experienced application developer. It provides smooth transitions from built-in database functions to a completely customized database.

The commands in the 4D language provide access to the standard record management editors. For example, when you use the **QUERY** command, you are presented with the Query Editor (which can be accessed in the Design mode using the **Query** command in the **Records** menu. You can tell the **QUERY** command to search for explicitly described data. For example, **QUERY** *([People];[People]Last Name="Smith")* will find all the people named Smith in your database.

The 4D language is very powerful—one command often replaces hundreds or even thousands of lines of code written in traditional computer languages. Surprisingly enough, with this power comes simplicity—commands have plain English names. For example, to perform a query, you use the **QUERY** command; to add a new record, you use the **ADD RECORD** command.

The language is designed for you to easily accomplish almost any task. Adding a record, sorting records, searching for data, and similar operations are specified with simple and direct commands. But the language can also control the serial ports, read disk documents, control sophisticated transaction processing, and much more.

The 4D language accomplishes even the most sophisticated tasks with relative simplicity. Performing these tasks without using the language would be unimaginable for many.
Even with the language's powerful commands, some tasks can be complex and difficult. A tool by itself does not make a task possible; the task itself may be challenging and the tool can only ease the process. For example, a word processor makes writing a book faster and easier, but it will not write the book for you. Using the 4D language will make the process of managing your data easier and will allow you to approach complicated tasks with confidence.

## Is it a "Traditional" Computer Language?

If you are familiar with traditional computer languages, this section may be of interest. If not, you may want to skip it.

The 4D language is not a traditional computer language. It is one of the most innovative and flexible languages available on a computer today. It is designed to work the way you do, and not the other way around.

To use traditional languages, you must do extensive planning. In fact, planning is one of the major steps in development. 4D allows you to start using the language at any time and in any part of your database. You may start by adding a method to a form, then later add a few more methods. As your database becomes more sophisticated, you might add a project method controlled by a menu. You can use as little or as much of the language as you want. It is not "all or nothing," as is the case with many other databases.

Traditional languages force you to define and pre-declare objects in formal syntactic terms. In 4D, you simply create an object, such as a button, and use it. 4D automatically manages the object for you. For example, to use a button, you draw it on a form and name it. When the user clicks the button, the language automatically notifies your methods.

Traditional languages are often rigid and inflexible, requiring commands to be entered in a very formal and restrictive style. The 4D language breaks with tradition, and the benefits are yours.

## Methods are the Gateway to the Language

A method is a series of instructions that causes 4D to perform a task. Each line of instruction in a method is called a statement. Each statement is composed of parts of the language.

Because you have already worked through the Quickstart tutorials (you did go through Quickstart, didn't you?), you have already written and used methods.

You can create five types of methods with 4D:

- **Object Methods**: Usually short methods used to control form objects.
- **Form Methods**: Manage the display or printing of a form.
- **Table Methods/Triggers**: Used to enforce the rules of your database.
- **Project methods**: Methods that are available for use throughout your database. For example, methods that can be attached to menus.
- **Database methods**: Execute initializations or special actions when a database is opened or closed, or when a Web browser connects to your database published as a Web Server on Internet an Intranet.

The following sections introduce each of these method types and give you a feel for how you can use them to automate your database.

### Getting started with object methods

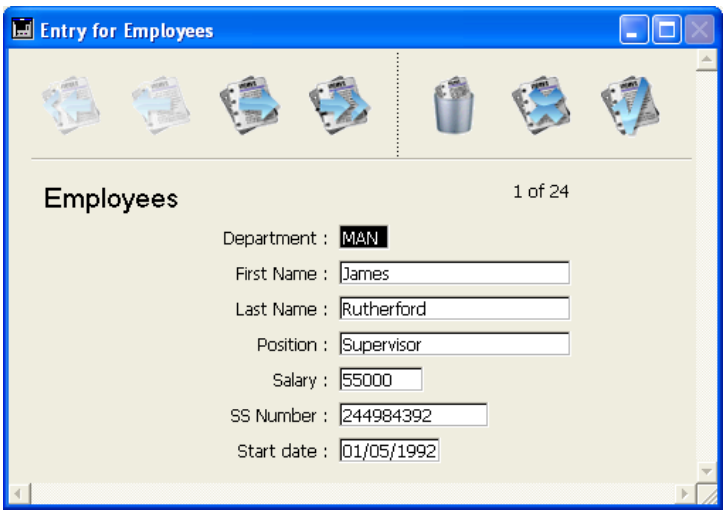
Any form object that can perform an action (that is, any active object) can have a method associated with it. An object method monitors and manages the active object during data entry and printing. A object method is bound to its active object even when the object is copied and pasted. This allows you to create reusable libraries of scripted objects. The object method takes control exactly when needed.

Object methods are the primary tools for managing the user interface, which is the doorway to your database. The user interface consists of the procedures and conventions by which a computer communicates with the user. The goal is to make the user interface of your database as simple and easy to use as possible. The user interface should make interaction with the computer a pleasant process, one that the user enjoys or does not even notice.

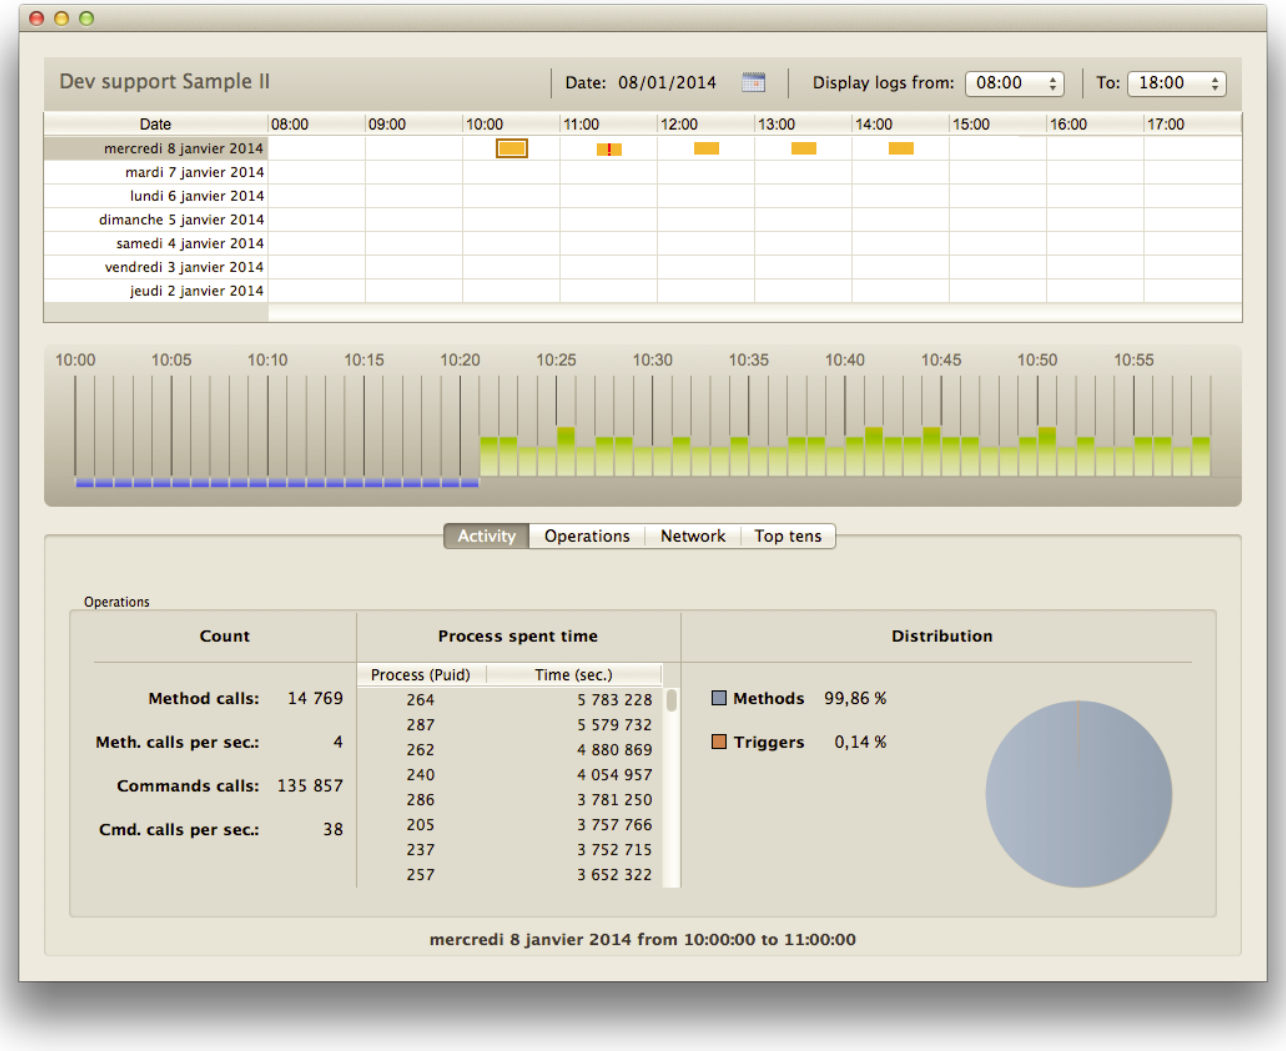
There are two basic types of active objects in a form:

- Those for entering, displaying, and storing data; such as fields and subfields
- Those for control; such as enterable areas, buttons, scrollable areas, hierarchical lists, and meters

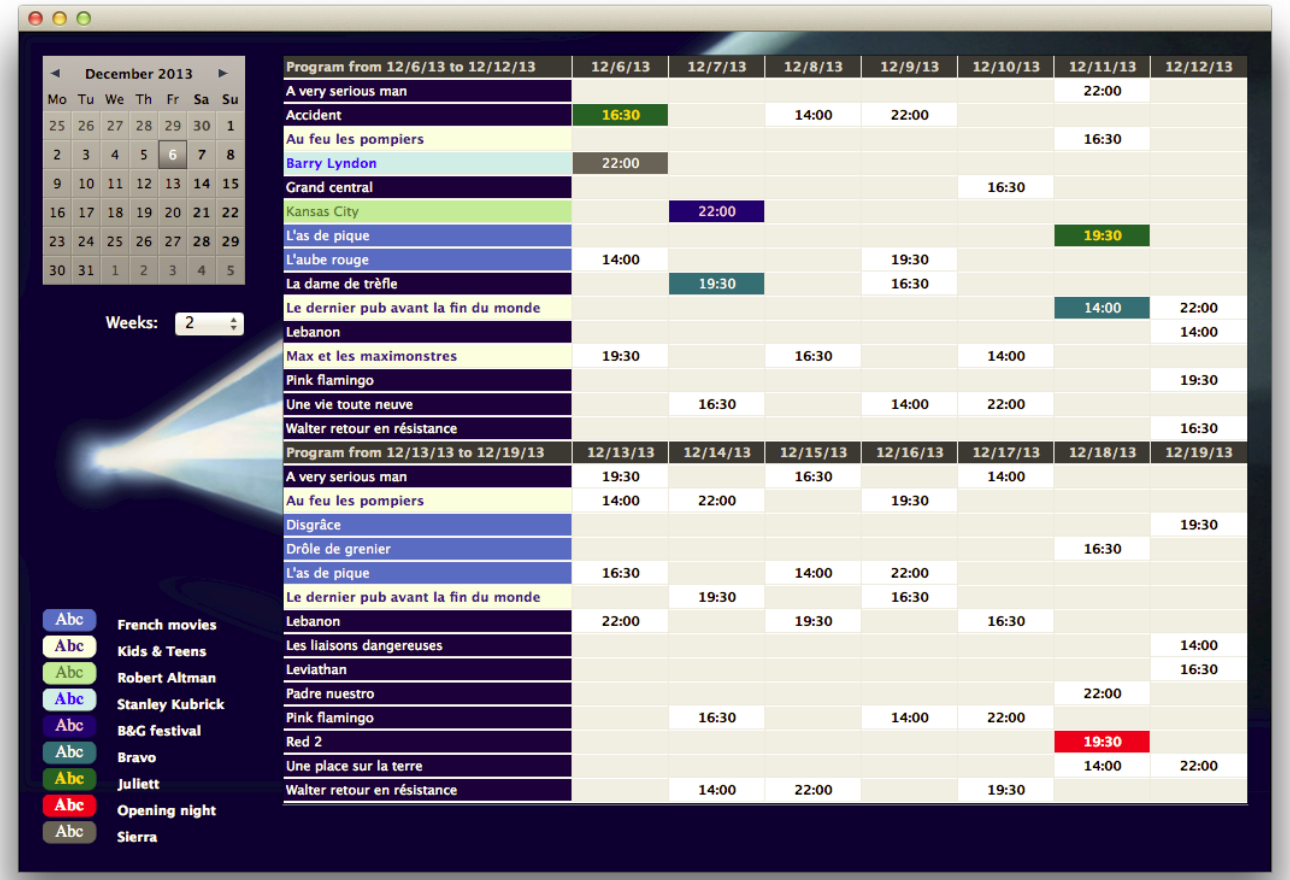
4D enables you to build classic forms, such as the one shown here:



You can also build forms with multiple graphic controls, such as this one:



You can even build forms that incorporate a graphical flair limited only by your imagination:

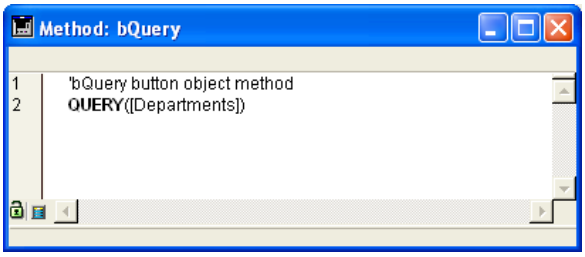


| Program from 12/6/13 to 12/12/13 | 12/6/13 | 12/7/13 | 12/8/13 | 12/9/13 | 12/10/13 | 12/11/13 | 12/12/13 |
|---|---|---|---|---|---|---|---|
| A very serious man | | | | | | 22:00 | |
| Accident | 16:30 | | 14:00 | 22:00 | | | |
| Au feu les pompiers | | | | | | 16:30 | |
| Barry Lyndon | 22:00 | | | | | | |
| Grand central | | | | | 16:30 | | |
| Kansas City | | 22:00 | | | | | |
| L'as de pique | | | | | | 19:30 | |
| L'aube rouge | 14:00 | | | 19:30 | | | |
| La dame de trèfle | | 19:30 | | 16:30 | | | |
| Le dernier pub avant la fin du monde | | | | | | 14:00 | 22:00 |
| Lebanon | | | | | | | 14:00 |
| Max et les maximonstres | 19:30 | | 16:30 | | 14:00 | | |
| Pink flamingo | | | | | | | 19:30 |
| Une vie toute neuve | | 16:30 | | 14:00 | 22:00 | | |
| Walter retour en résistance | | | | | | | 16:30 |
| **Program from 12/13/13 to 12/19/13** | **12/13/13** | **12/14/13** | **12/15/13** | **12/16/13** | **12/17/13** | **12/18/13** | **12/19/13** |
| A very serious man | 19:30 | | 16:30 | | 14:00 | | |
| Au feu les pompiers | 14:00 | 22:00 | | 19:30 | | | |
| Disgrâce | | | | | | | 19:30 |
| Drôle de grenier | | | | | | 16:30 | |
| L'as de pique | 16:30 | | 14:00 | 22:00 | | | |
| Le dernier pub avant la fin du monde | | 19:30 | | 16:30 | | | |
| Lebanon | 22:00 | | 19:30 | | 16:30 | | |
| Les liaisons dangereuses | | | | | | | 14:00 |
| Leviathan | | | | | | | 16:30 |
| Padre nuestro | | | | | | 22:00 | |
| Pink flamingo | | 16:30 | | 14:00 | 22:00 | | |
| Red 2 | | | | | | 19:30 | |
| Une place sur la terre | | | | | | 14:00 | 22:00 |
| Walter retour en résistance | | 14:00 | 22:00 | | 19:30 | | |

Whatever your style in building forms, all active objects have built-in aids, like range checking and entry filters for data entry areas, and automatic actions for controls, menus, and buttons. Always use these aids before adding object methods. The built-in aids are similar to methods in that they remain associated with the active object and are active only when the active object is being used. You will typically use a combination of built-in aids and object methods to control the user interface.

An object method associated with an active object used for data entry typically performs a data-management task specific to the field or variable. The method can perform data validation, data formatting, or calculations. It may even get related information from other files. Some of these tasks can, of course, also be performed with the built-in data entry aids for objects. Use object methods when the task is too complex for the built-in data entry aids to manage. For more information about the built-in data entry aids, refer to the 4D Design Reference manual.

Object methods are also associated with active objects used for control, such as buttons. Active objects used for control are essential to navigating within your database. Buttons allow you to move from record to record, move to different forms, and add and delete data. These active objects simplify the use of a database and reduce the time required to learn it. Buttons also have built-in aids and, as with data entry, you should use these built-in aids before adding methods. Object methods enable you to add actions that are not built-in, to your controls. For example, the following window is the object method for a button that, when clicked, displays the Query editor.



As you become more proficient with scripts, you will find that you can create libraries of objects with associated methods. You can copy and paste these objects and their methods between forms, tables, and databases.

### Controlling forms with form methods

In the same way that object methods are associated with the active objects in a form, a form method is associated with a form. Each form can have one form method. A form is the means through which you can enter, view, and print your data. Forms allow you to present the data to the user in different ways. Through the use of forms, you can create attractive and

easy-to-use data entry screens and printed reports. A form method monitors and manages the use of an individual form both for data entry and for printing.

Form methods manage forms at a higher level than do object methods. Object methods are activated only when the object is used, whereas a form method is activated when anything in the form is used. Form methods are typically used to control the interaction between the different objects and the form as a whole.

As forms are used in so many different ways, it is informative to monitor what is happening while your form is in use. You use the various **form events** for this purpose. They tell you what is currently happening with the form. Each type of event (i.e., clicks, double-clicks, keystrokes...) enables or disables the execution of the form method as well as the object method of each object of the form.

For more information about form, objects, events and methods, refer to the description of the **Form event** command.

### Enforcing the rules of your database using the table methods/triggers

A Trigger is attached to a table; for this reason, it is also called a Table Method. Triggers are automatically invoked by the 4D database engine each you manipulate the records of a table (Add, Delete, Modify and Load). Triggers are methods that can prevent “illegal” operations with the records of your database. For example, in an invoicing system, you can prevent anyone from adding an invoice without specifying the customer to whom the invoice is billed. Triggers are a very powerful tool to restrict operations on a table as well as to prevent accidental data loss or tampering. You can write very simple triggers, then make them more and more sophisticated.

For detailed information, see the **Triggers** section.

### Using project method throughout the database

Unlike object methods, form methods, and triggers, which are all associated with a particular object, form, or table, project methods are available for use throughout your database. Project methods are reusable, and available for use by any other method. If you need to repeat a task, you do not have to write identical methods for each case. You can call project methods wherever you need them—from other project methods or from object or form methods. When you call a project method, it acts as if you had written the method at the location where you called it. Project methods called from other method are often referred to as “subroutines.”

There is one other way to use project methods—associating them with menu commands. When you associate a project method with a menu command, the method is executed when the menu is chosen. You can think of the menu command as calling the project method.

### Handling working sessions with database methods

In the same way object and form methods are invoked when events occur in a form, there are methods associated with the database which are invoked when a working session event occurs. These are the **database methods**. For example, each time you open a database, you may want to initialize some variables that will be used during the whole working session. To do so, you use the **On Startup database method**, automatically executed by 4D when you open the database.

For more information about Database Methods, see the **Database Methods** section.

## Developing Your Database

Development is the process of customizing a database using the language and other built-in tools.

By simply creating a database, you have already taken the first steps to using the language. All the parts of your database—the tables and fields, the forms and their objects, and the menus—are tied to the language. The 4D language “knows” about all of these parts of your database.

Perhaps your first use of the language is to add a method to a form object in order to control data entry. Later, you might add a form method to control the display of your form. As the database becomes more complex, you can add a menu bar with project methods to completely customize your database.

As with other aspects of 4D, development is a very flexible process. There is no formal path to take during development—you can develop in a manner with which you are comfortable. There are, of course, some general patterns in the process.

- Implementation: Implement your design in the Design environment.
- Testing: You try out the design and test each customized element using the Test Application command to launch the Application environment.
- Usage: When your database is fully customized, you launch it directly in the Application environment.
- Corrections: If you find errors, you return to the Design environment to fix them.

Special development support tools, hidden until needed, are built into 4D. As you use the language more frequently, you will find that these tools facilitate the development process. For example, the Method Editor catches typing errors and formats

your work; the Interpreter (the engine that runs the language) catches errors in syntax and shows you where and what they are; and the Debugger lets you monitor the execution of your methods to catch errors in design.

## Building Applications

By now you are familiar with the general uses of a database—data entry, searching, sorting, and reporting. You have performed these actions in the Design environment, using the standard menus and editors.

As you use a database, you perform some sequences of tasks repeatedly. For example, in a database of personal contacts, you might search for your business associates, order them by last name, and print a specific report each time information about them is changed. These tasks may not seem difficult, but they can certainly be time-consuming after you have done them 20 times. In addition, if you don't use the database for a couple of weeks, you may return to find that the steps used to generate the report are not so fresh in your mind. The steps in methods are chained together, so a single command automatically performs all the tasks linked to it. Consequently, you do not have to worry about the specific steps.

Applications have custom menus and perform tasks that are specific to the needs of the person using your database. An application is composed of all the pieces of your database: the structure, the forms, the object, form and project methods, the menus, and the passwords.

You can compile your databases and create stand-alone Windows and Macintosh applications. Compiling databases increases the execution speed of the language, protects your databases, and allows you to create applications that are completely independent. The integrated compiler also checks the syntax and the types of variables in methods for consistency.

An application can be as simple as a single menu that lets you enter people's names and print a report, or as complex as an invoicing, inventory, and control system. There are no limits to the uses of database applications. Typically, an application grows from a database used in the Design environment to a database controlled completely by custom menus and forms.

## Where to go from here?

- Developing applications can be as simple or complex as you like. For a quick overview about building a simple 4D application, see the **Building a 4D Application** section.
- If you are new to 4D, refer to the **Language definition** sections to learn about the basics of the 4D language: start with **Introduction to the 4D Language**.

# Building a 4D Application

An application is a database designed to fill a specific need. It has a user interface designed specifically to facilitate its use. The tasks that an application performs are limited to those appropriate for its purpose. Creating applications with 4D is smoother and easier than with traditional programming. 4D can be used to create a variety of applications, including:

- An invoice system
- An inventory control system
- An accounting system
- A payroll system
- A personnel system
- A customer tracking system
- A database shared over the Internet or an Intranet

It is possible that a single application could even contain all of these systems. Applications like these are typical uses of databases. In addition, the tools in 4D allow you to create innovative applications, such as:

- A document tracking system
- A graphic image management system
- A catalog publishing application
- A serial device control and monitoring system
- An electronic mail system (E-mail)
- A multi-user scheduling system
- A list such as a menu list, video collection, or music collection

An application typically can start as a database used in the Design environment. The database “evolves” into an application as it is customized. What differentiates an application is that the systems required to manage the database are hidden from the user. Database management is automated, and users use menus to perform specific tasks.

When you use a 4D database in the Design environment, you must know the steps to take to achieve a result. In an application, you use the Application environment, in which you need to manage all the aspects that are automatic in the Design Environment. These include:

- Table Navigation: The **List of Tables** window, the Last used tables command or the navigation buttons are not available to the user. You can use menu commands and methods to control navigation between tables.
- Menus: In the Application environment, you only have the default File menu with the Quit menu command, the Edit menu, the Mode and the Help menu (as well as the application menu under Mac OS). If the application requires more menus, you have to create and manage them using 4D methods or standard actions.
- Editors: The editors, such as the Query and Order By editors, are no longer automatically available in the Application environment. If you want to use them, you have to call them using 4D methods.

The following sections include examples showing how the language can automate the use of a database.

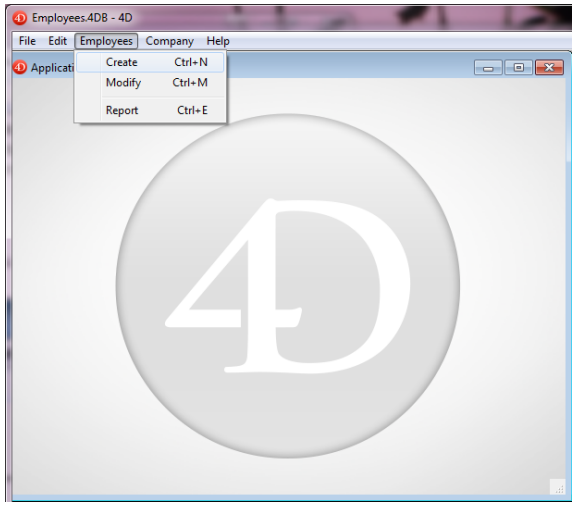
## Application Environment: an Example

Custom menus are the primary interface in an application. They make it easier for users to learn and use a database. Creating custom menus is very simple—you associate methods or automatic actions with each menu command (also called menu items) in the Menu editor.

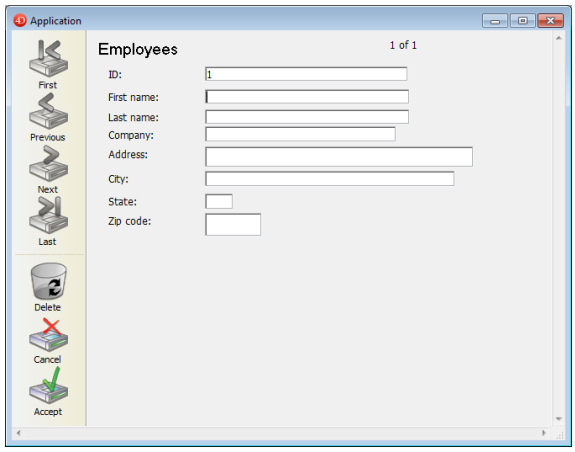
“The User's Perspective” section describes what happens when the user chooses a menu command. Next, “Behind the Scenes” describes the design work that made it happen. Although the example is simple, it should be apparent how custom menus make the database easier to use and learn. Rather than the “generic” tools and menu commands in the Design environment, the user sees only things that are appropriate to his or her needs.

### The User’s Perspective

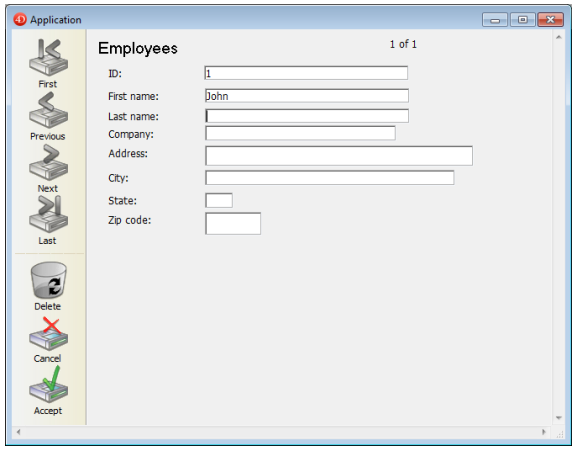
The user chooses a menu item called **Create** from the **Employees** menu to add a new person to the database.



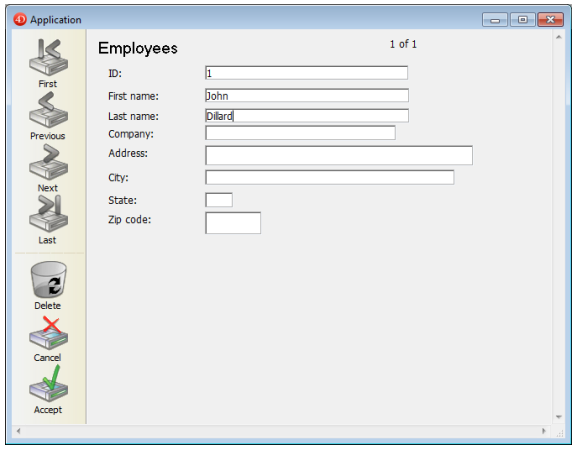
The Input form for the Employees table is displayed.



The user enters the person's first name and then tabs to the next field.

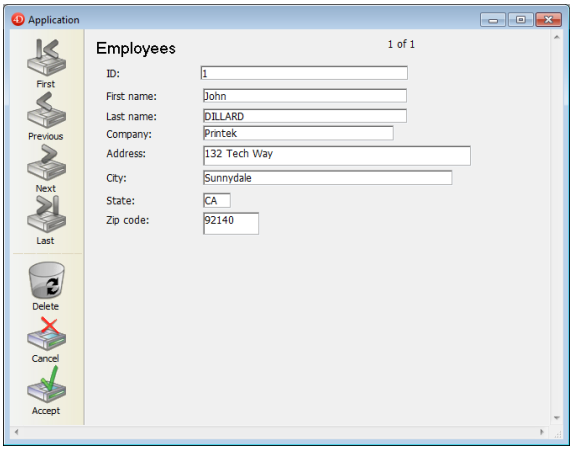


The user enters the person's last name.



The user tabs to the next field: the last name is converted to uppercase.

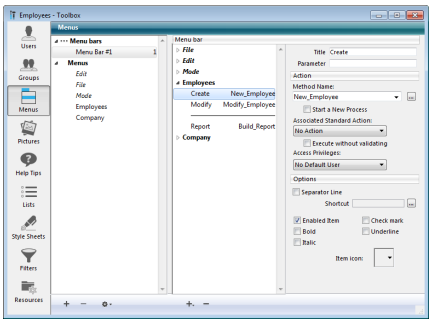
The user finishes entering the record and clicks the validation button (generally the last button in the button bar).



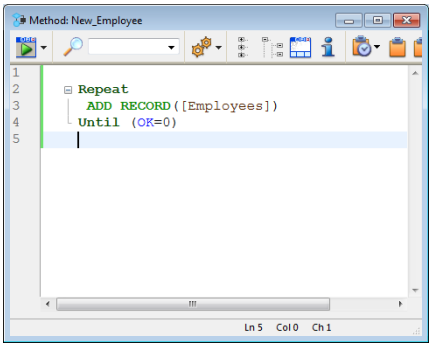
Another blank record appears, and the user clicks the Cancel button (the one with the "X") to terminate the "data entry loop." The user is returned to the menu bar.

### Behind the Scenes

The menu bar was created in the Design environment, using the Menu Bar Editor.



The menu item **New** has a project method named **New Employee** associated with it. This method was created in the Design environment, using the Method editor.



When the user chooses this menu item, the **New Employee** method executes:

```
Repeat
   ADD RECORD([Employees])
Until(OK=0)
```

The **Repeat...Until** loop with an **ADD RECORD** command within the loop acts just like the **New Record** menu item in the Design environment. It displays the input form to the user, so that he or she can add a new record. When the user saves the record, another new blank record appears. This **ADD RECORD** loop continues to execute until the user clicks the **Cancel** button.

When a record is entered, the following occurs:

- There is no method for the **First Name** field, so nothing executes.
- There is a method for the **Last Name** field. This Object Method was created in the Design environment, using the Form and Method editors. The method executes:

```
[Employees]Last Name:=Uppercase([Employees]Last Name)
```

This line converts the **Last Name** field to uppercase characters.

After a record has been entered, when the user clicks the Cancel button for the next one, the OK variable is set to zero, thus ending the execution of the **ADD RECORD** loop.

As there are no more statements to execute, the **New Employee** method stops executing and control returns to the menu bar.

## Comparing an Automated Task with the Actions to be performed in the Design environment

Let's compare the way a task is performed in the Design environment and the way the same task is performed using the language. The task is a common one:

- Find a group of records
- Sort them
- Print a report

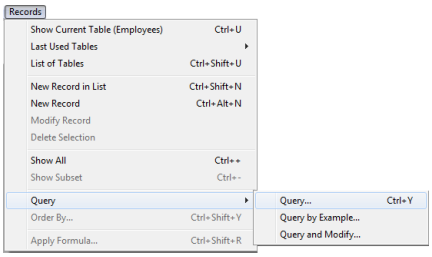
The next section, "Using a Database in the Design Environment," displays the tasks performed in the Design environment.

The following section, "Using the Built-in Editors within the Application environment," displays the same tasks performed in an application.

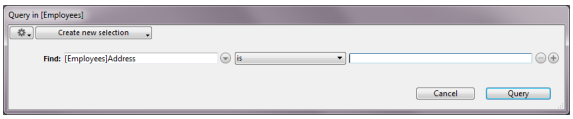
Note that although both methods perform the same task, the steps in the second section are automated using the language.

### Using a database in the Design environment

The user chooses **Query**>**Query...** in the **Records** menu.



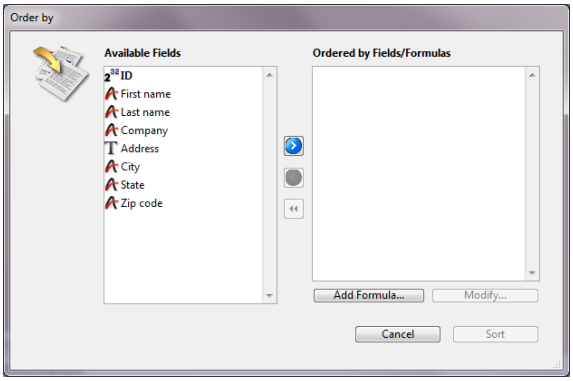
The **Query** editor is displayed.



The user enters the criteria and clicks the **Query** button. The search is performed.

The user chooses **Order by** from the **Records** menu.

The **Order By** editor is displayed.



The user enters the criteria and clicks the **Sort** button. The sort is performed.

Then, to print the records, these additional steps are required:

- The user chooses **Print** from the **File** menu.
- The **Choose Print Form** dialog box is displayed, because users need to know which form to print.

- The Printing dialog boxes are displayed. The user chooses the settings, and the report is printed.

### Using the built-in editors within the Application environment

Let's examine how this can be performed in the Application environment.

The User chooses **Report** from the Employees menu.

Even at this point, using an application is easier for the users—they did not need to know that querying is the first step!

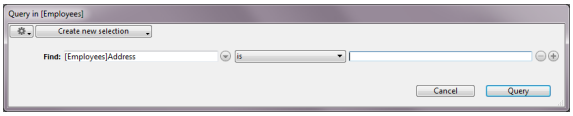
A method called **Build Report** is attached to the menu command; it looks like this:

```
QUERY([Employees])
ORDER BY([Employees])
FORM SET OUTPUT([Employees];"Report")
PRINT SELECTION([Employees])
```

The first line is executed:

```
QUERY([Employees])
```

The **Query** editor is displayed.



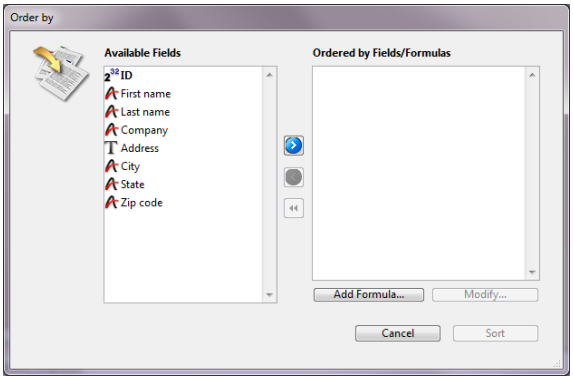
The user enters the criteria and clicks the **Query** button. The query is performed.

The second line of the **Build Report** method is executed:

```
ORDER BY([Employees])
```

Note that the user did not need to know that ordering the records was the next step.

The **Order By** Editor is displayed.



The user enters the criteria and clicks the **Sort** button. The sort is performed.

The third line of the **Build Report** method is executed:

```
FORM SET OUTPUT([Employees];"Report")
```

Once again, the user did not need to know what to do next; the method takes care of that.

The final line of the **Build Report** method is executed:

```
PRINT SELECTION([Employees])
```

The **Printing** dialog boxes are displayed. The User chooses the settings, and the report is printed.

## Automating the Application Further

The same commands used in the previous example can be used to further automate the database.

Let's take a look at the new version of the **Build Report** method.

The user chooses **Report** from the **Employees** menu. A method called **Build Report2** is attached to the menu command. It looks like this:

```
QUERY([Employees];[Employees]Company="Acme")
ORDER BY([Employees];[Employees]Last Name;>;[Employees]First Name;>)
FORM SET OUTPUT[Employees];"Report")
PRINT SELECTION([Employees];*)
```

The first line is executed:

```
QUERY([Employees];[Employees]Company="Acme")
```

The **Query** editor is not displayed. Instead, the query is specified and performed by the **QUERY** command. The user does not need to do anything.

The second line of the **Build Report2** method is executed:

```
ORDER BY([Employees];[Employees]Last Name;>;[Employees]First Name;>)
```

The **Order By** editor is not displayed, and the sort is immediately performed. Once again, no user actions are required.

The final lines of the **Build Report2** method are executed:

```
FORM SET OUTPUT[Employees];"Report")
PRINT SELECTION([Employees];*)
```

The **Printing** dialog boxes are not displayed. The **PRINT SELECTION** command accepts an optional asterisk (*) parameter that instructs the command to use the print settings that were in effect when the report form was created. The report is printed.

This additional automation saved the user from having to enter options in three dialog boxes. Here are the benefits :

- The query is automatically performed: users may select wrong criteria when making a query.
- The sort is automatically performed: users may select wrong criteria when defining a sort.
- The printing is automatically performed: users may select the wrong form to print.

## Help for Developing 4D Applications

As you develop a 4D application, you will discover many capabilities that you did not notice when you started. You can even augment the standard version of 4D by adding other tools and plug-ins to your 4D development environment.

### Plug-ins 4D

4D provides several plug-ins that can be used for increasing the capabilities of your 4D applications, including:

- **4D Write**: Word-processor
- **4D View**: Spreadsheet and list editor
- **4D Internet Commands** (built-in): Communication utilities via Internet.

- **4D ODBC Pro**: Connectivity via ODBC
- **4D for OCI**: Connectivity with ORACLE Call Interface

For more information, contact 4D or its Partners, or visit our Web site:

http://www.4d.com

### The 4D community and third party tools

There is a very active worldwide 4D community, composed of User Groups, Electronic Forums, and 4D Partners. 4D Partners produce **Third Party Tools**. You can suscribe to the user forum of 4D at the following address:

http://forums.4D.fr

The 4D community offers access to tips and tricks, solutions, information, and additional tools that will save you time and energy, and increase your productivity.

# Introduction to the 4D Language

The 4D language is made up of various components that help you perform tasks and manage your data.

- **Data types**: Classifications of data in a database. See discussion in this section as well as the detailed discussion in the section **Data Types**.
- **Variables**: Temporary storage places for data in memory. See detailed discussion in the section **Variables**.
- **Operators**: Symbols that perform a calculation between two values. See discussion in this section as well as the detailed discussion in the section **Operators** and its subsections.
- **Expressions**: Combinations of other components that result in a value. See discussion in this section.
- **Commands**: Built-in instructions to perform an action. All 4D commands, such as **ADD RECORD**, are described in this manual, grouped by theme; when necessary, the theme is preceded by an introductory section. You can use 4D Plug-ins to add new commands to your 4D development environment. For example, once you have added the 4D Write Plug-in to your 4D system, the 4D Write commands become available for creating and manipulating word-processing documents.
- **Predefined constants**: Constant values accessible by name. For example, XML DATA is a constant (value 6). Predefined constants allow writing more readable code. Constants are described with the commands that use them, and are fully listed in the **List of constant themes** section.
- **Methods**: Instructions that you write using all parts of the language listed here. See discussion in the section **Methods** and its subsections.

This section introduces **Data Types**, **Operators**, and **Expressions**. For the other components, refer to the sections cited above.

In addition:

- Language components, such as variables, have names called Identifiers. For a detailed discussion about identifiers and the rules for naming objects, refer to the section **Identifiers**.
- To learn more about array variables, refer to the section **Arrays**.
- To learn more about BLOB variables, refer to the section **BLOB Commands**.
- If you plan to compile your database, refer to the section **Compiler Commands** as well as the Design Reference manual of 4D.

## Language for commands and constants

Starting with 4D v15, 4D's Method editor uses the international "English-US" language by default, regardless of the 4D version or local system settings. This feature neutralizes any regional variations that might disrupt code interpretation between 4D applications (date formats for instance); and in French versions of 4D, commands and constants are now written in "English-US" as is already the case in other languages.

This default setting provides 4D developers with several advantages:

- It facilitates code sharing between developers, regardless of their country, regional settings, or the 4D version used. A 4D method can now be exchanged by simple copy/paste, or saved in a text file, with no compatibility issues.
- It also makes it possible to include 4D methods in source control tools, which often require exports to be independent from regional settings and languages.

This setting can be disabled using the "Use regional system settings" option in the 4D Preferences dialog box (see the **Methods Page**).

### Input principles in English-US

The English-US settings may have several effects on the way you write methods. This concerns code written in development mode as well as formulas in deployed applications. In this mode, code must comply with following rules:

- Decimal separators for real numbers must now be periods (".") in all versions (and not commas (",") as is the custom in French, for example).
- Date constants must now use the ISO format (!YYYY-MM-DD!) in all versions.

- Command and constant names must be in English (this change only concerns French versions of 4D, since this was already the case with other languages).

**Note:** The Method editor includes specific mechanisms that automatically fix incorrect entries if necessary.

The following table illustrates differences between code in 4D v15 (or higher) and in previous versions:

| | **Code sample in methods/formulas** |
|---|---|
| **4D v15 and higher (default mode, all versions)** | a:=12.50<br>b:=!2013-12-31!<br>Current date |
| **4D v14 or 4D v15 (preference checked, US version, for instance)** | a:=12.50<br>b:=!12/31/2013!<br>Current date |
| **4D v14 or 4D v15 (preference checked, French version)** | a:=12,50<br>b:=!31/12/2013!<br>Date du jour |

**Note:** When the preference is checked, real and date formats are based on system settings.

## Data Types

In the language, the various types of data that can be stored in a 4D database are referred to as data types. There are eight basic data types: string, numeric, date, time, Boolean, picture, and pointer.

- **String**: A series of characters, such as “Hello there”. Text fields and variables, as well as Alpha fields, are of the String data type
- **Numeric**: Numbers, such as 2 or 1,000.67. Integer, Long Integer, and Real fields and variables are of the numeric data type.
- **Date**: Calendar dates, such as 1/20/89. Date fields and variables are of the date data type.
- **Time**: Times, including hours, minutes, and seconds, such as 1:00:00 or 4:35:30 PM. Time fields and variables are of the time data type.
- **Boolean**: Logical values of TRUE or FALSE. Boolean fields and variables are of the Boolean data type.
- **Picture**: Picture fields and variables are of the picture data type.
- **Pointer**: A special type of data used in advanced programming. Pointer variables are of the pointer data type. There is no corresponding field type.
- **Object**: Composite data type which can contain any type of data sets in the form of key/value pairs. Object fields and variables are of the Object data type.

Note that in the list of data types, the string and numeric data types are associated with more than one type of field. When data is put into a field, the language automatically converts the data to the correct type for the field. For example, if an integer field is used, its data is automatically treated as numeric. In other words, you need not worry about mixing similar field types when using the language; it will manage them for you.

However, when using the language it is important that you do not mix different data types. In the same way that it makes no sense to store “ABC” in a Date field, it makes no sense to put “ABC” in a variable used for dates. In most cases, 4D is very tolerant and will try to make sense of what you are doing. For example, if you add a number to a date, 4D will assume that you want to add that number of days to the date, but if you try to add a string to a date, 4D will tell you that the operation cannot work.

There are cases in which you need to store data as one type and use it as another type. The language contains a full complement of commands that let you convert from one data type to another. For example, you may need to create a part number that starts with a number and ends with characters such as “abc”. In this case, you might write:

```
[Products]Part Number:=String(Number)+"abc"
```

If *Number* is 17, then *[Products]Part Number* will get the string “17abc”.

The data types are fully defined in the section **Data Types**.

## Operators

When you use the language, it is rare that you will simply want a piece of data. It is more likely that you will want to do something to or with that data. You perform such calculations with operators. Operators, in general, take two pieces of data and perform an operation on them that results in a new piece of data. You are already familiar with many operators. For

example, 1 + 2 uses the addition (or plus sign) operator to add two numbers together, and the result is 3. This table shows some familiar numeric operators:

| Operator | Operation | Example |
|---|---|---|
| + | Addition | 1 + 2 results in 3 |
| – | Subtraction | 3 – 2 results in 1 |
| * | Multiplication | 2 * 3 results in 6 |
| / | Division | 6 / 2 results in 3 |

Numeric operators are just one type of operator available to you. 4D supports many different types of data, such as numbers, text, dates, and pictures, so there are operators that perform operations on these different data types.

The same symbols are often used for different operations, depending on the data type. For example, the plus sign (+) performs different operations with different data:

| Data Type | Operation | Example |
|---|---|---|
| Number | Addition | 1 + 2 adds the numbers and results in 3 |
| String | Concatenation | “Hello ” + “there” concatenates (joins together) the strings and results in “Hello there” |
| Date and Number | Date addition | !1989-01-01! + 20 adds 20 days to the date January 1, 1989, and results in the date January 21, 1989 |

The operators are fully defined in the chapter **Operators** and its subsections.

## Expressions

Simply put, expressions return a value. In fact, when using the 4D language, you use expressions all the time and tend to think of them only in terms of the value they represent. Expressions are also sometimes referred to as formulas.

Expressions are made up of almost all the other parts of the language: commands, operators, variables, and fields. You use expressions to build statements (lines of code), which in turn are used to build methods. The language uses expressions wherever it needs a piece of data.

Expressions rarely “stand alone.” There are only a few places in 4D where an expression can be used by itself:

- Query by Formula dialog box
- Debugger where the value of expressions can be checked
- Apply Formula dialog box
- Quick Report editor as a formula for a column

An expression can simply be a constant, such as the number 4 or the string “Hello.” As the name implies, a constant’s value never changes. It is when operators are introduced that expressions start to get interesting. In preceding sections you have already seen expressions that use operators. For example, 4 + 2 is an expression that uses the addition operator to add two numbers together and return the result 6.

You refer to an expression by the data type it returns. There are eight expression types:

- String expression
- Numeric expression (also referred to as number)
- Date expression
- Time expression
- Boolean expression
- Picture expression
- Pointer expression
- Object expression.

The following table gives examples of each type of expression.

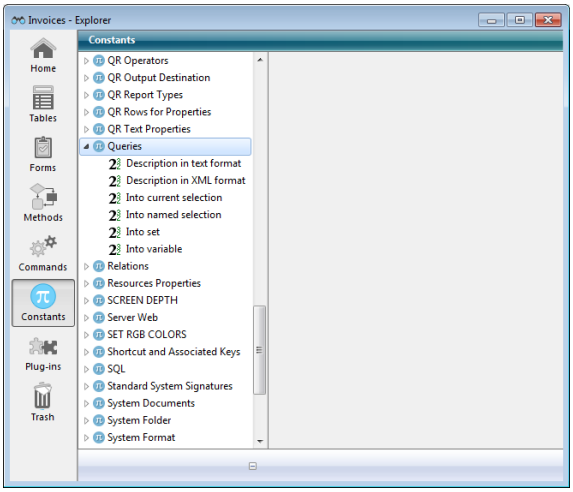
| Expression | Type | Explanation |
|---|---|---|
| “Hello” | String | The word Hello is a string constant, indicated by the double quotation marks. |
| “Hello ” + “there” | String | Two strings, “Hello ” and “there”, are added together (concatenated) with the string concatenation operator (+). The string “Hello there” is returned. |
| “Mr. ” + [People]Name | String | Two strings are concatenated: the string “Mr. ” and the current value of the Name field in the People table. If the field contains “Smith”, the expression returns “Mr. Smith”. |
| **Uppercase**(“smith”) | String | This expression uses **Uppercase**, a command from the language, to convert the string “smith” to uppercase. It returns “SMITH”. |
| 4 | Number | This is a number constant, 4. |
| 4 * 2 | Number | Two numbers, 4 and 2, are multiplied using the multiplication operator (*). The result is the number 8. |
| My Button | Number | This is the name of a button. It returns the current value of the button: 1 if it was clicked, 0 if not. |
| !1997-01-25! | Date | This is a date constant for the date 1/25/97 (January 25, 1997). |
| **Current date** + 30 | Date | This is a date expression that uses the **Current date** command to get today’s date. It adds 30 days to today’s date and returns the new date. |
| ?8:05:30? | Time | This is a time constant that represents 8 hours, 5 minutes, and 30 seconds. |
| ?2:03:04? + ?1:02:03? | Time | This expression adds two times together and returns the time 3:05:07. |
| **True** | Boolean | This command returns the Boolean value TRUE. |
| 10 # 20 | Boolean | This is a logical comparison between two numbers. The number sign (#) means “is not equal to”. Since 10 “is not equal to” 20, the expression returns TRUE. |
| “ABC” = “XYZ” | Boolean | This is a logical comparison between two strings. They are not equal, so the expression returns FALSE. |
| My Picture + 50 | Picture | This expression takes the picture in My Picture, moves it 50 pixels to the right, and returns the resulting picture. |
| ->[People]Name | Pointer | This expression returns a pointer to the field called [People]Name. |
| Table (1) | Pointer | This is a command that returns a pointer to the first table. |
| **JSON Parse**(MyString) | Object | This is a command that returns MyString as an object (if proper format) |

# Constants

A constant is an expression that has a fixed value. There are two types of constants: **predefined constants** that you select by name, and **literal constants** for which you type the actual value.

## Predefined Constants

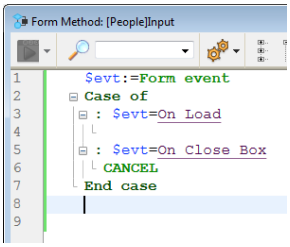
4D provides a set of **predefined constants.** These constants are grouped by themes in the Explorer Window:



To use a predefined constant in a **Method editor** window:

- Drag and drop the constant from the Explorer window to the Method editor window.
- Directly type its name in the Method editor window. The autocomplete mechanism suggests constants that correspond to the programming context.

Predefined constants appeared underlined by default within the Method Editor and Debugger windows:



In the window shown here, On Load, for example, is a predefined constant.

## Literal Constants

Literal Constants can be of four data types:

- String
- Numeric
- Date
- Time

### String Constants

A string constant is enclosed in double, straight quotation marks ("…"). Here are some examples of string constants:

*"Add Records"*
*"No records found."*
*"Invoice"*

An empty string is specified by two quotation marks with nothing between them ("").

### Numeric Constants

A numeric constant is written as a real number. Here are some examples of numeric constants:

*27*
*123.76*
*0.0076*

Negative numbers are specified with the minus sign(−). For example:

*−27*
*−123.76*
*−0.0076*

**Note:** Since 4D v15, the default decimal separator is a period (.), regardless of the system language. If you have checked the "Use regional system settings" option (see **Methods Page**), you must use the separator defined in your system.

### Date Constants

A date constant is enclosed by exclamation marks (!···!). Since 4D v15, a date must be structured using the ISO format (!YYYY-MM-DD!). Here are some examples of date constants:

*!1976-01-01!*
*!2004-09-29!*
*!2015-12-31!*

A null date is specified by *!00-00-00!*.

**Tip**: The Method Editor includes a shortcut for entering a null date. To type a null date, enter the exclamation (!) character and press Enter.

**Notes**:

- For compatibility reasons, 4D accepts two-digit years to be entered. A two-digit year is assumed to be in the 20th or 21st century based on whether it is greater or less than 30, unless this default setting has been changed using the **SET DEFAULT CENTURY** command.
- If you have checked the "Use regional system settings" option (see **Methods Page**), you must use the date format defined in your system. Generally, in a US environment, dates are entered in the form month/day/year, with a slash "/" separating the values.

### Time Constants

A time constant is enclosed by question marks (?...?).

In the US English version of 4D, a time constant is ordered hour:minute:second, with a colon (:) setting off each part. Times are specified in 24-hour format.

Here are some examples of time constants:

*?00:00:00? ` midnight*
*?09:30:00? ` 9:30 am*
*?13:01:59? ` 1 pm, 1 minute, and 59 seconds*

A null time is specified by ?00:00:00?

**Tip**: The Method Editor includes a shortcut for entering a null time. To type a null time, enter the question mark (?) character and press Enter.

# Variables

Data in 4D is stored in two fundamentally different ways. Fields store data permanently on disk; variables store data temporarily in memory.

When you set up your 4D database, you specify the names and types of fields that you want to use. Variables are much the same—you also give them names and different types.

The following variable types correspond to each of the data types:

- String(*) or Text: Alphanumeric string of up to 2 GB of text
- Integer: Integer from -32768 to 32767
- Long Integer: Integer from -2^31 to (2^31)-1
- Real: A number to ±1.7e±308 (13 significant digits)
- Date: 1/1/100 to 12/31/32767
- Time: 00:00:00 to 596000:00:00 (seconds from midnight)
- Boolean: True or False
- Picture: Any Windows or Macintosh picture
- Object: A set of "property/value" pairs structured in a JSON type format
- BLOB (Binary Large OBject): Series of bytes up to 2 GB in size
- Pointer: A pointer to a table, field, variable, array, or array element

(*) In Unicode mode, String and Text type variables are identical. In non-Unicode mode (compatibility mode), a String is a fixed alphanumeric string of up to 255 characters.

You can display variables (except Pointer and BLOB) on the screen, enter data into them, and print them in reports. In these ways, enterable and non-enterable area variables act just like fields, and the same built-in controls are available when you create them:

- Display formats
- Data validation, such entry filters and default values
- Character filters
- Choice lists (hierarchical lists)
- Enterable or non-enterable values

Variables can also do the following:

- Control buttons (buttons, check boxes, radio buttons, 3D buttons, and so on)
- Control sliders (meters, rulers, and dials)
- Control scrollable areas, pop-up menus, and drop-down list boxes
- Control hierarchical lists and hierarchical pop-up menus
- Control button grids, tab controls, picture buttons, and so on
- Display results of calculations that do not need to be saved.

## Creating Variables

You can create variables simply by using them; you do not necessarily need to formally define them as you do with fields. For example, if you want a variable that will hold the current date plus 30 days, you write:

```
MyDate:=Current date+30
```

4D creates *MyDate* and holds the date you need. The line of code reads “MyDate gets the current date plus 30 days.” You could now use *MyDate* wherever you need it in your database. For example, you might need to store the date variable in a field of same type:

```
[MyTable]MyField:=MyDate
```

However, it is usually recommended for a variable to be explicitly defined as a certain type. For more information about typing variables for a database, see the chapter **Compiler**.

## Assigning Data to Variables

Data can be put into and copied out of variables. Putting data into a variable is called **assigning the data to the variable** and is done with the *assignment operator* (*:=*). The assignment operator is also used to assign data to fields.

The assignment operator is the primary way to create a variable and to put data into it. You write the name of the variable that you want to create on the left side of the assignment operator. For example:

```
MyNumber:=3
```

creates the variable **MyNumber** and puts the number *3* into it. If **MyNumber** already exists, then the number *3* is just put into it.

Of course, variables would not be very useful if you could not get data out of them. Once again, you use the assignment operator. If you need to put the value of **MyNumber** in a field called *[Products]Size*, you would write **MyNumber** on the right side of the assignment operator:

```
[Products]Size:=MyNumber
```

In this case, *[Products]Size* would be equal to 3. This example is rather simple, but it illustrates the fundamental way that data is transferred from one place to another by using the language.

**Important**: Be careful not to confuse the assignment operator (*:=*) with the comparison operator, equal (=). Assignment and comparison are very different operations. For more information about the comparison operators, see the section **Operators**.

## Local, Process, and Interprocess Variables

You can create three types of variables: **local** variables, **process** variables, and **interprocess** variables. The difference between the three types of variables is their scope, or the objects to which they are available.

### Local variables

A local variable is, as its name implies, local to a method—accessible only within the method in which it was created and not accessible outside of that method. Being local to a method is formally referred to as being “local in scope.” Local variables are used to restrict a variable so that it works only within the method.

You may want to use a local variable to:

- Avoid conflicts with the names of other variables
- Use data temporarily
- Reduce the number of process variables

The name of a local variable always starts with a dollar sign ($) and can contain up to 31 additional characters. If you enter a longer name, 4D truncates it to the appropriate length.

When you are working in a database with many methods and variables, you often find that you need to use a variable only within the method on which you are working. You can create and use a local variable in the method without worrying about whether you have used the same variable name somewhere else.

Frequently, in a database, small pieces of information are needed from the user. The **Request** command can obtain this information. It displays a dialog box with a message prompting the user for a response. When the user enters the response, the command returns the information the user entered. You usually do not need to keep this information in your methods for very long. This is a typical way to use a local variable. Here is an example:

```
$vsID:=Request("Please enter your ID:")
If(OK=1)
   QUERY([People];[People]ID =$vsID)
End if
```

This method simply asks the user to enter an ID. It puts the response into a local variable, *$vsID*, and then searches for the *ID* that the user entered. When this method finishes, the *$vsID* local variable is erased from memory. This is fine, because the variable is needed only once and only in this method.

### Process variables

A process variable is available only within a process. It is accessible to the process method and any other method called from within the process.

A process variable does not have a prefix before its name. A process variable name can contain up to 31 characters.

In interpreted mode, variables are maintained dynamically; they are created and erased from memory “on the fly.” In compiled mode, all processes you create (user processes) share the same definition of process variables, but each process has a different instance for each variable. For example, the variable *myVar* is one variable in the process *P_1* and another one in the process *P_2*.

A process can “peek and poke” process variables from another process using the commands **GET PROCESS VARIABLE** and **SET PROCESS VARIABLE**. It is good programming practice to restrict the use of these commands to the situation for which they were added to 4D:

- Interprocess communication at specific places or your code
- Handling of interprocess drag and drop
- In Client/Server, communication between processes on client machines and the stored procedures running on the server machines

For more information, see the chapter **Processes** and the description of these commands.

### Interprocess variables

Interprocess variables are available throughout the database and are shared by all processes. They are primarily used to share information between processes.

The name of an interprocess variable always begins with the symbols (<>) — a “less than” sign followed by a “greater than” sign— followed by 31 characters.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (Option-Shift-V on US keyboard).

In Client/Server, each machine (Client machines and Server machine) share the same definition of interprocess variables, but each machine has a different instance for each variable.

## Form Object Variables

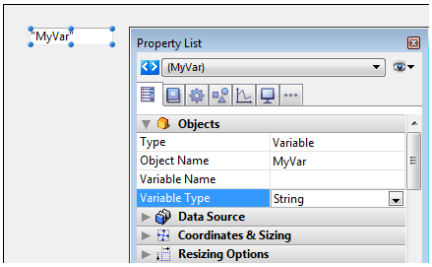
In the Form editor, naming an active object—button, radio button, check box, scrollable area, meter bar, and so on—automatically creates a variable, having the same name by default. For example, if you create a button named *MyButton*, a variable named *MyButton* is also created. Note that this variable name is not the label for the button, but is the name of the button.

The form object variables allow you to control and monitor the objects. For example, when a button is clicked, its variable is set to 1; at all other times, it is 0. The variable associated with a meter or dial lets you read and change the current setting. For example, if you drag a meter to a new setting, the value of the variable changes to reflect the new setting. Similarly, if a method changes the value of the variable, the meter is redrawn to show the new value.

For more information about variables and forms, see the 4D Design Reference Manual as well as the chapter **Form Events**.

### Dynamic variables

You can leave it up to 4D to create variables associated with your form objects (buttons, enterable variables, check boxes, etc.) dynamically and according to your needs. To do this, simply leave the "Variable Name" field blank in the Property list for the object:



When a variable is not named, when the form is loaded, 4D creates a new variable for the object, with a calculated name that is unique in the space of the process variables of the interpreter (which means that this mechanism can be used even in compiled mode). This temporary variable will be destroyed when the form is closed.
In order for this principle to work in compiled mode, it is imperative that dynamic variables are explicitly typed. There are two ways to do this:

- You can set the type using the "Variable Type" menu of the Property list.
  **Note:** When the variable is named, the "Variable Type" menu does not actually type the variable but simply allows the options of the Property list to be updated (except for picture variables). In order to type a named variable, it is necessary to use the commands of the **Compiler** theme.

- You can use a specific initialization code when the form is loaded that uses, for example, the **VARIABLE TO VARIABLE** command:

```
If(Form event=On Load)
   C_TEXT($init)
   $Ptr_object:=OBJECT Get pointer(Object named;"comments")
   $init:=""
   VARIABLE TO VARIABLE(Current process;$Ptr_object->;$init)
End if
```

**Note:** If you specify a dynamic variable, select the value **None** in the "Variable Type" menu, and do not use initialization code, a typing error will be returned by the compiler.

In the 4D code, dynamic variables can be accessed using a pointer obtained with the **OBJECT Get pointer** command. For example:

```
 // assign the time 12:00:00 to the variable for the "tstart" object
$p :=OBJECT Get pointer(Object named;"tstart")
$p->:=?12:00:00?
```

There are two advantages with this mechanism:

- On the one hand, it allows the development of "subform" type components that can be used several times in the same host form. Let us take as an example the case of a *datepicker* subform that is inserted twice in a host form to set a start date and an end date. This subform will use objects for choosing the date of the month and the year. It will be necessary for these objects to work with different variables for the start date and the end date. Letting 4D create their variable with a unique name is a way of resolving this difficulty.
- On the other hand, it can be used to limit memory usage. In fact, form objects only work with process or inter-process variables. However, in compiled mode, an instance of each process variable is created in all the processes, including the server processes. This instance takes up memory, even when the form is not used during the session. Therefore, letting 4D create variables dynamically when loading the forms can economize memory.

**Note:** When there is no variable name, the object name is shown in quotation marks in the form editor (when the object display a variable name by default).

## System Variables

4D maintains a number of variables called **system variables**. These variables let you monitor many operations. System variables are all process variables, accessible only from within a process.

The most important system variable is the **OK** system variable. As its name implies, it tells you if everything is OK in the particular process. Was the record saved? Has the importing operation been completed? Did the user click the OK button? The OK system variable is set to 1 when a task is completed successfully, and to 0 when it is not.

For more information about system variables, see the section **System Variables**.

# System Variables

4D manages **system variables**, which allow you to control the execution of different operations. All system variables are process variables that can only be accessed within one process. This section describes 4D system variables.

For more information about the type of these variables, refer to **System variables** in the **Typing Guide**.

## OK

This is the most commonly used system variable. Usually it is set to 1 when an operation is successfully executed. It is set to 0 when the operation fails. Many 4D commands modify the value of the **OK** system variable. Refer to the description of each command to find out whether it affects this system variable.

In this documentation, the pictogram  indicates that a command modifies the value of the OK variable. You can click on this picture in order to generate a list of all the commands concerned.

## Document

**Document** contains the "long name" (access path+name) of the last file opened or created using the following commands:

| | |
|---|---|
| **Append document** | **BUILD APPLICATION** |
| **Create document** | **_o_Create resource file** |
| **EXPORT DATA** | **EXPORT DIF** |
| **EXPORT SYLK** | **EXPORT TEXT** |
| **GET DOCUMENT ICON** | **IMPORT DATA** |
| **IMPORT DIF** | **IMPORT SYLK** |
| **IMPORT TEXT** | **LOAD SET** |
| **LOAD VARIABLES** | **Open document** |
| **Open resource file** | **PRINT LABEL** |
| **QR REPORT** | **READ PICTURE FILE** |
| **SAVE VARIABLES** | **SAVE SET** |
| **Select document** | **SELECT LOG FILE** |
| **SET CHANNEL** | **USE CHARACTER SET** |
| **WRITE PICTURE FILE** | |

## FldDelimit

**FldDelimit** contains the character code that will be used as a field separator when importing or exporting text. By default, this value is set to 9, which is the character code for the Tab key. To use a different field separator, assign a new value to **FldDelimit**.

## RecDelimit

**RecDelimit** contains the character code that will be used as a record separator when importing or exporting text. By default, this value is set to 13, which is the character code for the Carriage Return key. To use a different record separator, assign a new value to **RecDelimit**.

## Error, Error method, Error line, Error formula

These variables can only be used in an error-catching method installed by the **ON ERR CALL** command. If you want for them to be accessible in the method that caused the error, copy their value into your own process variables.

- **Error**: Longint type system variable. This variable contains the error code. 4D error codes and system error codes are listed in sections of the **Error Codes** theme.
- **Error method**: Text type system variable. This variable contains the full name of the method that triggered the error.
- **Error line**: Longint type system variable. This variable contains the line number at the origin of the error in the method that triggered the error.
- **Error formula**: Text type system variable. This variable contains the formula of the 4D code (raw text) which is at the origin of the error. The text of the formula is expressed in the current language of the 4D code.
  If the source code responsible for the error cannot be found, **Error formula** contains an empty string. This case can occur in compiled databases when:
  - the source code was deleted from the compiled structure using the application builder.
  - the source code is available but the database was compiled without the **Range Checking** option.

## MouseDown, MouseX, MouseY, KeyCode, Modifiers and MouseProc

These system variables can only be used in a method installed by the **ON EVENT CALL** command (except **MouseX** and **MouseY** in some cases, see below).

- **MouseDown** is set to 1 when the mouse button is pushed. Otherwise, it is set to 0.
- If the event is a **MouseDown** (**MouseDown**=1), the **MouseX** and **MouseY** system variables are respectively set to the vertical and horizontal coordinates of the location where the click took place. Both values are expressed in pixels and use the local coordinate system of the window.
- In case of picture fields or variables, the **MouseX** and **MouseY** system variables return the local coordinates of a mouse click in the On Clicked, On Double Clicked and On Mouse Up form events. Local coordinates of the mouse cursor are also returned in the On Mouse Enter and On Mouse Move form events. The coordinates are expressed in pixels with respect to the top left corner of the picture (0,0). For more information, please refer to the **Pictures** section and the **SVG Find element ID by coordinates** command.

- **KeyCode** is set to the character code of the key that was just pressed. If the key is a function key, **KeyCode** is set to a special code. Character codes and function key codes are listed in the sections **Unicode Codes**, **EXPORT TEXT** and **Function Key Codes**.
- **Modifiers** is set to the keyboard modifier keys (**Ctrl/Command**, **Alt/Option**, **Shift**, **Caps Lock**). This variable is only significant in an "interruption on event" installed by the command **ON EVENT CALL**.
- **MouseProc** is set to the process number in which the last event took place.

# Pointers

## Description

Pointers provide an advanced way (in programming) to refer to data.

When you use the language, you access various objects—in particular, tables, fields, variables, and arrays—by simply using their names. However, it is often useful to refer to these elements and access them without knowing their names. This is what pointers let you do.

The concept behind pointers is not that uncommon in everyday life. You often refer to something without knowing its exact identity. For example, you might say to a friend, “Let’s go for a ride in your car” instead of “Let’s go for a ride in the car with license plate 123ABD.” In this case, you are referencing the car with license plate 123ABD by using the phrase “your car.” The phrase “car with license plate 123ABD” is like the name of an object, and using the phrase “your car” is like using a pointer to reference the object.

Being able to refer to something without knowing its exact identity is very useful. In fact, your friend could get a new car, and the phrase “your car” would still be accurate—it would still be a car and you could still take a ride in it. Pointers work the same way. For example, a pointer could at one time refer to a numeric field called Age, and later refer to a numeric variable called Old Age. In both cases, the pointer references numeric data that could be used in a calculation.

You can use pointers to reference tables, fields, variables, arrays, and array elements. The following table gives an example of each data type:

| Object | To Reference | To Use | To Assign |
|---|---|---|---|
| Table | vpTable:=->[Table] | DEFAULT TABLE(vpTable->) | n/a |
| Field | vpField:=->[Table]Field | ALERT(vpField->) | vpField->:="John" |
| Variable | vpVar:=->Variable | ALERT(vpVar->) | vpVar->:="John" |
| Array | vpArr:=->Array | SORT ARRAY(vpArr->;>) | COPY ARRAY (Arr;vpArr->) |
| Array element | vpElem:=->Array{1} | ALERT (vpElem->) | vpElem->:="John" |

## Using Pointers: An Example

It is easiest to explain the use of pointers through an example. This example shows how to access a variable through a pointer. We start by creating a variable:

```
MyVar:="Hello"
```

**MyVar** is now a variable containing the string *“Hello.”* We can now create a pointer to **MyVar**:

```
MyPointer:=->MyVar
```

The -> symbol means “get a pointer to.” This symbol is formed by a dash followed by a “greater than” sign. In this case, it gets the pointer that references or “points to” **MyVar**. This pointer is assigned to **MyPointer** with the assignment operator.

**MyPointer** is now a variable that contains a pointer to **MyVar**. **MyPointer** does not contain *“Hello”*, which is the value in **MyVar**, but you can use **MyPointer** to get this value. The following expression returns the value in **MyVar**:

```
MyPointer->
```

In this case, it returns the string *“Hello”*. The -> symbol, when it follows a pointer, references the object pointed to. This is called **dereferencing**.

It is important to understand that you can use a pointer followed by the -> symbol anywhere that you could have used the object that the pointer points to. This means that you could use the expression **MyPointer->** anywhere that you could use the original **MyVar** variable.

For example, the following line displays an alert box with the word Hello in it:

```
ALERT(MyPointer->)
```

You can also use **MyPointer** to change the data in **MyVar**. For example, the following statement stores the string *"Goodbye"* in the variable **MyVar**:

```
MyPointer->:="Goodbye"
```

If you examine the two uses of the expression **MyPointer->**, you will see that it acts just as if you had used **MyVar** instead. In summary, the following two lines perform the same action—both display an alert box containing the current value in the variable **MyVar**:

```
ALERT(MyPointer->)
ALERT(MyVar)
```

The following two lines perform the same action— both assign the string *"Goodbye"* to **MyVar**:

```
MyPointer->:="Goodbye"
MyVar:="Goodbye"
```

## Using Pointers to Buttons

This section describes how to use a pointer to reference a button. A button is (from the language point of view) nothing more than a variable. Although the examples in this section use pointers to reference buttons, the concepts presented here apply to the use of all types of objects that can be referenced by a pointer.

Let's say that you have a number of buttons in your forms that need to be enabled or disabled. Each button has a condition associated with it that is TRUE or FALSE. The condition says whether to disable or enable the button. You could use a test like this each time you need to enable or disable the button:

```
If(Condition) ` If the condition is TRUE…
   OBJECT SET ENABLED(MyButton;True) ` enable the button
Else ` Otherwise…
   OBJECT SET ENABLED(MyButton;False) ` disable the button
End if
```

You would need to use a similar test for every button you set, with only the name of the button changing. To be more efficient, you could use a pointer to reference each button and then use a subroutine for the test itself.

You must use pointers if you use a subroutine, because you cannot refer to the button's variables in any other way. For example, here is a project method called **SET BUTTON**, which references a button with a pointer:

```
  ` SET BUTTON project method
  ` SET BUTTON ( Pointer ; Boolean )
  ` SET BUTTON ( -> Button ; Enable or Disable )
  `
  ` $1 - Pointer to a button
  ` $2 - Boolean. If TRUE, enable the button. If FALSE, disable the button

If($2) ` If the condition is TRUE…
   OBJECT SET ENABLED($1->;True) ` enable the button
Else ` Otherwise…
   OBJECT SET ENABLED($1->;False) ` disable the button
End if
```

You can call the **SET BUTTON** project method as follows:

```
  ` ...
SET BUTTON(->bValidate;True)
  ` ...
SET BUTTON(->bValidate;False)
  ` ...
SET BUTTON(->bValidate;([Employee]Last Name#""))
  ` ...
For($vlRadioButton;1;20)
   $vpRadioButton:=Get pointer("r"+String($vlRadioButton))
   SET BUTTON($vpRadioButton;False)
End for
```

## Using Pointers to Tables

Anywhere that the language expects to see a table, you can use a dereferenced pointer to the table.
You create a pointer to a table by using a line like this:

```
TablePtr:=->[anyTable]
```

You can also get a pointer to a table by using the **Table** command. For example:

```
TablePtr:=Table(20)
```

You can use the dereferenced pointer in commands, like this:

```
DEFAULT TABLE(TablePtr->)
```

## Using Pointers to Fields

Anywhere that the language expects to see a field, you can use a dereferenced pointer to reference the field. You create a pointer to a field by using a line like this:

```
FieldPtr:=->[aTable]ThisField
```

You can also get a pointer to a field by using the **Field** command. For example:

```
FieldPtr:=Field(1;2)
```

You can use the dereferenced pointer in commands, like this:

```
OBJECT SET FONT(FieldPtr->;"Arial")
```

## Using Pointers to Variables

The example at the beginning of this section illustrates the use of a pointer to a variable:

```
MyVar:="Hello"
MyPointer:=->MyVar
```

You can use pointers to interprocess, process and, starting with version 2004.1, local variables.

When you use pointers to process or local variables, you must be sure that the variable pointed to is already set when the pointer is used. Keep in mind that local variables are deleted when the method that created them has completed its execution and process variables are deleted at the end of the process that created them. When a pointer calls a variable that no longer exists, this causes a syntax error in interpreted mode (variable not defined) but it can generate a more serious error in compiled mode.

**Note about local variables:** Pointers to local variables allow you to save process variables in many cases. Pointers to local variables can only be used within the same process.
In the debugger, when you display a pointer to a local variable that has been declared in another method, the original method name is indicated in parentheses, after the pointer. For example, if you write in Method1:

```
$MyVar:="Hello world"
Method2(->$MyVar)
```

In Method2, the debugger will display *$1* as follows:

```
$1   ->$MyVar (Method1)
```

The value of *$1* will be:

```
$MyVar (Method1)   "Hello world"
```

## Using Pointers to Array Elements

You can create a pointer to an array element. For example, the following lines create an array and assign a pointer to the first array element to a variable called **ElemPtr**:

```
ARRAY REAL(anArray;10) ` Create an array
ElemPtr:=->anArray{1} ` Create a pointer to the array element
```

You could use the dereferenced pointer to assign a value to the element, like this:

```
ElemPtr->:=8
```

## Using Pointers to Arrays

You can create a pointer to an array. For example, the following lines create an array and assign a pointer to the array to a variable called **ArrPtr**:

```
ARRAY REAL(anArray;10) ` Create an array
ArrPtr:=->anArray ` Create a pointer to the array
```

It is important to understand that the pointer points to the array; it does not point to an element of the array. For example, you can use the dereferenced pointer from the preceding lines like this:

```
SORT ARRAY(ArrPtr->;>) ` Sort the array
```

If you need to refer to the fourth element in the array by using the pointer, you do this:

```
ArrPtr->{4}:=84
```

## Using an Array of Pointers

It is often useful to have an array of pointers that reference a group of related objects.

One example of such a group of objects is a grid of variables in a form. Each variable in the grid is sequentially numbered, for example: **Var1**,**Var2**,…, **Var10**. You often need to reference these variables indirectly with a number. If you create an array of pointers, and initialize the pointers to point to each variable, you can then easily reference the variables. For example, to create an array and initialize each element, you could use the following lines:

```
ARRAY POINTER(apPointers;10) ` Create an array to hold 10 pointers
For($i;1;10) ` Loop once for each variable
   apPointers{$i}:=Get pointer("Var"+String($i)) ` Initialize the array element
End for
```

The **Get pointer** function returns a pointer to the named object.

To reference any of the variables, you use the array elements. For example, to fill the variables with the next ten dates (assuming they are variables of the date type), you could use the following lines:

```
For($i;1;10) ` Loop once for each variable
   apPointers{$i}->:=Current date+$i  ` Assign the dates
End for
```

## Setting a Button Using a Pointer

If you have a group of related radio buttons in a form, you often need to set them quickly. It is inefficient to directly reference each one of them by name. Let's say you have a group of radio buttons named **Button1**, **Button2**,…, **Button5**.

In a group of radio buttons, only one radio button is on. The number of the radio button that is on can be stored in a numeric field. For example, if the field called *[Preferences]Setting* contains *3*, then **Button3** is selected. In your form method, you could use the following code to set the button:

```
Case of
   :(Form event=On Load)
` ...
      Case of
         :([Preferences]Setting=1)
```

```
            Button1:=1
         :([Preferences]Setting=2)
            Button2:=1
         :([Preferences]Setting=3)
            Button3:=1
         :([Preferences]Setting=4)
            Button4:=1
         :([Preferences]Setting=5)
            Button5:=1
      End case
   ` ...
End case
```

A separate case must be tested for each radio button. This could be a very long method if you have many radio buttons in your form. Fortunately, you can use pointers to solve this problem. You can use the **Get pointer** command to return a pointer to a radio button. The following example uses such a pointer to reference the radio button that must be set. Here is the improved code:

```
Case of
   :(Form event=On Load)
   ` ...
      $vpRadio:=Get pointer("Button"+String([Preferences]Setting))
      $vpRadio->:=1
   ` ...
End case
```

The number of the set radio button must be stored in the field called *[Preferences]Setting*. You can do so in the form method for the On Clicked event:

```
[Preferences]Setting:=Button1+(Button2*2)+(Button3*3)+(Button4*4)+(Button5*5)
```

## Passing Pointers to Methods

You can pass a pointer as a parameter to a method. Inside the method, you can modify the object referenced by the pointer. For example, the following method, **TAKE TWO**, takes two parameters that are pointers. It changes the object referenced by the first parameter to uppercase characters, and the object referenced by the second parameter to lowercase characters. Here is the method:

```
   ` TAKE TWO project method
   ` $1 - Pointer to a string field or variable. Change this to uppercase.
   ` $2 - Pointer to a string field or variable. Change this to lowercase.
$1->:=Uppercase($1->)
$2->:=Lowercase($2->)
```

The following line uses the **TAKE TWO** method to change a field to uppercase characters and to change a variable to lowercase characters:

```
TAKE TWO(->[My Table]My Field;->MyVar)
```

If the field *[My Table]My Field* contained the string *"jones",* it would be changed to the string *"JONES"*. If the variable **MyVar** contained the string *"HELLO",* it would be changed to the string *"hello"*.

In the **TAKE TWO** method, and in fact, whenever you use pointers, it is important that the data type of the object being referenced is correct. In the previous example, the pointers must point to an object that contains a string or text.

## Pointers to Pointers

If you really like to complicate things, you can use pointers to reference other pointers. Consider this example:

```
MyVar:="Hello"
PointerOne:=->MyVar
PointerTwo:=->PointerOne
(PointerTwo->)->:="Goodbye"
ALERT((Point Two->)->)
```

It displays an alert box with the word *"Goodbye"* in it.

Here is an explanation of each line of the example:

- *MyVar:="Hello"*
  --> This line puts the string *"Hello"* into the variable **MyVar**.
- *PointerOne:=->MyVar*
  --> **PointerOne** now contains a pointer to **MyVar**.
- *PointerTwo:=->PointerOne*
  --> **PointerTwo** (a new variable) contains a pointer to **PointerOne**, which in turn points to **MyVar**.
- *(PointerTwo->)->:="Goodbye"*
  --> **PointerTwo->** references the contents of **PointerOne**, which in turn references **MyVar**. Therefore (**PointerTwo->)->** references the contents of **MyVar**. So in this case, **MyVar** is assigned *"Goodbye"*.
- *ALERT ((PointerTwo->)->)*
  --> Same thing: **PointerTwo->** references the contents of **PointerOne**, which in turn references **MyVar**. Therefore (**PointerTwo->)->** references the contents of **MyVar**. So in this case, the alert box displays the contents of *myVar*.

The following line puts *"Hello"* into **MyVar**:

```
(PointerTwo->)->:="Hello"
```

The following line gets *"Hello"* from **MyVar** and puts it into **NewVar**:

```
NewVar:=(PointerTwo->)->
```

**Important**: Multiple dereferencing requires parentheses.

# Identifiers

This section describes the conventions for naming various objects in the 4D language. The names for all objects follow these rules:

- A name must begin with an alphabetic character or an underscore.
- Thereafter, the name can include alphabetic characters, numeric characters, the space character, and the underscore character.
- Periods, slashes, quotation marks and colons are not allowed.
- Characters reserved for use as operators, such as * and +, are not allowed.
- 4D ignores any trailing spaces.

**Note**: Additional rules need to be respected when objects need to be handled via SQL: only the characters *_0123456789abcdefghijklmnopqrstuvwxyz* are accepted, and the name must not include any SQL keywords (command, attribute, etc.). The "SQL" area of the Inspector in the Structure editor automatically indicates any unauthorized characters in the name of a table or field.

## Tables

You denote a table by placing its name between brackets: *[...]*. A table name can contain up to 31 characters.

Examples

```
DEFAULT TABLE([Orders])
FORM SET INPUT([Clients];"Entry")
ADD RECORD([Letters])
```

## Fields

You denote a field by first specifying the table to which the field belongs. The field name immediately follows the table name. A field name can contain up to 31 characters.

Examples

```
[Orders]Total:=Sum([Line]Amount)
QUERY([Clients];[Clients]Name="Smith")
[Letters]Text:=Capitalize text([Letters]Text)
```

## Interprocess Variables

You denote an interprocess variable by preceding the name of the variable with the symbols (<>) — a “less than” sign followed by a “greater than” sign.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (Option-Shift-V on US keyboard).

An interprocess variable can have up to 31 characters, not including the <> symbols.

Examples

```
<>vlProcessID:=Current process
<>vsKey:=Char(KeyCode)
If(<>vtName#"")
```

## Process Variables

You denote a process variable by using its name (which cannot start with the <> symbols nor the dollar sign *$*). A process variable name can contain up to 31 characters.

Examples

```
<>vrGrandTotal:=Sum([Accounts]Amount)
If(bValidate=1)
   vsCurrentName:=""
```

## Local Variables

You denote a local variable with a dollar sign ($) followed by its name. A local variable name can contain up to 31 characters, not including the dollar sign.

Examples

```
For($vlRecord;1;100)
   If($vsTempVar="No")
      $vsMyString:="Hello there"
```

## Arrays

You denote an array by using its name, which is the name you passed to the array declaration (such as **ARRAY LONGINT**) when you created the array. Arrays are variables, and from the scope point of view, like variables, there are three different types of arrays:

- Interprocess arrays,
- Process arrays,
- Local arrays.

**Interprocess Arrays**

The name of an interprocess array is preceded by the symbols (<>) — a “less than” sign followed by a “greater than” sign.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (Option-Shift-V on US keyboard).

An interprocess array name can contain up to 31 characters, not including the <> symbols.

Examples

```
ARRAY TEXT(<>atSubjects;Records in table([Topics]))
SORT ARRAY(<>asKeywords;>)
ARRAY INTEGER(<>aiBigArray;10000)
```

**Process Arrays**

You denote a process array by using its name (which cannot start with the <> symbols nor the dollar sign $). A process array name can contain up to 31 characters.

Examples

```
ARRAY TEXT(atSubjects;Records in table([Topics]))
SORT ARRAY(asKeywords;>)
ARRAY INTEGER(aiBigArray;10000)
```

**Local Arrays**

The name of a local array is preceded by the dollar sign ($). An local array name can contain up to 31 characters, not including the dollar sign.

Examples

```
ARRAY TEXT($atSubjects;Records in table([Topics]))
SORT ARRAY($asKeywords;>)
ARRAY INTEGER($aiBigArray;10000)
```

**Elements of arrays**

You reference an element of an interprocess, process or local array by using the curly braces({…}). The element referenced is denoted by a numeric expression.

Examples

```
  ` Addressing an element of an interprocess array
If(<>asKeywords{1}="Stop")
   <>atSubjects{$vlElem}:=[Topics]Subject
   $viNextValue:=<>aiBigArray{Size of array(<>aiBigArray)}

  ` Addressing an element of a process array
   If(asKeywords{1}="Stop")
      atSubjects{$vlElem}:=[Topics]Subject
      $viNextValue:=aiBigArray{Size of array(aiBigArray)}

  ` Addressing an element of a local array
      If($asKeywords{1}="Stop")
         $atSubjects{$vlElem}:=[Topics]Subject
         $viNextValue:=$aiBigArray{Size of array($aiBigArray)}
```

**Elements of two-dimensional arrays**

You reference an element of a two-dimensional array by using the curly braces ({…}) twice. The element referenced is denoted by two numeric expressions in two sets of curly braces.

Examples

```
  ` Addressing an element of a two-dimensional interprocess array
If(<>asKeywords{$vlNextRow}{1}="Stop")
   <>atSubjects{10}{$vlElem}:=[Topics]Subject
   $viNextValue:=<>aiBigArray{$vlSet}{Size of array(<>aiBigArray{$vlSet})}

  ` Addressing an element of a two-dimensional process array
   If(asKeywords{$vlNextRow}{1}="Stop")
      atSubjects{10}{$vlElem}:=[Topics]Subject
      $viNextValue:=aiBigArray{$vlSet}{Size of array(aiBigArray{$vlSet})}

  ` Addressing an element of a two-dimensional local array
      If($asKeywords{$vlNextRow}{1}="Stop")
         $atSubjects{10}{$vlElem}:=[Topics]Subject
         $viNextValue:=$aiBigArray{$vlSet}{Size of array($aiBigArray{$vlSet})}
```

## Forms

You denote a form by using a string expression that represents its name. A form name can contain up to 31 characters.

Examples

```
FORM SET INPUT([People];"Input")
FORM SET OUTPUT([People];"Output")
DIALOG([Storage];"Note box"+String($vlStage))
```

## Form objects

You designate a form object by passing its name as a string, preceded by the* parameter. An object name can contain up to 255 bytes.

Example :

```
OBJECT SET FONT(*;"Binfo";"Times")
```

See also the **Object Properties** section.

## Methods

You denote a method (procedure and function) by using its name. A method name can contain up to 31 characters.

**Note**: A method that does not return a result is also called a **procedure**. A method that returns a result is also called a **function**.

Examples

```
If(New client)
   DELETE DUPLICATED VALUES
   APPLY TO SELECTION([Employees];INCREASE SALARIES)
```

**Tip**: It is a good programming technique to adopt the same naming convention as the one used by 4D for built-in commands. Use uppercase characters for naming your methods; however if a method is a function, capitalize the first character of its name. By doing so, when you reopen a database for maintenance after a few months, you will already know if a method returns a result by simply looking at its name in the Explorer window.

**Note**: When you call a method, you just type its name. However, some 4D built-in commands, such as **ON EVENT CALL**, as well as all the Plug-In commands, expect the name of a method as a string when a method parameter is passed. Example:

Examples

```
 ` This command expects a method (function) or formula
QUERY BY FORMULA([aTable];Special query)
 ` This command expects a method (procedure) or statement
APPLY TO SELECTION([Employees];INCREASE SALARIES)
 ` But this command expects a method name
ON EVENT CALL("HANDLE EVENTS")
 ` And this Plug-In command expects a method name
WR ON ERROR("WR HANDLE ERRORS")
```

Methods can accept parameters (arguments). The parameters are passed to the method in parentheses, following the name of the method. Each parameter is separated from the next by a semicolon (*;*). The parameters are available within the called method as consecutively numbered local variables: *$1*, *$2*,…, *$n*. In addition, multiple consecutive (and last) parameters can be addressed with the syntax *${n}*where n, numeric expression, is the number of the parameter.

Inside a function, the *$0* local variable contains the value to be returned.

Examples

```
 ` Within DROP SPACES $1 is a pointer to the field [People]Name
DROP SPACES(->[People]Name)

 ` Within Calc creator:
 ` - $1 is numeric and equal to 1
 ` - $2 is numeric and equal to 5
 ` - $3 is text or string and equal to "Nice"
 ` - The result value is assigned to $0
$vsResult:=Calc creator(1;5;"Nice")

 ` Within Dump:
 ` - The three parameters are text or string
 ` - They can be addressed as $1, $2 or $3
 ` - They can also be addressed as, for instance, ${$vlParam} where $vlParam is 1, 2 or 3
 ` - The result value is assigned to $0
vtClone:=Dump("is";"the";"it")
```

## Plug-In Commands (External Procedures, Functions and Areas)

You denote a plug-in command by using its name as defined by the plug-in. A plug-in command name can contain up to 31 characters.

Examples

```
WR BACKSPACE(wrArea;0)
$pvNewArea:=PV New offscreen area
```

## Sets

From the scope point of view, there are two types of sets:

- Interprocess sets
- Process sets.

4D Server also includes:

- Client sets.

**Interprocess Sets**
A set is an interprocess set if the name of the set is preceded by the symbols (<>) — a “less than” sign followed by a “greater than” sign.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (Option-Shift-V on US keyboard).

An interprocess set name can contain up to 255 characters, not including the <> symbols.

**Process Sets**
You denote a process set by using a string expression that represents its name (which cannot start with the <> symbols or the dollar sign *$*). A set name can contain up to 255 characters.

**Client Sets**
The name of a client set is preceded by the dollar sign (*$*). A client set name can contain up to 255 characters, not including the dollar sign.

**Note**: Sets are maintained on the Server machine. In certain cases, for efficiency or special purposes, you may need to work with sets locally on the Client machine. To do so, you use Client sets.

Examples

```
  ` Interprocess sets
USE SET("<>Deleted Records")
CREATE SET([Customers];"<>Customer Orders")
If(Records in set("<>Selection"+String($i))>0)
  ` Process sets
   USE SET("Deleted Records")
   CREATE SET([Customers];"Customer Orders")
   If(Records in set("<>Selection"+String($i))>0)
  ` Client sets
      USE SET("$Deleted Records")
      CREATE SET([Customers];"$Customer Orders")
      If(Records in set("$Selection"+String($i))>0)
```

## Named Selections

From the scope point of view, there are two types of named selections:

- Interprocess named selections
- Process named selections.

**Interprocess Named Selections**
A named selection is an interprocess named selection if its name is preceded by the symbols (<>) — a “less than” sign followed by a “greater than” sign.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (Option-Shift-V on US keyboard).

An interprocess named selection name can contain up to 255 characters, not including the <> symbols.

**Process Named Selections**
You denote a process named selection by using a string expression that represents its name (which cannot start with the <> symbols nor the dollar sign *$*). A named selection name can contain up to 255 characters.

Examples

```
  ` Interprocess Named Selection
USE NAMED SELECTION([Customers];"<>ByZipcode")
  ` Process Named Selection
USE NAMED SELECTION([Customers];"<>ByZipcode")
```

## Processes

In the single-user version, or in Client/Server on the Client side, there are two types of processes:

- Global processes
- Local processes.

**Global Processes**

You denote a global process by using a string expression that represents its name (which cannot start with the dollar sign *$*). A process name can contain up to 255 characters.

**Local Processes**

You denote a local process if the name of the process is preceded by a dollar (*$*) sign. The process name can contain up to 255 characters, not including the dollar sign.

Example

```
  ` Starting the global process "Add Customers"
$vlProcessID:=New process("P_ADD_CUSTOMERS";48*1024;"Add Customers")
  ` Starting the local process "$Follow Mouse Moves"
$vlProcessID:=New process("P_MOUSE_SNIFFER";16*1024;"$Follow Mouse Moves")
```

## Summary of Naming Conventions

The following table summarizes 4D naming conventions.

| Type | Max. Length | Example |
|---|---|---|
| Table | 31 | [Invoices] |
| Field | 31 | [Employees]Last Name |
| Interprocess Variable | <> + 31 | <>vlNextProcessID |
| Process Variable | 31 | vsCurrentName |
| Local Variable | $ + 31 | $vlLocalCounter |
| Form | 31 | "My Custom Web Input" |
| Form object | 31 | "MyButton" |
| Interprocess Array | <> + 31 | <>apTables |
| Process Array | 31 | asGender |
| Local Array | $ + 31 | $atValues |
| Method | 31 | M_ADD_CUSTOMERS |
| Plug-in Routine | 31 | WR INSERT TEXT |
| Interprocess Set | <> + 255 | "<>Records to be Archived" |
| Process Set | 255 | "Current selected records" |
| Client Set | $ + 255 | "$Previous Subjects" |
| Named Selection | 255 | "Employees A to Z" |
| Interprocess Named Selection | <> + 255 | "<>Employees Z to A" |
| Local Process | $ + 255 | "$Follow Events" |
| Global Process | 255 | "P_INVOICES_MODULE" |
| Semaphore | 255 | "mysemaphore" |

## Resolving Naming Conflicts

If a particular object has the same name as another object of a different type (for example, if a field is named Person and a variable is also named Person), 4D uses a priority system to identify the object. It is up to you to ensure that you use unique names for the parts of your database.

4D identifies names used in procedures in the following order:

1. Fields
2. Commands
3. Methods
4. Plug-in routines
5. Predefined constants
6. Variables.

For example, 4D has a built-in command called **Date**. If you named a method Date, 4D would recognize it as the built-in **Date** command, and not as your method. This would prevent you from calling your method. If, however, you named a field *"Date"*, 4D would try to use your field instead of the **Date** command.

# Control Flow

Regardless of the simplicity or complexity of a method, you will always use one or more of three types of programming structures. Programming structures control the flow of execution, whether and in what order statements are executed within a method. There are three types of structures:

- Sequential
- Branching
- Looping

The 4D language contains statements that control each of these structures.

## Sequential structure

The sequential structure is a simple, linear structure. A sequence is a series of statements that 4D executes one after the other, from first to last. For example:

```
OUTPUT FORM([People];"Listing")
ALL RECORDS([People])
DISPLAY SELECTION([People])
```

A one-line routine, frequently used for object methods, is the simplest case of a sequential structure. For example:

```
[People]Last Name:=Uppercase([People]Last Name)
```

**Note:** The **Begin SQL** / **End SQL** keywords can be used to delimit sequential structures to be executed by the SQL engine of 4D. For more information, please refer to the description of these keywords.

## Branching structures

A branching structure allows methods to test a condition and take alternative paths, depending on the result. The condition is a Boolean expression, an expression that evaluates TRUE or FALSE. One branching structure is the **If...Else...End if** structure, which directs program flow along one of two paths. The other branching structure is the **Case of...Else...End case** structure, which directs program flow to one of many paths.

## Looping structures

When writing methods, it is very common to find that you need a sequence of statements to repeat a number of times. To deal with this need, the language provides three looping structures:

- **While...End while**
- **Repeat...Until**
- **For...End for**

The loops are controlled in two ways: either they loop until a condition is met, or they loop a specified number of times. Each looping structure can be used in either way, but While loops and Repeat loops are more appropriate for repeating until a condition is met, and For loops are more appropriate for looping a specified number of times.

**Note**: 4D allows you to embed programming structures (If/While/For/Case of/Repeat) up to a "depth" of 512 levels.

## If...Else...End if

---

The formal syntax of the **If...Else...End if** control flow structure is:

```
If(Boolean_Expression)
   statement(s)
Else
   statement(s)
End if
```

Note that the **Else** part is optional; you can write:

```
If(Boolean_Expression)
   statement(s)
End if
```

The **If...Else...End if** structure lets your method choose between two actions, depending on whether a test (a Boolean expression) is TRUE or FALSE.

When the Boolean expression is TRUE, the statements immediately following the test are executed. If the Boolean expression is FALSE, the statements following the **Else** statement are executed. The **Else** statement is optional; if you omit **Else**, execution continues with the first statement (if any) following the **End if**.

Note that the Boolean expression is always fully evaluated. Consider in particular the following test:

```
If(MethodA & MethodB)
   ...
End if
```

The expression is TRUE only if both methods are TRUE. However, even if ***MethodA*** returns FALSE, 4D will still evaluate ***MethodB***, which is a useless waste of time. In this case, it is more interesting to use a structure like:

```
If(MethodA)
   If(MethodB)
      ...
   End if
End if
```

The result is similar and ***MethodB*** is evaluated only if necessary.

### Example

```
   ` Ask the user to enter a name
$Find:=Request(Type a name)
If(OK=1)
   QUERY([People];[People]LastName=$Find)
Else
   ALERT("You did not enter a name.")
End if
```

**Tip**: Branching can be performed without statements to be executed in one case or the other. When developing an algorithm or a specialized application, nothing prevents you from writing:

```
If(Boolean_Expression)
Else
   statement(s)
End if
```

or:

```
If(Boolean_Expression)
   statement(s)
Else
End if
```

## Case of...Else...End case

The formal syntax of the **Case of...Else...End case** control flow structure is:

```
Case of
   :(Boolean_Expression)
      statement(s)
   :(Boolean_Expression)
      statement(s)
      .
      .
      .

   :(Boolean_Expression)
      statement(s)
   Else
      statement(s)
End case
```

Note that the **Else** part is optional; you can write:

```
Case of
   :(Boolean_Expression)
      statement(s)
   :(Boolean_Expression)
      statement(s)
      .
      .
      .

   :(Boolean_Expression)
      statement(s)
End case
```

As with the **If...Else...End if** structure, the **Case of...Else...End case** structure also lets your method choose between alternative actions. Unlike the **If...Else...End if** structure, the **Case of...Else...End case** structure can test a reasonable unlimited number of Boolean expressions and take action depending on which one is TRUE.

Each Boolean expression is prefaced by a colon (*:*). This combination of the colon and the Boolean expression is called a case. For example, the following line is a case:

```
:(bValidate=1)
```

Only the statements following the first TRUE case (and up to the next case) will be executed. If none of the cases are TRUE, none of the statements will be executed (if no **Else** part is included).

You can include an **Else** statement after the last case. If all of the cases are FALSE, the statements following the **Else** will be executed.

### Example

This example tests a numeric variable and displays an alert box with a word in it:

```
Case of
   :(vResult=1) ` Test if the number is 1
      ALERT("One.") ` If it is 1, display an alert
   :(vResult=2) ` Test if the number is 2
      ALERT("Two.") ` If it is 2, display an alert
   :(vResult=3) ` Test if the number is 3
      ALERT("Three.") ` If it is 3, display an alert
   Else ` If it is not 1, 2, or 3, display an alert
```

```
      ALERT("It was not one, two, or three.")
End case
```

For comparison, here is the **If...Else...End if** version of the same method:

```
If(vResult=1) ` Test if the number is 1
   ALERT("One.") ` If it is 1, display an alert
Else
   If(vResult=2) ` Test if the number is 2
      ALERT("Two.") ` If it is 2, display an alert
   Else
      If(vResult=3) ` Test if the number is 3
         ALERT("Three.") ` If it is 3, display an alert
      Else ` If it is not 1, 2, or 3, display an alert
         ALERT("It was not one, two, or three.")
      End if
   End if
End if
```

Remember that with a **Case of...Else...End case** structure, only the first TRUE case is executed. Even if two or more cases are TRUE, only the statements following the first TRUE case will be executed.

Consequently, when you want to implement hierarchical tests, you should make sure the condition statements that are lower in the hierarchical scheme appear first in the test sequence. For example, the test for the presence of condition1 covers the test for the presence of condition1&condition2 and should therefore be located last in the test sequence. For example, the following code will never see its last condition detected:

```
Case of
   :(vResult=1)
      ... `statement(s)
   :((vResult=1) & (vCondition#2)) `this case will never be detected
      ... `statement(s)
End case
.
```

In the code above, the presence of the second condition is not detected since the test "vResult=1" branches off the code before any further testing. For the code to operate properly, you can write it as follows:

```
Case of
   :((vResult=1) & (vCondition#2)) `this case will be detected first
      ... `statement(s)
   :(vResult=1)
      ... `statement(s)
End case
.
```

Also, if you want to implement hierarchical testing, you may consider using hierarchical code.

**Tip**: Branching can be performed without statements to be executed in one case or another. When developing an algorithm or a specialized application, nothing prevents you from writing:

```
Case of
   :(Boolean_Expression)
   :(Boolean_Expression)

      .
      .
      .

   :(Boolean_Expression)
      statement(s)
   Else
      statement(s)
End case
```

or:

```
Case of
   :(Boolean_Expression)
   :(Boolean_Expression)
      statement(s)
      .
      .
      .

   :(Boolean_Expression)
      statement(s)
   Else
End case
```

or:

```
Case of
   Else
      statement(s)
End case
```

## While...End while

The formal syntax of the **While...End while** control flow structure is:

```
While(Boolean_Expression)
   statement(s)
End while
```

A **While...End while** loop executes the statements inside the loop as long as the Boolean expression is TRUE. It tests the Boolean expression at the beginning of the loop and does not enter the loop at all if the expression is FALSE.

It is common to initialize the value tested in the Boolean expression immediately before entering the **While...End while** loop. Initializing the value means setting it to something appropriate, usually so that the Boolean expression will be TRUE and **While...End while** executes the loop.

The Boolean expression must be set by something inside the loop or else the loop will continue forever. The following loop continues forever because NeverStop is always TRUE:

```
NeverStop:=True
While(NeverStop)
End while
```

If you find yourself in such a situation, where a method is executing uncontrolled, you can use the trace facilities to stop the loop and track down the problem. For more information about tracing a method, see the chapter **Debugging**.

### Example

```
CONFIRM("Add a new record?") ` The user wants to add a record?
While(OK=1) ` Loop as long as the user wants to
   ADD RECORD([aTable]) ` Add a new record
End while ` The loop always ends with End while
```

In this example, the OK system variable is set by the **CONFIRM** command before the loop starts. If the user clicks the OK button in the confirmation dialog box, the OK system variable is set to 1 and the loop starts. Otherwise, the OK system variable is set to 0 and the loop is skipped. Once the loop starts, the **ADD RECORD** command keeps the loop going because it sets the OK system variable to 1 when the user saves the record. When the user cancels (does not save) the last record, the OK system variable is set to 0 and the loop stops.

# Repeat...Until

The formal syntax of the **Repeat...Until** control flow structure is:

```
Repeat
   statement(s)
Until(Boolean_Expression)
```

A **Repeat...Until** loop is similar to a **While...End while** loop, except that it tests the Boolean expression after the loop rather than before. Thus, a **Repeat...Until** loop always executes the loop once, whereas if the Boolean expression is initially False, a **While...End while** loop does not execute the loop at all.

The other difference with a **Repeat...Until** loop is that the loop continues until the Boolean expression is TRUE.

## Example

Compare the following example with the example for the **While...End while** loop. Note that the Boolean expression does not need to be initialized—there is no **CONFIRM** command to initialize the OK variable.

```
Repeat
   ADD RECORD([aTable])
Until(OK=0)
```

# For...End for

The formal syntax of the **For...End for** control flow structure is:

```
For(Counter_Variable;Start_Expression;End_Expression{;Increment_Expression})
   statement(s)
End for
```

The **For...End for** loop is a loop controlled by a counter variable:

- The counter variable **Counter_Variable** is a numeric variable (Real, Integer, or Long Integer) that the **For...End for** loop initializes to the value specified by **Start_Expression**.
- Each time the loop is executed, the counter variable is incremented by the value specified in the optional value **Increment_Expression**. If you do not specify **Increment_Expression**, the counter variable is incremented by one (*1*), which is the default.
- When the counter variable passes the **End_Expression** value, the loop stops.

**Important**: The numeric expressions **Start_Expression**, **End_Expression** and **Increment_Expression** are evaluated once at the beginning of the loop. If these expressions are variables, changing one of these variables **within** the loop **will not** affect the loop.

**Tip**: However, for special purposes, you can change the value of the counter variable **Counter_Variable** **within** the loop; this **will** affect the loop.

- Usually **Start_Expression** is less than **End_Expression**.
- If **Start_Expression** and **End_Expression** are equal, the loop will execute only once.
- If **Start_Expression** is greater than **End_Expression,** the loop will not execute at all unless you specify a negative **Increment_Expression**. See the examples.

## Basic Examples

1. The following example executes 100 iterations:

```
For(vCounter;1;100)
  ` Do something
End for
```

2. The following example goes through all elements of the array *anArray*:

```
For($vlElem;1;Size of array(anArray))
  ` Do something with the element
   anArray{$vlElem}:=...
End for
```

3. The following example goes through all the characters of the text *vtSomeText*:

```
For($vlChar;1;Length(vtSomeText))
  ` Do something with the character if it is a TAB
   If(Character code(vtSomeText≤$vlChar≥)=Tab)
  ` ...
   End if
End for
```

4. The following example goes through the selected records for the table *[aTable]*:

```
FIRST RECORD([aTable])
For($vlRecord;1;Records in selection([aTable]))
  ` Do something with the record
   SEND RECORD([aTable])
  ` ...
```

```
   ` Go to the next record
   NEXT RECORD([aTable])
End for
```

Most of the **For...End for** loops you will write in your databases will look like the ones listed in these examples.

## Decrementing variable counter

In some cases, you may want to have a loop whose counter variable is decreasing rather than increasing. To do so, you must specify **Start_Expression** greater than **End_Expression** and a negative **Increment_Expression**. The following examples do the same thing as the previous examples, but in reverse order:

5. The following example executes 100 iterations:

```
For(vCounter;100;1;-1)
   ` Do something
End for
```

6. The following example goes through all elements of the array *anArray*:

```
For($vlElem;Size of array(anArray);1;-1)
   ` Do something with the element
   anArray{$vlElem}:=...
End for
```

7. The following example goes through all the characters of the text *vtSomeText*:

```
For($vlChar;Length(vtSomeText);1;-1)
   ` Do something with the character if it is a TAB
   If(Character code(vtSomeText≤$vlChar≥)=Tab)
   ` ...
   End if
End for
```

8. The following example goes through the selected records for the table *[aTable]*:

```
LAST RECORD([aTable])
For($vlRecord;Records in selection([aTable]);1;-1)
   ` Do something with the record
   SEND RECORD([aTable])
   ` ...
   ` Go to the previous record
   PREVIOUS RECORD([aTable])
End for
```

## Incrementing the counter variable by more than one

If you need to, you can use an **Increment_Expression** (positive or negative) whose absolute value is greater than one.

9. The following loop addresses only the even elements of the array anArray:

```
For($vlElem;2;Size of array(anArray);2)
   ` Do something with the element #2,#4...#2n
   anArray{$vlElem}:=...
End for
```

## Getting out of a loop by changing the counter variable

In some cases, you may want to execute a loop for a specific number of iterations, but then get out of the loop when another condition becomes TRUE. To do so, you can test this condition within the loop and if it becomes TRUE, explicitly set the counter variable to a value that exceeds the end expression.

10. In the following example, a selection of the records is browsed until this is actually done or until the interprocess variable *<>vbWeStop*, intially set to FALSE, becomes TRUE. This variable is handled by an ***ON EVENT CALL*** project method that allows you to interrupt the operation:

```
<>vbWeStop:=False
ON EVENT CALL("HANDLE STOP")
  ` HANDLE STOP sets <>vbWeStop to True if Ctrl-period (Windows) or Cmd-Period (Macintosh) is pressed
$vlNbRecords:=Records in selection([aTable])
FIRST RECORD([aTable])
For($vlRecord;1;$vlNbRecords)
  ` Do something with the record
   SEND RECORD([aTable])
  ` ...
  ` Go to the next record
   If(<>vbWeStop)
      $vlRecord:=$vlNbRecords+1 ` Force the counter variable to get out of the loop
   Else
      NEXT RECORD([aTable])
   End if
End for
ON EVENT CALL("")
If(<>vbWeStop)
   ALERT("The operation has been interrupted.")
Else
   ALERT("The operation has been successfully completed.")
End if
```

## Comparing looping structures

Let's go back to the first **For...End for** example:

The following example executes 100 iterations:

```
For(vCounter;1;100)
  ` Do something
End for
```

It is interesting to see how the **While...End while** loop and **Repeat...Until** loop would perform the same action.

Here is the equivalent **While...End while** loop:

```
$i :=1 ` Initialize the counter
While($i<=100) ` Loop 100 times
  ` Do something
   $i :=$i +1 ` Need to increment the counter
End while
```

Here is the equivalent **Repeat...Until** loop:

```
$i :=1 ` Initialize the counter
Repeat
  ` Do something
   $i :=$i +1 ` Need to increment the counter
Until($i=100) ` Loop 100 times
```

**Tip**: The **For...End for** loop is usually faster than the **While...End while** and **Repeat...Until** loops, because 4D tests the condition internally for each cycle of the loop and increments the counter. Therefore, use the **For...End for** loop whenever possible.

## Optimizing the execution of the For...End for loops

You can use Real, Integer, and Long Integer variables as well as interprocess, process, and local variable counters. For lengthy repetitive loops, especially in compiled mode, use local Long Integer variables.

11. Here is an example:

```
C_LONGINT($vlCounter) ` use local Long Integer variables
For($vlCounter;1;10000)
  ` Do something
End for
```

## Nested For...End for looping structures

You can nest as many control structures as you (reasonably) need. This includes nesting **For...End for** loops. To avoid mistakes, make sure to use different counter variables for each looping structure.

Here are two examples:

12. The following example goes through all the elements of a two-dimensional array:

```
For($vlElem;1;Size of array(anArray))
  ` ...
  ` Do something with the row
  ` ...
   For($vlSubElem;1;Size of array(anArray{$vlElem}))
  ` Do something with the element
      anArray{$vlElem}{$vlSubElem}:=...
   End for
End for
```

13. The following example builds an array of pointers to all the date fields present in the database:

```
ARRAY POINTER($apDateFields;0)
$vlElem:=0
For($vlTable;1;Get last table number)
   If(Is table number valid($vlTable))
      For($vlField;1;Get last field number($vlTable))
         If(Is field number valid($vlTable;$vlField))
            $vpField:=Field($vlTable;$vlField)
            If(Type($vpField->)=Is date)
               $vlElem:=$vlElem+1
               INSERT IN ARRAY($apDateFields;$vlElem)
               $apDateFields{$vlElem}:=$vpField
            End if
         End if
      End for
   End if
End for
```

# Methods

In order to make the commands, operators, and other parts of the language work, you put them in methods. There are several kinds of methods: Object methods, Form methods, Table methods (Triggers), Project methods, and Database methods. This section describes features common to all types of methods.

A method is composed of **statements**; each statement consists of one line in the method. A statement performs an action, and may be simple or complex. Although a statement is always one line, that one line can be as long as needed (up to 32,000 characters, which is probably enough for most tasks).

For example, the following line is a statement that will add a new record to the [People] table:

```
ADD RECORD([People])
```

A method also contains **tests** and **loops** that control the flow of the execution. For a detailed discussion about the control flow programming structures, see the section **Control Flow**.

**Note**: The maximum size of a method is limited to 2 GB of text or 32 000 lines of command. Beyond these limits, a warning message appears, indicating that the extra lines will not be displayed.

## Types of Methods

There are five types of methods in 4D:

- **Object methods**: An object method is a property of an object. It is usually a short method associated with an active form object. Object methods generally “manage” the object while the form is displayed or printed. You do not call an object method—4D calls it automatically when an event involves the object to which the object method is attached.
- **Form methods**: A form method is a property of a form. You can use a form method to manage data and objects, but it is generally simpler and more efficient to use an object method for these purposes. You do not call a form method—4D calls it automatically when an event involves the form to which the form method is attached.

For more information about Object methods and Form methods, see the 4D Design Reference Manual as well as the chapter **Form Events**.

- **Table methods (Triggers)**: A Trigger is a property of a table. You do not call a Trigger. Triggers are automatically called by the 4D database engine each time that you manipulate the records of a table (Add, Delete and Modify). Triggers are methods that can prevent “illegal” operations with the records of your database. For example, in an invoicing system, you can prevent anyone from adding an invoice without specifying the customer to whom the invoice is billed. Triggers are a very powerful tool to restrict operations on a table, as well as to prevent accidental data loss or tampering. You can write very simple triggers, and then make them more and more sophisticated.

For detailed information about Triggers, see the section **Triggers**.

- **Project methods**: Unlike object methods, form methods, and triggers, which are all associated with a particular object, form, or table, project methods are available for use throughout your database. Project methods are reusable, and available for use by any other method. If you need to repeat a task, you do not have to write identical methods for each case. You can call project methods wherever you need them—from other project methods or from object or form methods. When you call a project method, it acts as if you had written the method at the location where you called it. Project methods called from other methods are often referred to as “subroutines.” A project method that returns a result can also be called a **function**.

There is one other way to use project methods—associating them with menu commands. When you associate a project method with a menu command, the method is executed when the menu command is chosen. You can think of the menu command as calling the project method.

For detailed information about Project methods, see the section **Project Methods**.

- **Database methods**: In the same way that object and form methods are called when events occur in a form, there are methods associated with the database that are called when a working session event occurs. These are the **database methods**. For example, each time you open a database, you may want to initialize some variables that will be used

during the whole working session. To do so, you use the **On Startup database method**, automatically executed by 4D when you open the database.

For more information about Database Methods, see the chapter **Database Methods**.

## An Example Project Method

All methods are fundamentally the same—they start at the first line and work their way through each statement until they reach the last line (i.e., they execute sequentially). Here is an example project method:

```
QUERY([People]) ` Display the Query editor
If(OK=1) ` The user clicked OK, not cancel
   If(Records in selection([People])=0) ` If no record was found…
      ADD RECORD([People]) ` Let the user add a new record
   End if
End if ` The end
```

Each line in the example is a **statement** or line of code. Anything that you write using the language is loosely referred to as code. Code is executed or run; this means that 4D performs the task specified by the code.

We will examine the first line in detail and then move on more quickly:

```
QUERY([People]) ` Display the Query editor
```

The first element in the line, **QUERY**, is a command. A command is part of the 4D language—it performs a task. In this case, **QUERY** displays the Query editor. This is similar to choosing Query from the Records menu in the Design environment.

The second element in the line, specified between parantheses, is an argument to the **QUERY** command. An argument (or **parameter**) is data required by a command in order to complete its task. In this case, *[People]* is the name of a table. Table names are always specified inside square brackets (*[…]*). In our example, the People table is an argument to the **QUERY** command. A command can accept several parameters.

The third element is a **comment** at the end of the line. A comment tells you (and anyone else who might read your code) what is happening in the code. It is indicated by the reverse apostrophe (`). Anything (on the line) following the comment mark will be ignored when the code is run. A comment can be put on a line by itself, or you can put comments to the right of the code, as in the example. Use comments generously throughout your code; this makes it easier for you and others to read and understand the code.

**Note**: A comment can be up to 32 000 characters long.

The next line of the method checks to see if any records were found:

```
If(Records in selection([People])=0) ` If no record was found…
```

The **If** statement is a **control-of-flow statement**—a statement that controls the step-by-step execution of your method. The **If** statement performs a test, and if the statement is true, execution continues with the subsequent lines. **Records in selection** is a function—a command that returns a value. Here, **Records in selection** returns the number of records in the current selection for the table passed as argument.

**Note**: Notice that only the first letter of the function name is capitalized. This is the naming convention for 4D functions.

You should already know what the current selection is—it is the group of records you are working on at any given time. If the number of records is equal to 0 (in other words, if no records were found), then the following line is executed:

```
ADD RECORD([People]) ` Let the user add a new record
```

The **ADD RECORD** command displays a form so that the user can add a new record. 4D formats your code automatically; notice that this line is indented to show you that it is dependent on the control-of-flow statement (If).

```
End if ` The end
```

The **End if** statement concludes the **If** statement's section of control. Whenever there is a control-of-flow statement, you need to have a corresponding statement telling the language where the control stops.

Be sure you feel comfortable with the concepts in this section. If they are all new, you may want to review them until they are clear to you.

## Where to go from here?

To learn more about:

- Object methods and Form methods, see the description of the **Form event** command as well as the 4D Design Reference manual.
- Triggers, see the section **Triggers**.
- Project methods, see the section **Project Methods**.
- Database methods, see the section **Database Methods**.

# Project Methods

Project methods are aptly named. Whereas form and object methods are bound to forms and objects, a project method is available anywhere; it is not specifically attached to any particular object of the database. A project method can have one of the following roles, depending on how it is executed and used:

- Menu method
- Subroutine and function
- Process method
- Event catching method
- Error catching method

These terms do not distinguish project methods by what they are, but by what they do.

A **menu method** is a project method called from a custom menu. It directs the flow of your application. The menu method takes control—branching where needed, presenting forms, generating reports, and generally managing your database.

The **subroutine** is a project method that can be thought of as a servant. It performs those tasks that other methods request it to perform. A function is a subroutine that returns a value to the method that called it.

A **process method** is a project method that is called when a process is started. The process lasts only as long as the process method continues to execute. For more information about processes, see the chapter **Processes**. Note that a menu method attached to a menu command whose property **Start a New Process** is selected, is also the process method for the newly started process.

An **event catching method** runs in a separate process as the process method for catching events. Usually, you let 4D do most of the event handling for you. For example, during data entry, 4D detects keystrokes and clicks, then calls the correct object and form methods so you can respond appropriately to the events from within these methods. In other circumstances, you may want to handle events directly. For example, if you run a lengthy operation (such as **For...End for** loop browsing records), you may want to be able to interrupt the operation by typing Ctrl-Period (Windows) or Cmd-Period (Macintosh). In this case, you should use an event catching method to do so. For more information, see the description of the command **ON EVENT CALL**.

An **error catching method** is an interrupt-based project method. Each time an error or an exception occurs, it executes within the process in which it was installed. For more information, see the description of the command **ON ERR CALL**.

## Menu Methods

A menu method is invoked in the Application environment when you select the custom menu command to which it is attached. You assign the method to the menu command using the Menu editor. The menu executes when the menu command is chosen. This process is one of the major aspects of customizing a database. By creating custom menus with menu methods that perform specific actions, you personalize your database. Refer to the 4D Design Reference manual for more information about the Menu editor.

Custom menu commands can cause one or more activities to take place. For example, a menu command for entering records might call a method that performs two tasks: displaying the appropriate input form, and calling the **ADD RECORD** command until the user cancels the data entry activity.

Automating sequences of activities is a very powerful capability of the programming language. Using custom menus, you can automate task sequences and thus provide more guidance to users of the database.

## Subroutines

When you create a project method, it becomes part of the language of the database in which you create it. You can then call the project method in the same way that you call 4D's built-in commands. A project method used in this way is called a subroutine.

You use subroutines to:

- Reduce repetitive coding
- Clarify your methods
- Facilitate changes to your methods

- Modularize your code

For example, let's say you have a database of customers. As you customize the database, you find that there are some tasks that you perform repeatedly, such as finding a customer and modifying his or her record. The code to do this might look like this:

```
 ` Look for a customer
QUERY BY EXAMPLE([Customers])
 ` Select the input form
FORM SET INPUT([Customers];"Data Entry")
 ` Modify the customer's record
MODIFY RECORD([Customers])
```

If you do not use subroutines, you will have to write the code each time you want to modify a customer's record. If there are ten places in your custom database where you need to do this, you will have to write the code ten times. If you use subroutines, you will only have to write it once. This is the first advantage of subroutines—to reduce the amount of code.

If the previously described code was a method called ***MODIFY CUSTOMER***, you would execute it simply by using the name of the method in another method. For example, to modify a customer's record and then print the record, you would write this method:

```
MODIFY CUSTOMER
PRINT SELECTION([Customers])
```

This capability simplifies your methods dramatically. In the example, you do not need to know how the ***MODIFY CUSTOMER*** method works, just what it does. This is the second reason for using subroutines—to clarify your methods. In this way, your methods become extensions to the 4D language.

If you need to change your method of finding customers in this example database, you will need to change only one method, not ten. This is the next reason to use subroutines—to facilitate changes to your methods.

Using subroutines, you make your code modular. This simply means dividing your code into modules (subroutines), each of which performs a logical task. Consider the following code from a checking account database:

```
FIND CLEARED CHECKS ` Find the cleared checks
RECONCILE ACCOUNT ` Reconcile the account
PRINT CHECK BOOK REPORT ` Print a checkbook report
```

Even for someone who doesn't know the database, it is clear what this code does. It is not necessary to examine each subroutine. Each subroutine might be many lines long and perform some complex operations, but here it is only important that it performs its task.

We recommend that you divide your code into logical tasks, or modules, whenever possible.

## Passing Parameters to Methods

You'll often find that you need to pass data to your methods. This is easily done with parameters.

**Parameters** (or arguments) are pieces of data that a method needs in order to perform its task. The terms parameter and argument are used interchangeably throughout this manual. Parameters are also passed to built-in 4D commands. In this example, the string "Hello" is an argument to the **ALERT** command:

```
ALERT("Hello")
```

Parameters are passed to methods in the same way. For example, if a method named ***DO SOMETHING*** accepted three parameters, a call to the method might look like this:

```
DO SOMETHING(WithThis;AndThat;ThisWay)
```

The parameters are separated by semicolons (*;*).

In the subroutine (the method that is called), the value of each parameter is automatically copied into sequentially numbered local variables: *$1*, *$2*, *$3*, and so on. The numbering of the local variables represents the order of the parameters.

The local variables/parameters are not the actual fields, variables, or expressions passed by the **calling method**; they only contain the values that have been passed.

Within the subroutine, you can use the parameters *$1*, *$2...* in the same way you would use any other local variable.

**Note**: However, in the case where you use commands that modify the value of the variable passed as parameter (for example **Find in field**), the parameters *$1*, *$2, and so on* cannot be used directly. You must first copy them into standard local variables (for example: *$myvar:=$1*).

Since they are local variables, they are available only within the subroutine and are cleared at the end of the subroutine. For this reason, a subroutine cannot change the value of the actual fields or variables passed as parameters at the calling method level. For example:

```
 ` Here is some code from the method MY METHOD
 ` ...
DO SOMETHING([People]Last Name) ` Let's say [People]Last Name is equal to "williams"
ALERT([People]Last Name)

 ` Here is the code of the method DO SOMETHING
$1:=Uppercase($1)
ALERT($1)
```

The alert box displayed by ***DO SOMETHING*** will read “WILLIAMS” and the alert box displayed by ***MY METHOD*** will read “williams”. The method locally changed the value of the parameter *$1*, but this does not affect the value of the field *[People]Last Name* passed as parameter by the method ***MY METHOD***.

There are two ways to make the method ***DO SOMETHING*** change the value of the field:

1. Rather than passing the field to the method, you pass a pointer to it, so you would write:

```
 ` Here is some code from the method MY METHOD
 ` ...
DO SOMETHING(->[People]Last Name) ` Let's say [People]Last Name is equal to "williams"
ALERT([People]Last Name)

 ` Here the code of the method DO SOMETHING
$1->:=Uppercase($1->)
ALERT($1->)
```

Here the parameter is not the field, but a pointer to it. Therefore, within the ***DO SOMETHING*** method, *$1* is no longer the value of the field but a pointer to the field. The object **referenced** by *$1* (*$1->* in the code above) is the actual field. Consequently, changing the referenced object goes beyond the scope of the subroutine, and the actual field is affected. In this example, both alert boxes will read “WILLIAMS”.

For more information about **Pointers**, see the section **Pointers**.

2. Rather than having the method ***DO SOMETHING*** “doing something,” you can rewrite the method so it returns a value. Thus you would write:

```
 ` Here is some code from the method MY METHOD
 ` ...
[People]Last Name:=DO SOMETHING([People]Last Name) ` Let's say [People]Last Name is equal to "williams"
ALERT([People]Last Name)
 ` Here the code of the method DO SOMETHING
$0:=$1
ALERT($0)
```

This second technique of returning a value by a subroutine is called “using a function.” This is described in the next paragraphs.

**Advanced note**: Parameters within the subroutine are accessible through the local variables *$1*, *$2*... In addition, parameters can be optional and can be referred to using the syntax *${...}*. For more information on parameters, see the description of the command **Count parameters**.

## Functions: Project Methods that return a value

Data can be returned from methods. A method that returns a value is called a **function**.

4D or 4D Plug-in commands that return a value are also called functions.

For example, the following line is a statement that uses the built-in function, **Length**, to return the length of a string. The statement puts the value returned by **Length** in a variable called *MyLength*. Here is the statement:

```
MyLength:=Length("How did I get here?")
```

Any subroutine can return a value. The value to be returned is put into the local variable *$0*.

For example, the following function, called ***Uppercase4***, returns a string with the first four characters of the string passed to it in uppercase:

```
$0:=Uppercase(Substring($1;1;4))+Substring($1;5)
```

The following is an example that uses the ***Uppercase4*** function:

```
NewPhrase:=Uppercase4("This is good.")
```

In this example, the variable *NewPhrase* gets "THIS is good."

The **function result**, *$0*, is a local variable within the subroutine. It can be used as such within the subroutine. For example, in the previous ***DO SOMETHING*** example, *$0* was first assigned the value of *$1*, then used as parameter to the **ALERT** command. Within the subroutine, you can use *$0* in the same way you would use any other local variable. It is 4D that returns the value of *$0* (as it is when the subroutine ends) to the called method.

## Recursive Project Methods

Project methods can call themselves. For example:

- The method A may call the method B which may call A, so A will call B again and so on.
- A method can call itself.

This is called **recursion**. The 4D language fully supports recursion.

Here is an example. Let's say you have a *[Friends and Relatives]* table composed of this extremely simplified set of fields:
- *[Friends and Relatives]Name*
- *[Friends and Relatives]ChildrensName*

For this example, we assume the values in the fields are unique (there are no two persons with the same name). Given a name, you want to build the sentence "A friend of mine, John who is the child of Paul who is the child of Jane who is the child of Robert who is the child of Eleanor, does this for a living!":

1. You can build the sentence in this way:

```
$vsName:=Request("Enter the name:";"John")
If(OK=1)
   QUERY([Friends and Relatives];[Friends and Relatives]Name=$vsName)
   If(Records in selection([Friends and Relatives])>0)
      $vtTheWholeStory:="A friend of mine, "+$vsName
      Repeat
         QUERY([Friends and Relatives];[Friends and Relatives]ChildrensName=$vsName)
         $vlQueryResult:=Records in selection([Friends and Relatives])
         If($vlQueryResult>0)
            $vtTheWholeStory:=$vtTheWholeStory+" who is the child of "+[Friends and Relatives]Name
            $vsName:=[Friends and Relatives]Name
         End if
      Until($vlQueryResult=0)
      $vtTheWholeStory:=$vtTheWholeStory+", does this for a living!"
      ALERT($vtTheWholeStory)
   End if
End if
```

2. You can also build it this way:

```
$vsName:=Request("Enter the name:";"John")
If(OK=1)
   QUERY([Friends and Relatives];[Friends and Relatives]Name=$vsName)
   If(Records in selection([Friends and Relatives])>0)
      ALERT("A friend of mine, "+Genealogy of($vsName)+", does this for a living!")
   End if
End if
```

with the recursive function ***Genealogy of*** listed here:

```
` Genealogy of project method
` Genealogy of ( String ) -> Text
` Genealogy of ( Name ) -> Part of sentence
```

```
$0:=$1
QUERY([Friends and Relatives];[Friends and Relatives]ChildrensName=$1)
If(Records in selection([Friends and Relatives])>0)
   $0:=$0+" who is the child of "+Genealogy of([Friends and Relatives]Name)
End if
```

Note the ***Genealogy of*** method which calls itself.

The first way is an **iterative algorithm**. The second way is a **recursive algorithm**.

When implementing code for cases like the previous example, it is important to note that you can always write methods using iteration or recursion. Typically, recursion provides more concise, readable, and maintainable code, but using it is not mandatory.

Some typical uses of recursion in 4D are:

- Treating records within tables that relate to each other in the same way as in the example.
- Browsing documents and folders on your disk, using the commands **FOLDER LIST** and **DOCUMENT LIST**. A folder may contain folders and documents, the subfolders can themselves contain folders and documents, and so on.

**Important**: Recursive calls should always end at some point. In the example, the method ***Genealogy of*** stops calling itself when the query returns no records. Without this condition test, the method would call itself indefinitely; eventually, 4D would return a “Stack Full” error becuase it would no longer have space to “pile up” the calls (as well as parameters and local variables used in the method).

# Debugging

- Why a Debugger?
- Syntax Error Window
- Debugger
- Watch Pane
- Call Chain Pane
- Custom Watch Pane
- Source Code Pane
- Break Points
- Break List
- Catching Commands
- Debugger Shortcuts

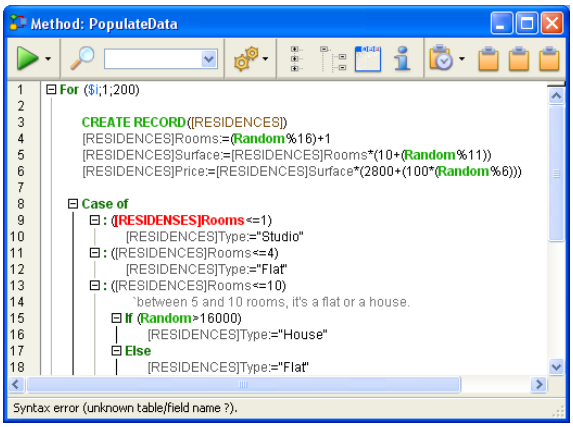
# Why a Debugger?

When developing and testing your methods, it is important that you find and fix the errors they may contain.

There are several types of errors you can make when using the language: typing errors, syntax or environmental errors, design or logic errors, and runtime errors.

## Typing Errors

Typing errors are detected by the **Method editor** and displayed in red and a message is displayed in the information area at the bottom of the method window. The following window shows a typing error:



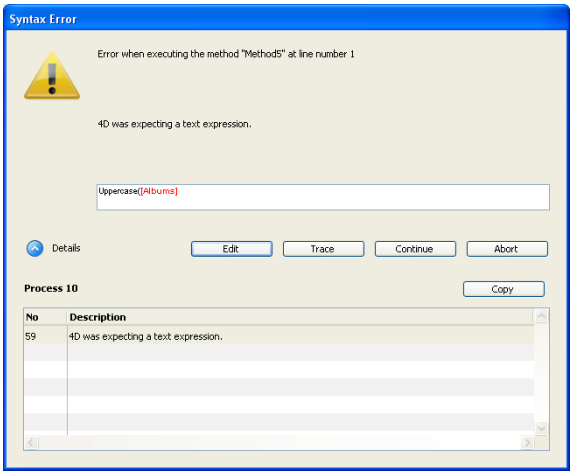
**Note**: The comments have been manually inserted for the purpose of this manual. Only the color is modified by 4D at the location of the error.

Such typing errors usually cause syntax errors (in this case, the name of the table is unknown). The information area displays a description of the error when you validate the line of code.

When this occurs, fix the typing error and type Enter (on the numeric pad) to validate the fix. For more information about the Method editor, refer to the 4D Design Reference.

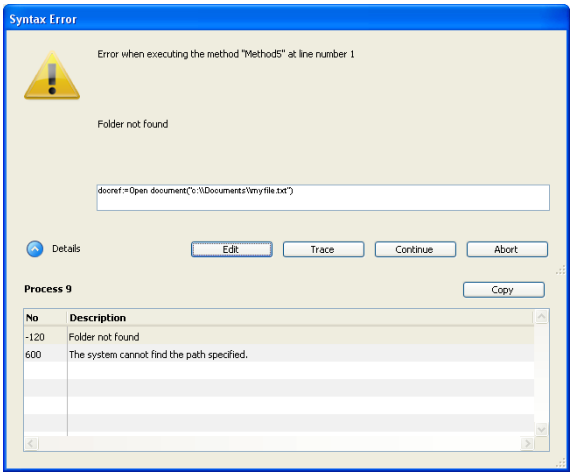
## Syntax or Environmental Errors

Some errors can be caught only when you execute the method. The **Syntax Error Window** is displayed when an error occurs. For example:



In this window, the error is that a table name is passed to the **Uppercase** command, which expects a text expression. To learn about this window and its button, see the section **Syntax Error Window**. In the above picture, the "Details" area is expanded in order to display the last error and its number.

Occasionally, there there may not be enough memory to create an array or a BLOB. When you access a document on disk, the document may not exist or may already open by another application.



These errors do not directly occur because of your code or the way you wrote it; they occur because sometimes “bad things just happen.” Most of the time, these errors are easy to treat with an error catching method installed using the command **ON ERR CALL**.

For more information about this window, refer to the **Syntax Error Window** section.

## Design or Logic Error

These are generally the most difficult type of error to find—use the **Debugger** to detect them. Note that, other than typing errors, all the previous error types are to a certain extent covered by the expression “Design or logic error.” For example:

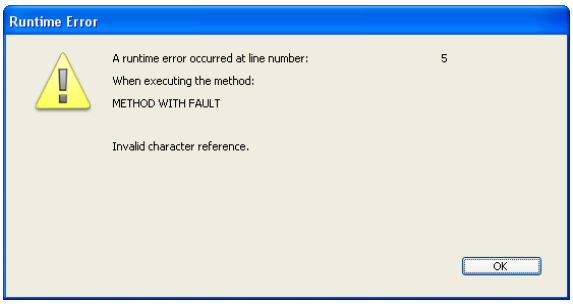
- A syntax error may occur because you try to use a variable that has not yet been initialized.
- An environmental error may occur because you try to open a document whose name is received by a subroutine which does not get the right value in the parameter. Note that in this example, the piece of code that actually “breaks” may be different than the code that is actually the origin of the problem.

Design or logic errors also include such situations as:

- A record is not properly updated because, while calling **SAVE RECORD**, you forgot to first test whether or not the record was locked.
- A method does not do exactly what you expect, because the presence of an optional parameter is not tested.

## Runtime Error

In Application mode, you can obtain errors that you never saw in interpreted mode. Here is an example:



This message indicates that you are trying to access a character whose position is beyond the length of a string. To quickly find the origin of the problem, note the name of the method and the line number, reopen the interpreted version of the structure file, and go to that method at the indicated line.

## What To Do When an Error Occurs?

Errors are common. It would be unusual to write a substantial number of lines of code (let’s say several hundred) without generating any errors. Conversely, treating and/or fixing errors is normal, too!

With its multi-tasking environment, 4D enables you to quickly edit/run methods by simply switching windows. You will discover how quickly you can fix mistakes and errors when you do not have to rerun the whole thing each time. You will also discover how quickly you can track errors if you use the **Debugger**.

A common beginner mistake in dealing with error detection is to click Abort in the Syntax Error Window, go back to the Method Editor, and try to figure out what's going by looking at the code. Do not do that! You will save plenty of time and energy by **always** using the **Debugger**.

- If an unexpected syntax error occurs, use the **Debugger**.
- If an environmental error occurs, use the **Debugger**.
- If any other type of error occurs, use the **Debugger**.

In 99% of the cases, the **Debugger** displays the information you need in order to understand why an error occurred. Once you have this information, you know how to fix the error.

**Tip**: A few hours spent in learning and experimenting with the **Debugger** can save days and weeks in the future when you have to track down errors.

Another reason to use the **Debugger** is for developing code. Sometimes you may write an algorithm that is more complex than usual. Despite all feelings of accomplishment, you are not totally sure that your coding is correct, even before trying it. Instead of running it "blind," use the **TRACE** command at the beginning of your code. Then, execute it step by step to control what happens and to check whether your suspicion was correct or not. A purist may dislike this method, but sometimes pragmatism pays off more quickly. Anyway... use the **Debugger**.

## General Conclusion

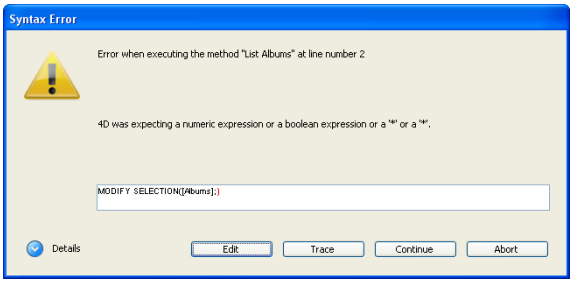
Use the **Debugger**.

# Syntax Error Window

The **Syntax Error Window** is displayed when method execution is halted. Method execution can be halted for one of the following reasons:

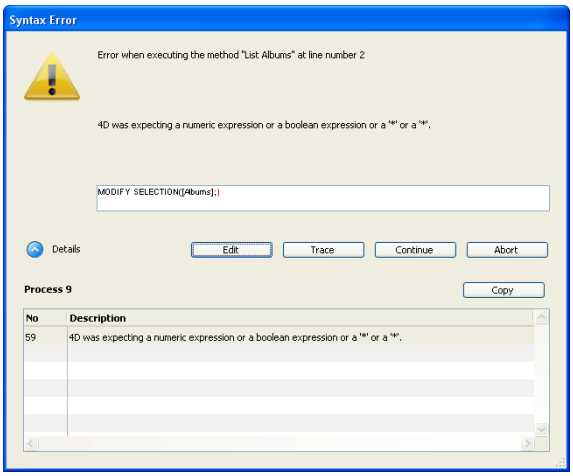
- 4D halts execution because there is an error preventing further method execution.
- The method produces a false assertion (see the **ASSERT** command).

Here is a Syntax Error window:



The upper text area of the **Syntax Error Window** displays a message describing the error. The lower text area shows the line that was executing when the error occurred; the area where the error occurred is highlighted.

The **Details** button can be used to expand the lower part of the window displaying the "stack" of errors related to the process:



There are five option buttons at the bottom of the window: **Abort**, **Trace**, **Continue**, **Edit** and (if the window is expanded) **Copy.**

- **Abort**: The method is halted, and you return to where you were before you started executing the method. If a form or object method is executing in response to an event, it is stopped and you return to the form. If the method is executing from within the Application environment, you return to this environment.
- **Trace**: You enter Trace/Debugger mode, and the **Debugger** window is displayed. If the current line has been partially executed, you may have to click the Trace button several times. Once the line finishes, you end up in the **Debugger** window.
- **Continue**: Execution continues. The line with the error may be partially executed, depending on where the error was. Continue with caution—the error may prevent the remainder of your method from executing properly. Usually, you do not want to continue. You can click **Continue** if the error is in a trivial call, such as **SET WINDOW TITLE**, which does not prevent executing and testing the rest of your code. You can thus concentrate on more important code, and fix a minor error later.
  **Note:** If you hold down the **Alt** (Windows) or **Option** (Mac OS) key, the **Continue** button changes to **Ignore**. Clicking **Ignore** means that the window will not be displayed if the same error, triggered by the same method at the same line, occurs again. This shortcut is useful in the case of an error that occurs repeatedly, for example in a loop. In this case, everything continues as if the user was clicking on the **Continue** button each time.
- **Edit**: All method execution is halted. 4D switches to the Design environment. The method in which the error occurred is opened in the Method editor, allowing you to correct the error. Use this option when you immediately recognize the

mistake and can fix it without further investigation.

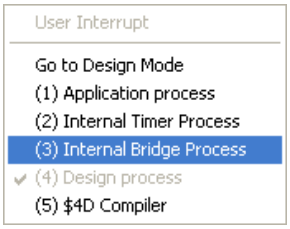
- **Copy**: This button copies the debugging information into the clipboard. This information describes the internal environment of the error (number, internal component, etc.). It is formatted as tabbed text. Once you have clicked this button, you can paste the contents of the clipboard into a text file, a spreadsheet, an e-mail, etc. for analysis purposes.

# Debugger

The term Debugger comes from the term bug. A bug in a method is a mistake that you want to eliminate. When an error has occurred, or when you need to monitor the execution of your methods, you use the debugger. A debugger helps you find bugs by allowing you to slowly step through your methods and examine method information. This process of stepping through methods is called **tracing**.

You can cause the Debugger window to display and then trace the methods in the following ways:

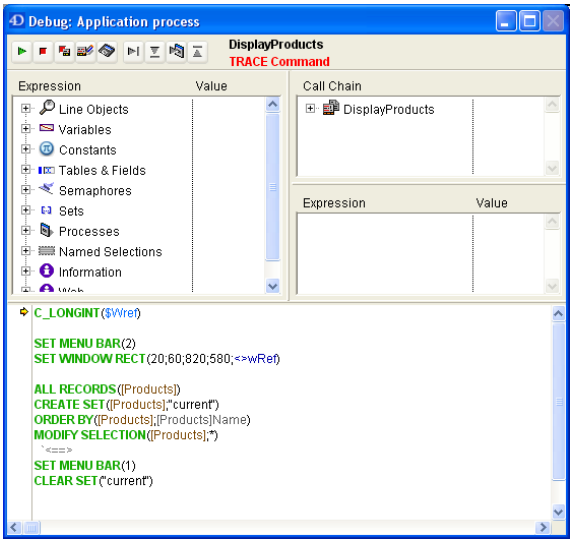
- Clicking the **Trace** button in the **Syntax Error Window**
- Using the **TRACE** command
- Clicking the **Debug** button in the Execute Method window.
- Pressing Alt+Shift+Right click (Windows) or Control+Option+Command+Click (Macintosh) while a method is executing, then selecting the process to trace in the pop-up menu:



- Clicking the **Trace** button when a process is selected in the **Process** page of the **Runtime Explorer**.
- Creating or editing a break point in the Method Editor window, or in the **Break** and **Catch** pages of the **Runtime Explorer**.

**Note**: If a password system exists for the database, only the designer and users belonging to the group that has design access privileges can trace methods.

The Debugger window is displayed here:

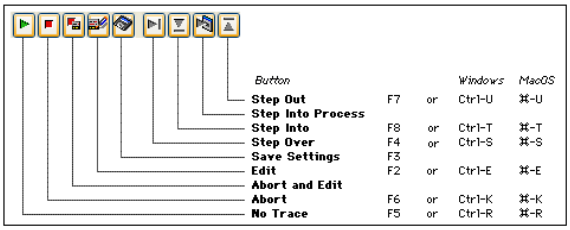


You can move the Debugger Window and/or resize any of its internal window panes as necessary. Displaying a new debug window uses the same configuration (size and position of the window, placing of the division lines and contents of the area that evaluates the expressions) as the last window displayed in the same session.

4D is a multi-tasking environment. If you run several user processes, you can trace them independently. You can have one debugger window open for each process.

## Execution Control Tool Bar Buttons

Nine buttons are located in the **Execution Control Tool Bar** at the top of the Debugger window:



### No Trace Button

Tracing is halted and normal method execution resumes.

**Note**: **Shift+F5** or **Shift+click** on the **No Trace** button resumes execution. It also disables all the subsequent **TRACE** calls for the current process.

### Abort Button

The method is halted, and you return to where you were before you started executing the method. If you were tracing a form or object method executing in response to an event, it is stopped and you return to the form. If you were tracing a method executing from within the Application environment, you return to the this environment.

### Abort and Edit Button

The method is halted as if you clicked on **Abort**. Also, 4D opens a Method Editor window for the method that was executing at the time the **Abort and Edit** button was clicked.

**Tip**: Use this button when you know which changes are required in your code and when these changes are required to pursue the testing of your methods. After you are finished with the changes, rerun the method.

### Edit Button

Clicking the Edit button does the same as Clicking **Abort and Edit** button, but does not abort the current execution. The method execution is paused at that point. 4D opens a Method Editor window for the method that was executing at the time the **Edit** button was clicked.

**Important**: You can modify this method; however, these modifications will not appear or execute in the instance of the method currently being traced in the debugger window. After the method has either aborted or completed successfully, the modifications will appear on the next execution of this method. In other words, the method must be reloaded so its modifications will be taken into account.

**Tip**: Use this button when you know which changes are required in your code and when they do not interfere with the rest of the code to be executed or traced.

**Tip**: Object Methods are reloaded for each event. If you are tracing an object method (i.e., in response to a button click), you do not need to leave the form. You can edit the object method, save the changes, then switch back to the form and retry. For tracing/changing form methods, you must exit the form and reopen it in order to reload the form method. When doing extensive debugging of a form, a trick is to put the code (that you are debugging) into a project method that you use as subroutine from within a form method. In doing so, you can stay in the form while you trace, edit, and retest your form, because the subroutine is reloaded each time it is called by the form method.

### Save Settings Button

Saves the current configuration of the debug window (size and position of the window, placing of the division lines and contents of the area that evaluates the expressions), so that it will be used by default each time the database is opened. These parameters are stored in the database's structure file.

### Step Over Button

The current method line (the one indicated by the yellow arrow—called the **program counter**) is executed, and the Debugger steps to the next line. The **Step Over** button does not step into subroutines and functions; it stays at the level of the method you are currently tracing. If you want to also trace subroutines and functions calls, use the **Step Into** button.

### Step Into Button

On execution of a line that calls another method (subroutine or function), this button causes the Debugger window to display the method being called and allows you to step through this method. The new method becomes the current (top) method in the **Call Chain Pane** of the Debugger window. On execution of a line that does not call another method, this button acts in the same manner as the **Step Over** button.

### Step Into Process Button

On execution of a line that creates a new process (i.e., calling the **New process** command), this button opens a new Debugger window that allows you to trace the process method of the newly created process. On execution of a line that does not creates a new process, this button acts in the same manner as the **Step Over** button.

### Step Out Button

If you are tracing subroutines and functions, clicking on this button allows you to execute the entire method currently being traced and to step back to the caller method. The Debugger window is brought back to the previous method in the call chain. If the current method is the last method in the call chain, the Debugger window is closed.

## Execution Control Tool Bar Information

On the right side of the execution control tool bar, the debugger provides the following information:

- The name of the method you are currently tracing (displayed in black)
- The problem caused the appearance of the Debugger window (displayed in red)

Using the example window shown above, the following information is displayed:

- The method ***DE_DebugDemo*** is the method being traced.
- The debugger window appeared because it detected a call to the **C_DATE** command and this command was one of the commands to be caught.

Here are the possible reasons for the debugger to appear and for the message (displayed in red):

- **TRACE Command**: A call to **TRACE** has been issued.
- **Break Point Reached**: A break point has been encountered.
- **User Interrupt**: You used Alt+Shift+Right click (Windows) or Control+Option+Command+Click (Macintosh), or you clicked on the **Trace** button in the **Process** page of the Design environment Runtime Explorer.
- **Caught a call to: Name of the command**: A call to a 4D command to be caught is on the point of being performed.
- **Stepping into a new process**: You used the **Step Into Process** button and this message is displayed by the Debugger window opened for the newly created process.

## The Debugger Window's Panes

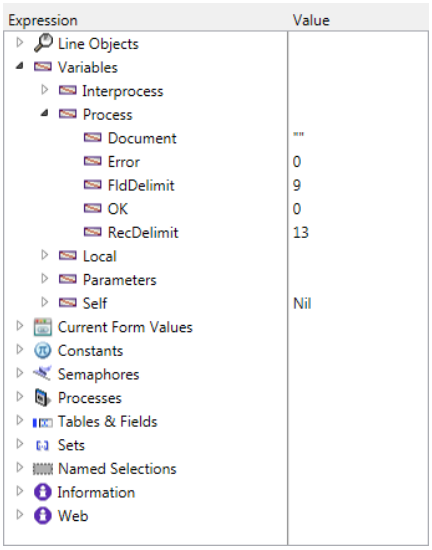
The Debugger window consists of the previously described Execution Control Tool Bar and four resizable panes:

- **Watch Pane**
- **Call Chain Pane**
- **Custom Watch Pane**
- **Source Code Pane**

The first three panes use easy-to-navigate hierarchical lists to display pertinent debugging information. The fourth one, **Source Code Pane**, displays the source code of the method being traced. Each pane has its own function to assist you in your debugging efforts. You can use the mouse to vertically and horizontally resize the debugger window and also each pane. In addition, the first three panes include a dotted separation line between the two columns they display. Using the mouse, you can move this dotted line to horizontally resize the columns, at your convenience.

# Watch Pane

The **Watch pane** is displayed in the top left corner of the Debugger window, below the Execution Control Tool Bar. Here is an example:



The **Watch Pane** displays useful general information about the system, the 4D environment, and the execution environment.

The **Expression** column displays the names of the objects or expressions. The **Value** column displays the current value of corresponding the object or expression.

Clicking on any value on the right side of the pane allows you to modify the value of the object, if this is permitted for that object.

The multi-level hierarchical lists are organized by theme at the main level. The themes are:

- Line Objects
- Variables
- Current Form Values
- Constants
- Semaphores
- Processes
- Tables & Fields
- Sets
- Named Selections
- Information
- Web

Depending on the theme, each item may have one or several sublevels. Clicking the list node next to a theme name expands or collapses the theme. If the theme is expanded, the items in that theme are visible. If the theme has several levels of information, click the list node next to each item for exploring all the information provided by the theme.

At any point, you can drag and drop themes, theme sublists (if any), and theme items to the **Custom Watch Pane**.

## Line Objects

This theme displays the values of the objects or expressions that are:

- used in the line of code to be executed (the one marked with the program counter—the yellow arrow in the **Source Code Pane**), or
- used in the previous line of code.

Since the previous line of code is the one that was just executed before, the Line Objects theme therefore shows the objects or expressions of the current line before and after that the line was executed. Let's say you execute the following method:

```
TRACE
a:=1
b:=a+1
c:=a+b
```

1. You enter the Debugger window with the **Source Code Pane** program counter set to the line *a:=1*. At this point the Line Objects theme displays:

| | |
|---|---|
| *a:* | Undefined |

The *a* variable is shown because it is used in the line to be executed (but has not yet been initialized).

2. You step one line. The program counter is now set to the line *b:=a+1*. At this point, the Line Objects theme displays:

| | |
|---|---|
| *a:* | *1* |
| *b:* | Undefined |

The *a* variable is shown because it is used in the line that was just executed and was assigned the numeric value *1*. It is also shown because it is used in the line to be executed as the expression to be assigned to the variable *b*. The *b* variable is shown because it is used in the line to be executed (but has not yet been initialized).

3. Again, you step one line. The program counter is now set to the line *c:=a+b*. At this point the Line Objects theme displays:

| | |
|---|---|
| *c:* | Undefined |
| *a:* | *1* |
| *b:* | *2* |

The *c* variable is shown because it is used in the line to be executed (but has not yet been initialized). The *a* and *b* variables are shown because there were used in the previous line and are used in the line to be executed. And so on...

The Line Objects theme is a very convenient tool—each time you execute a line, you do not need to enter an expression in the **Custom Watch Pane**, just watch the values displayed by the Line Objects theme.

## Variables

This theme is composed of the following subthemes:

- **Interprocess**: Displays the list of the interprocess variables being used at this moment. This list can be empty if you do not use interprocess variables. The values of the interprocess variables can be modified.
- **Process**: Displays the list of the process variables being used by the current process. This list is rarely empty. The values of the process variables can be modified.
- **Local**: Displays the list of the local variables being used by the method being traced (the one being shown in the *source code pane*). This list can be empty if no local variable is used or has not yet been created. The values of the local variables can be modified.
- **Parameters**: Displays the list of parameters received by the method. This list can be empty if no parameter were passed to the method being traced (the one being shown in the *source code pane*). The values of the parameters can be modified.
- **Self Pointer**: Displays a pointer to the current object if you are tracing an Object Method. This value cannot be modified

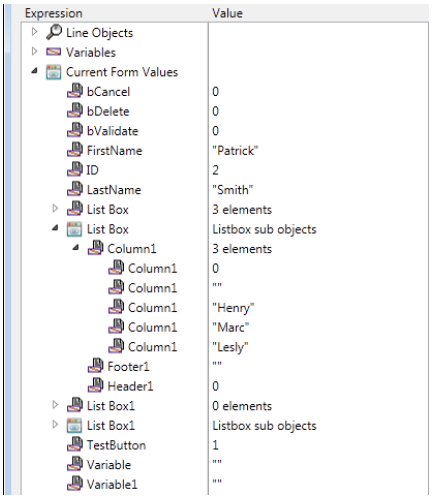
**Note**: You can modify String, Text, Numeric, Date, and Time variables; in other words, you can modify the variables whose value can be entered with the keyboard.

Arrays, like other variables, appear in the Interprocess, Process, and Locals subthemes, depending on their scope. The debugger displays each array with an additional hierarchical level; this enables you to obtain or change the values of the array elements, if any. The debugger displays the first 100 elements, including the element zero. The Value column displays the size of the array in regard to its name. After you have deployed the array, the first sub-item displays the current selected element number, then the element zero, then the other elements (up to 100). You can modify String, Text, Numeric, and Date arrays. You can modify the selected element number, the element zero, and the other elements (up to 100). You cannot modify the size of the array.

**Reminder**: At any time, you can drag and drop an item from the **Watch Pane** to the **Custom Watch Pane**, including an individual array element.

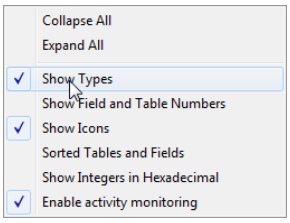
## Current Form Values

This theme contains the name of each dynamic object included in the current form, as well as the value of its associated variable:



Some objects, such as list box arrays, can be presented as two distinct objects (the variable of the object itself and its data source).

This list is particularly useful when your forms use dynamic variables intensively: it is easy to identify dynamic variables through the form object names. You can display the internal name of dynamic variables by selecting **Show Types** in the context menu:



Dynamic variable names are of the "$form.4B9.42" form:

## Constants

This theme displays predefined constants provided by 4D. like the Constants page of the Explorer window. The expressions from this theme cannot be modified.

## Tables and Fields

This theme lists the tables and fields in the database; it does not list subfields. For each Table item, the Value column displays the size of the current selection for the current process as well as (if the Table item is expanded) the number of locked records. For each Field item, the Value column displays the value of the field (except picture, subtable, and BLOB) for the current record, if any. In this theme, the field values can be modified (there is no undo), but the table information cannot.

## Semaphores

This theme lists the local semaphores currently being set. For each semaphore, the Value column provides the name of the process that sets the semaphore. This list may be empty if you do not use semaphores. The expressions from this theme cannot be modified. Global semaphores are not displayed.

## Sets

This theme lists the sets defined in the current process (the one you're currently tracing); it also lists the interprocess sets. For each set, the Value column displays the number of records and the table name. This list may be empty if you do not use sets. The expressions from this theme cannot be modified.

## Processes

This theme lists the processes started since the beginning of the working session. The value column displays the time used and the current state for each process (i.e., Executing, Paused, and so on). The expressions from this theme cannot be modified.

## Named Selections

This theme lists the process named selections that are defined in the current process (the one you're currently tracing); it also lists the interprocess named selections. For each named selection, the Value column displays the number of records and the table name. This list may be empty if you do not use named selections. The expressions from this theme cannot be modified.

## Information

This theme displays general information concerning database operation, such as the current default table (if one exists), physical, virtual, free and used memory space, query destination, etc. This information allows you to examine database functioning.

## Web

This theme displays information concerning the Web server of the application (only available if the Web server is active):

- Web File To Send: name of Web file waiting to be sent (if any)
- Web Cache Usage: number of pages present in Web cache as well as its use percentage,,
- Web Server Elapsed Time: duration of Web server use in hours:minutes:seconds format
- Web Hits Count: total number of HTTP requests received since Web server launch, as well as the instantaneous number of requests per second
- Number of active Web processes: number of active Web processes, all Web processes together.

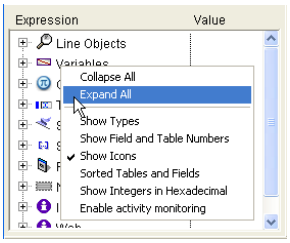
The expressions contained within this theme cannot be modified.

## Context Menu

Additional options are provided by the context menu of the Watch pane. To display this menu:

- On Windows, click anywhere in the Watch pane using the **right** mouse button.
- On Macintosh, Control-Click anywhere in the Watch pane.

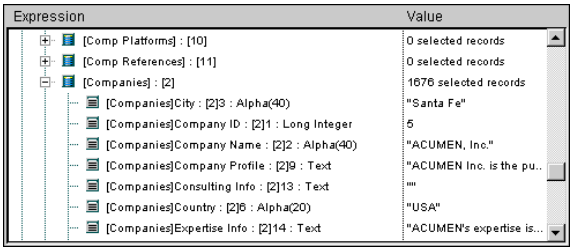
The context menu of the Watch pane is shown here:



- **Collapse All**: Collapses all levels of the Watch hierarchical list.
- **Expand All**: Expand all levels of the Watch hierarchical list.
- **Show Types**: Displays the object type for each object (when appropriate).
- **Show Field and Table Numbers**: Displays the number of each table or field of the **Fields**. If you work with table or field numbers, or with pointers using the commands such as **Table** or **Field**, this option is very useful.
- **Show Icons**: Displays an icon denoting the object type for each object. You can turn this option off in order to speed up the display, or just because you prefer to use only the **Show Types** option.
- **Sorted Tables and Fields**: Forces the table and fields to be displayed in alphabetical order, within their respective lists.

- **Show Integers in Hexadecimal**: Numbers are usually displayed in decimal notation. This option displays them in hexadecimal notation. **Note:** To enter a numeric value in hexadecimal, type 0x (zero + "x"), followed by the hexadecimal digits.
- **Enable activity monitoring**: Activates the monitoring of activity (advanced checking of internal activity of the application) and displays the information retrieved in the additional themes: **Scheduler**, **Web** and **Network**.

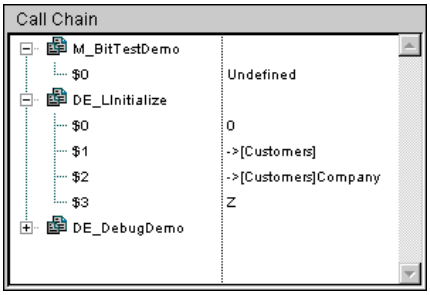
The following is a view of the **Watch Pane** with all options selected:



## Call Chain Pane

---

One method may call other methods, which may call other methods. For this reason, it is very helpful to see the chain of methods, or **Call Chain,** during the debugging process. The **Call Chain Pane**, which provides this useful function, is the top right pane of the Debugger window. This pane is displayed using a hierarchical list. Here is an example of the **Call Chain Pane**:



- Each main level item is a name of a method. The top item is the method you are currently tracing, the next main level item is the name of the caller method (the method that called the method you are currently tracing), the next one is the caller's caller method, and so on. In the example above, the method **M_BitTestDemo** is being traced; it has been called by the method **DE_LInitialize,** which has been called by **DE_DebugDemo**.

- Double-clicking the name of a method in the Call Chain pane “transports” you back to the caller method, displaying its source code in the **Source Code Pane**. In doing so, you can quickly see “how” the caller method made its call to the called method. You can examine any stage of the call chain this way.

- Clicking the node next to a Method name expands or collapses the parameter ($1, $2...) and the optional function result (*$0*) list for the method. The values appear on the right side of the pane. Clicking on any value on the right side allows you to change the value of any parameter or function result. In the figure above:

  1. **M_BitTestDemo** has not received any parameter.
  2. **M_BitTestDemo**'s *$0* is currently undefined, as the method did not assign any value to *$0* (because it has not executed this assignment yet or because the method is a subroutine and not a function).
  3. **DE_LInitialize** has received three parameters from **DE_DebugDemo**. *$1* is a pointer to the table *[Customers*], *$2* is a pointer to the field *[Customers]Company,* and *$3* is an alphanumeric parameter whose value is *"Z"*.

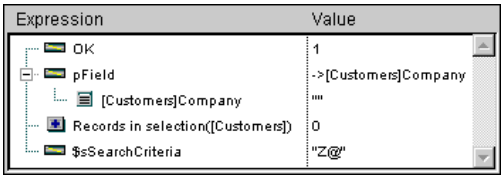
- After you have deployed the parameter list for a method, you can also drag and drop parameters and function results to the **Custom Watch Pane**.

# Custom Watch Pane

Directly below the **Call Chain Pane** is the **Custom Watch Pane**. This pane is used to evaluate expressions. Any type of expression can be evaluated, including fields, variables, pointers, calculations, built-in functions, your own functions, and anything else that returns a value.

You can evaluate any expression that can be shown in text form. This does not cover picture and BLOB fields or variables. On the other hand, the Debugger uses deployed hierarchical lists to let you display arrays and pointers. To display BLOB contents, you can use BLOB commands, such as **BLOB to text**.

In the following example, you can see several of these items: two variables, a field pointer variable and the result of a built-in function, and a calculation.



## Inserting a new expression

You can add an expression to be evaluated in the **Custom Watch Pane** in the following way:

- Drag and drop an object or expression from the **Watch Pane DISTINCT ATTRIBUTE VALUES**
- Drag and drop an object or expression from the **Call Chain Pane**
- In the **Source Code Pane** , click on an expression that can be evaluated

To create a blank expression, double-click somewhere in the empty space of the Custom Watch pane. This adds an expression ` *New expression* and then goes into editing mode so you can edit it. You can enter any 4D formula that returns a result.

After you have entered the formula, type **Enter** or **Return** (or click somewhere else in the pane) to evaluate the expression.

To change the expression, click on it to select it, then click again (or press Enter — numeric key pad) to go into editing mode.

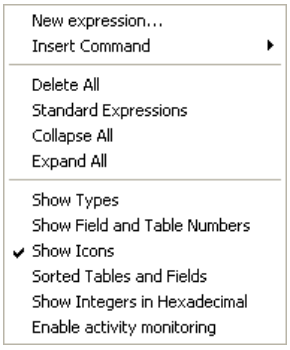
If you no longer need an expression, click on it to select it, then press **Backspace** or **Delete**.

**Warning:** Be careful when you evaluate a 4D expression modifying the value of one of the **System Variables** (for instance, the OK variable) because the execution of the rest of the method may be altered.

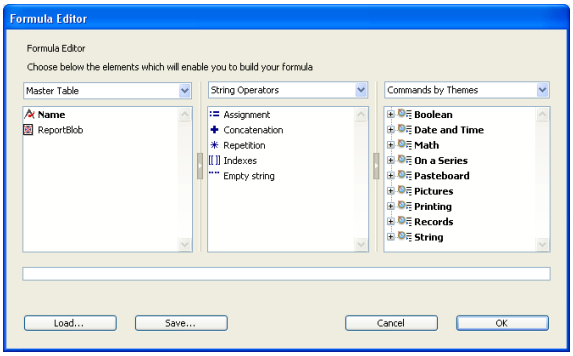
## Custom Watch Pane Context Menu

To help you enter and edit an expression, the Custom Watch Pane's context menu gives you access the 4D formula editor. In fact, the context menu also proposes additional options.

To display this menu, click anywhere in the Custom Watch pane using the **right** mouse button



- **New Expression**: This inserts a new expression and displays the 4D Formula Editor (as shown) so you can edit the new expression.



For more information about the Formula Editor, see the 4D Design Reference manual.

- **Insert Command**: This hierarchical menu item is a shortcut for inserting a command as a new expression, without using the Formula Editor.
- **Delete All**: Deletes all the expressions currently present.
- **Standard Expressions**: Recopies the list of objects in the Expression area.
- **Collapse All/Expand All**: Collapses or Expands all the expressions whose evaluation is done by the means of a hierarchical list (i.e., pointers, arrays,...)
- **Show Types**: Displays the object type for each object (when appropriate).
- **Show Field and Table Numbers**: Displays the number of each table or field of the **Fields**. If you work with table or field number or pointers using the commands such as **Table** or **Field**, this option is very useful.
- **Show Icons**: Displays an icon denoting the object type for each object. You can turn this option off in order to speed up the display, or just because you prefer to use only the **Show Types** option.
- **Sorted Tables and Fields**: Forces the table and fields to be displayed in alphabetical order, within their respective lists.
- **Show Integers in Hexadecimal**: Numbers are displayed using the decimal notation. This option displays them hexadecimal notation. **Note:** To enter a numeric value in hexadecimal, type 0x (zero + "x"), followed by the hexadecimal digits.
- **Enable activity monitoring**: Activates and displays activity monitoring information (see the **Watch Pane** section).

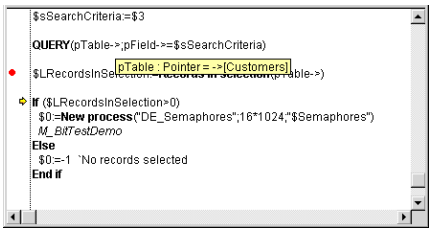
## Source Code Pane

The **Source Code Pane** shows the source code of the method being traced.

If the method is too long to fit in the text area, you can scroll to view other parts of the method.

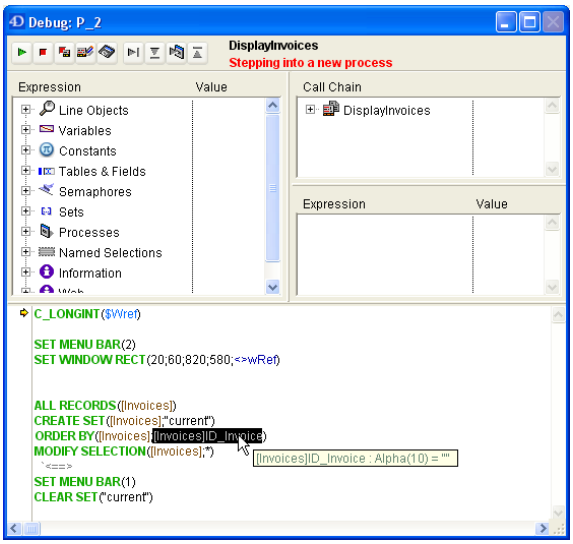
Moving the mouse pointer over any expression that can be evaluated (field, variable, pointer, array,...) will cause a **Tool Tip** to display the current value of the object or expression and its declared type.

Here is an example of the **Source Code Pane**:



A tool tip is displayed because the mouse pointer was over the variable *pTable* which, according to the tool tip, is a pointer to the table *[Customers]*.

You can also select a portion of the text in the area displaying the code being executed. In this case, when the cursor is placed above the selected text, a tip displays the selected object's value:



When you click on a variable name or field, it is automatically selected.

**Tip**: It is possible to copy any selected expression (that can be evaluated) from the **Source Code Pane** to the **Custom Watch Pane**. You can use one of the following ways:

- by simply dragging and dropping (click on the selected text, drag it and drop it in the evaluation area).
- by using the **Ctrl+D** (Windows) or **Command+D** (Mac OS) key combinations.

## Program Counter

A yellow arrow in the left margin of the Source Code pane (see the figure above) marks the next line that will be executed. This arrow is called the **program counter**. The program counter always indicates the line that is about to be executed.

For debugging purposes, you can **change** the program counter for the method being on top of the call chain (the method actually being executed). To do so, click and drag the yellow arrow vertically, to the line you want.

**WARNING**: Use this feature with caution!

Moving the program counter forward does NOT mean that the debugger is rapidly executing the lines you skip. Similarly, moving the program counter backward does NOT mean that the debugger is reversing the effect of the lines that has already been executed.

Moving the program counter simply tells the debugger to "pursue tracing or executing from here." All current settings, fields, variables, and so on are not affected by the move.

Here is an example of moving the program counter. Let's say you are debugging the following code:

```
  ` ...
If(This condition)
   DO SOMETHING
Else
   DO SOMETHING ELSE
End if
  ` ...
```

The program counter is set to the line **If (This condition)**. You step once and you see that the program counter moves to the line **DO SOMETHING ELSE**. This is unfortunate, because you wanted to execute the other alternative of the branch. In this case, and provided that the expression **This condition** does not perform operations affecting the next steps in your testing, just move the program counter back to the line **DO SOMETHING**. You can now continuing tracing the part of the code in which you are interested.

## Setting Break Points in the Debugger

In the debugging process, you may need to skip the tracing of some parts of the code. The debugger offers you several ways to execute code **up to a certain point**:

- While stepping, you can click on the **Step Over** button instead of **Step Into** button. This is useful when you do not want to enter into possible subroutines or functions called in the program counter line.
- If you mistakenly entered into a subroutine, you can execute it and directly go back to the caller method by clicking on the **Step Out** button.
- If you have a **TRACE** call placed at some point, you can click the **No Trace** button, which resumes the execution up to that call.

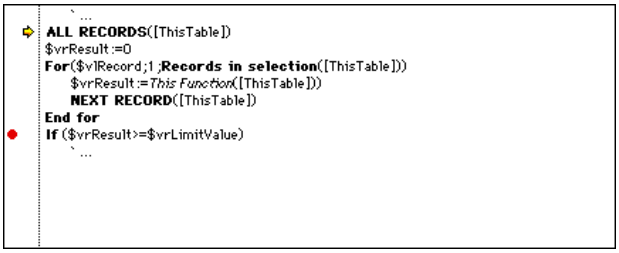
Now, let's say you are executing the following code, with the program counter set to the line *ALL RECORDS([ThisTable])*:

```
  ` ...
ALL RECORDS([ThisTable])
$vrResult:=0
For($vlRecord;1;Records in selection([ThisTable]))
   $vrResult:=This Function([ThisTable]))
   NEXT RECORD([ThisTable])
End for
If($vrResult>=$vrLimitValue)
  ` ...
```

Your goal is to evaluate the value of *$vrResult* after the For loop has been completed. Since it takes quite some execution time to reach this point in your code, you do not want to abort the current execution, then edit the method in order to insert a **TRACE** call before the line *If ($vrResult...*.

One solution is to step through the loop, however, if the table *[ThisTable]* contains several hundreds records, you are going to spend the entire day for this operation. In this type of situation, the *debugger* offers you **break points**. You can insert break points by clicking in the left margin of the Source Code pane.

For example:
You click in the left margin of the Source Code pane at the level of the line *If ($vrResult...*:



This inserts a break point for the line. The break point is indicated by a red bullet. Then click the **No Trace** button.

This resumes the normal execution **up to** the line marked with the break point. That line is not executed itself—you are back to the trace mode. In this example, the whole loop has consequently been executed normally. Then, when reaching the break point, you just need to move the mouse button over *$vrResult* to evaluate its value at the exit point of the loop.

Setting a break point beyond the program counter and clicking the **No Trace** button allows you to skip **portions** of the method being traced.

**Note**: You can also set break points directly in 4D's Method Editor. Please refer to the section **Break Points**.

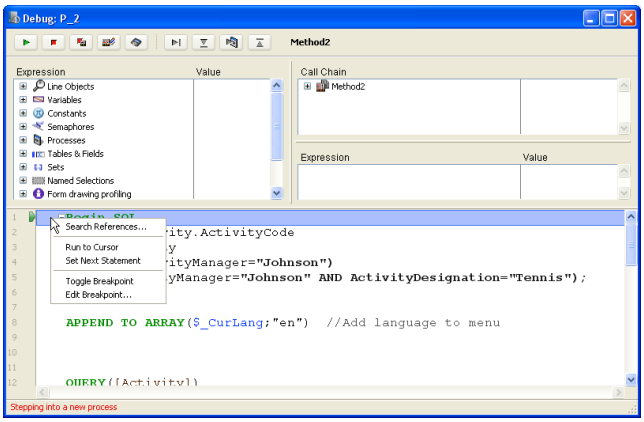
Once you add a break point, it remains associated with the method. Even if you quit the database and then reopen it later on, the break point is still there.

There are two ways to eliminate a persistent break point:

- If you are through with it, just remove it by clicking on the red bullet—the break point disappears.
- If you are not totally through with it, you may want to keep the break point. You can temporarily disable the break point by editing it. This explained in the section **Break Points**.

## Context menu of Source Code Pane

The context menu of the **Source Code Pane** provides access to several functions that are useful when executing methods in Trace mode:



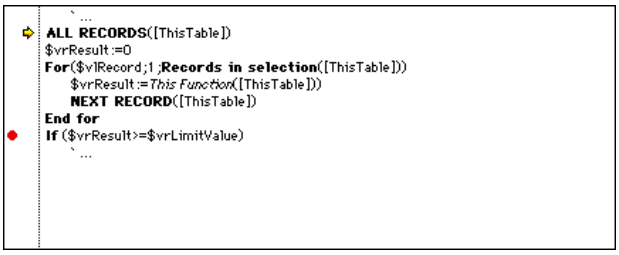
- **Goto Definition:** Goes to where the selected object is defined. This command is available for the following objects:
  - *Project methods*: displays method contents in a new window of the Method editor..
  - *Fields*: Displays field properties in the inspector of the Structure window,
  - *Tables*: Displays table properties in the inspector of the Structure window,
  - *Forms*: Displays form in the Form editor,
  - *Variables* (local, process, interprocess or $n parameter):displays the line in the current method or among the compiler methods where the variable is declared.
- **Search References** (also available in Method editor): Searches all database objects (methods and forms) in which the current element of the method is referenced. The current element is the one selected or the one where the cursor is located. This can be the name of a field, variable, command, string, and so on. Search results are displayed in a new standard results window.
- **Run to Cursor**:Executes statements found between the program counter (yellow arrow) and the selected line of the method (where the cursor is found).
- **Set Next Statement**:Moves program counter to the selected line without executing this line or any intermediate ones. The designated line is only run if the user clicks on one of the execution buttons.
- **Toggle Breakpoint** (also available in Method editor): Alternately inserts or removes the breakpoint corresponding to the selected line. This modifies the breakpoint permanently: for instance, if you remove a breakpoint in the debugger, it no longer appears in the original method.
- **Edit Breakpoint** (also available in Method editor):Displays the Breakpoint Properties dialog box. Any changes made modify the breakpoint permanently .

## Break Points

As explained in the **Source Code Pane** section, you set a break point by clicking in the left margin of the Source Code pane or of the Method Editor window, at the same level as the line of code on which you want to create the break.

**Note:** Since you can insert, modify or delete break points either in the debugger's Source Code pane or directly in the Method Editor, there is a dynamic interaction between the Method Editor and the debugger (as well as the Runtime Explorer) in regards to break points.

In the following figure, a break point has been set, in the debugger, on the line **If($vrResult>=$vrLimitValue)**:



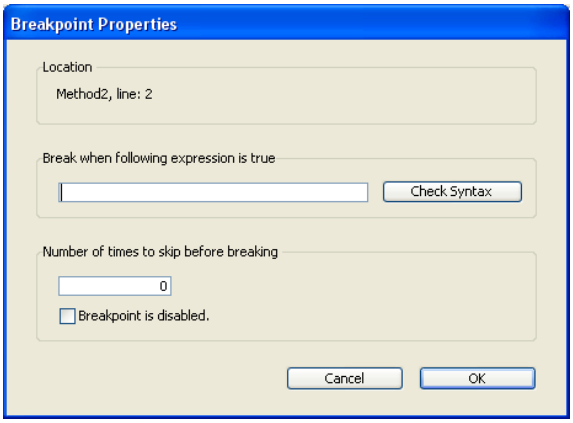
If you click again on the red bullet, the break point is deleted.

### Editing a Breakpoint

You can access the **Breakpoint Properties** window by selecting the **Edit Breakpoint** command in the context menu of the **Source Code Pane** or by pressing Alt-click (Windows) or Option-click (Macintosh) in the left margin of the window (or the Method Editor window).

- If you click on an existing break point, the window is displayed for that break point.
- If you click on a line where no break point was set, the debugger creates one and displays the window for the newly created break point.

The **Breakpoint Properties** window is shown here:



Here are the properties:

**Location**: This tells you the name of the method and the line number where the break point is set. You cannot change this information.

**Break when following expression is true**: You can create conditional break points by entering a 4D formula that returns True or False. For example, if you want to break at a line only when *Records in selection([aTable])=0*, enter this formula, and the break will occur only if there no record selected for the table *[aTable]*, when the debugger encounters the line with this break point. If you are not sure about the syntax of your formula, click the **Check Syntax** button.

**Number of times to skip before breaking**: You can set a break point to a line of code located in a loop structure (While, Repeat, or For) or located in subroutine or function called from within a loop. For example, you know that the “problem” you are tracking does not occur before at least the 200th iteration of the loop. Enter 200, and the break point will activate at the 201st iteration.

**Breakpoint is disabled**: If you currently do not need a break point, but you may need it later, you can temporarily disable the break point by editing it. A disabled break point appears as a dash (-) instead of a bullet (•) in the *source code pane* of

the debugger window, in the Method Editor and in the Break page of the Runtime Explorer.

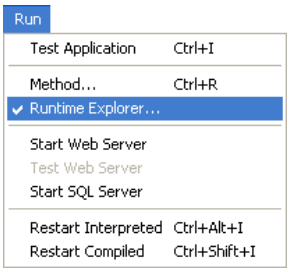
You create and edit break point from within the Debugger or the Method Editor window. You can also edit existing break points using the Break page of the Runtime Explorer. For more information, see the section **Break List**.

# Break List

The **Break List** is a page of the Runtime Explorer that enables you to manage the break points created in the Debugger Window or in the Method Editor.

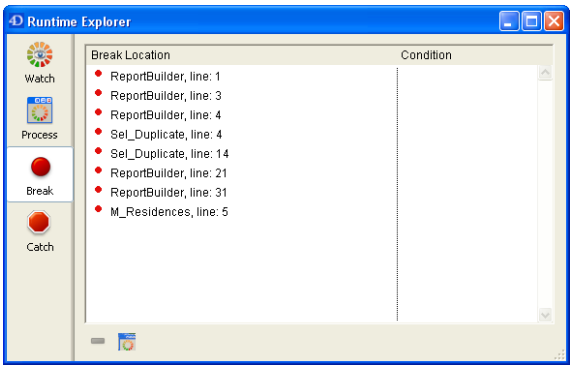
To open the Break List page:

1. Choose **Runtime Explorer** from the **Run** menu.
The Runtime Explorer can be displayed in a floating palette which always remains displayed in the front. To do this, hold down the **Shift** key while selecting **Runtime Explorer** from the **Run** menu. The Runtime Explorer is then available in all the 4D environments. For more information, please refer to the Design Reference manual.



The Runtime Explorer window appears.

2. Click on the **Break** button to display the Break List:



The Break List is composed of two columns:

- The left column displays the Enable/Disable status of the break point, followed by the name of the method and the line number where the break point has been set (using the Debugger window or the Method Editor).
- The right column displays the condition associated with the break point, if any.

Using this window, you can:

- Set a condition for a break point,
- Enable, disable or delete each break point,
- Open a Method Editor window displaying the method in which a break point is defined, by double-clicking on the break point.

However, you cannot add a new break point from this window. Break points can only be created from within the Debugger window or the Method Editor.

## Setting a Condition for a Break Point

To set a condifition for a break point, proceed as follows:

1. Click on the entry in the right column
2. Enter a 4D formula (expression or command call or project method) that returns a Boolean value.

**Note**: To remove a condition, delete its formula.

## Disabling/Enabling a Break Point

To disable or enable a break point:

1. Select the break point by clicking on it or by using the arrows to navigate through the list (if the current selected entry is not already in edit mode).
2. Choose **Enable/Disable** from the context menu.

**Shortcut**: Each entry in the list may be disabled/enabled by clicking directly on the bullet (•). The bullet changes to a dash (–) when disabled.

## Deleting a Break Point

To delete a break point:

1. Select the break point by clicking on it or by using the arrows to navigate through the list (if the current selected entry is not already in edit mode).
2. Press the **Delete** or **Backspace** key or click on the **Delete** button below the list.

**Note**: To delete all the break points, click on the **Delete All** button (second button below the list) or choose **Delete All** in the context menu.

# Catching Commands

The **Catching Commands** is a page of the Runtime Explorer that enables you to add additional breaks to your code by catching calls to 4D commands.

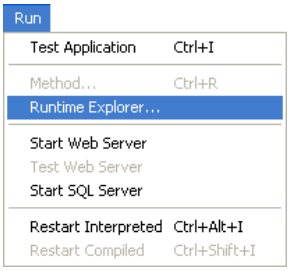
Catching a command enables you to start tracing the execution of any process as soon as a command is called by that process. Unlike a break point, which is located in a particular project method (and therefore triggers a trace exception only when it is reached), the scope of catching a command includes all the processes that execute 4D code and call that command.

Catching a command is a convenient way to trace large portions of code without setting break points at arbitrary locations. For example, if a record that should not be deleted is deleted after you have executed one or several processes, you can try to reduce the field of your investigation by catching commands such as **DELETE RECORD** and **DELETE SELECTION**. Each time these commands are called, you can check if the record in question has been deleted, and thus isolate the faulty part of the code.

With some experience, you can combine the use of Break points and command catching.

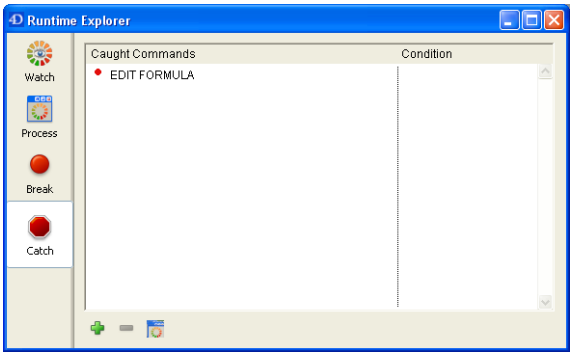
To open the Caught Commands page:

1. Choose **Runtime Explorer** from the **Run** menu.
The Runtime Explorer can be displayed in a floating palette. In this case, the floating palette always remains displayed in the front. To do this, hold down the **Shift** key while selecting **Runtime Explorer** from the **Tools** menu. For more information, please refer to the Design Reference manual.



The Runtime Explorer window appears.

2. Click on the **Catch** button to display the Caught Commands List:



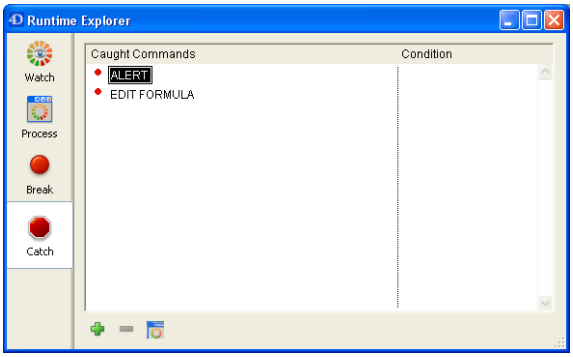
This page lists the commands to be caught during execution. It is composed of two columns:

- The left column displays the Enable/Disable status of the caught command, followed by the name of the command.
- The right column displays the condition associated with the caught command, if any.

## Adding a New Command to be Caught

To add a new command:

1. Click on the **Add New Catch** button (in the shape of a +) located below the list. A new entry is added to the list with the **ALERT** command as default.



You can then click on label **ALERT** and enter the name of the command you want to catch. Once you have finished, hit **Enter** or **Return** to validate your choice.

## Editing the Name of a Caught Command

To edit the name of a caught command:

1. Select the entry by clicking it or by using the arrow keys to navigate through the list (if the current selected entry is not already in edit mode).
2. To toggle an entry between edit mode and select mode, press **Enter** or **Return**.
3. Enter or modify the name of the command.
4. To validate your changes, press **Enter** or **Return**.

## Disabling/Enabling a Caught Command

To disable or enable a caught command:

1. Click on the bullet (•) placed in front of the command label.
   This allows you to alternately activate and/or disable the break point. The bullet's color indicates its status:
   - red = activated,
   - orange = disabled.

**Note:** Disabling a caught command has almost the same effect as deleting it. During execution, the debugger spends almost no time on the entry. The advantage of disabling an entry is that you do not have to recreate it when you need it again.

## Deleting a Caught Command

To delete a caught command:

1. Select the entry by clicking it or by using the arrow keys to navigate through the list (if the current selected entry is not already in edit mode).
2. Press the **Backspace** or **Delete** key or click on **Delete** button located beneath the list.
3. To delete all the caught commands, click on the **Delete All** button.

## Setting a Condition for Catching a Command

To set a condition for catching a command:

1. Click on the entry in the right column.
   An input cursor appears.
2. Enter a 4D formula (expression, command call or project method) that returns a Boolean value.

**Note**: To remove a condition, delete its formula.

Adding conditions allows you to stop execution when the command is invoked only if the condition is met. For example, if you associate the condition "**Records in selection**([Emp]>10)" with the break point on the **DELETE SELECTION** command, the code will not be stopped during execution of the **DELETE SELECTION** command if the current selection of the [Emp] table only contains 9 records (or less).

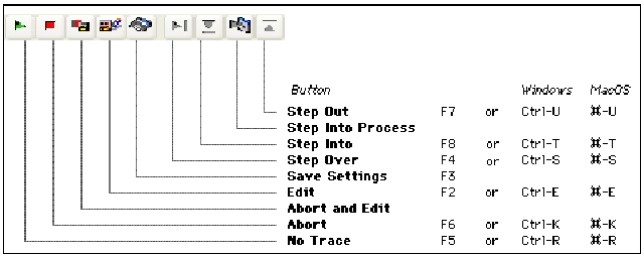
Adding conditions to caught commands slows the execution, because the condition has to be evaluated each time an exception is met. On the other hand, adding conditions accelerates the debugging process, because 4D automatically skips occurrences that do not match the conditions.

# Debugger Shortcuts

This section lists all the shortcuts available in the debugger window.

## Execution Control Tool Bar

The following figure shows the shortcuts for the nine buttons located in the top left corner of the debugger window:



Shift+F5 or Shift+click on the **No Trace** button resumes execution. Also, they disable all the next **TRACE** calls for the current process.

## Watch Pane

- Right mouse button click (Windows) or Control-Click (Macintosh) in the **Watch Pane** pulls down the Watch context menu.
- Double-click on an item of the **Watch Pane** copies the item to the **Custom Watch Pane**.

## Call Chain Pane

- Double-Click on a method name in the **Call Chain Pane** displays the method in the **Custom Watch Pane** at the line corresponding to the call in the call chain.

## Custom Watch Pane

- Right mouse button click (Windows) or Control-Click (Macintosh) in the **Custom Watch Pane** pulls down the Custom Watch context menu.
- Double-Click in the **Custom Watch Pane** creates a new watch.

## Source Code Pane

- Click in the left margin sets (persistent) or removes break points.
- **Alt-Shift-Click** (Windows) or **Option-Shift Click** (Macintosh) sets a temporary break point.
- **Alt-Click** (Windows) or **Option-Click** displays the **Edit Break** window for a new or existing break point.
- A selected expression or object can be copied to the **Custom Watch Pane** by simple drag and drop.
- **Ctrl+D** (Windows) or **Command+D** (Mac OS) key combinations copy the selected text to the **Custom Watch Pane**.

## All Panes

- **Ctrl + *** (Windows) or **Command + *** (Mac OS) forces the updating of the **Watch Pane**.
- When no item is selected in any pane, typing **Enter** steps by one line.
- When an item value is selected, use the arrows keys to navigate through the list.
- When an item is being edited, use the arrow keys to move the cursor; use **Ctrl-A/X/C/V** (Windows) or **Command-A/X/C/V** (Macintosh) as shortcuts to the **Select All/Cut/Copy/Paste** menu commands of the **Edit** menu.

# Application file

Application file -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ➲ | Long name of the 4D executable file or application |

## Description

The **Application file** command returns the long name of the 4D executable file or application you are running.

*On Windows*
If, for example, you are running 4D located at ¥PROGRAMS¥4D on the volume E, the command returns E:¥PROGRAMS¥4D¥4D.EXE.

*On Macintosh*
If, for example, you are running 4D in the Programs folder on the disk Macintosh HD, the command returns Macintosh HD:Programs:4D.app.

## Example

At startup on Windows, you need to check if a DLL Library is correctly located at the same level as the 4D executable file. In the **On Startup database method** of your application you can write:

```
If(On Windows & (Application type#4D Server))
   If(Test path name(Long name to path name(Application file)+"XRAYCAPT.DLL")#Is a document)
   ` Display a dialog box explaining that the library XRAYCAPT.DLL
   ` is missing. Therefore, the X-ray capture capability will not be available.
   End if
End if
```

**Note:** The project methods ***On Windows*** and ***Long name to path name*** are listed in the **System Documents** section.

# Application type

Application type -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Numeric value denoting the type of the application |

## Description

The **Application type** command returns a numeric value that denotes the type of 4D environment that you are running. 4D provides the following predefined constants:

| Constant | Type | Value |
|---|---|---|
| 4D Desktop | Longint | 3 |
| 4D Local mode | Longint | 0 |
| 4D Remote mode | Longint | 4 |
| 4D Server | Longint | 5 |
| 4D Volume desktop | Longint | 1 |

**Note:** *4D Desktop* incorporates certain deployment offers, such as, for example,"4D SQL Desktop".

## Example

Somewhere in your code, other than in the **On Server Startup Database Method**, you need to check if you are running 4D Server. You can write:

```
If(Application type=4D Server)
  ` Perform appropriate actions
End if
```

# Application version

Application version {( buildNum {; *} )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| buildNum | Longint | ⇦ | Build number |
| * | Operator | ⇨ | Long version number if passed, otherwise Short version number |
| Function result | String | ⇩ | Version number encoded string |

## Description

The **Application version** command returns an encoded string value that expresses the version number of the 4D environment you are running.
- If you do not pass the optional * parameter, a 4-character string is returned, formatted as follows:

| Characters | Description |
|---|---|
| 1-2 | Version number |
| 3 | "R" number |
| 4 | Revision number |

- If you pass the optional * parameter, an 8-character string is returned, formatted as follows:

| Characters | Description |
|---|---|
| 1 | "F" denotes a final version |
| | "B" denotes a beta version |
| | Other characters denote an 4D internal version |
| 2-3-4 | Internal 4D compilation number |
| 5-6 | Version number |
| 7 | "R" number |
| 8 | Revision number |

**Compatibility note (4D v14)**

Version numbering has been changed beginning with version 14 of 4D:

- the **"R" number** is the number of the "R" version of 4D, for example 3 for version R3 (contains 0 for a bug fix version),
- the **revision number** is the number of the bug fix version of 4D (contains 0 for an "R" version).

In previous versions of 4D, the number of the "R" version was the update number; it designated the revision and the revision number itself was always 0.

Examples for a short version number:

| Versions | Value returned | |
|---|---|---|
| 4D v13.1 | "1310" | *Previous numbering system* |
| 4D v14 R2 | "1420" | Release R2 |
| 4D v14 R3 | "1430" | Release R3 |
| 4D v14.1 | "1401" | First bug fix version of 4D v14 |
| 4D v14.2 | "1402" | Second bug fix version of 4D v14 |

Examples for a long version number:

| Versions | Value returned |
|---|---|
| 4D v12.5 beta | "B0011250" |
| 4D v14 R2 beta | "B0011420" |
| 4D v14 R3 final | "F0011430" |
| 4D v14.1 beta | "B0011401" |

The **Application version** command can return additional information in the optional *buildNum* parameter: the build number of the current version of the 4D application. This is an internal compilation number that can be used for versioning or when contacting the 4D Technical Services department.

**Note:** In the case of applications that are compiled and merged with 4D Volume License, the build number returned is not significant. In this context, version information is managed by the developer.

## Example 1

This example displays the 4D environment version number:

```
$vs4Dversion:=Application version
ALERT("You are using the version "+String(Num(Substring($vs4Dversion;1;2)))+"."+
$vs4Dversion≤3≥+"."+$vs4Dversion≤4≥)
```

## Example 2

This example tests to verify that you are using a final version:

```
If(Substring(Application version(*);1;1)#"F")
   ALERT("Please make sure you are using a Final Production version of 4D with this database!")
   QUIT 4D
End if
```

## Example 3

You want to use the application's short version value returned by the command to display the 4D application release name. You can write:

```
C_LONGINT($Lon_build)
C_TEXT($Txt_info;$Txt_major;$Txt_minor;$Txt_release;$Txt_version)

$Txt_version:=Application version($Lon_build)

$Txt_major:=$Txt_version[[1]]+$Txt_version[[2]] //version number, e.g. 14
$Txt_release:=$Txt_version[[3]] //Rx
$Txt_minor:=$Txt_version[[4]] //.x

$Txt_info:="4D v"+$Txt_major
If($Txt_release="0") //4D v14.x
   $Txt_info:=$Txt_info+Choose($Txt_minor#"0";"."+$Txt_minor;"")

Else //4D v14 Rx
   $Txt_info:=$Txt_info+" R"+$Txt_release
End if
```

# BUILD APPLICATION

BUILD APPLICATION {( projectName )}

| Parameter | Type | | Description |
|---|---|---|---|
| projectName | String | ⇨ | Full access path of the project to use |

## Description

The **BUILD APPLICATION** command launches the application generation process. It takes into account parameters set in the current application project or the application project set in the *projectName* parameter.

An application project is an XML file that contains all the parameters used to generate an application. Most parameters can be seen in the Build Application... dialog box (for more information, refer to the **Application builder** section of the 4D Design Reference manual).
By default, 4D creates an application project named “buildapp.xml” (default) for each database and places it in the BuildApp subfolder in the database Preferences folder.

If the database has not yet been compiled or if the compiled code is outdated, the command will first launch the compiler process. In this case, the compiler window does not appear (unless an error occurs), only a progress bar is displayed.
You can hide this progress bar using the **MESSAGES OFF** command.

If you do not pass the optional *projectName* parameter, the command displays a standard open file dialog box, so that you can designate a project file. When the dialog box has been validated, the system variable Document contains the full pathname of the open project file.

If you pass the access path and name of an XML file for a valid application project (UTF-8 encoding and “.xml” extension), the command will use the parameters defined in the file. For more information on the structure and the keys that can be used in the XML file of an application project, refer to the **4D XML Keys BuildApplication** manual.

## Example

This example builds two applications in a single method:

```
BUILD APPLICATION("c:¥¥folder¥¥projects¥¥myproject1.xml")
If(OK=1)
   BUILD APPLICATION("c:¥¥folder¥¥projects¥¥myproject2.xml")
End if
```

## System Variables or Sets

The system variable OK is set to 1 if the command has been correctly executed. Otherwise, it is set to 0. The system variable Document contains the full pathname of the open project file.

## Error Handling

If the command fails, an error is generated that you can intercept using the **ON ERR CALL** command.

# Compact data file

Compact data file ( structurePath ; dataPath {; archiveFolder {; option {; method}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| structurePath | Text | ⇒ | Pathname of structure file |
| dataPath | Text | ⇒ | Pathname of data file to be compacted |
| archiveFolder | Text | ⇒ | Pathname of folder where original data file will be put |
| option | Longint | ⇒ | Compacting options |
| method | Text | ⇒ | Name of 4D callback method |
| Function result | Text | ⇐ | Complete pathname of folder containing original data file |

## Description

The **Compact data file** command compacts the data file designated by the *dataPath* parameter associated with the *structurePath* structure file. For more information about compacting, refer to the Design Reference manual.

To ensure the continuity of the database operation, the new compacted data file automatically replaces the original file. For security, the original file is not modified and is moved into a special folder named “Replaced files (compacting) YYYY-MM-DD HH-MM-SS” where YYYY-MM-DD HH-MM-SS represents the date and time of the backup. For example: “Replaced files (compacting) 2007-09-27 15-20-35”.

The command returns the complete pathname of the folder actually created to store the original data file. This command can only be executed from 4D (local mode) or 4D Server (stored procedure). The data file to be compacted must correspond to the structure file designated by *structurePath*. In addition, the data file must not be open when the command is executed; otherwise an error is generated.
If an error occurs during the compacting process, the original files are kept in their initial location. If an index file (.4DIndx file) is associated with the data file, it is also compacted. As with the data file, the original file is saved and the new compacted version replaces the previous one.

- In the *structurePath* parameter, pass the complete pathname of the structure file associated with the data file that you want to compact. This information is needed for the compacting procedure. The pathname must be expressed in the syntax of the operating system. You can also pass an empty string; in this case, the standard Open file dialog box appears so that you can designate the structure file to be used.
- In the *dataPath* parameter, you can pass an empty string, a file name or a complete pathname, expressed in the syntax of the operating system. If you pass an empty string, the standard Open file dialog box appears so that the user can designate the data file to be compacted. This file must correspond to the structure file defined in the *structurePath* parameter. If you only pass the name of the data file, 4D will look for it at the same level as the structure file.
- The optional *archiveFolder* parameter can be used to specify the location of the “Replaced files (compacting) DateTime” folder intended to receive the original versions of the data files as well as any index files.
  The command returns the complete pathname of the folder actually created.
  - If you omit this parameter, the original files are automatically put in a “Replaced files (compacting) DateTime” folder that is created next to the structure file.
  - If you pass an empty string, a standard Open folder dialog box will appear so that the user can specify the location of the folder to be created.
  - If you pass a pathname (expressed in the syntax of the operating system), the command will create a “Replaced files (compacting) DateTime” folder at this location.
- The optional *options* parameter is used to set various compacting options. To do so, use the following constants, found in the “**Data File Maintenance**” theme. You can pass several options by combining them:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Compact address table | Longint | 131072 | Force the address table of the records to be rewritten (slows down compacting). Note that in this case, record numbers are rewritten. If you only pass this option, 4D automatically enables the 'Update records' option. |
| Create process | Longint | 32768 | When this option is passed, compacting will be asynchronous and you will need to manage the results using the callback method (see below). 4D will not display the progress bar (it is possible to do so using the callback method). The OK system variable is set to 1 if the process has been launched correctly and 0 in all other cases. When this option is not passed, the OK variable is set to 1 if the compacting takes place correctly and 0 otherwise. |
| Do not create log file | Longint | 16384 | Generally, this command creates a log file in XML format (refer to the end of the command description). With this option, no log file will be created. |
| Timestamp log file name | Longint | 262144 | When this option is passed, the name of the log file generated will contain the date and time of its creation; as a result, it will not replace any log file already generated previously. By default, if this option is not passed, log file names are not timestamped and each new file generated replaces the previous one. |
| Update records | Longint | 65536 | Force all records to be rewritten according to current definition of the fields in the structure |

- The *method* parameter is used to set a callback method which will be called regularly during the compacting if the Create process option has been passed. Otherwise, the callback method is never called. For more information about this method, please refer to the description of the **VERIFY DATA FILE** command.
  If the callback method does not exist in the database, an error is generated and the system variable OK is set to 0.

By default, the **Compact data file** command creates a log file in XML format (if you have not passed the Do not create log file option, see the *options* parameter). This file is placed in the **Logs** folder of the current database and its name is also based on the structure file of the current database. For example, for a structure file named "myDB.4db," the log file will be named "myDB_Compact_Log.xml."
If you have passed the Timestamp log file name option, the name of the log file includes the date and time of its creation in the form "YYYY-MM-DD HH-MM-SS", which gives us, for example: "myDB_Compact_Log_2015-09-27 15-20-35.xml". This means that each new log file does not replace the previous one, but it might require subsequent manual action to remove unnecessary files.
Regardless of the option selected, as soon as a log file is generated, its path is returned in the *Document* system variable after execution of the command.

## Example

The following example (Windows) carries out the compacting of a data file:

```
$structFile:=Structure file
$dataFile:="C:¥Databases¥Invoices¥January¥Invoices.4dd"
$origFile:="C:¥Databases¥Invoices¥Archives¥January¥"
$archFolder:=Compact data file($structFile;$dataFile;$origFile)
```

## System variables and sets

If the compacting operation is carried out correctly, the OK system variable is set to 1; otherwise, it is set to 0. If a log file was generated, its complete pathname is returned in the Document system variable.

# COMPONENT LIST

COMPONENT LIST ( componentsArray )

| Parameter | Type | | Description |
|---|---|---|---|
| componentsArray | Text array | ⇦ | Names of the components |

## Description

The **COMPONENT LIST** command sizes and fills the *componentsArray* array with the names of the components loaded by the 4D application for the current host database.

When a database is opened, 4D loads the valid components found in the Components folder(s):

- the Components folder that is next to the structure file (if any),
- the Components folder that is next to the 4D application executable file.

**Reminder:** If the same component is placed in both locations, 4D will only load the one located next to the structure.

This command can be called from the host database or from a component. If the database does not use any components, the *componentsArray* array is returned empty.

The names of the components are the names of the structure files of the matrix databases (.4db, .4dc or .4dbase). This command can be used for setting up architectures and modular interfaces that offer additional functionalities according to the presence of components.

For more information about 4D components, please refer to the Design Reference manual.

# CREATE DATA FILE

CREATE DATA FILE ( accessPath )

| Parameter | Type | | Description |
|---|---|---|---|
| accessPath | String | ⇨ | Name or complete access path of the data file to create |

## Description

The **CREATE DATA FILE** command creates a new data file to disk and replaces the data file opened by the 4D application on-the-fly.

The general functioning of this command is identical to that of the **OPEN DATA FILE** command; the only difference is that the new data file set by the *accessPath* parameter is created just after the structure is re-opened.

Before launching the operation, the command verifies that the specified access path does not correspond to an existing file.

**4D Server:** Beginning with 4D v13, this command can be executed with 4D Server. In this context, it performs an internal call to **QUIT 4D** on the server (which causes a dialog box to appear on each remote machine, indicating that the server is in the process of quitting) before creating the designated file.

# Data file

Data file {( segment )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| segment | Longint | ⇒ | Obsolete, do not use |
| Function result | String | ⇄ | Long name of the data file for the database |

## Description

The **Data file** command returns the long name of the data file for the database with which you are currently working.

Starting with version 11 of 4D, data segments are no longer supported. The *segment* parameter is now ignored and must no longer be used.

*On Windows*
If, for example, you are working with the database MyCDs located at ¥DOCS¥MyCDs on the volume G, a call to **Data file** returns G:¥DOCS¥MyCDs¥MyCDs.4DD (provided that you accepted the default location and name proposed by 4D when you created the database).

*On Macintosh*
If, for example, you are working with the database located in the folder Documents:MyCDs*ƒ*: on the disk Macintosh HD, a call to **Data file** returns Macintosh HD:Documents:MyCDs*ƒ*:MyCDs.data (provided that you accepted the default location and name proposed by 4D when you created the database).

**WARNING:** If you call this command from 4D in remote mode, only the name of the data file is returned, not the long name.

# Get 4D file

Get 4D file ( file {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| file | Longint | ⇒ | File type |
| * | Operator | ⇒ | Return file path of host database |
| Function result | String | ⇐ | Pathname to 4D file |

## Description

The **Get 4D file** command returns the pathname to the 4D environment file specified by the *file* parameter. The path is returned using the system syntax.

This command allows you to get the actual pathname of specific files, whose name or location can depend on database context. It also helps you to write generic code which is independent from the 4D version or the OS.

In *file*, pass a value to specify the file for which you want to get the full pathname. You can use one of the following constants, located in the "**4D Environment**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Backup configuration file | Longint | 1 | Backup.xml file, stored in Preferences/Backup folder next to database structure file. |
| Last backup file | Longint | 2 | Last backup file, named <databaseName>[bkpNum].4BK, stored at a custom location. |
| User settings file for data | Longint | 4 | settings.4DSettings file for current data file, stored in Preferences folder next to the data file. |
| User structure settings file | Longint | 3 | settings.4DSettings file for all data files, stored in Preferences folder next to database structure file if enabled. |

When the command is called from a component, pass the optional * parameter to get the *file* path of the host database. In this case, if you omit the * parameter, an empty string is always returned.

Regarding User settings file for data and User structure settings file, a path is returned only if the **Enable User Settings in External File** security option has been checked in the "Database Settings" dialog box (see **Enabling User Settings mode**).

## Example

You want to get the path of the last backup file:

```
C_TEXT($path)
$path:=Get 4D file(Last backup file)
 // $path = "C:¥Backups¥Countries¥Countries[0025].4BK" for example
```

# Get 4D folder

Get 4D folder {( folder {; *} )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| folder | Longint | ⇒ | Folder type (if omitted = active 4D folder) |
| * | Operator | ⇒ | Return folder of host database |
| Function result | String | ⇐ | Pathname to 4D Folder |

## Description

The **Get 4D folder** command returns the pathname to the active 4D folder of the current application, or to the 4D environment folder specified by the *folder* parameter, if passed. This command allows you to get the actual pathname of the folders used by the 4D application. By using this command, you ensure that your code will work on any platform running any localized system.

In *folder*, you can pass one of the following constants, which are located in the "**4D Environment**" theme:

| Constant | Type | Value |
|---|---|---|
| 4D Client database folder | Longint | 3 |
| Active 4D Folder | Longint | 0 |
| Current resources folder | Longint | 6 |
| Data folder | Longint | 9 |
| Database folder | Longint | 4 |
| Database folder Unix syntax | Longint | 5 |
| HTML Root folder | Longint | 8 |
| Licenses folder | Longint | 1 |
| Logs folder | Longint | 7 |

You will find below a description of each folder:

**Preliminary notes about folder names:**

- {Disk} is the disk where the system is installed.
- The word User represents the name of the user that opened the session.

### Active 4D Folder

The 4D environment uses a specific folder to store the following information:

- Preferences files used by the 4D environment applications
- Shortcuts.xml file (custom keyboard shortcuts)
- Macros v2 folder (macro commands of Method editor)
- Favorites v1x folder, for example Favorites v13 (pathnames for local and remote databases that have been opened)

With the main 4D applications (4D and 4D Server), the active 4D folder is named **4D** and is created by default at the following location:

- On Windows 7 and higher: *{Disk}:¥Users¥<userName>¥AppData¥Roaming¥4D*
- On OS X: *{Disk}:Users:<userName>:Library:Application Support:4D*

Starting with 4D v13, in the case of an application merged with 4D Volume Desktop, the active 4D folder is found at the following location:

- On Windows 7 and higher: *{Disk}:¥Users¥<userName>¥AppData¥Roaming¥<databaseName>*
- On OS X: *{Disk}:Users:<userName>:Library:Application Support:<databaseName>*

### Licenses Folder

Folder containing the Licenses files of the machine.
The **Licenses** folder is placed at the following location:

- On Windows 7 and higher: *{Disk}:¥ProgramData¥4D¥Licenses*

- On OS X: *{Disk}:Library:Application Support:4D:Licenses*

**Notes:**

- In the case of an application merged with 4D Volume Desktop, the licenses folder is included in the package of the application.
- If the licenses folder cannot be created in the system because of a lack of authorization, it is created at the following locations:
  - On Windows 7 and higher: *{Disk}:¥Users¥<userName>¥AppData¥Roaming¥4D¥Licenses*
  - On OS X: *{Disk}:Users:<userName>:Library:Application Support:4D:Licenses*

### Data Folder

Path of the folder containing the current data file. The pathname is expressed using the standard syntax of the current platform.

### 4D Client Database Folder (Client machines)

4D database folder created on each 4D client machine for storing files and folders related to the database (resources, plug-ins, Resources folder, etc.).
The **4D Client Database Folder** is placed at the following location on each client machine:

- On Windows 7 and higher: *{Disk}:¥Users¥<userName>¥AppData¥Local¥4D¥<databaseName_Address>*
- On OS X: *{Disk}:Users:<userName>:Library:Caches:4D:<databaseName_Address>*

### Database Folder

Folder containing the database structure file. The pathname is expressed using the standard syntax of the current platform. With the 4D Client application, this constant is strictly equivalent to the previous 4D Client database folder constant: the command returns the pathname of the folder created locally.

### Database Folder Unix Syntax

Folder containing the database structure file. This constant designates the same folder as the previous one but the pathname returned is expressed using the Unix syntax (Posix), of the type /Users/... This syntax is mainly used when you use the **LAUNCH EXTERNAL PROCESS** command under OS X.

### Current Resources folder

Resources folder of the database. This folder contains the additional items (pictures, texts) used for the database interface. A component can have its own Resources folder. The Resources folder is located next to the database structure file.
In client/server mode, this folder can be used to organize the transfer of custom data (pictures, files, subfolders, etc.) between the server machine and the client machines. The contents of this folder are automatically updated on each client machine when it connects. All referencing mechanisms associated with the Resources folder are supported in client/server mode (.lproj folder, XLIFF, pictures, and so on). In addition, 4D provides various tools that can be used to manage and update this folder dynamically, more particularly a resources explorer.

**Note:** If the *Resources* folder does not exist for the database, executing the **Get 4D folder** command with the Current resources folder constant will create it.

### Logs Folder

The Logs folder of the database. This folder centralizes the log files of the current database. It is created at the same level as the structure file and contains the following log files:

- database conversion,
- Web server requests,
- data verification and repair,
- structure verification and repair,
- backup/restore activities journal,
- command debugging,
- 4D Server requests (generated on client machines and on the server).

**Note:** If the **Logs** folder does not exist for the database, executing the **Get 4D folder** command with the Logs folder constant will create it.

### HTML Root Folder

Current HTML root folder of the database. The pathname returned is expressed with the standard syntax of the current platform. The HTML root folder is the folder in which the 4D Web server looks for the requested Web pages and files. By default, it is named **WebFolder** and is placed next to the structure file (or its local copy in the case of 4D in remote mode).

Its location can be set on the Web/Configuration page of the Preferences or dynamically via the **WEB SET ROOT FOLDER** command.

If the **Get 4D folder** command is called from a remote 4D, the path returned is that of the remote machine, not that of 4D Server.

The optional * parameter is useful in the case of an architecture using components: it can be used to determine the database (host or component) for which you want to get the folder pathname. This parameter is only valid for Database folder, Database folder UNIX syntax and Current resources folder folders. It is ignored in all other cases.
When the command is called from a component:

- If the * parameter is passed, the command returns the pathname of the host database folder,
- If the * parameter is not passed, the command returns the pathname of the component folder.
  The database folder (Database folder and Database folder UNIX syntax) returned differs according to the type of the component architecture:
  - In the case of a .4dbase folder/package, the command returns the pathname of the .4dbase folder/package,
  - In the case of a .4db or .4dc file, the command returns the pathname of the “Components” folder,
  - In the case of an alias or shortcut, the command returns the pathname of the folder containing the original matrix database. The result differs according to the format of this database (.4dbase folder/package or .4db/.4dc file), as described above.

  When the command is called from the host database, it always returns the pathname of the host database folder, regardless of whether or not the * parameter is passed.

### Extras Folder (obsolete)

Folder with customized contents downloaded to each client machine.

**Compatibility Note:** Beginning with version 11.2 of 4D v11 SQL, it is no longer advisable to use the *Extras* folder for customized communication between the server and remote machines. It is now recommended to use the *Resources* folder for this purpose (see the description of the current *Resources* folder below). The *Extras* folder is nevertheless still supported by 4D Server so as to maintain the compatibility of existing applications.

**Note:** If the *Extras* folder does not exist for the database, executing the **Get 4D folder** command with the Extras folder constant will create it.

## Example 1

During the startup of a single-user database, you want to load (or create) your own settings in a file located in the 4D folder. To do so, in the **On Startup database method**, you can write code similar to this:

```
MAP FILE TYPES("PREF";"PRF";"Preferences file")
 ` Map PREF Mac OS file type to .PRF Windows file extension
$vsPrefDocName:=Get 4D folder+"MyPrefs" ` Build pathname to the Preferences file
 ` Check if the file exists
If(Test path name($vsPrefDocName+(".PRF"*Num(On Windows)))#Is a document)
   $vtPrefDocRef:=Create document($vsPrefDocName;"PREF") ` If not, create it
Else
   $vtPrefDocRef:=Open document($vsPrefDocName;"PREF") ` If so, open it
End if
If(OK=1)
 ` Process document contents
   CLOSE DOCUMENT($vtPrefDocRef)
Else
 ` Handle error
End if
```

## Example 2

This example illustrates the use of the Database folder UNIX syntax constant under Mac OS to list the contents of the database folder:

```
$posixpath:="¥""+Get 4D folder(Database folder Unix syntax)+"¥""
$myfolder:="ls -l "+$posixpath
$in:=""
$out:=""
$err:=""
LAUNCH EXTERNAL PROCESS($myfolder;$in;$out;$err)
```

**Note:** Under Mac OS, it is necessary to put pathnames in quotes when they contain the names of files or folders with spaces in them. The escape sequence "¥" can be used to insert the quotation mark character into the string. You can also use the statement **Char(Double quote)**.

## Example 3

You can compute the paths to the user settings files:

```
$UserSettings4Data:=Get 4D folder(Data folder)+"Preferences"+Folder separator+"settings.4DSettings"
$UserSettings:=Get 4D folder(Database folder)+"Preferences"+Folder separator+"settings.4DSettings"
```

## System variables and sets

If the *folder* parameter is invalid or if the pathname returned is empty, the OK system variable is set to 0.

# Get database localization

Get database localization {( languageType )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| languageType | Longint | ⇒ | Type of language |
| Function result | String | ⇐ | Current language of the database |

## Description

The **Get database localization** command returns the default language or the language of the database specified by the *languageType*, expressed in the standard defined by the RFC 3066. Typically, the command returns “en” for English, “es” for Spanish, etc. For more information about this standard and the values returned by this command, please refer to **MissingRef** in the *Design Reference* manual.

Several different language settings can be used simultaneously in the application. To designate the setting to be obtained, in *languageType* you can pass one of the following constants, found in the **4D Environment** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Current localization | Longint | 1 | Current language of the application: default language or language set via the **SET DATABASE LOCALIZATION** command. |
| Default localization | Longint | 0 | Language set automatically by 4D on startup according to the Resources folder and the system environment (not modifiable). |
| Internal 4D localization | Longint | 3 | Language used by 4D for sorts and text comparisons (set in the Preferences of the application). |
| User system localization | Longint | 2 | Language set by the current user of the system. |

By default, if you omit the *languageType* parameter, the command returns the default language (0).

The current language of the database can be used to determine the .lproj folder where the program will look for the localized items of the database. 4D automatically determines the current language on database startup according to the contents of the **Resources** folder and the system environment. How it works is that 4D loads the first .lproj folder of the database that corresponds to the reference language, with the following order of priority:

1. System language (under Mac OS, several languages can be set by order of preference, 4D uses this setting).
2. Language of the 4D application.
3. English
4. First language found in the **Resources** folder.

**Note:** If the database does not have an .lproj folder, 4D applies the following order of priority: 1. System language, 2. English (if the system language cannot be identified).

# Get database measures

Get database measures {( options )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| options | Object | ⇒ | Return options |
| Function result | Object | ⇐ | Object containing database measures |

## Description

The **Get database measures** command allows you to get detailed information about 4D database engine events. Returned information includes data read/write access from/to the disk or the memory cache, as well as the use of database indexes, queries and sorts.

**Get database measures** returns a single object that contains all the relevant measures. The *options* object parameter allows you to set options for the returned information.

### Overview of the returned object

The returned object contains a single property named "DB" that has the following basic structure:

```
{
    "DB": {
        "diskReadBytes": {…},
        "cacheReadBytes": {…},
        "cacheMissBytes": {…},
        "diskWriteBytes": {…},

        "diskReadCount": {…},
        "cacheReadCount": {…},
        "cacheMissCount": {…},
        "diskWriteCount": {…},

        "dataSegment1": {…},
        "indexSegment": {…},

        "tables": {…},
        "indexes": {…}

    }
}
```

This object is made up of eight properties that contain basic measures ("diskReadBytes", "cacheReadBytes", "cacheMissBytes", "diskWriteBytes", "diskReadCount", "cacheReadCount", "cacheMissCount", "diskWriteCount") and additional properties ("dataSegment1", "indexSegment", "tables", "index") that can also contain elementary properties but at a different level and with a different scope (see below).

**Note:** A property is only present inside the object if it receives contents. Properties that do not have any contents are not included in the object. For example, if the database has been opened in read-only mode and indexes have not been used, the returned object will not contain "diskWriteBytes", "diskWriteCount", "indexSegment" or "indexes".

### Elementary properties

Elementary properties can be found at different levels in the DB object. They return the same information but at different scopes. Here is a description of the elementary properties:

| Name | Information returned |
|---|---|
| diskReadBytes | Bytes read from disk |
| cacheReadBytes | Bytes read from cache |
| cacheMissBytes | Bytes missed from cache |
| diskWriteBytes | Bytes written to disk |
| diskReadCount | Read accesses from disk |
| cacheReadCount | Read accesses from cache |
| cacheMissCount | Read accesses missed from cache |
| diskWriteCount | Write accesses to disk |

The eight elementary properties all have the same object structure, for example:

```
"diskReadBytes": {     "value": 33486473620,     "history": [        // optional          {"value": 52564,"time": -1665},          {"value": 54202,"time": -1649},                ···     ] }
```

- "**value**" (number): The "value" property contains a number that represents either a quantity of bytes or a count of accesses. Basically, this value is the sum of the value(s) of the "history" object (even if the "history" object is not present).

- "**history**" (array of objects): The "history" object array is a compilation of event values grouped by second. The "history" property is present only if requested through the *options* parameter (see below). The history array will hold a maximum of 200 items. Each element of the array is itself an object that contains two properties: "value" and "time".
  - "value" (number): quantity of bytes or accesses handled during the time period designated in the associated "time" property.
  - "time" (number): number of seconds elapsed since the function has been called. In the example above ("time": -1649) means 1649 seconds ago (or more precisely between 1649 and 1650 seconds ago). During this one-second period, 54,202 bytes have been read on disk.
    The history array does not contain sequential values (-1650,-1651,-1652, etc.) The previous value is -1665, which means that nothing was read on the disk in the 15-second period between 1650 and 1665.
    **Note:** By default the array will only contain useful information.
    Since the maximum size of the array is 200, if the database is used intensively (e.g., something is read every second on the disk), the maximum length of the history will be 200 seconds. On the other hand, if almost nothing happens except, for example, once every 3 minutes, the length of the history will be 600 minutes (3*200).
    This example can be represented in the following diagram:

| 4D internal history | | Requested history: 30 | |
|---|---|---|---|
| time | value | time | value |
| -2 | 4629 | 0 | 0 |
| -4 | 7788 | -1 | 0 |
| -6 | 3718 | -2 | 4629 |
| -8 | 8814 | -3 | 0 |
| -10 | 3925 | -4 | 7788 |
| -12 | 775 | -5 | 0 |
| -14 | 6807 | -6 | 3718 |
| -16 | 3265 | -7 | 0 |
| -18 | 8086 | -8 | 8814 |
| -20 | 2539 | -9 | 0 |
| | | -10 | 3925 |
| | | -11 | 0 |
| | | -12 | 775 |
| | | -13 | 0 |
| | | -14 | 6807 |
| | | -15 | 0 |
| | | -16 | 3265 |
| | | -17 | 0 |
| | | -18 | 8086 |
| | | -19 | 0 |
| | | -20 | 2539 |
| | | -21 | -1 |
| | | -22 | -1 |
| | | -23 | -1 |
| | | -24 | -1 |
| | | -25 | -1 |
| | | -26 | -1 |
| | | -27 | -1 |
| | | -28 | -1 |
| | | -29 | -1 |
| | | -30 | -1 |

### dataSegment1 and indexSegment

The "dataSegment1" and "indexSegment" properties contain up to four elementary properties (when available):

```
"dataSegment1": {
    "diskReadBytes": {···},
    "diskWriteBytes": {···},
    "diskReadCount": {···},
    "diskWriteCount": {···}
    },
"indexSegment": {
```

```
"diskReadBytes": {…},
"diskWriteBytes": {…},
"diskReadCount": {…},
"diskWriteCount": {…}
}
```

These properties return the same information as the elementary properties, but detailed for each database file:

- "dataSegment1" represents the .4dd data file on the disk
- "indexSegment" represents the .4dx index file on the disk

For example, you can get the following object:

```
{ "DB": { "diskReadBytes": {  "value": 718260  }, "diskReadCount": {  "value": 229  }, "dataSegment1": {  "diskReadBytes": {
"value": 679092  },  "diskReadCount": {  "value": 212  }  }, "indexSegment": {  "diskReadBytes": {  "value": 39168  },
"diskReadCount": {  "value": 17  } }
```

You can figure out how it works by adding up the returned values:

*diskReadBytes.value = dataSegment1.diskReadBytes.value + indexSegment.diskReadBytes.value*
*diskWriteBytes.value = dataSegment1.diskWriteBytes.value + indexSegment.diskWriteBytes.value*
*diskReadCount.value = dataSegment1.diskReadCount.value + indexSegment.diskReadCount.value*
*diskWriteCount.value = dataSegment1.diskWriteCount.value + indexSegment.diskWriteCount.value*

### tables

The "tables" property contains as many properties as there are tables that have been accessed either in read or write mode since the opening of the database. The name of each property is the name of the table involved. For example:

```
"tables": {  "Employees": {…}  "Companies": {…}  }
```

Each table objects contains up to 12 properties:

- The first eight properties are the *elementary properties* (see above) with values related to the table involved.
- Two other properties, "records" and "blobs", also have the same eight elementary properties, but concerning only certain field types:
  - The "records" property concerns all fields of the table (strings, dates, nums, etc.) except for text, pictures and Blobs
  - The "blobs" property concerns the text, picture and Blob fields of the table.
- One or two additional properties, "fields" and "queries", may also be present depending on the queries and sorts performed on the table concerned:
  - The "fields" property contains as many "field name" attributes (which are also sub-objects) as the number of fields used for queries or sorts.
    Each field name object contains:
    - a "queryCount" object (with or without history, depending on the *options* parameter) if any query has been performed using this field
    - and/or a "sortCount" object (with or without history, depending on the *options* parameter) if any sort has been performed using this field.

    This attribute is not based on index use; all types of queries and sorts are taken into account.
    Example: Since the moment the database was launched, several queries and sorts have been carried out using the *CompID*, *Name* and *FirstName* fields. The returned object contains the following "fields" sub-object (*options* are with path and without history):

```
{  "DB": {  "tables": {  "Employees": {  "fields": {  "CompID": {
"queryCount": {  "value": 3  }  },
"Name": {  "queryCount": {  "value": 1  },
"sortCount": {  "value": 3  }  },
"FirstName": {  "sortCount": {  "value": 2  }
} (...)
```

    **Note**:The "fields" attribute is created only if a query or sort has been performed on the table; otherwise this attribute will not be present.
  - "queries" is an array of objects that provides a description of each query performed on the table. Each element of the array will contain three attributes:
    - "queryStatement" (string): query string (containing field names but not criteria values). For example: " (Companies.PK_ID != ?)"
    - "queryCount" (object):
      - "value" (number): number of times the query statement has been executed, regardless of the criteria values.
      - "history" (array of objects) (if requested in *options*): "value" and "time" standard history properties

- "duration" (object) (if the "value" is >0)
  - "value" (number): number of milliseconds
  - "history" (array of objects) (if requested in *options*): "value" and "time" standard history properties.

Example: Since the moment the database was launched, a single query has been performed on the Employees table (*options* are with path and with history):

```
{     "DB": {         "tables": {             "Employees": {                 "queries": [                     {
"queryStatement": "(Employees.Name == ?)",                         "queryCount": {                          "value": 1,
                            "history": [                                 {                                "value": 1,
                                "time": -2022                                }                            ]
},                          "duration": {                                "value": 2,                     "history": [
                                {                                        "value": 2,                             "time": -2022
                                }                                }                                       }, (...)
```

**Note:** The "queries" attribute is created when at least one query has been performed on the table.

### indexes

This is the most complex object. All tables that have been accessed using one or more of their indexes are stored as properties and, inside the properties, the names of the indexes used are also included as properties. Keyword indexes appear separately and their names are followed by "*(Keyword)*". Finally, each index name property object contains the eight elementary properties related to this index as well as up to four sub-objects depending on index use in the database since it was launched (each sub-object only exists if their corresponding operation has been performed at some point since the launch of the database).

Example: Since the moment the database was launched, several indexes of the [Employees]EmpLastName field have been solicited. In addition, 2 records were created and 16 were deleted in the [Companies] table. This table has a "name" field that is indexed. The table also has been queried and sorted using this field. The resulting object will contain:

```
"indexes": {     "Employees": {         "EmpLastName": {                 "diskReadBytes": {…},                 "cacheReadBytes": {…},
            "cacheMissBytes": {…},                 "diskWriteBytes": {…},                 "diskReadCount": {…},
"cacheReadCount": {…},                 "cacheMissCount": {…},                 "diskWriteCount": {…}             }         "EmpLastName
(Keyword)": {...},         "index3Name": {…},         "index4Name": {…},         …         }         "Companies": {             "Name":
(...)             "queryCount": {                 "value": 41             },             "sortCount": {                 "value": 3
            },             "insertKeyCount": {                 "value": 2             },             "deleteKeyCount": {
            "value": 16             }     table3Name: {…} }
```

### options parameter

The *options* parameter allows you to customize the actual information returned by the command. In *options*, you pass an object that can contain up to three properties: "withHistory", "historyLength", and "path".

| Property | Type | Description |
|---|---|---|
| "withHistory" | Boolean | "true" means the history will be returned by the function inside the returned object; "false" means the object returned by the function will not contain any history |
| "historyLength" | number | Defines the size of the returned history array in seconds(*). |
| "path" | string \| string array | Full path of specific property or array of full paths for all specific properties that you want to get. When you pass a string, only the corresponding value is returned in the "DB" object (if the path is valid). Example: "DB.tables.Employees.records.diskWriteBytes". When you pass an array of strings, all the corresponding values are returned in the "DB" object (if the paths are valid). Example: ["DB.tables.Employee.records.diskWriteBytes", "DB.tables.Employee.records.diskReadCount","DB.dataSegment1.diskReadBytes"] |

(*) As described above, the history is not stored as a sequence of seconds but only with relevant values. If nothing happens during a couple of seconds or more, nothing will be stored and a gap will appear in the internal history array. "time" can contain, for example, -2, -4, -5, -10, -15, -30 with values 200, 300, 250, 400, 500,150. If the "historyLength" property value is set to 600 (10 minutes), then the returned array will contain 0, -1, -2, -3 … -599 for time, and only the values of -2, -4, -5, -10, -15, -30 will be filled. All the other values will get 0 (zero) as a value. Also as described above, the only limit of the internal array is the size (200), not the time. This means that if there is low activity for a specific property, the oldest time can be very remote (e.g.: -3600 for one hour ago). It may also contain less than 200 values if the database was just started. In these cases, if the internal history time is more recent than the requested one OR if all the relevant values have already been set in the returned array, then the returned value will be -1.

Example: The database has just been started 20 seconds ago and the request history is 60 seconds. The returned values between 0 and -20 will be set with values or zeros, and the other ones will be set with -1. When a "-1" value is returned, this means that either the request time is too old or the value is no longer in the internal history array (i.e., the 200-item limit has been reached and older values have been removed).

### About client/server and components

This command returns information about database usage. This means that it will return a valid object with relevant values only when called:

- in 4D local mode (if called from a component, it returns information about the host database)

- on the server side in client/server mode.

If the command is called from a remote 4D, then the object will be left empty.
In this context, if you need to get information about the database on the server, the simplest way to perform this action is to create a method with the "Execute on server" option enabled.
This principle will also work for a component: if the component is used in a 4D local context, it will return information about the host database; in a 4D remote context, it will return information about the server database.

## Example 1

You want to have the history logged in the returned object:

```
C_OBJECT($param)
C_OBJECT($measures)
OB SET($param;"withHistory";True)
$measures:=Get database measures($param)
```

## Example 2

We only want to know the global number of bytes read in the cache ("cacheReadBytes"):

```
C_OBJECT($oStats)
C_OBJECT($oParams)
OB SET($oParams;"path";"DB.cacheReadBytes")
$oStats:=Get database measures($oParams)
```

The object returned contains, for example:

```
{    "DB": {        "cacheReadBytes": {            "value": 9516637        }    } }
```

## Example 3

We want to request measures for cache bytes read within the last two minutes:

```
C_OBJECT($oParams)
C_OBJECT($measures)
OB SET($oParams;"path";"DB.cacheReadBytes")
OB SET($oParams;"withHistory";True)
OB SET($oParams;"historyLength";2*60)
$measures:=Get database measures($oParams)
```

# Get database parameter

Get database parameter ( {aTable ;} selector {; stringValue} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to get the parameter, or Default table if this parameter is omitted |
| selector | Longint | ⇒ | Code of the database's parameter |
| stringValue | String | ⇐ | String value of the parameter |
| Function result | Real | ⇒ | Current value of the parameter |

## Description

The **Get database parameter** command allows you to get the current value of a 4D database parameter. When the parameter value is a character string, it is returned in the *stringValue* parameter.

The *selector* parameter designates the parameter to get. 4D offers you the following predefined constants, which are in the "**Database Parameters**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Direct2D disabled | Longint | 0 | See selector 69 (Direct2D Status) |
| Direct2D hardware | Longint | 1 | See selector 69 (Direct2D Status) |
| Direct2D software | Longint | 3 | See selector 69 (Direct2D Status) |
| Minimum Web process | Longint | 6 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Minimum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 0 (see below). |
| Maximum Web process | Longint | 7 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Maximum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 10.<br>In non-contextual mode, for the Web server to be reactive, 4D delays the Web processes for 5 seconds and reuses them to execute any possible future HTTP queries. In terms of performance, this is actually more advantageous than creating a new process for each query. Once a Web process is reused, it is delayed again for 5 seconds. When the maximum number of Web processes has been reached, the web process is then aborted. If no query has been attributed to a Web process within the 5 second delay, the process is aborted, except if the minimum number of Web processes has been reached (in which case the process is delayed again).<br>These parameters allow you to adjust how your Web server operates in relation to the number of requests and the memory available as well as other parameters. |
| _o_Web conversion mode | Longint | 8 | **** *Selector disabled* **** |
| _o_Database cache size | Longint | 9 | **Scope**: 4D application<br>**Kept between two sessions**: -<br>**Description**: *Constant obsolete (kept for compatibility reasons only)*. We now recommend using the **Get cache size** command. |
| 4D Local mode scheduler | Longint | 10 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |
| 4D Server scheduler | Longint | 11 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Remote mode scheduler | Longint | 12 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: for selectors 10, 11 and 12, the *value* parameter is expressed in hexadecimal *0x00aabbcc* as follows:<br>*aa* = minimum number of ticks per call to the system (0 to 100 included).<br>*bb* = maximum number of ticks per call to the system (0 to 100 included).<br>*cc* = number of ticks between calls to the system (0 to 20 included).<br>If one of the values is out of range, 4D sets it to its maximum. You can pass one of the following preset standard values in the *value* parameter:<br>• *value* = -1: maximum priority allocated to 4D,<br>• *value* = -2: average priority allocated to 4D,<br>• *value* = -3: minimum priority allocated to 4D.<br>**Description**: This parameter allows you to dynamically set the 4D system internal calls. Depending on the Selector, the scheduler value will be set for:<br>• 4D local mode when the command is called from a 4D single-user application (*selector=10*).<br>• 4D Server when the command is called from 4D Server (*selector=11*).<br>• 4D remote mode when the command is called from a 4D connected to 4D Server (*selector=12*).<br>**Note:** The operation of selector 12 (4D Remote Mode Scheduler) differs according to whether the **SET DATABASE PARAMETER** command is executed on the server machine or on the client machine:<br>- If the command is executed on the server machine, the new value will be applied to all the client machines that connect to it subsequently.<br>- If the command is executed on the client machine, the new value is applied to the client machine immediately as well as to all the client machines that connect to the server subsequently.<br>You can use this operation to implement a dynamic and individualized management of priority for each client machine. This consists in executing the command initially on the client machine to be configured, then a second time on the server machine using the default value, which will then be used for the client machines that connect to it subsequently.<br>This operation is in effect in 4D starting with versions 6.8.6, 2003.3 and 2004.<br>**Warning**: Configuring these selectors inappropriately can cause serious degradation of application performance. It is recommended to only modify the default values with full knowledge of the facts. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| 4D Server timeout | Longint | 13 | **Scope**: 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Possible values**: 0 -> 32 767<br>**Description**: Value of the 4D Server timeout. The default 4D Server timeout value is defined on the "Client-Server/Network options" page of the Database settings dialog box on the server side.<br>The server timeout sets the maximum period "authorized" to wait for a client response, for example when it is executing a blocking operation. After this period, 4D Server disconnects the client. The 4D Server Timeout selector allows you to set, in the corresponding *value* parameter, a new timeout expressed in minutes. This feature is particularly useful to increase the timeout before executing a blocking and time-consuming operation on the client, such as printing a large number of pages, which can cause an unexpected timeout.<br>You also have two options:<br>• If you pass a **positive** value in the *value* parameter, you set a global and permanent timeout: the new value is applied to all process and is stored in the preferences of the 4D application (equivalent to change in the Preferences dialog box).<br>• If you pass a **negative** value in the *value* parameter, you set a local and temporary timeout: The new value is applied to the calling process only (the other processes keep the default values) and is reset to default as soon as the server receives any signal of activity from the client — for example, when the operation is finished. This option is useful for managing long operations initiated by 4D plug-ins.<br>To set the "No timeout" option, pass 0 in *value*. See example 1. |
| 4D Remote mode timeout | Longint | 14 | **Scope** (legacy network layer only): 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Description**: To be used in very specific cases. Value of the timeout granted by the remote 4D machine to the 4D Server machine. The default timeout value used by 4D in remote mode is set on the "Client-Server/Network options" page of the Database settings dialog box on the remote machine.<br>The 4D Remote mode timeout selector is only taken into account if you are using the legacy network. It is ignored when the *ServerNet* layer is activated: this setting is entirely managed by the 4D Server timeout (13) selector. |
| Port ID | Longint | 15 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Description**: TCP port ID used by the 4D Web server with 4D in local mode and 4D Server. The default value, which can be set on the "Web/Configuration" page of the Preferences dialog box, is 80. You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>The Port ID selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode). For more information about the TCP port ID, refer to the **Web Server Settings** section. |
| IP Address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Max concurrent Web processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Client minimum Web process | Longint | 19 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 6<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client maximum Web process | Longint | 20 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 7<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client Max Web requests size | Longint | 21 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 27<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client port ID | Longint | 22 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 15<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client IP address to listen | Longint | 23 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 16<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client character set | Longint | 24 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 17<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client max concurrent Web proc | Longint | 25 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 18<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Maximum Web requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Server log recording | Longint | 28 | **Scope**: 4D Server, 4D remote<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, added to the file name).<br>**Description**: Starts or stops the recording of standard requests received by 4D Server (excluding Web requests). By default, the value is 0 (requests not recorded).<br>4D Server lets you record each request received by the server machine in a log file. When this mechanism is enabled, two files are created in the Logs folder of the database, next to the database structure file.They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file of the same name already exists, it is replaced directly. You can set the starting number of the sequence using the *value* parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes. It can be imported, for example, into a spreadsheet software in order to be processed. |
| _o_Web Log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Client Web log recording | Longint | 30 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br>**Description**: Starts or stops the recording of Web requests received by the Web servers of all the client machines. By default, the value is 0 (requests not recorded).<br>The operation of this selector is identical to that of selector 29; however, it applies to all the 4D remote machines used as Web servers. The "logweb.txt" file is, in this case, automatically placed in the Logs subfolder of the remote 4D database folder (cache folder). If you only want to set values for certain client machines, use the Preferences dialog box of 4D in remote mode. |
| Table sequence number | Longint | 31 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: Any longint value.<br>**Description**: This selector is used to modify or get the current unique number for records of the table passed as parameter. "Current number" means "last number used": if you modify this value using **SET DATABASE PARAMETER**, the next record will be created with a number that consists of the value passed + 1. This new number is the one returned by the **Sequence number** command as well in any field of the table to which the "Autoincrement" property has been assigned in the Structure editor or via SQL.<br>By default, this unique number is set by 4D and corresponds to the order of record creation. For additional information, refer to the documentation of the **Sequence number** command. |
| _o_Real display precision | Longint | 32 | **** *Selector disabled* **** |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Debug log recording | Longint | 34 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Starts or stops the sequential recording of events occurring at the 4D programming level in the *4DDebugLog* file, which is automatically placed in the Logs subfolder of the database, next to the structure file. A new, more compact, tabbed text format is used in the event log file "4DDebugLog[_n].txt" starting with 4D v14 (where _n is the segment number of the file).<br>**Possible values**: Longint containing a bit field: value = bit1(1)+bit2(2)+bit3(4)+bit4(8)+⋯).<br>- Bit 1 (value 1) requests to enable the file (note that any other non-null value also enables it as well)<br>- Bit 2 (value 2) requests call parameters to methods and commands.<br>- Bit 3 (value 4) enables new tabbed format.<br>- Bit 4 (value 8) disables immediate writing of each operation on disk (enabled by default). Immediate writing is slower but more effective, for example for investigating causes of a crash. If you disable this mode, the file contents are more compact and are generated more quickly.<br>- Bit 5 (value 16) disables recording of plug-in calls (enabled by default).<br>In the (former) non-tabbed format, execution times are expressed in milliseconds and the "< ms" value is displayed when an operation lasts less than one millisecond.<br>In the new tabbed format, execution times are expressed in microseconds.<br>Examples:<br>SET DATABASE PARAMETER (34;1) // enables mode v13 file without parameters, with runtimes<br>SET DATABASE PARAMETER (34;2) // enables mode v13 file with parameters and runtimes<br>SET DATABASE PARAMETER (34;2+4) // enables file with v14 format, with parameters and runtimes<br>SET DATABASE PARAMETER (34;0) // disables file<br>To avoid having a file record too much information, you can restrict the 4D commands that are examined by using selector 80, Log Command list.<br>This option can be enabled for any type of 4D application (4D all modes, 4D Server, 4D Volume Desktop), in interpreted or compiled mode.<br>**Note:** This option is provided solely for the purpose of debugging and must not be put into production since it may lead to deterioration of the application performance and saturation of the hard disk. For more information about this format and on the use of the 4DDebugLog[_n].txt file, please contact the Technical Support of 4D Inc. |
| Client Server port ID | Longint | 35 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number where the 4D Server publishes the database (bound for 4D remote machines). By default, the value is 19813.<br>Customizing this value means that several 4D client-server applications can be used on the same machine with the TCP protocol; in this case, you must indicate a different port number for each application.<br>The value is stored in the database structure file. It can be set with 4D in local mode but is only taken into account in client-server configuration.<br>When you modify this value, it is necessary to restart the server machine in order for the new value to be taken into account. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Invert objects | Longint | 37 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0, 1 or 2 (0 = mode disabled, 1 = automatic mode, 2 = mode enabled).<br>**Description**: Configuration of the "object inversion" mode which is used to invert forms, objects, menu bars, and so on, in Application mode when the database is displayed under Windows in a right-to-left language. This mode can also be configured on the Interface/Right-to-left languages page of the Database Settings.<br>• Value 0 indicates that the mode is never enabled, regardless of the system configuration (corresponds to the Never value in the Database Settings).<br>• Value 1 indicates that the mode is enabled or disabled depending on the system configuration (corresponds to the Automatic value in the Database Settings).<br>• Value 2 indicates that the mode is enabled, regardless of the system configuration (corresponds to the Always value in the Database Settings).<br>For more information, refer to the *Design Reference* manual of 4D. |
| HTTPS Port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Client HTTPS port ID | Longint | 40 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector can be used to modify by programming the TCP port used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector operates exactly the same way as selector 39; however, it applies to all the 4D remote machines used as Web servers. If you only want to modify the value of certain specific client machines, use the Preferences dialog box of the remote 4D. |
| Unicode mode | Longint | 41 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (compatibility mode) or 1 (Unicode mode)<br>**Description**: Current database operating mode, with regards to the character set. 4D supports the Unicode character set but can function in “compatibility” mode (based on the Mac ASCII character set). By default, converted databases are executed in compatibility mode (0) and databases created with version 11 or higher are executed in Unicode mode. The execution mode can be controlled via an option in the Preferences and can also be read or (for testing purposes) modified via this selector. Modifying this option requires the database to be restarted in order for it to be taken into account. Note that within a component it is not possible to modify this value, but only to read it. |
| SQL Autocommit | Longint | 43 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (deactivation) or 1 (activation)<br>**Description**: Activation or deactivation of the SQL auto-commit mode. By default, the value is 0 (deactivated mode)<br>The auto-commit mode is used to strengthen the referential integrity of the database. When this mode is active, all **SELECT**, **INSERT**, **UPDATE** and **DELETE** (SIUD) queries are automatically included in ad hoc transactions when they are not already executed within a transaction. This mode can also be set in the Preferences of the database. |

| --- | --- | --- | --- |
| SQL Engine case sensitivity | Longint | 44 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (case not taken into account) or 1 (case-sensitive)<br>**Description**: Activation or deactivation of case-sensitivity for string comparisons carried out by the SQL engine.<br>By default, the value is 1 (case-sensitive): the SQL engine differentiates between upper and lower case and between accented characters when comparing strings (sorts and queries). For example “ABC”= “ABC” but “ABC” # “Abc” and "abc" # "âbc." In certain cases, for example so as to align the functioning of the SQL engine with that of the 4D engine, you may wish for string comparisons to not be case-sensitive (“ABC”=“Abc"="âbc").<br>This option can also be set on the **SQL page** of the Database settings. |
| Client log recording | Longint | 45 | **Scope**: Remote 4D machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, attached to file name).<br>**Description**: Starts or stops recording of standard requests carried out by the 4D client machine that executed the command (excluding Web requests). By default, the value is 0 (no recording of requests).<br>4D lets you record the log of requests carried out by the client machine. When this mechanism is activated, two files are created on the client machine, in the Logs subfolder of the local folder of the database. They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file with the same name already exists, it is directly replaced. You can set the starting number for the sequence using the value parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes |

| Query by formula on server | Longint | 46 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description**: Execution location of **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands for the *table* passed in the parameter.<br>When using a database in client-server mode, the query "by formula" commands can be executed either on the server or on the client machine:<br>• In databases created with 4D v11 SQL, these commands are executed on the server.<br>• In converted databases, these commands are executed on the client machine, as in previous versions of 4D.<br>• In converted databases, a specific preference (Application/Compatibility page) can be used to globally modify the execution location of these commands.<br>This difference in execution location influences not only application performance (execution on the server is usually faster) but also programming. In fact, the value of the components of the formula (in particular variables called via a method) differ according to the execution context. You can use this selector to punctually adapt the operation of your application.<br>If you pass 0 in the *value* l'parameter, the execution location of query "by formula" commands will depend on the database configuration: in databases created with 4D v11 SQL, these commands will be executed on the server. In converted databases, they will be executed on the client machine or the server according to the database preferences. Pass 1 or 2 in *value* to "force" the execution of these commands, respectively, on the client or on the server machine.<br>Refer to example 4.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |
| Order by formula on server | Longint | 47 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description** : Execution location of **ORDER BY FORMULA** command for the table passed in the parameter.<br>When using a database in client-server mode, this command can be executed either on the server or on the client machine. This selector can be used to specify the execution location of this command (server or client). This mode can also be set in the database preferences. For more information, please refer to the description of selector 46, Query By Formula On Server.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |

|---|---|---|---|
| Auto synchro resources folder | Longint | 48 | **Scope**: 4D remote machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 (no synchronization), 1 (auto synchronization) or 2 (ask).<br>**Description**: Dynamic synchronization mode for *Resources* folder of 4D client machine that executed the command with that of the server.<br>When the contents of the *Resources* folder on the server has been modified or a user has requested synchronization (for example via the resources explorer or following the execution of the **SET DATABASE LOCALIZATION** command), the server notifies the connected client machines.<br>Three synchronization modes are then possible on the client side. The Auto Synchro Resources Folder selector is used to specify the mode to be used by the client machine for the current session:<br>• 0 (default value): no dynamic synchronization (synchronization request is ignored)<br>• 1: automatic dynamic synchronization<br>• 2: display of a dialog box on the client machines, with the possibility of allowing or refusing synchronization.<br>The synchronization mode can also be set globally in the application Preferences. |
| Query by formula joins | Longint | 49 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (always use automatic relations) or 2 (use SQL joins if possible).<br>**Description**: Operating mode of the **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands relating to the use of "SQL joins."<br>In databases created starting with version 11.2 of 4D v11 SQL, these commands carry out joins based on the SQL joins model. This mechanism can be used to modify the selection of a table according to a query carried out on another table without these tables being connected by an automatic relation (necessary condition in previous versions of 4D).<br>The QUERY BY FORMULA Joins selector lets you specify the operating mode of the query by formula commands for the current process:<br>• 0: Uses the current settings of the database (default value). In databases created starting with version 11.2 of 4D v11 SQL, "SQL joins" are always activated for queries by formula. In converted databases, this mechanism is not activated by default for compatibility reasons but can be implemented via a preference.<br>• 1: Always use automatic relations (= functioning of previous versions of 4D). In this mode, a relation is necessary in order to set the selection of a table according to queries carried out on another table. 4D does not do "SQL joins."<br>• 2: Use SQL joins if possible (= default operation of databases created in version 11.2 and higher of 4D v11 SQL ). In this mode, 4D establishes "SQL joins" for queries by formula when the formula is suited for it (with two notable exceptions, see the description of the **QUERY BY FORMULA** or **QUERY SELECTION BY FORMULA** command).<br>**Note:** With 4D in remote mode, "SQL joins" can only be used if the formulas are executed on the server (they must have access to the records). To configure where formulas are to be executed, please refer to selectors 46 and 47. |
| HTTP compression level | Longint | 50 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| HTTP compression threshold | Longint | 51 | **Scope**:4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Server base process stack size | Longint | 53 | **Scope**: 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Size of the stack allocated to each preemptive system process on the server, expressed in bytes. The default size is determined by the system.<br>Preemptive system processes (processes of the 4D client base process type) are loaded to control the main 4D client processes. The size allocated by default to the stack of each preemptive process allows a good ease of execution but may prove to be consequential when very large numbers of processes (several hundred) are created. For optimization purposes, this size can be reduced considerably if the operations carried out by the database allow for it (for example if the database does not carry out sorts of large quantities of records). Values of 512 or even 256 KB are possible. Be careful, under-sizing the stack is critical and can be harmful to the operation of 4D Server. Setting this parameter should be done with caution and must take the database conditions of use into account (number of records, type of operations, etc.).<br>In order to be taken into account, this parameter must be executed on the server machine (for example in the **On Server Startup Database Method**). |
| Idle connections timeout | Longint | 54 | **Scope**:4D application unless value is negative<br>**Kept between two sessions**: No<br>**Possible values**: Whole value expressing a duration in seconds. The value can be positive (new connections) or negative (existing connections). By default, the value is 20.<br>**Description**: Maximum period of inactivity (timeout) for connections to both the 4D database engine and the SQL engine, as well as, in *ServerNet* mode (new network layer), to the 4D application server. When an idle connection reaches this limit, it is automatically put on standby, which freezes the client/server session and closes the network socket. In the server administration window, the state of the user process is indicated as "Postponed". This functioning is completely transparent for the user: as soon as there is new activity on the connection which is on standby, the socket is automatically reopened and the client/server session is restored.<br>On the one hand, this setting lets you save resources on the server: connections on standby close the socket and free up a process on the server. On the other hand, it lets you avoid losing connections due to the closing of idle sockets by the firewall. For this, the timeout value for idle connections must be lower than that of the firewall in this case.<br>If you pass a positive value in *value*, it applies to all new connections in all the processes. If you pass a negative value, it applies to connections that are open in the current process. If you pass 0, idle connections are not subjected to a timeout.<br>This parameter can be set on both the server and client side. If you pass two different durations, the shorter one is taken into account. Usually, you do not need to change this value. |
| PHP interpreter IP address | Longint | 55 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Formatted string of the type "nnn.nnn.nnn.nnn" (for example "127.0.0.1").<br>**Description**: IP address used locally by 4D to communicate with the PHP interpreter via FastCGI. By default, the value is "127.0.0.1". This address must correspond to the machine where 4D is located. This parameter can also be set globally for all the machines via the Database Settings.<br>For more information about the PHP interpreter, please refer to the *Design Reference* manual. |
| PHP interpreter port | Longint | 56 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 8002.<br>**Description**: Number of the TCP port used by the PHP interpreter of 4D. This parameter can also be modified globally for all the machines via the Database Settings.<br>For more information about the PHP interpreter, please refer to the *Design Reference* manual. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| PHP number of children | Longint | 57 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 5.<br>**Description**: Number of child processes to be created and maintained locally by the PHP interpreter of 4D. For optimization reasons, the PHP interpreter creates and uses a set (pool) of system processes called "child processes" for processing script execution requests. You can vary the number of child processes according to the needs of your application. This parameter can also be modified globally for all the machines via the Database Settings. For more information about the PHP interpreter, please refer to the *Design Reference* manual.<br>**Note:** Under Mac OS, all the child processes share the same port. Under Windows, each child process uses a specific port number. The first number is the one set for the PHP interpreter; the other child processes increment the first one. For example, if the default port is 8002 and you launch 5 child processes, they will use ports 8002 to 8006. |
| PHP max requests | Longint | 58 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 500.<br>**Description**: Maximum number of requests accepted by the PHP interpreter. When this maximum number is reached, the interpreter returns errors of the "server busy" type. For security or performance reasons, you can modify this value. This parameter can also be modified globally for all the machines via the Database Settings. For more information about this parameter, please refer to the FastCGI-PHP documentation.<br>**Note:** On the 4D side, these parameters are applied dynamically; it is not necessary to exit 4D in order for them to be taken into account. On the other hand, if the PHP interpreter is already launched, it will be necessary to exit and relaunch it in order for these modifications to be taken into account. |
| PHP use external interpreter | Longint | 60 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values** : 0 = use internal interpreter, 1 = use external interpreter<br>**Description**: Value indicating whether PHP requests in 4D are sent to the internal interpreter provided by 4D or to an external interpreter. By default the value is 0 (use of interpreter provided by 4D). If you want to use your own PHP interpreter, for example in order to use additional modules or a specific configuration, pass 1 in *value*. In this case, 4D does not launch its internal interpreter in the case of PHP requests.<br>The custom PHP interpreter must have been compiled in FastCGI and be located on the same machine as the 4D engine. Note that in this case, you must manage the interpreter entirely; it will not be started nor stopped by 4D. This parameter can also be modified globally for all the machines via the Database Settings. |
| Maximum temporary memory size | Longint | 61 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Maximum size of temporary memory that 4D can allocate to each process, expressed in MB. By default, the value is 0 (no maximum size). 4D uses a special temporary memory dedicated to indexing and sorting operations. This memory is intended to preserve the "standard" cache memory during massive operations. It is activated only when needed. By default, the size of the temporary memory is limited only by the resources available (according to the system memory configuration).<br>This mechanism is suitable for most applications. However, in certain specific contexts, more particularly when a client-server application simultaneously carries out a large number of sequential sorts, the size of the temporary memory can increase critically, to the point where it can render the system unstable. In this context, setting a maximum size for the temporary memory allows you to preserve proper functioning of the application. In return, the running speed might be affected: when the maximum size is reached for a process, 4D uses disk files which may slow down processing. For specific needs such as those described above, a maximum size of around 50 MB is generally a good compromise. However, the ideal value will need to be determined according to the specificities of the application and will generally be the result of real-time volumetric testing. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| SSL cipher list | String | 64 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Sequence of strings separated by colons (for example "RC4-MD5:RC4-64-MD5:....")<br>**Description:** Cipher list used by 4D for the secure protocol. This list modifies the priority of ciphering algorithms implemented by 4D. For example, you can pass the following string in the *value* parameter: "AES:ALL:!aNULL:!eNULL:+RC4:@STRENGTH". For a complete description of the syntax for the ciphers list, refer to the ciphers page of the OpenSSL site.<br>This setting applies to the entire 4D application (it concerns the HTTP server, SQL server, client/server connections, as well as the HTTP client and all the 4D commands that make use of the secure protocol) but it is temporary (it is not maintained between sessions).<br>When the cipher list has been modified, you will need to restart the server concerned in order for the new settings to be taken into account.<br>To reset the cipher list to its default value (stored permanently in the SLI file), call the **SET DATABASE PARAMETER** command and pass an empty string ("") in the *value* parameter.<br>**Note:** With the **Get database parameter** command, the cipher list is returned in the optional *stringValue* parameter and the return parameter is always 0. |
| Cache unload minimum size | Longint | 66 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint > 1.<br>**Description**: Minimum size of memory to release from the database cache when the engine needs to make space in order to allocate an object to it (value in bytes).<br>The purpose of this selector is to reduce the number of times that data is released from the cache in order to obtain better performance. You can vary this setting according to the size of the cache and that of the blocks of data being handled in your database.<br>By default, if this selector is not used, 4D unloads at least 10% of the cache when space is needed. |
| Direct2D status | Longint | 69 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Activation mode to implement Direct2D under Windows.<br>**Possible values**: One of the following constants (mode 3 by default):<br>Direct2D Disabled (0): Direct2D mode is not enabled and the database functions in the previous mode (GDI/GDIPlus).<br>Direct2D Hardware (1): Use Direct2D as graphics hardware context for entire 4D application. If this context is not available, use Direct2D graphics software context (except under Vista, in which case GDI/GDIPlus mode is used for better performance).<br>Direct2D Software (3) (Default mode): Beginning with Windows 7, use Direct2D graphics software context for entire 4D application. Under Vista, GDI/GDIPlus mode is used for better performance.<br>**Compatibility note:** Starting with 4D v14, hybrid modes are disabled and redirected to available modes (the former mode 2 is equivalent to 1; former modes 4 and 5 are equivalent to mode 3). |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Direct2D get active status | Longint | 74 | **Note**: You can only use this selector with the **Get database parameter** command and its value cannot be set.<br>**Description**: Returns active implementation of Direct2D under Windows.<br>**Possible values**: 0, 1, 2, 3, 4 or 5 (see values of selector 69). The value returned depends on the availability of Direct2D, the hardware and the quality of Direct2D support by the operating system.<br>For example, if you execute:<br>`SET DATABASE PARAMETER(Direct2D status;Direct2D Hardware)`<br>`$mode:=Get database parameter(Direct2D get active status)`<br><br>- On Windows 7 and higher, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 3 (software context).<br>- On Windows Vista, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 0 (disabling of Direct2D).<br>- On Windows XP, *$mode* is always set to 0 (not compatible with Direct2D). |
| Diagnostic log recording | Longint | 79 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 or 1 (0 = do not record, 1 = record)<br>**Description**: Starts or stops recording of the 4D diagnostic file. By default, the value is 0 (do not record).<br>4D can continuously record a set of events related to the internal application operation into a diagnostic file. Information contained in this file is intended for the development of 4D applications and can be analyzed with the help of the 4D tech support. When you pass 1 in this selector, a diagnostic file, named *DatabaseName_X*.txt, is automatically created (or opened) in the database **Logs** folder. Once this file reaches a size of 10 MB, it is closed and a new file named *DatabaseName_X*.txt is generated, with an incremented sequence number X.<br>Note that you can include custom information in this file using the **LOG EVENT** command. |
| Log command list | String | 80 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: String containing a list of 4D command numbers to record (separated by semi-colons) or "all" to record all the commands or "" (empty string) to record none of them.<br>**Description**: List of 4D commands to record in the debugging file (see selector 34, Debug Log Recording). By default, all 4D commands are recorded.<br>This selector restricts the quantity of information saved in the debugging file by limiting the 4D commands whose execution you want to record. For example, you can write:<br>`SET DATABASE PARAMETER(Log command list;"277;341") //Record only the QUERY and QUERY SELECTION commands` |
| Spellchecker | Longint | 81 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 (default) = native OS X spellchecker (Hunspell disabled), 1 = Hunspell spellcheck enabled.<br>**Description**: Enables the Hunspell spellcheck under OS X. By default, the native spellchecker is enabled on this platform. You may prefer to use the Hunspell spellcheck, for example, in order to unify the interface for your cross-platform applications (under Windows, only the Hunspell spellcheck is available). For more information, refer to **Support of Hunspell dictionaries**. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| QuickTime support | Longint | 82 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (default) = QuickTime disabled, 1 = QuickTime enabled.<br>**Description**: In 4D starting with v14, by default QuickTime codecs are no longer supported. For compatibility, you can use this selector to re-enable them in your database. Modification of this option requires that the database be restarted. Nevertheless, you should note that in future versions of 4D, QuickTime support is permanently removed. |
| JSON use local time | Longint | 85 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 = ignore local time zone, 1 (default) = take time zone into account.<br>**Description**: By default, 4D dates converted to JSON format take the local time zone into account. For example, converting the date !23/08/2013! gives you "2013-08-22T22:00:00Z" in JSON format when the operation is performed in France during Daylight Savings Time (GMT+2). This principle conforms to the standard operation of JavaScript.<br>This can be a source of errors when you want to send JSON date values to someone in a different time zone. This is the case, for example, when you export a table using **Selection to JSON** in France that is meant to be reimported in the US using **JSON TO SELECTION**. By default, since dates are re-interpreted in each time zone, the values stored in the database will be different. In this case, you can modify the conversion mode for dates so that they do not take the time zone into account by passing 0 in this selector. Converting the date !23/08/2013! will then give you "2013-08-23T00:00:00Z" in all cases. |
| Use legacy network layer | Longint | 87 | **Scope**: 4D in local mode, 4D Server<br>**Kept between two sessions**: Yes<br>**Description:** Sets or gets the current status of the legacy network layer for client/server connections. The legacy network layer is obsolete beginning with 4D v14 R5 and should be replaced progressively in your applications with the *ServerNet* network layer. *ServerNet* will be required in upcoming 4D releases in order to benefit from future network evolutions. For compatibility reasons, the legacy network layer is still supported to allow a smooth transition for existing applications; (it is used by default in applications converted from a release prior to v14 R5). Pass 1 in this parameter to use the legacy network layer (and disable *ServerNet*) for your client/server connections, and pass 0 to disable the legacy network (and use the *ServerNet*).<br>This property can also be set by means of the "Use legacy network layer" option found on the **Compatibility page** of the Database Settings (see **Network and Client-Server options**). In this section, you will also find a discussion about migration strategy. We recommend that you activate the *ServerNet* as soon as possible.<br>You will need to restart the application in order for this parameter to be taken into account. It is not available in 4D Server v14 R5 64-bit version for OS X, which only supports the *ServetNet*; (it always returns 0).<br>**Possible values:** 0 or 1 (0 = do not use legacy layer, 1 = use legacy layer)<br>**Default value:** 0 in databases created with 4D v14 R5 or higher, 1 in databases converted from 4D v14 R4 or earlier. |
| SQL Server Port ID | Longint | 88 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: Yes<br>**Description**: Gets or sets the TCP port number used by the integrated SQL server of 4D in local mode or 4D Server. By default, the value is 19812. When this selector is set, the database setting is updated. You can also set the TCP port number on the "SQL" page of the Database Settings dialog box.<br>**Possible values**: 0 to 65535.<br>**Default value**: 19812 |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Circular log limitation | Longint | 90 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: No<br>**Possible values**: Any integer value, 0 = keep all logs<br>**Description**: Maximum number of files to keep in rotation for each type of log. By default, all files are kept. If you pass a value *X*, only the *X* most recent files are kept, with the oldest being erased automatically when a new one is created. This setting applies to each of the following log files: request logs (selectors 28 and 45), debug log (selector 34), events log (selector 79), as well as Web request logs and Web debug logs (selectors 29 and 84 of the **WEB SET OPTION** command). |
| Number of formulas in cache | Longint | 92 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longints<br>**Default value**: 0 (no cache)<br>**Description**: Sets or gets the maximum number of formulas to be kept in the cache of formulas, which is used by the **EXECUTE FORMULA** command. This limit is applied to all processes, but each process has its own formula cache. Caching formulas accelerates the **EXECUTE FORMULA** command execution in compiled mode since each cached formula is tokenized only once in this case. When you change the cache value, existing contents are reset even if the new size is larger than the previous one. Once the maximum number of formulas in the cache is reached, a new executed formula will erase the oldest one in the cache (FIFO mode). This parameter is only taken into account in compiled databases or compiled components. |
| Cache flush periodicity | Longint | 95 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: longint > 1 (seconds)<br>**Description**: Gets or sets the current cache flush periodicity, expressed in seconds. Modifying this value overrides the **Flush Cache every X Seconds** option in the **Database/Memory page** of the Database settings for the session (it is not stored in the Database settings). |

## Example 1

The following method allows you to get 4D scheduler current values:

```
C_LONGINT($ticksbtwcalls;$maxticks;$minticks;$lparams)
If(Application type=4D Local Mode) ` 4D local mode is used
   $lparams:=Get database parameter(4D Local Mode Scheduler)
   $ticksbtwcalls:=$lparams &0x00ff
   $maxticks:=($lparams>>8)&0x00ff
   $minticks:=($lparams>>16)&0x00ff
End if
```

## Example 2

The selector 16 (IP address to listen) lets you get the IP address on which the 4D Web server receives HTTP requests. The following example splits up the hexadecimal value:

```
C_LONGINT($a;$b;$c;$d)
C_LONGINT($addr)
$addr:=Get database parameter(IP Address to listen)
$a:=($addr>>24)&0x000000ff
$b:=($addr>>16)&0x000000ff
$c:=($addr>>8)&0x000000ff
$d:=$addr&0x000000ff
```

# Get last update log path

Get last update log path -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Text |  | Pathname of most recent update log |

## Description

The **Get last update log path** command returns the complete pathname of the most recent update log file found on the machine where it is called.

The update log is generated by 4D during automatic update processes. It contains information about the updates performed as well as any errors that occurred.

This command is intended to be used in an automatic update process for a merged application (server or single-user). For more information, refer to **Finalizing and deploying final applications** in the *Design Reference* manual.

# GET SERIAL INFORMATION

GET SERIAL INFORMATION ( key ; user ; company ; connected ; maxUser )

| Parameter | Type | | Description |
|---|---|---|---|
| key | Longint | ⇦ | Unique product key (encrypted) |
| user | String | ⇦ | Registered name |
| company | String | ⇦ | Registered organization |
| connected | Longint | ⇦ | Number of connected users |
| maxUser | Longint | ⇦ | Maximum number of connected users |

## Description

The **GET SERIAL INFORMATION** command returns various information about the 4D current version serialization.

- *key*: unique ID of the installed product. A unique number is associated to a 4D application (such as 4D Server, 4D in local mode, 4D Desktop, etc.) installed on a machine. This number is encrypted, of course.
- *user*: Name application user as defined when installing.
- *company*: User's company or organization name as defined during installation.
- *connected*: Number of connected users when executing the command.
- *maxUsers*: Maximal number of users concurrently connected.

**Note:** The last two parameters always return 1 for 4D single user except in demonstration versions (0 is then returned).

**GET SERIAL INFORMATION** is part of the general component protection scheme implemented in 4D. Component developers can associate a copy of their product to a given installed 4D application, in order to avoid any illegal copies.

The serialization works as follows: a user who wants to get a component sends his unique key generated through the **GET SERIAL INFORMATION** command to the developer. This can be done through an Order form included in a demo version of the component. The generated key is unique and is associated to a specific 4D application.

The component developer can then generate his own serial number combining the key and a given cipher. The delivered component will offer a function verifying if the information returned by the **GET SERIAL INFORMATION** matches this serial number. Otherwise, the user will not be able to use the component.

**Note:** Plug-ins developers can use this protection scheme too. For more information, refer to the *4D Plugin API Reference*.

# Get table fragmentation

Get table fragmentation ( aTable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to get the fragmentation rate |
| Function result | Real | ⇐ | Percentage of fragmentation |

## Description

The **Get table fragmentation** command returns the percentage of logical fragmentation for the records of the table designated by the *aTable* parameter.

The rate of logical fragmentation of the records indicates whether the records are stored in an ordered manner in the data file. If the fragmentation becomes too high, this can considerably slow down sorts and sequential searches on the table. A fragmentation percentage of 0 corresponds to no fragmentation. Beyond a rate of 20%, it may be useful to compact the data file.

## Example

This maintenance method lets you request the compacting of the data file in the case where there is considerable fragmentation in at least one table of the database:

```
ToBeCompacted:=False
For($i ;1;Get last table number)
   If(Is table number valid($i))
      If(Get table fragmentation(Table($i)->)>20)
         ToBeCompacted:=True
      End if
   End if
End for
If(ToBeCompacted)
 // Places a marker requesting compacting
End if
```

# Is compiled mode

Is compiled mode {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Returns information about host database |
| Function result | Boolean | ⮌ | Compiled (True), Interpreted (False) |

## Description

**Is compiled mode** tests whether you are running in compiled mode (True) or interpreted mode (False).

The optional * parameter is useful in the case of an architecture using components: it can be used to determine the database (host or component) for which you want to find out the running mode.

- When the command is called from a component:
  - If the * parameter is passed, the command returns **True** or **False** depending on the mode in which the host database is running,
  - If the * parameter is not passed, the command returns **True** or **False** depending on the mode in which the component is running.
- When the command is called from a method of the host database, it returns **True** or **False** depending on the mode in which the host database is running.

## Example

In one of your routines, you include debugging code useful only when you are running in interpreted mode, so surround this debugging code with a test that calls **Is compiled mode**:

```
  ` ...
If(Not(Is compiled mode))
  ` Include debugging code here
End if
  ` ...
```

# Is data file locked

Is data file locked -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | True = file/segment locked False = file/segment not locked |

## Description

The **Is data file locked** command returns True if the data file of the open database or at least one of its segments is locked — i.e. write protected.

Placed, for instance, in the **On Startup database method**, this command enables the prevention of any risk of accidental opening of a locked data file.

## Example

This method will prevent the opening of the database if the data file is locked:

```
If(Is data file locked)
   ALERT("The data file is locked. Impossible to open database.")
   QUIT 4D
End if
```

# NOTIFY RESOURCES FOLDER MODIFICATION

NOTIFY RESOURCES FOLDER MODIFICATION
Does not require any parameters

## Description

The **NOTIFY RESOURCES FOLDER MODIFICATION** command "forces" 4D Server to send a notification to all the connected 4D machines indicating that the *Resources* folder of the database has been modified so that they can synchronize their local *Resources* folder.

This command can be used more particularly to manage the synchronization of the *Resources* folders of remote machines after this folder has been modified by a stored procedure on the server.

For more information about managing the *Resources* folder in remote mode, please refer to the 4D Server Reference Guide.

Only the information that modification has occurred is sent. Remote machines react according to current settings. The options are the following:

- No synchronization of the local *Resources* local folder during the session,
- Automatic synchronization of the local *Resources* folder during the session,
- Display of a warning so that the user may carry out a synchronization if desired.

Current settings are set either:

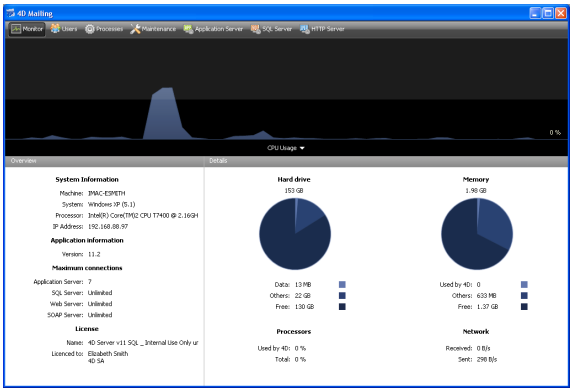
- at the overall database level using the **Update Resources folder during a session** parameter of the Database settings. In this case, it applies to all the remote machines;
- locally, using the **SET DATABASE PARAMETER** command executed on the remote machine (Auto synchro resources folder selector). In this case, it "overrides" the database setting and applies only to the remote machine for the duration of the session.

# OPEN ADMINISTRATION WINDOW

OPEN ADMINISTRATION WINDOW
Does not require any parameters

## Description

The **OPEN ADMINISTRATION WINDOW** command displays the server administration window on the machine that executes it. The 4D Server administration window can be used to view the current parameters and to carry out various maintenance operations (see the 4D Server Reference Guide). Beginning with version 11 of 4D Server, this window can be displayed from a client machine:



This command must be called in the context of a connected 4D application or a 4D Server. It does nothing if:

- it is called in a 4D application in local mode,
- it is executed by a user other than the Designer or the Administrator (in this case, the error -9991 is generated, see the **Database Engine Errors (-10602 -> 4004)** section).

## Example

Here is the code for an administration button:

```
If(Application type=4D local mode)
   OPEN SECURITY CENTER
   ...
End if
If(Application type=4D remote mode)
   OPEN ADMINISTRATION WINDOW
   ...
End if
If(Application type=4D Server)
   ...
   OPEN SECURITY CENTER
End if
```

## System variables and sets

If the command has been executed correctly, the OK system variable is set to 1. Otherwise, it is set to 0.

# OPEN DATA FILE

OPEN DATA FILE ( accessPath )

| Parameter | Type | | Description |
|---|---|---|---|
| accessPath | String | ⇨ | Name or complete access path of the data file to open |

## Description

The **OPEN DATA FILE** command allows changing the data file opened by the 4D application on-the-fly.

Pass the name or the full access path of the data file to open (file with a ".4DD" suffix) in the *accessPath* parameter. If you pass only the file name, it must be placed next to the structure file of the database.

If the access path sets a valid data file, 4D quits the database in progress and re-opens it with the specified data file. In single-user mode, the **On Exit database method** and the **On Startup database method** are successively called.

**Warning:** Since this command causes the application to quit before re-opening with the specified data file, it must be used with precaution in the **On Startup database method** or in a method called by this database method, so as to avoid generating an infinite loop.

The command is executed in an asynchronous manner: after its call, 4D continues executing the rest of the method. Then, the application behaves as if the **Quit** command was selected in the **File** menu: open dialog boxes are cancelled, any open processes have 10 seconds to finish before being terminated, etc.

Before launching the operation, the command checks the validity of the specified data file. Also, if the file was already open, the command verifies that it corresponds to the current structure.

If you pass an empty string in *accessPath*, the command will re-open the database without changing the data file.

**4D Server:** Beginning with 4D v13, this command can be executed with 4D Server. In this context, it makes an internal call to **QUIT 4D** on the server (which causes a dialog box to appear on each remote machine indicating that the server is in the process of quitting) before opening the designated file.

## Example

In the context of deploying a merged application, you want to open or create the user data file in the On Startup database method. This example uses the default data file (see **Data file management in final applications**):

```
If(Data file="@default.4dd")
   If(Version type?? Merged application)
      If(Is data file locked)
         $dataPath:=Get 4D folder(Active 4D Folder)+"data.4dd"
 //If a local data file already exists
         If(Test path name($dataPath)=Is a document)
            OPEN DATA FILE($dataPath) //open it
         Else
            CREATE DATA FILE($dataPath) //create it
         End if
      End if
   End if
End if
```

# OPEN DATABASE

OPEN DATABASE ( filePath )

| Parameter | Type | | Description |
|---|---|---|---|
| filePath | String | ⇒ | File name (.4db, .4dc, .4dbase or .4dlink) or complete access path of database to open |

## Description

The **OPEN DATABASE** command closes the current 4D database and opens on-the-fly the database defined by *filePath*. This command is useful for automatic testing purposes, or to reopen a database automatically after a compilation.

In the *filePath* parameter, pass the name or full access path of the database to be opened. You can use files having one of the following extensions:

- .4db (interpreted structure file),
- .4dc (compiled structure file),
- .4dbase (OS X package),
- .4dlink (shortcut file).

If you pass only a file name, this file must be placed at the same level as the structure file of the current database.

If the access path defines a valid database, 4D quits the database that is already open and then opens the specified database. In single-user mode, the **On Exit database method** of the database being closed and the **On Startup database method** of the database being opened are called successively.

**Warning:** Since this command causes the application to quit before re-opening with the specified database, it is not recommended to use it in the **On Startup database method**, or in a method called by this database method.

The command is executed in an asynchronous manner: after its call, 4D continues executing the rest of the method. Then, the application behaves as if the **Quit** command was selected in the **File** menu: open dialog boxes are cancelled, any open processes have 10 seconds to finish before being terminated, and so on.

If the target database file is not found or is invalid, a standard file system error is returned and 4D does nothing.

This command can only be executed from a standard database. If it is called from an engined application (single user or server), the error -10509 "Can't open database" is returned.

## Example

```
OPEN DATABASE("C:¥¥databases¥¥Invoices¥¥Invoices.4db")
```

# OPEN SECURITY CENTER

OPEN SECURITY CENTER
Does not require any parameters

## Description

The **OPEN SECURITY CENTER** command displays the Maintenance and Security Center (MSC) window.

Depending on the access rights of the current user, some functions available in this window may be disabled.

**Note:** This command works on the same principle as a call to **DIALOG** with the * parameter: the MSC is displayed in a window and the command immediately returns control to the 4D code. If the current process finishes, the window is automatically closed by simulating a **CANCEL**. So you need to manage its display through the code of the process being executed.

# OPEN SETTINGS WINDOW

OPEN SETTINGS WINDOW ( selector {; access}{; settingsType} )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | String | ⇒ | Key designating a theme or a page or a group of parameters in the Preferences or Settings dialog box |
| access | Boolean | ⇒ | True=Lock the other pages of the dialog box False or omitted=Leave the other pages of the dialog box active |
| settingsType | Longint | ⇒ | 0 or omitted = Structure settings, 1 = User settings |

## Description

The **OPEN SETTINGS WINDOW** command opens the Preferences dialog box of 4D or the Database Settings of the current 4D application and displays the parameters or the page corresponding to the key passed in *selector*.

The *selector* parameter must contain a “key” indicating the dialog box and the page to opened. This key is constructed as follows: */Dialog{/Page{/Parameters}}*. *Dialog* indicates the dialog box to be displayed: you can pass "4D" (for the Preferences) or "Database" (for Database Settings). For example, to indicate the Compiler page of the Database Settings, *selector* should contain "*/Database/Compiler*". The list of keys that can be used is provided below. If you just pass a slash ("/") in *selector*, the command displays the first page of the Database Settings dialog box.

The *access* parameter lets you control user actions in the Preferences or Database Settings dialog box by locking the other pages. Typically, you may want for the user to be able to customize certain parameters while preventing others from being modified. In this case, passing True in the *access* parameter means that only the page specified by the *selector* parameter will be active and modifiable, while access to all other pages will be locked (clicking on the buttons in the navigation bar will have no effect). If you pass False or omit the *access* parameter, all the pages of the dialog box will be accessible with no restriction.

The *settingsType* parameter is taken into account in databases configured in "User settings" mode only (in this mode, custom "User settings" or "User settings for data file" are generated in an external file and used instead of the standard settings, see the **User settings** section in the *Design Reference* manual). In this context, this parameter lets you indicate whether you want to access the "Structure settings", the "User settings", or the "User settings for data file" dialog box. You pass one of the following constants, found in the "**4D Environment**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Structure settings | Longint | 0 | Access to "Structure settings" (default value if parameter omitted). In this mode, values used for *selector* are identical to those in standard mode. |
| User settings | Longint | 1 | Access to "User settings". In this mode, only certain keys can be used in the *selector* parameter |
| User settings for data | Longint | 2 | Access to "User settings for data file", that is, user settings stored at the same level as the data file. In this mode, only certain keys can be used with the *selector* parameter (same subset as the User settings) |

If you pass an invalid key, the first page of the Database Settings dialog box is displayed.

### Path keys (standard mode)

Here are the keys that can be used in the *selector* parameter in standard mode, in other words with the "Structure settings":

*/4D*
*/4D/General*
*/4D/Structure*
*/4D/Form editor*
*/4D/Method editor*
*/4D/Client-Server*
*/4D/Shortcuts*
*/Database*
*/Database/General*
*/Database/Mover*
*/Database/Interface*
*/Database/Interface/Developper*
*/Database/Interface/User*
*/Database/Interface/Shortcuts*

*/Database/Compiler*
*/Database/Database*
*/Database/Database/Data storage*
*/Database/Database/Memory and cpu*
*/Database/Database/International*
*/Database/Backup*
*/Database/Backup/Scheduler*
*/Database/Backup/Configuration*
*/Database/Backup/Backup and restore*
*/Database/Client-Server*
*/Database/Client-Server/Network*
*/Database/Client-Server/IP configuration*
*/Database/Web*
*/Database/Web/Config*
*/Database/Web/Options 1*
*/Database/Web/Options 2*
*/Database/Web/Log format*
*/Database/Web/Log scheduler*
*/Database/Web/Webservices*
*/Database/SQL*
*/Database/php*
*/Database/Compatibility*
*/Database/Security*

**Compatibility note:** You can still use keys defined for 4D versions 11.x or previous using this command; 4D automatically establishes the correspondence. However, we recommend that you replace the former calls with the keys listed above.

### Path keys (User settings mode)

Here are the keys that can be used in the *selector* parameter in "User settings" mode:

*/Database*
*/Database/Interface*
*/Database/Database/Memory and cpu*
*/Database/Client-Server*
*/Database/Client-Server/Network*
*/Database/Client-Server/IP configuration*
*/Database/Web*
*/Database/Web/Config*
*/Database/Web/Options 1*
*/Database/Web/Options 2*
*/Database/Web/Log format*
*/Database/Web/Log scheduler*
*/Database/Web/Webservices*
*/Database/SQL*
*/Database/php*

## Example 1

Open the “Methods” page of the 4D Preferences:

```
OPEN SETTINGS WINDOW("/4D/Method editor")
```

## Example 2

Open the “Shortcuts” parameters in the Database Settings while locking the other settings:

```
OPEN SETTINGS WINDOW("/Database/Interface/Shortcuts";True)
```

## Example 3

Open Database Settings on the first page:

```
OPEN SETTINGS WINDOW("/")
```

## Example 4

Access to the Interface page of the Database settings in "User settings" mode:

```
OPEN SETTINGS WINDOW("/Database/Interface";1)
```

## System variables and sets

If the Preferences/Settings dialog box is validated, the system variable OK returns 1. Otherwise, it returns 0.

# PLUGIN LIST

PLUGIN LIST ( numbersArray ; namesArray )

| Parameter | Type | | Description |
|---|---|---|---|
| numbersArray | Longint array | ⇦ | Numbers of plug-ins |
| namesArray | String array | ⇦ | Names of plug-ins |

## Description

The **PLUGIN LIST** command fills in the *numbersArray* and *namesArray* arrays with the numbers and names of the plug-ins loaded and usable by the 4D application. These two arrays are automatically sized and synchronized by the command.

**Note:** You can compare the values returned in *numbersArray* with the constants of the **Is License Available** theme.

**PLUGIN LIST** takes all plug-ins into account, including those that are integrated (for example, 4D Chart), and third-party plug-ins.

# QUIT 4D

QUIT 4D {( time )}

| Parameter | Type | | Description |
|---|---|---|---|
| time | Longint | ⇨ | Time (sec) before quitting the server |

## Description

The **QUIT 4D** command exits the current 4D application and returns to the Desktop.

The command processing is different whether it is executed on 4D (local or remote mode) or on 4D Server.

### With 4D local mode and remote mode

After you call **QUIT 4D**, the current process stops its execution, then 4D acts as follows:

- If there is an **On Exit database method**, 4D starts executing this method within a newly created local process. For example, you can use this database method to inform other processes, via interprocess communication, that they must close (data entry) or stop the execution of operations started by the **On Startup database method** (connection from 4D to another database server). Note that 4D will eventually quit; the **On Exit database method** can perform all the cleanup or closing operations you wish, but cannot refuse the quit and will at some point end.
- If there is no **On Exit database method**, 4D aborts each running process one by one, without distinction.

If the user is performing data entry, the records will be cancelled and not saved.

If you want to let the user save data entry modifications made in the current open windows, you can use interprocess communication to signal all the other user processes that the database is going to be exited. To do so, you can adopt two strategies:

- Perform these operations from within the current process before calling **QUIT 4D**
- Handle these operations from within the **On Exit database method**.

A third strategy is also possible. Before calling **QUIT 4D**, you check whether a window will need validation; if that is the case, you ask the user to validate or cancel these windows and then to choose Quit again. However, from a user interface standpoint, the first two strategies are preferable.

**Note:** The *time* parameter cannot be used with 4D in local or remote mode.

### With 4D Server (Stored procedure)

The **QUIT 4D** command can be executed on the server machine, in a stored procedure. In this case, it accepts the *time* optional parameter.

The *time* parameter allows setting a timeout to the 4D Server before the application actually quits, allowing client machines the time to disconnect. You must pass a value in seconds in *time*. This parameter is only taken into consideration during an execution on the server machine. With 4D in local or remote mode, it is ignored.

If you do not pass a parameter for *time*, 4D Server will wait until all client machines are disconnected before quitting.

Unlike 4D, the processing of **QUIT 4D** by 4D Server is asynchronous: the method where the command is called is not interrupted after is has been executed.

If there is an **On Server Shutdown Database Method**, it is executed after the delay set by the *time* parameter, or after all clients have disconnected, depending on your parameters.

The action of the **QUIT 4D** command used in a stored procedure is the same as the one for the Quit command of the 4D Server File menu: it causes a dialog box to appear on each client machine indicating that the server is about to quit.

## Example

The project method listed here is associated with the Quit or Exit menu item in the File menu.

```
` M_FILE_QUIT Project Method

CONFIRM("Are you sure that you want to quit?")
```

```
If(OK=1)
   QUIT 4D
End if
```

# RESTART 4D

RESTART 4D {( time {; message} )}

| Parameter | Type | | Description |
|---|---|---|---|
| time | Longint | ⇒ | Time delay (seconds) before 4D restarts |
| message | String | ⇒ | Text to display on client machines |

## Description

The **RESTART 4D** command restarts the current 4D application.

This command is mainly intended for use in the context of a merged application (client/server or single-user) and in conjunction with the **SET UPDATE FOLDER** command. In this case, the automatic update process is launched: the new version of the application designated by **SET UPDATE FOLDER** automatically replaces the current version at the time of the restart resulting from **RESTART 4D**. The pathname of the data file is saved and used automatically.

If no update information was specified using the **SET UPDATE FOLDER** command in the current session, the command simply restarts the 4D application with the current structure and data files.

You can use the *time* parameter to defer restarting the application in order to give client machines time to disconnect. You must pass a value in seconds for the *time*. If you omit this parameter, the server application waits, for a maximum of 10 minutes, for all the client applications to be disconnected. After that, all client applications are automatically disconnected.

**Note:** The *time* and *message* parameters are only taken into account with server applications (they are ignored if the command is executed in a single-user or remote application).

The optional *message* parameter displays a custom message for connected client applications.

If the command is executed correctly, the OK system variable is set to 1; otherwise, it is set to 0 and the application restarts. You can intercept any errors generated by the command using a method installed using the **ON ERR CALL** command.

# SET DATABASE LOCALIZATION

SET DATABASE LOCALIZATION ( languageCode {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| languageCode | Text | ➡ | Language selector |
| * | Operator | ➡ | Scope of command |

## Description

The **SET DATABASE LOCALIZATION** command is used to modify the current language of the database for the current session.

The current language of the database lets you specify the .lproj folder where the program will look for the localized elements of the application (text and pictures). By default, 4D automatically determines the current language according to the contents of the **Resources** folder and the system environment (see the description of the **Get database localization** command). **SET DATABASE LOCALIZATION** can be used to modify the default current language.

The command does not modify the language of forms that are already loaded, only elements displayed after the command is called will take the new configuration into account.

Pass the language to be used for the application in *languageCode*, expressed in the standard specified by RFC 3066, ISO639 and ISO3166. Typically, you must pass "fr" for French, "es" for Spanish, "en-us" for American English, and so on. For more information about this standard, please refer to **MissingRef** in the *Design Reference* manual.

By default, the command applies to all the databases and components that are open, for all the processes. The optional * parameter, if passed, specifies that the command must only apply to the database that called it. This parameter can be used more particularly to specify separately the language of the database and that of a component.

If the command has been executed correctly, the *OK* system variable is set to 1; otherwise, it is set to 0.

**Note:** In accordance with the RFC, the command uses the "-" (dash) to separate the language code and the region code, for example "fr-ca" or "en-us". On the other hand, the "lproj" folders of the **Resources** folder use the "_" (underscore), for example "fr_ca.lproj" or "en_us.lproj".

**4D Server:** With 4D Server, the languages available are those located on the remote machine that called the command. You must therefore make sure that the **Resources** folders are synchronized.

## Example 1

We want to set French as the interface language:

```
SET DATABASE LOCALIZATION("fr")
```

## Example 2

The interface of your application uses the static string ":xliff:shopping". The XLIFF files contain more particularly the following information:

- FR folder:

```
<trans-unit id="15" resname="Shopping"> <source>Shopping</source> <target>Faire les courses</target> </trans-unit>
```

- FR_CA folder:

```
<trans-unit id="15" resname="Shopping"> <source>Shopping</source> <target>Magasiner</target> </trans-unit>
```

```
SET DATABASE LOCALIZATION("fr")
 //the string ":xliff:shopping" displays "Faire les courses"
```

```
SET DATABASE LOCALIZATION("fr-ca")
 //the string ":xliff:shopping" displays "Magasiner"
```

# SET DATABASE PARAMETER

SET DATABASE PARAMETER ( {aTable ;} selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to set the parameter or, Default table if this parameter is omitted |
| selector | Longint | ⇒ | Code of the database parameter to modify |
| value | Real, String | ⇒ | Value of the parameter |

## Description

The **SET DATABASE PARAMETER** command allows you to modify various internal parameters of the 4D database.

The *selector* designates the database parameter to modify. 4D offers predefined constants, which are located in the "**Database Parameters**" theme. The following table lists each constant, describes its scope and indicates whether any changes made are kept between two sessions:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Direct2D disabled | Longint | 0 | See selector 69 (Direct2D Status) |
| Direct2D hardware | Longint | 1 | See selector 69 (Direct2D Status) |
| Direct2D software | Longint | 3 | See selector 69 (Direct2D Status) |
| Minimum Web process | Longint | 6 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Minimum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 0 (see below). |
| Maximum Web process | Longint | 7 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Maximum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 10.<br>In non-contextual mode, for the Web server to be reactive, 4D delays the Web processes for 5 seconds and reuses them to execute any possible future HTTP queries. In terms of performance, this is actually more advantageous than creating a new process for each query. Once a Web process is reused, it is delayed again for 5 seconds. When the maximum number of Web processes has been reached, the web process is then aborted. If no query has been attributed to a Web process within the 5 second delay, the process is aborted, except if the minimum number of Web processes has been reached (in which case the process is delayed again).<br>These parameters allow you to adjust how your Web server operates in relation to the number of requests and the memory available as well as other parameters. |
| _o_Web conversion mode | Longint | 8 | **** *Selector disabled* **** |
| _o_Database cache size | Longint | 9 | **Scope**: 4D application<br>**Kept between two sessions**: -<br>**Description**: *Constant obsolete (kept for compatibility reasons only)*. We now recommend using the **Get cache size** command. |
| 4D Local mode scheduler | Longint | 10 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |
| 4D Server scheduler | Longint | 11 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Remote mode scheduler | Longint | 12 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: for selectors 10, 11 and 12, the *value* parameter is expressed in hexadecimal *0x00aabbcc* as follows:<br>*aa* = minimum number of ticks per call to the system (0 to 100 included).<br>*bb* = maximum number of ticks per call to the system (0 to 100 included).<br>*cc* = number of ticks between calls to the system (0 to 20 included).<br>If one of the values is out of range, 4D sets it to its maximum. You can pass one of the following preset standard values in the *value* parameter:<br>• *value* = -1: maximum priority allocated to 4D,<br>• *value* = -2: average priority allocated to 4D,<br>• *value* = -3: minimum priority allocated to 4D.<br>**Description**: This parameter allows you to dynamically set the 4D system internal calls. Depending on the Selector, the scheduler value will be set for:<br>• 4D local mode when the command is called from a 4D single-user application (*selector=10*).<br>• 4D Server when the command is called from 4D Server (*selector=11*).<br>• 4D remote mode when the command is called from a 4D connected to 4D Server (*selector=12*).<br>**Note:** The operation of selector 12 (4D Remote Mode Scheduler) differs according to whether the **SET DATABASE PARAMETER** command is executed on the server machine or on the client machine:<br>- If the command is executed on the server machine, the new value will be applied to all the client machines that connect to it subsequently.<br>- If the command is executed on the client machine, the new value is applied to the client machine immediately as well as to all the client machines that connect to the server subsequently.<br>You can use this operation to implement a dynamic and individualized management of priority for each client machine. This consists in executing the command initially on the client machine to be configured, then a second time on the server machine using the default value, which will then be used for the client machines that connect to it subsequently.<br>This operation is in effect in 4D starting with versions 6.8.6, 2003.3 and 2004.<br>**Warning**: Configuring these selectors inappropriately can cause serious degradation of application performance. It is recommended to only modify the default values with full knowledge of the facts. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Server timeout | Longint | 13 | **Scope**: 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Possible values**: 0 -> 32 767<br>**Description**: Value of the 4D Server timeout. The default 4D Server timeout value is defined on the "Client-Server/Network options" page of the Database settings dialog box on the server side.<br>The server timeout sets the maximum period "authorized" to wait for a client response, for example when it is executing a blocking operation. After this period, 4D Server disconnects the client. The 4D Server Timeout selector allows you to set, in the corresponding *value* parameter, a new timeout expressed in minutes. This feature is particularly useful to increase the timeout before executing a blocking and time-consuming operation on the client, such as printing a large number of pages, which can cause an unexpected timeout.<br>You also have two options:<br>• If you pass a **positive** value in the *value* parameter, you set a global and permanent timeout: the new value is applied to all process and is stored in the preferences of the 4D application (equivalent to change in the Preferences dialog box).<br>• If you pass a **negative** value in the *value* parameter, you set a local and temporary timeout: The new value is applied to the calling process only (the other processes keep the default values) and is reset to default as soon as the server receives any signal of activity from the client — for example, when the operation is finished. This option is useful for managing long operations initiated by 4D plug-ins.<br>To set the "No timeout" option, pass 0 in *value*. See example 1. |
| 4D Remote mode timeout | Longint | 14 | **Scope** (legacy network layer only): 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Description**: To be used in very specific cases. Value of the timeout granted by the remote 4D machine to the 4D Server machine. The default timeout value used by 4D in remote mode is set on the "Client-Server/Network options" page of the Database settings dialog box on the remote machine.<br>The 4D Remote mode timeout selector is only taken into account if you are using the legacy network. It is ignored when the *ServerNet* layer is activated: this setting is entirely managed by the 4D Server timeout (13) selector. |
| Port ID | Longint | 15 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Description**: TCP port ID used by the 4D Web server with 4D in local mode and 4D Server. The default value, which can be set on the "Web/Configuration" page of the Preferences dialog box, is 80. You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>The Port ID selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode). For more information about the TCP port ID, refer to the **Web Server Settings** section. |
| IP Address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Max concurrent Web processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Client minimum Web process | Longint | 19 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 6<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client maximum Web process | Longint | 20 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 7<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client Max Web requests size | Longint | 21 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 27<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client port ID | Longint | 22 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 15<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client IP address to listen | Longint | 23 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 16<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client character set | Longint | 24 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 17<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client max concurrent Web proc | Longint | 25 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 18<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Maximum Web requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Server log recording | Longint | 28 | **Scope**: 4D Server, 4D remote<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, added to the file name).<br>**Description**: Starts or stops the recording of standard requests received by 4D Server (excluding Web requests). By default, the value is 0 (requests not recorded).<br>4D Server lets you record each request received by the server machine in a log file. When this mechanism is enabled, two files are created in the Logs folder of the database, next to the database structure file.They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file of the same name already exists, it is replaced directly. You can set the starting number of the sequence using the *value* parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes. It can be imported, for example, into a spreadsheet software in order to be processed. |
| _o_Web Log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Client Web log recording | Longint | 30 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br>**Description**: Starts or stops the recording of Web requests received by the Web servers of all the client machines. By default, the value is 0 (requests not recorded).<br>The operation of this selector is identical to that of selector 29; however, it applies to all the 4D remote machines used as Web servers. The "logweb.txt" file is, in this case, automatically placed in the Logs subfolder of the remote 4D database folder (cache folder). If you only want to set values for certain client machines, use the Preferences dialog box of 4D in remote mode. |
| Table sequence number | Longint | 31 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: Any longint value.<br>**Description**: This selector is used to modify or get the current unique number for records of the table passed as parameter. "Current number" means "last number used": if you modify this value using **SET DATABASE PARAMETER**, the next record will be created with a number that consists of the value passed + 1. This new number is the one returned by the **Sequence number** command as well in any field of the table to which the "Autoincrement" property has been assigned in the Structure editor or via SQL.<br>By default, this unique number is set by 4D and corresponds to the order of record creation. For additional information, refer to the documentation of the **Sequence number** command. |
| _o_Real display precision | Longint | 32 | **** *Selector disabled* **** |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Debug log recording | Longint | 34 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Starts or stops the sequential recording of events occurring at the 4D programming level in the *4DDebugLog* file, which is automatically placed in the Logs subfolder of the database, next to the structure file. A new, more compact, tabbed text format is used in the event log file "4DDebugLog[_n].txt" starting with 4D v14 (where _n is the segment number of the file).<br>**Possible values**: Longint containing a bit field: value = bit1(1)+bit2(2)+bit3(4)+bit4(8)+⋯).<br>- Bit 1 (value 1) requests to enable the file (note that any other non-null value also enables it as well)<br>- Bit 2 (value 2) requests call parameters to methods and commands.<br>- Bit 3 (value 4) enables new tabbed format.<br>- Bit 4 (value 8) disables immediate writing of each operation on disk (enabled by default). Immediate writing is slower but more effective, for example for investigating causes of a crash. If you disable this mode, the file contents are more compact and are generated more quickly.<br>- Bit 5 (value 16) disables recording of plug-in calls (enabled by default).<br>In the (former) non-tabbed format, execution times are expressed in milliseconds and the "< ms" value is displayed when an operation lasts less than one millisecond.<br>In the new tabbed format, execution times are expressed in microseconds.<br>Examples:<br>SET DATABASE PARAMETER (34;1) // enables mode v13 file without parameters, with runtimes<br>SET DATABASE PARAMETER (34;2) // enables mode v13 file with parameters and runtimes<br>SET DATABASE PARAMETER (34;2+4) // enables file with v14 format, with parameters and runtimes<br>SET DATABASE PARAMETER (34;0) // disables file<br>To avoid having a file record too much information, you can restrict the 4D commands that are examined by using selector 80, Log Command list.<br>This option can be enabled for any type of 4D application (4D all modes, 4D Server, 4D Volume Desktop), in interpreted or compiled mode.<br>**Note:** This option is provided solely for the purpose of debugging and must not be put into production since it may lead to deterioration of the application performance and saturation of the hard disk. For more information about this format and on the use of the 4DDebugLog[_n].txt file, please contact the Technical Support of 4D Inc. |
| Client Server port ID | Longint | 35 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number where the 4D Server publishes the database (bound for 4D remote machines). By default, the value is 19813.<br>Customizing this value means that several 4D client-server applications can be used on the same machine with the TCP protocol; in this case, you must indicate a different port number for each application.<br>The value is stored in the database structure file. It can be set with 4D in local mode but is only taken into account in client-server configuration.<br>When you modify this value, it is necessary to restart the server machine in order for the new value to be taken into account. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Invert objects | Longint | 37 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0, 1 or 2 (0 = mode disabled, 1 = automatic mode, 2 = mode enabled).<br>**Description**: Configuration of the "object inversion" mode which is used to invert forms, objects, menu bars, and so on, in Application mode when the database is displayed under Windows in a right-to-left language. This mode can also be configured on the Interface/Right-to-left languages page of the Database Settings.<br>• Value 0 indicates that the mode is never enabled, regardless of the system configuration (corresponds to the Never value in the Database Settings).<br>• Value 1 indicates that the mode is enabled or disabled depending on the system configuration (corresponds to the Automatic value in the Database Settings).<br>• Value 2 indicates that the mode is enabled, regardless of the system configuration (corresponds to the Always value in the Database Settings).<br>For more information, refer to the *Design Reference* manual of 4D. |
| HTTPS Port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Client HTTPS port ID | Longint | 40 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector can be used to modify by programming the TCP port used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector operates exactly the same way as selector 39; however, it applies to all the 4D remote machines used as Web servers. If you only want to modify the value of certain specific client machines, use the Preferences dialog box of the remote 4D. |
| Unicode mode | Longint | 41 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (compatibility mode) or 1 (Unicode mode)<br>**Description**: Current database operating mode, with regards to the character set. 4D supports the Unicode character set but can function in “compatibility” mode (based on the Mac ASCII character set). By default, converted databases are executed in compatibility mode (0) and databases created with version 11 or higher are executed in Unicode mode. The execution mode can be controlled via an option in the Preferences and can also be read or (for testing purposes) modified via this selector. Modifying this option requires the database to be restarted in order for it to be taken into account. Note that within a component it is not possible to modify this value, but only to read it. |
| SQL Autocommit | Longint | 43 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (deactivation) or 1 (activation)<br>**Description**: Activation or deactivation of the SQL auto-commit mode. By default, the value is 0 (deactivated mode)<br>The auto-commit mode is used to strengthen the referential integrity of the database. When this mode is active, all **SELECT**, **INSERT**, **UPDATE** and **DELETE** (SIUD) queries are automatically included in ad hoc transactions when they are not already executed within a transaction. This mode can also be set in the Preferences of the database. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| SQL Engine case sensitivity | Longint | 44 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (case not taken into account) or 1 (case-sensitive)<br>**Description**: Activation or deactivation of case-sensitivity for string comparisons carried out by the SQL engine.<br>By default, the value is 1 (case-sensitive): the SQL engine differentiates between upper and lower case and between accented characters when comparing strings (sorts and queries). For example “ABC”= “ABC” but “ABC” # “Abc” and "abc" # "âbc." In certain cases, for example so as to align the functioning of the SQL engine with that of the 4D engine, you may wish for string comparisons to not be case-sensitive (“ABC”=“Abc"="âbc").<br>This option can also be set on the **SQL page** of the Database settings. |
| Client log recording | Longint | 45 | **Scope**: Remote 4D machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, attached to file name).<br>**Description**: Starts or stops recording of standard requests carried out by the 4D client machine that executed the command (excluding Web requests). By default, the value is 0 (no recording of requests).<br>4D lets you record the log of requests carried out by the client machine. When this mechanism is activated, two files are created on the client machine, in the Logs subfolder of the local folder of the database. They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file with the same name already exists, it is directly replaced. You can set the starting number for the sequence using the value parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Query by formula on server | Longint | 46 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description**: Execution location of **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands for the *table* passed in the parameter.<br>When using a database in client-server mode, the query "by formula" commands can be executed either on the server or on the client machine:<br>• In databases created with 4D v11 SQL, these commands are executed on the server.<br>• In converted databases, these commands are executed on the client machine, as in previous versions of 4D.<br>• In converted databases, a specific preference (Application/Compatibility page) can be used to globally modify the execution location of these commands.<br>This difference in execution location influences not only application performance (execution on the server is usually faster) but also programming. In fact, the value of the components of the formula (in particular variables called via a method) differ according to the execution context. You can use this selector to punctually adapt the operation of your application.<br>If you pass 0 in the *value* l'parameter, the execution location of query "by formula" commands will depend on the database configuration: in databases created with 4D v11 SQL, these commands will be executed on the server. In converted databases, they will be executed on the client machine or the server according to the database preferences. Pass 1 or 2 in *value* to "force" the execution of these commands, respectively, on the client or on the server machine.<br>Refer to example 4.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |
| Order by formula on server | Longint | 47 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description** : Execution location of **ORDER BY FORMULA** command for the table passed in the parameter.<br>When using a database in client-server mode, this command can be executed either on the server or on the client machine. This selector can be used to specify the execution location of this command (server or client). This mode can also be set in the database preferences. For more information, please refer to the description of selector 46, Query By Formula On Server.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Auto synchro resources folder | Longint | 48 | **Scope**: 4D remote machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 (no synchronization), 1 (auto synchronization) or 2 (ask).<br>**Description**: Dynamic synchronization mode for *Resources* folder of 4D client machine that executed the command with that of the server.<br>When the contents of the *Resources* folder on the server has been modified or a user has requested synchronization (for example via the resources explorer or following the execution of the **SET DATABASE LOCALIZATION** command), the server notifies the connected client machines.<br>Three synchronization modes are then possible on the client side. The Auto Synchro Resources Folder selector is used to specify the mode to be used by the client machine for the current session:<br>• 0 (default value): no dynamic synchronization (synchronization request is ignored)<br>• 1: automatic dynamic synchronization<br>• 2: display of a dialog box on the client machines, with the possibility of allowing or refusing synchronization.<br>The synchronization mode can also be set globally in the application Preferences. |
| Query by formula joins | Longint | 49 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (always use automatic relations) or 2 (use SQL joins if possible).<br>**Description**: Operating mode of the **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands relating to the use of "SQL joins."<br>In databases created starting with version 11.2 of 4D v11 SQL, these commands carry out joins based on the SQL joins model. This mechanism can be used to modify the selection of a table according to a query carried out on another table without these tables being connected by an automatic relation (necessary condition in previous versions of 4D).<br>The QUERY BY FORMULA Joins selector lets you specify the operating mode of the query by formula commands for the current process:<br>• 0: Uses the current settings of the database (default value). In databases created starting with version 11.2 of 4D v11 SQL, "SQL joins" are always activated for queries by formula. In converted databases, this mechanism is not activated by default for compatibility reasons but can be implemented via a preference.<br>• 1: Always use automatic relations (= functioning of previous versions of 4D). In this mode, a relation is necessary in order to set the selection of a table according to queries carried out on another table. 4D does not do "SQL joins."<br>• 2: Use SQL joins if possible (= default operation of databases created in version 11.2 and higher of 4D v11 SQL ). In this mode, 4D establishes "SQL joins" for queries by formula when the formula is suited for it (with two notable exceptions, see the description of the **QUERY BY FORMULA** or **QUERY SELECTION BY FORMULA** command).<br>**Note:** With 4D in remote mode, "SQL joins" can only be used if the formulas are executed on the server (they must have access to the records). To configure where formulas are to be executed, please refer to selectors 46 and 47. |
| HTTP compression level | Longint | 50 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| HTTP compression threshold | Longint | 51 | **Scope**:4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Server base process stack size | Longint | 53 | **Scope**: 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Size of the stack allocated to each preemptive system process on the server, expressed in bytes. The default size is determined by the system.<br>Preemptive system processes (processes of the 4D client base process type) are loaded to control the main 4D client processes. The size allocated by default to the stack of each preemptive process allows a good ease of execution but may prove to be consequential when very large numbers of processes (several hundred) are created. For optimization purposes, this size can be reduced considerably if the operations carried out by the database allow for it (for example if the database does not carry out sorts of large quantities of records). Values of 512 or even 256 KB are possible. Be careful, under-sizing the stack is critical and can be harmful to the operation of 4D Server. Setting this parameter should be done with caution and must take the database conditions of use into account (number of records, type of operations, etc.).<br>In order to be taken into account, this parameter must be executed on the server machine (for example in the **On Server Startup Database Method**). |
| Idle connections timeout | Longint | 54 | **Scope**:4D application unless value is negative<br>**Kept between two sessions**: No<br>**Possible values**: Whole value expressing a duration in seconds. The value can be positive (new connections) or negative (existing connections). By default, the value is 20.<br>**Description**: Maximum period of inactivity (timeout) for connections to both the 4D database engine and the SQL engine, as well as, in *ServerNet* mode (new network layer), to the 4D application server. When an idle connection reaches this limit, it is automatically put on standby, which freezes the client/server session and closes the network socket. In the server administration window, the state of the user process is indicated as "Postponed". This functioning is completely transparent for the user: as soon as there is new activity on the connection which is on standby, the socket is automatically reopened and the client/server session is restored.<br>On the one hand, this setting lets you save resources on the server: connections on standby close the socket and free up a process on the server. On the other hand, it lets you avoid losing connections due to the closing of idle sockets by the firewall. For this, the timeout value for idle connections must be lower than that of the firewall in this case.<br>If you pass a positive value in *value*, it applies to all new connections in all the processes. If you pass a negative value, it applies to connections that are open in the current process. If you pass 0, idle connections are not subjected to a timeout.<br>This parameter can be set on both the server and client side. If you pass two different durations, the shorter one is taken into account. Usually, you do not need to change this value. |
| PHP interpreter IP address | Longint | 55 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Formatted string of the type "nnn.nnn.nnn.nnn" (for example "127.0.0.1").<br>**Description**: IP address used locally by 4D to communicate with the PHP interpreter via FastCGI. By default, the value is "127.0.0.1". This address must correspond to the machine where 4D is located. This parameter can also be set globally for all the machines via the Database Settings.<br>For more information about the PHP interpreter, please refer to the *Design Reference* manual. |
| PHP interpreter port | Longint | 56 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 8002.<br>**Description**: Number of the TCP port used by the PHP interpreter of 4D. This parameter can also be modified globally for all the machines via the Database Settings.<br>For more information about the PHP interpreter, please refer to the *Design Reference* manual. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| PHP number of children | Longint | 57 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 5.<br>**Description**: Number of child processes to be created and maintained locally by the PHP interpreter of 4D. For optimization reasons, the PHP interpreter creates and uses a set (pool) of system processes called "child processes" for processing script execution requests. You can vary the number of child processes according to the needs of your application. This parameter can also be modified globally for all the machines via the Database Settings. For more information about the PHP interpreter, please refer to the *Design Reference* manual.<br>**Note:** Under Mac OS, all the child processes share the same port. Under Windows, each child process uses a specific port number. The first number is the one set for the PHP interpreter; the other child processes increment the first one. For example, if the default port is 8002 and you launch 5 child processes, they will use ports 8002 to 8006. |
| PHP max requests | Longint | 58 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 500.<br>**Description**: Maximum number of requests accepted by the PHP interpreter. When this maximum number is reached, the interpreter returns errors of the "server busy" type. For security or performance reasons, you can modify this value. This parameter can also be modified globally for all the machines via the Database Settings. For more information about this parameter, please refer to the FastCGI-PHP documentation.<br>**Note:** On the 4D side, these parameters are applied dynamically; it is not necessary to exit 4D in order for them to be taken into account. On the other hand, if the PHP interpreter is already launched, it will be necessary to exit and relaunch it in order for these modifications to be taken into account. |
| PHP use external interpreter | Longint | 60 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values** : 0 = use internal interpreter, 1 = use external interpreter<br>**Description**: Value indicating whether PHP requests in 4D are sent to the internal interpreter provided by 4D or to an external interpreter. By default the value is 0 (use of interpreter provided by 4D). If you want to use your own PHP interpreter, for example in order to use additional modules or a specific configuration, pass 1 in *value*. In this case, 4D does not launch its internal interpreter in the case of PHP requests.<br>The custom PHP interpreter must have been compiled in FastCGI and be located on the same machine as the 4D engine. Note that in this case, you must manage the interpreter entirely; it will not be started nor stopped by 4D. This parameter can also be modified globally for all the machines via the Database Settings. |
| Maximum temporary memory size | Longint | 61 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Maximum size of temporary memory that 4D can allocate to each process, expressed in MB. By default, the value is 0 (no maximum size). 4D uses a special temporary memory dedicated to indexing and sorting operations. This memory is intended to preserve the "standard" cache memory during massive operations. It is activated only when needed. By default, the size of the temporary memory is limited only by the resources available (according to the system memory configuration).<br>This mechanism is suitable for most applications. However, in certain specific contexts, more particularly when a client-server application simultaneously carries out a large number of sequential sorts, the size of the temporary memory can increase critically, to the point where it can render the system unstable. In this context, setting a maximum size for the temporary memory allows you to preserve proper functioning of the application. In return, the running speed might be affected: when the maximum size is reached for a process, 4D uses disk files which may slow down processing. For specific needs such as those described above, a maximum size of around 50 MB is generally a good compromise. However, the ideal value will need to be determined according to the specificities of the application and will generally be the result of real-time volumetric testing. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| SSL cipher list | String | 64 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Sequence of strings separated by colons (for example "RC4-MD5:RC4-64-MD5:....")<br>**Description:** Cipher list used by 4D for the secure protocol. This list modifies the priority of ciphering algorithms implemented by 4D. For example, you can pass the following string in the *value* parameter: "AES:ALL:!aNULL:!eNULL:+RC4:@STRENGTH". For a complete description of the syntax for the ciphers list, refer to the ciphers page of the OpenSSL site.<br>This setting applies to the entire 4D application (it concerns the HTTP server, SQL server, client/server connections, as well as the HTTP client and all the 4D commands that make use of the secure protocol) but it is temporary (it is not maintained between sessions).<br>When the cipher list has been modified, you will need to restart the server concerned in order for the new settings to be taken into account.<br>To reset the cipher list to its default value (stored permanently in the SLI file), call the **SET DATABASE PARAMETER** command and pass an empty string ("") in the *value* parameter.<br>**Note:** With the **Get database parameter** command, the cipher list is returned in the optional *stringValue* parameter and the return parameter is always 0. |
| Cache unload minimum size | Longint | 66 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint > 1.<br>**Description**: Minimum size of memory to release from the database cache when the engine needs to make space in order to allocate an object to it (value in bytes).<br>The purpose of this selector is to reduce the number of times that data is released from the cache in order to obtain better performance. You can vary this setting according to the size of the cache and that of the blocks of data being handled in your database.<br>By default, if this selector is not used, 4D unloads at least 10% of the cache when space is needed. |
| Direct2D status | Longint | 69 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Activation mode to implement Direct2D under Windows.<br>**Possible values**: One of the following constants (mode 3 by default):<br>Direct2D Disabled (0): Direct2D mode is not enabled and the database functions in the previous mode (GDI/GDIPlus).<br>Direct2D Hardware (1): Use Direct2D as graphics hardware context for entire 4D application. If this context is not available, use Direct2D graphics software context (except under Vista, in which case GDI/GDIPlus mode is used for better performance).<br>Direct2D Software (3) (Default mode): Beginning with Windows 7, use Direct2D graphics software context for entire 4D application. Under Vista, GDI/GDIPlus mode is used for better performance.<br>**Compatibility note:** Starting with 4D v14, hybrid modes are disabled and redirected to available modes (the former mode 2 is equivalent to 1; former modes 4 and 5 are equivalent to mode 3). |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Direct2D get active status | Longint | 74 | **Note**: You can only use this selector with the **Get database parameter** command and its value cannot be set.<br>**Description**: Returns active implementation of Direct2D under Windows.<br>**Possible values**: 0, 1, 2, 3, 4 or 5 (see values of selector 69). The value returned depends on the availability of Direct2D, the hardware and the quality of Direct2D support by the operating system.<br>For example, if you execute:<br>`SET DATABASE PARAMETER(Direct2D status;Direct2D Hardware)`<br>`$mode:=Get database parameter(Direct2D get active status)`<br><br>- On Windows 7 and higher, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 3 (software context).<br>- On Windows Vista, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 0 (disabling of Direct2D).<br>- On Windows XP, *$mode* is always set to 0 (not compatible with Direct2D). |
| Diagnostic log recording | Longint | 79 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 or 1 (0 = do not record, 1 = record)<br>**Description**: Starts or stops recording of the 4D diagnostic file. By default, the value is 0 (do not record).<br>4D can continuously record a set of events related to the internal application operation into a diagnostic file. Information contained in this file is intended for the development of 4D applications and can be analyzed with the help of the 4D tech support. When you pass 1 in this selector, a diagnostic file, named *DatabaseName_X*.txt, is automatically created (or opened) in the database **Logs** folder. Once this file reaches a size of 10 MB, it is closed and a new file named *DatabaseName_X*.txt is generated, with an incremented sequence number X.<br>Note that you can include custom information in this file using the **LOG EVENT** command. |
| Log command list | String | 80 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: String containing a list of 4D command numbers to record (separated by semi-colons) or "all" to record all the commands or "" (empty string) to record none of them.<br>**Description**: List of 4D commands to record in the debugging file (see selector 34, Debug Log Recording). By default, all 4D commands are recorded.<br>This selector restricts the quantity of information saved in the debugging file by limiting the 4D commands whose execution you want to record. For example, you can write:<br>`SET DATABASE PARAMETER(Log command list;"277;341") //Record only the QUERY and QUERY SELECTION commands` |
| Spellchecker | Longint | 81 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 (default) = native OS X spellchecker (Hunspell disabled), 1 = Hunspell spellcheck enabled.<br>**Description**: Enables the Hunspell spellcheck under OS X. By default, the native spellchecker is enabled on this platform. You may prefer to use the Hunspell spellcheck, for example, in order to unify the interface for your cross-platform applications (under Windows, only the Hunspell spellcheck is available). For more information, refer to **Support of Hunspell dictionaries**. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| QuickTime support | Longint | 82 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (default) = QuickTime disabled, 1 = QuickTime enabled.<br>**Description**: In 4D starting with v14, by default QuickTime codecs are no longer supported. For compatibility, you can use this selector to re-enable them in your database. Modification of this option requires that the database be restarted. Nevertheless, you should note that in future versions of 4D, QuickTime support is permanently removed. |
| JSON use local time | Longint | 85 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 = ignore local time zone, 1 (default) = take time zone into account.<br>**Description**: By default, 4D dates converted to JSON format take the local time zone into account. For example, converting the date !23/08/2013! gives you "2013-08-22T22:00:00Z" in JSON format when the operation is performed in France during Daylight Savings Time (GMT+2). This principle conforms to the standard operation of JavaScript.<br>This can be a source of errors when you want to send JSON date values to someone in a different time zone. This is the case, for example, when you export a table using **Selection to JSON** in France that is meant to be reimported in the US using **JSON TO SELECTION**. By default, since dates are re-interpreted in each time zone, the values stored in the database will be different. In this case, you can modify the conversion mode for dates so that they do not take the time zone into account by passing 0 in this selector. Converting the date !23/08/2013! will then give you "2013-08-23T00:00:00Z" in all cases. |
| Use legacy network layer | Longint | 87 | **Scope**: 4D in local mode, 4D Server<br>**Kept between two sessions**: Yes<br>**Description:** Sets or gets the current status of the legacy network layer for client/server connections. The legacy network layer is obsolete beginning with 4D v14 R5 and should be replaced progressively in your applications with the *ServerNet* network layer. *ServerNet* will be required in upcoming 4D releases in order to benefit from future network evolutions. For compatibility reasons, the legacy network layer is still supported to allow a smooth transition for existing applications; (it is used by default in applications converted from a release prior to v14 R5). Pass 1 in this parameter to use the legacy network layer (and disable *ServerNet*) for your client/server connections, and pass 0 to disable the legacy network (and use the *ServerNet*).<br>This property can also be set by means of the "Use legacy network layer" option found on the **Compatibility page** of the Database Settings (see **Network and Client-Server options**). In this section, you will also find a discussion about migration strategy. We recommend that you activate the *ServerNet* as soon as possible.<br>You will need to restart the application in order for this parameter to be taken into account. It is not available in 4D Server v14 R5 64-bit version for OS X, which only supports the *ServetNet*; (it always returns 0).<br>**Possible values:** 0 or 1 (0 = do not use legacy layer, 1 = use legacy layer)<br>**Default value:** 0 in databases created with 4D v14 R5 or higher, 1 in databases converted from 4D v14 R4 or earlier. |
| SQL Server Port ID | Longint | 88 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: Yes<br>**Description**: Gets or sets the TCP port number used by the integrated SQL server of 4D in local mode or 4D Server. By default, the value is 19812. When this selector is set, the database setting is updated. You can also set the TCP port number on the "SQL" page of the Database Settings dialog box.<br>**Possible values**: 0 to 65535.<br>**Default value**: 19812 |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Circular log limitation | Longint | 90 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: No<br>**Possible values**: Any integer value, 0 = keep all logs<br>**Description**: Maximum number of files to keep in rotation for each type of log. By default, all files are kept. If you pass a value *X*, only the *X* most recent files are kept, with the oldest being erased automatically when a new one is created. This setting applies to each of the following log files: request logs (selectors 28 and 45), debug log (selector 34), events log (selector 79), as well as Web request logs and Web debug logs (selectors 29 and 84 of the **WEB SET OPTION** command). |
| Number of formulas in cache | Longint | 92 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longints<br>**Default value**: 0 (no cache)<br>**Description**: Sets or gets the maximum number of formulas to be kept in the cache of formulas, which is used by the **EXECUTE FORMULA** command. This limit is applied to all processes, but each process has its own formula cache. Caching formulas accelerates the **EXECUTE FORMULA** command execution in compiled mode since each cached formula is tokenized only once in this case. When you change the cache value, existing contents are reset even if the new size is larger than the previous one. Once the maximum number of formulas in the cache is reached, a new executed formula will erase the oldest one in the cache (FIFO mode). This parameter is only taken into account in compiled databases or compiled components. |
| Cache flush periodicity | Longint | 95 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: longint > 1 (seconds)<br>**Description**: Gets or sets the current cache flush periodicity, expressed in seconds. Modifying this value overrides the **Flush Cache every X Seconds** option in the **Database/Memory page** of the Database settings for the session (it is not stored in the Database settings). |

**Note**: The *table* parameter is only used by selectors 31, 32, 46 and 47. In all other cases, it is ignored if it is passed.

## Example 1

The following statement will avoid any unexpected timeout:

```
 `Increasing the timeout to 3 hours for the current process
SET DATABASE PARAMETER(4D Server Timeout;-60*3)
 `Executing a time-consuming operation with no control from 4D
...
WR PRINT MERGE(Area;3;0)
...
```

## Example 2

This example temporarily forces the execution of a query by formula command on the client machine:

```
curVal:=Get database parameter([table1];Query By Formula On Server) `Store the current setting
SET DATABASE PARAMETER([table1];Query By Formula On Server;1) `Force execution on the client machine
QUERY BY FORMULA([table1];myformula)
SET DATABASE PARAMETER([table1];Query By Formula On Server;curVal) `Re-establish current setting
```

## Example 3

You want to export data in JSON that contains a converted 4D date. Note that conversion occurs when the date is saved in the object, so you must call the **SET DATABASE PARAMETER** command before calling **OB SET**:

```
C_OBJECT($o)
SET DATABASE PARAMETER(JSON use local time;0)
```

```
OB SET($o ;"myDate";Current date) // JSON conversion
$json:=JSON Stringify($o)
SET DATABASE PARAMETER(JSON use local time;1)
```

# SET UPDATE FOLDER

SET UPDATE FOLDER ( folderPath {; silentErrors} )

| Parameter | Type | | Description |
|---|---|---|---|
| folderPath | String | ⇒ | Pathname of folder (package under OS X) containing updated application |
| silentErrors | Boolean | ⇒ | False (default) = report errors visibly, True = do not report them |

## Description

The **SET UPDATE FOLDER** command specifies the folder containing the update of the current merged 4D application. This information is stored in the 4D session until the **RESTART 4D** method is called. If the application is exited manually, this information is not kept.

This command is intended to be used in an automatic update process for a merged application (server or single-user). For more information, refer to the **Finalizing and deploying final applications** section in the *Design Reference* manual.

**Note:** This command only works with 4D Server or a single-user application merged with 4D Volume Desktop.

In the *folderPath* parameter, pass the complete pathname for the folder of the new version of the merged application (folder containing the *my4DApp.exe* application under Windows or the *my4DApp.app* package under OS X), created by the 4D application builder.

**Note:** We recommend that you use the same names for the files in the new version of the application as the ones in the original, since the application folder is replaced during the update. If you use different names for these files, any stored shortcuts and/or paths will no longer work.

If the parameters are valid, the update is placed "on hold" in the session until the **RESTART 4D** command is called. If you executed **SET UPDATE FOLDER** several times before calling **RESTART 4D**, the last valid call is taken into account.

In case of anomaly, an error is generated; the *silentErrors* parameter determines whether or not these errors are displayed (see below).

You can pass an empty string ("") in the *folderPath* parameter to reset the update information for the current session.

The optional *silentErrors* parameter specifies how errors are reported during the update:

- When you pass **False** or when this parameter is omitted, errors are recorded in the update journal and displayed in a warning dialog box.
- If you pass **True**, errors are simply recorded in the update journal.

Exception: if the journal file cannot be created, a warning dialog box is displayed, regardless of the value of the *silentErrors* parameter. For more information, refer to the description of the **Get last update log path** command.

If the command is executed correctly, the OK system variable is set to 1; otherwise, it is set to 0. You can intercept any errors generated by the command using a method installed using the **ON ERR CALL** command.

## Example

You created a "MyUpdates" folder on your disk, where you placed a new version of the "MyApp" application. You do not want to display errors. To prepare the update, you write:

```
 // Windows syntax
SET UPDATE FOLDER("C:¥¥MyUpdates"+Folder separator+"MyApp"+Folder separator;True)

 // OS X syntax
SET UPDATE FOLDER("MacHD:MyUpdates"+Folder separator+"MyApp.app"+Folder separator;True)
```

# Structure file

Structure file {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Returns structure file of host database |
| Function result | String | ⮌ | Long name of the database structure file |

## Description

The **Structure file** command returns the long name of the structure file for the database with which you are currently working.

*On Windows*
If, for example, you are working with the database MyCDs located in ¥DOCS¥MyCDs on the volume G, the command returns G:¥DOCS¥MyCDs¥MyCDs.4DB.

*On Macintosh*
If, for example, you are are working with the database located in the folder Documents:MyCDsƒ: on the disk Macintosh HD, the command returns Macintosh HD:Documents:MyCDsƒ:MyCDs.

**Note:** In the particular case of a database that has been compiled and merged with 4D Volume Desktop, this command returns the pathname of the application file (executable application) under Windows and OS X. Under OS X, this file is located inside the software package, in the [Contents:Mac OS] folder. This stems from a former mechanism and is kept for compatibility reasons. If you want to get the full name of the software package itself, it is preferable to use the **Application file** command. The technique consists of testing the application using the **Application type** command, then executing **Structure file** or **Application file** depending on the context.

**WARNING:** If you call this command when using 4D in remote mode, only the name of the structure file is returned; the long name is not returned.

The optional * parameter is useful in the case of an architecture using components: it can be used to determine the structure (host or component) for which you want to get the long name depending on the context in which the command is called:

- When the command is called from a component:
  - If the * parameter is passed, the command returns the long name of the structure file of the host database,
  - If the * parameter is not passed, the command returns the long name of the structure file of the component. The structure file of the component corresponds to the .4db or .4dc file of the component found in the “Components” folder of the database. However, a component can also be installed as an alias/shortcut or a .4dbase folder/package:
    - In the case of a component installed as an alias/shortcut, the command returns the pathname of the original .4db or .4dc file (the alias or shortcut is resolved).
    - In the case of a component installed as a .4dbase folder/package, the command returns the pathname of the .4db or .4dc file located within this folder/package.
- When the command is called from a method of the host database, it always returns the long name of the structure file of the host database, regardless of whether or not the * parameter is passed.

## Example 1

This example displays the name and the location of the structure file currently in use:

```
If(Application type#4D Remote mode)
   $vsStructureFilename:=Long name to file name(Structure file)
   $vsStructurePathname:=Long name to path name(Structure file)
   ALERT("You are currently using the database "+Char(34)+$vsStructureFilename+Char(34)+
   " located at "+Char(34)+$vsStructurePathname+Char(34)+".")
Else
   ALERT("You are connected to the database "+Char(34)+Structure file+Char(34))
End if
```

**Note:** The project methods **Long name to file name** and **Long name to path name** are listed in the section **System Documents**.

## Example 2

The following example can be used to find out whether the method is called from a component:

```
C_BOOLEAN($0)
$0:=(Structure file#Structure file(*))
  ` $0=True if method is called from a component
```

# VERIFY CURRENT DATA FILE

VERIFY CURRENT DATA FILE {( objects ; options ; method {; tablesArray {; fieldsArray}} )}

| Parameter | Type | | Description |
|---|---|---|---|
| objects | Longint | ⇒ | Objects to check |
| options | Longint | ⇒ | Checking options |
| method | Text | ⇒ | Name of 4D callback method |
| tablesArray | Longint array | ⇒ | Numbers of tables to be checked |
| fieldsArray | 2D Integer array, 2D Longint array, 2D Real array | ⇒ | Numbers of indexes to be checked |

## Description

The **VERIFY CURRENT DATA FILE** command carries out a structural check of the objects found in the data file currently opened by 4D.

This command has the same functioning as the **VERIFY DATA FILE** command, except that it only applies to the current data file of the open database. It therefore does not require parameters specifying the structure and data.

Refer to the **VERIFY DATA FILE** command for a description of the parameters.

If you pass the **VERIFY CURRENT DATA FILE** command with no parameters, the verification is carried out with the default values of the parameters:

- *objects* = Verify All (= value 16)
- *options* = 0 (log file is created but not timestamped)
- *method* = ""
- *tablesArray* and *fieldsArray* are omitted.

When this command is executed, the data cache is flushed and all operations accessing the data are blocked during the verification.

If a log file has been generated, its complete pathname is returned in the *Document* system variable.

## System variables and sets

If the callback method does not exist, the verification is not carried out, an error is generated and the system variable OK is set to 0. If a log file was generated, its complete pathname is returned in the Document system variable.

# VERIFY DATA FILE

VERIFY DATA FILE ( structurePath ; dataPath ; objects ; options ; method {; tablesArray {; fieldsArray}} )

| Parameter | Type | | Description |
|---|---|---|---|
| structurePath | Text | ➡ | Pathname of 4D structure file to be checked |
| dataPath | Text | ➡ | Pathname of 4D data file to be checked |
| objects | Longint | ➡ | Objects to be checked |
| options | Longint | ➡ | Checking options |
| method | Text | ➡ | Name of 4D callback method |
| tablesArray | Longint array | ➡ | Numbers of tables to be checked |
| fieldsArray | 2D Integer array, 2D Longint array, 2D Real array | ➡ | Numbers of indexes to be checked |

## Description

The **VERIFY DATA FILE** command carries out a structural check of the objects contained in the 4D data file designated by *structurePath* and *dataPath*.

**Note:** For more information about checking data, please refer to the Design Reference manual. *structurePath* designates the structure file (compiled or not) associated with the data file to be checked. This can be the open structure file or any other structure file. You must pass a complete pathname, expressed with the syntax of the operating system. You can also pass an empty string, in this case a standard Open file dialog box appears so that the user can specify the structure file to be used.

*dataPath* designates a 4D data file (.4DD). It must correspond to the structure file defined by the *structurePath* parameter. Be careful, you can designate the current structure file but the data file must not be the current (open) file. To verify the currently open data file, use the **VERIFY CURRENT DATA FILE** command. If you attempt to verify the current data file with the **VERIFY DATA FILE** command, an error is generated.

The data file designated is opened in read only. You must make sure that no application accesses this file in write mode, otherwise the results of the check may be distorted.

In the *dataPath* parameter, you can pass an empty string, a file name or a complete pathname, expressed in the syntax of the operating system. If you pass an empty string, the standard Open file dialog box appears so that the user can specify the file to be checked (note that in this case, it is not possible to select the current data file). If you only pass a data file name, 4D will look for it at the same level as the specified structure file.

The *objects* parameter is used to designate which types of objects will be checked. Two types of objects can be checked: records and indexes. You can use the following constants, found in the "**Data File Maintenance**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Verify all | Longint | 16 | |
| Verify indexes | Longint | 8 | This option checks the physical consistency of the indexes, without any link with the data. It signals invalid keys but does not permit you to detect duplicated keys (two indexes that point to the same record). This type of error can only be detected with the Verify All option. |
| Verify records | Longint | 4 | |

To verify both the records and the indexes, pass the total of Verify Records+Verify Indexes. The value 0 (zero) can also be used to obtain the same result. The Verify All option carries out complete internal verification. This verification is compatible with the creation of a log.

The *options* parameter is used to set verification options. The following options are available, found in the"**Data File Maintenance**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Do not create log file | Longint | 16384 | Generally, this command creates a log file in XML format (refer to the end of the command description). With this option, no log file will be created. |
| Timestamp log file name | Longint | 262144 | When this option is passed, the name of the log file generated will contain the date and time of its creation; as a result, it will not replace any log file already generated previously. By default, if this option is not passed, log file names are not timestamped and each new file generated replaces the previous one. |

Generally, the **VERIFY DATA FILE** command creates a log file in XML format (please refer to the end of the description of this command). You can cancel this operation by passing this option. To create the log file, pass 0 in *options*.

The *method* parameter is used to set a callback method that will be called regularly during the verification. If you pass an empty string, no method is called. If the method passed does not exist, the verification is not carried out, an error is generated and the OK variable is set to 0. When it is called, this method receives up to 5 parameters depending on the objects being verified and on the event type originating the call (see calls table). It is imperative to declare these parameters in the method:

| | | |
|---|---|---|
| - $1 | Longint | Message type (see table) |
| - $2 | Longint | Object type |
| - $3 | Text | Message |
| - $4 | Longint | Table number |
| - $5 | Longint | Reserved |

The following table describes the contents of the parameters depending on the event type:

| Event | $1 (Longint) | $2 (Longint) | $3 (Text) | $4 (Longint) | $5 (Longint) |
|---|---|---|---|---|---|
| Message | 1 | 0 | Progression message | Percentage done (0-100) | Reserved |
| Verification finished(*) | 2 | Object type (**) | OK message test | Table or index number | Reserved |
| Error | 3 | Object type (**) | Text of error-message | Table or index number | Reserved |
| End of execution | 4 | 0 | DONE | 0 | Reserved |
| Warning | 5 | Object type(**) | Text of error message | Table or index number | Reserved |

(*) The *Verification finished* ($1=2) event is never returned when the mode is Verify All. It is only used in Verify Records or Verify Indexes mode.
(**) *Object type*: When an object is verified, a "finished" message ($1=2), error ($1=3) or warning ($1=5) can be sent. The object type returned in $2 can be one of the following:

- 0 = undetermined
- 4 = record
- 8 = index
- 16 = structure object (preliminary check of data file).

*Special case*: When $4 = 0 for $1=2, 3 or 5, the message does not concern a table or an index but rather the data file as a whole.

The callback method must also return a value in $0 (Longint), which is used to check the execution of the operation:

- If $0 = 0, the operation continues normally
- If $0 = -128, the operation is stopped without any error generated
- If $0 = another value, the operation is stopped and the value passed in $0 is returned as the error number. This error can be intercepted by an error-handling method.

**Note:** You cannot interrupt execution via $0 after the *End of execution* event ($4=1) has been generated.

Two optional arrays can also be used by this command:

- The *tablesArray* array contains the numbers of the tables whose records are to be checked. It can be used to limit checking to only certain tables. If this parameter is not passed or if the array is empty and the *objects* parameter contains Verify Records, all the tables will be checked.
- The *fieldsArray* array contains the numbers of the indexed fields whose indexes are to be checked. If this parameter is not passed or if the array is empty and the *objects* parameter contains Verify Indexes, all the indexes will be checked. The command ignores fields that are not indexed. If a field contains several indexes, they are all checked. If a field is part of a composite index, the entire index is checked.
  You must pass a 2D array in *fieldsArray*. For each row of the array:
  - The element {0} contains the table number,
  - The other elements {1...x} contain the field numbers.

By default, the **VERIFY DATA FILE** command creates a log file in XML format (if you have not passed the Do not create log file option, see the *options* parameter). This file is placed in the **Logs** folder of the current database and its name is also based on the structure file of the current database. For example, for a structure file named “myDB.4db,” the log file will be named “myDB_Verify_Log.xml.”
If you have passed the Timestamp log file name option, the name of the log file includes the date and time of its creation in the form "YYYY-MM-DD HH-MM-SS", which gives us, for example: “myDB_Verify_Log_2015-09-27 15-20-35.xml”. This means that each new log file does not replace the previous one, but it might require subsequent manual action to remove unnecessary files.
Regardless of the option selected, as soon as a log file is generated, its path is returned in the *Document* system variable after execution of the command.

## Example 1

Simple checking of data and indexes:

```
VERIFY DATA FILE($StructName;$DataName;Verify indexes+Verify records;Do not create log file;"")
```

## Example 2

Complete verification with log file:

```
VERIFY DATA FILE($StructName;$DataName;Verify all;0;"")
```

## Example 3

Checking of records only:

```
VERIFY DATA FILE($StructName;$DataName;Verify records;0;"")
```

## Example 4

Checking of records from tables 3 and 7 only:

```
ARRAY LONGINT($arrTableNums;2)
$arrTableNums{1}:=3
$arrTableNums{2}:=7
VERIFY DATA FILE($StructName;$DataName;Verify records;0;"FollowScan";$arrTableNums)
```

## Example 5

Checking of specific indexes (index of field 1 of table 4 and index of fields 2 and 3 of table 5):

```
ARRAY LONGINT($arrTableNums;0) `not used but mandatory
ARRAY LONGINT($arrIndex;2;0) `2 rows (columns added later)
$arrIndex{1}{0}:=4 ` table number in element 0
APPEND TO ARRAY($arrIndex{1};1) `number of 1st field to be checked
$arrIndex{2}{0}:=5 ` table number in element 0
APPEND TO ARRAY($arrIndex{2};2) ` number of 1st field to be checked
```

```
APPEND TO ARRAY($arrIndex{2};3) ` number of 2nd field to be checked
VERIFY DATA FILE($StructName;$DataName;Verify indexes;0;"FollowScan";$arrTableNums;$arrIndex)
```

## System variables and sets

If the callback method does not exist, the verification is not carried out, an error is generated and the system variable OK is set to 0. If a log file was generated, its complete pathname is returned in the Document system variable.

# Version type

Version type -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Demo or full version, 64-bit or 32-bit version, 4D database / Merged application |

## Description

The **Version type** command returns a numeric value that denotes the type of 4D or 4D Server version that you are running. 4D provides the following predefined constants, found in the **4D Environment** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| 64 bit version | Longint | 1 | |
| Demo version | Longint | 0 | |
| Merged application | Longint | 2 | Version is an application merged with 4D Volume Desktop |

**Note:** In current versions of 4D, the demo mode is not available.

**Version type** returns a value in the form of a *bit field*; it is necessary to use bitwise operators to interpret it (see the examples).

**COMPATIBILITY NOTE:** In versions of 4D prior to 13.2, a different set of constants was available for this command; however, these constants did not handle some cases properly, so they were modified. This modification means that your code must be adapted (see example). However, if you wish to keep the previous functioning, you can just replace the constants in your existing code with their former values: 2 for 64 bit Version, 1 for Demo Version, 0 for Full Version.

## Example 1

Your 4D application contains specific code based on the version running. You can find out the execution environment using the following code:

```
If(Version type?? 64 bit Version)
 // We are in a 64-bit version
Else
 // We are in a 32-bit version
End if
```

## Example 2

This test lets you run different code depending on whether the version is a merged application or a database opened by 4D / 4D Server:

```
If(Version type?? Merged application)
 // We are in a merged application
Else
 // We are in a database executed by 4D
End if
```

# _o_ADD DATA SEGMENT

_o_ADD DATA SEGMENT
Does not require any parameters

## Description

**Compatibility note:** Starting with version 11 of 4D, data segments are no longer supported (the size of the data file is now unlimited). When it is called, this command does nothing.

# _o_DATA SEGMENT LIST

_o_DATA SEGMENT LIST ( segments )

| Parameter | Type | | Description |
|---|---|---|---|
| segments | String array | ⇦ | Long names of data segments for the database |

## Compatibility note

Since version 11 of 4D, data segments are no longer supported (the data file size is now unlimited). This command now systematically returns an array with one element containing the pathname of the data file of the database.

WP CREATE BOOKMARK ( rangeObj ; bkName )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇨ | 4D Write Pro range |
| bkName | String | ⇨ | Name of the bookmark to create |

## Description

The **WP CREATE BOOKMARK** command creates a new bookmark named *bkName* based upon the 4D Write Pro *rangeObj* in the range parent document.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP DELETE BOOKMARK

WP DELETE BOOKMARK ( wpDoc ; bkName )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | 4D Write Pro document |
| bkName | String | ⇒ | Name of the bookmark to delete |

## Description

The **WP DELETE BOOKMARK** command removes the bookmark named *bkName* from *wpDoc*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP EXPORT DOCUMENT

WP EXPORT DOCUMENT ( wpDoc ; filePath {; format {; options}} )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ➡ | 4D Write Pro variable |
| filePath | String | ➡ | Path of exported file |
| format | Longint | ➡ | Document output format |
| options | Longint | ➡ | Export options |

## Description

The **WP EXPORT DOCUMENT** command exports the *wpDoc* 4D Write Pro object to a document on disk defined by the *filePath* parameter as well as any optional parameters.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP EXPORT VARIABLE

WP EXPORT VARIABLE ( wpDoc ; destination ; format {; options} )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | 4D Write Pro variable |
| destination | Text variable, BLOB variable | ⇐ | Variable to receive exported contents |
| format | Longint | ⇒ | Variable output format |
| options | Longint, String | ⇒ | Export options |

## Description

The **WP EXPORT VARIABLE** command exports the *wpDoc* 4D Write Pro object to the 4D *destination* variable in the specified *format* and with any *options* specified.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP GET ATTRIBUTES

WP GET ATTRIBUTES ( rangeObj | wpDoc ; attribName ; attribValue {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj \| wpDoc | Object | ⇒ | 4D Write Pro range or document |
| attribName | String | ⇒ | Name of attribute to get |
| attribValue | String, Real, Boolean, Array | ⇐ | Current value of attribute for text range |

## Description

The **WP GET ATTRIBUTES** command returns the value of any attribute in a 4D Write Pro range or document.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get bookmark range

WP Get bookmark range ( wpDoc ; bkName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | 4D Write Pro variable |
| bkName | Text | ⇒ | Name of bookmark whose range you want to get |
| Function result | Object | ⇐ | Range of bookmark |

## Description

The **WP Get bookmark range** command returns a text range object (*rangeObj*) containing the range for the bookmark with the specified *bkName* in *wpDoc*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP GET BOOKMARKS

WP GET BOOKMARKS ( wpDoc ; arrBKNames )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | 4D Write Pro document |
| arrBKNames | Text array | ⇐ | Array of bookmark names |

## Description

The **WP GET BOOKMARKS** command returns an array containing the names of all bookmarks defined in *wpDoc*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get page count

WP Get page count ( wpDoc ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | 4D Write Pro document |
| Function result | Longint | ⇐ | Number of pages in the document |

## Description

The **WP Get page count** command returns the total number of pages defined in the *wpDoc* 4D Write Pro document.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get paragraphs

WP Get paragraphs ( rangeObj ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇒ | Range from which to get paragraphs |
| Function result | Object | ⇐ | Range addressing only paragraphs |

## Description

The **WP Get paragraphs** command returns a specific range object that addresses only the paragraphs contained in the *rangeObj* you passed as parameter.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get pictures

WP Get pictures ( rangeObj ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇒ | Range from which to get pictures |
| Function result | Object | ⇐ | Range object containing pictures only |

## Description

The **WP Get pictures** command returns a specific range object that addresses only the pictures contained in the *rangeObj* you passed as parameter.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get range

WP Get range ( wpArea ; startRange ; endRange ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| wpArea | Object | ⇒ | 4D Write Pro object variable or field |
| startRange | Longint | ⇒ | Starting offset of range in the area |
| endRange | Longint | ⇒ | Ending offset of range in the area |
| Function result | Object | ⇐ | Range object |

## Description

The **WP Get range** command returns a new text range object (*rangeObj*) containing the selection between *startRange* and *endRange* in the *wpArea* 4D Write Pro area.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Get selection

WP Get selection ( {* ;} wpArea ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, wpArea is a form object name (string). If omitted, wpArea is an object field or variable. |
| wpArea | String, Object | ⇒ | Form object name (if * is specified) or 4D Write Pro object variable or field (if * is omitted) |
| Function result | Object | ⇐ | Range object |

## Description

The **WP Get selection** command returns a new text range object (*rangeObj*) based upon the currently selected text in the *wpArea* 4D Write Pro area.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Import document

WP Import document ( filePath ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| filePath | String | ⇒ | Path to a 4D Write document (.4w7 or .4wt) or a 4D Write Pro document (.4wp) |
| Function result | Object | ⇐ | 4D Write Pro object |

## Description

The **WP Import document** command converts an existing 4D Write Pro or 4D Write document (.4wp, .4w7 or .4wt) to a new 4D Write Pro object.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP INSERT BREAK

WP INSERT BREAK ( rangeObj ; breakType ; mode {; rangeUpdate} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ➡ | 4D Write Pro range object |
| breakType | Longint | ➡ | Type of break to insert |
| mode | Longint | ➡ | Insertion mode |
| rangeUpdate | Longint | ➡ | Range update mode |

## Description

The **WP INSERT BREAK** command inserts a new break of the *breakType* type in the *rangeObj* range according to the specified insertion *mode* and *rangeUpdate* parameter.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP INSERT DOCUMENT

WP INSERT DOCUMENT ( rangeObj ; wpDoc ; mode {; rangeUpdate} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ➡ | 4D Write Pro range |
| wpDoc | Object | ➡ | 4D Write Pro document |
| mode | Longint | ➡ | Insertion mode |
| rangeUpdate | Longint | ➡ | Range update mode |

## Description

The **WP INSERT DOCUMENT** command inserts the *wpDoc* document in the *rangeObj* range according to the specified insertion *mode* and *rangeUpdate* parameter.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP INSERT PICTURE

WP INSERT PICTURE ( rangeObj ; picture ; mode {; rangeUpdate} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇒ | Range object |
| picture | Picture, String | ⇒ | Picture field or variable, or path to picture file on disk |
| mode | Longint | ⇒ | Insertion mode |
| rangeUpdate | Longint | ⇒ | Range update mode |

## Description

The **WP INSERT PICTURE** command inserts the *picture* in *rangeObj* according to the specified insertion *mode* and *rangeUpdate* parameter.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP Is font style supported

WP Is font style supported ( rangeObj ; wpFontStyle ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇒ | Range object to parse |
| wpFontStyle | Longint | ⇒ | Font style constant: wk font bold, wk font italic, wk text underline style, wk text linethrough style |
| Function result | Boolean | ⇐ | True if any part of range supports wpFontStyle; False otherwise |

## Description

The **WP Is font style supported** command returns True if the *wpFontStyle* style is supported by any part of the text in *rangeObj*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP New

WP New {( source )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String, BLOB, Object | ⇒ | String: 4D HTML source,<br>BLOB: 4D Write Blob document (.4w7/.4wt) or 4D Write Pro document (.4wp)<br>Object: a 4D Write Pro object range |
| Function result | Object | ⇐ | 4D Write Pro object |

## Description

The **WP New** command creates and returns a new 4D Write Pro object that is either empty or filled with the contents defined by *source*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP PRINT

WP PRINT ( wpDoc {; printLayout} )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇒ | Name of 4D Write Pro document |
| printLayout | Longint | ⇒ | Print layout for 4D Write Pro document: 0 (default)=4D Write Pro layout, 1=HTML WYSIWYG |

## Description

The **WP PRINT** command launches a print job for the 4D Write Pro document specified in *wpDoc* or (64-bit versions only) adds the document to the current print job if it is called between **OPEN PRINTING JOB** and **CLOSE PRINTING JOB**.

**Note for 32-bit users:** This command is supported on 4D 32-bit versions but in this context, it cannot be used within a print job open with **OPEN PRINTING JOB**.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP RESET ATTRIBUTES

WP RESET ATTRIBUTES ( rangeObj ; attribName {; attribName2 ; ... ; attribNameN} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj | Object | ⇒ | 4D Write Pro range |
| attribName | String | ⇒ | Name of attribute(s) to remove |

## Description

The **WP RESET ATTRIBUTES** command allows you to reset the value of one or more attributes in the 4D Write Pro *rangeObj*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP SELECT

WP SELECT ( {* ;} wpArea {; rangeObj}{; startRange ; endRange} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, wpArea is a form object name (string). If omitted, wpArea is an object field or variable. |
| wpArea | String, Object | ⇒ | Form object name (if * is specified) or 4D Write Pro object variable or field (if * is omitted) |
| rangeObj | Object | ⇒ | Range object to apply to create a selection |
| startRange | Longint | ⇒ | Starting offset of text range |
| endRange | Longint | ⇒ | Ending offset of text range |

## Description

The **WP SELECT** command creates a new text selection in the *wpArea* 4D Write Pro area, based upon the *rangeObj* or a new range defined by *startRange* and *endRange*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP SET ATTRIBUTES

WP SET ATTRIBUTES ( rangeObj | wpDoc ; attribName ; attribValue {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| rangeObj \| wpDoc | Object | ➡ | 4D Write Pro range or document |
| attribName | String | ➡ | Name of attribute to set |
| attribValue | String, Real, Boolean | ➡ | New attribute value |

## Description

The **WP SET ATTRIBUTES** command allows you to set the value of any attribute in a 4D Write Pro range or document.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# WP USE PAGE SETUP

WP USE PAGE SETUP ( wpDoc )

| Parameter | Type | | Description |
|---|---|---|---|
| wpDoc | Object | ⇨ | Name of 4D Write Pro document |

## Description

The **WP USE PAGE SETUP** command modifies the current printer page settings based on the page size and orientation attributes for the 4D Write Pro document passed in *wpDoc*.

For more information, refer to the description of this command in the **4D Write Pro Language** chapter of the *4D Write Pro Reference* manual.

# Arrays

- Arrays

- MULTI SORT ARRAY
- SELECTION RANGE TO ARRAY
- SELECTION TO ARRAY
- Size of array
- SORT ARRAY
- TEXT TO ARRAY
- *_o_ARRAY STRING*

# Arrays

An **array** is an ordered series of variables of the same type. Each variable is called an **element** of the array. The **size** of an array is the number of elements it holds. An array is given its size when it is created; you can then resize it as many times as needed by adding, inserting, or deleting elements, or by resizing the array using the same command used to create it.

You create an array with one of the array declaration commands. For details, see the **Creating Arrays** section.

Elements are numbered from **1 to N**, where N is the size of the array. An array always has an **element zero** that you can access just like any other element of the array, but this element is not shown when an array is present in a form. Although the element zero is not shown when an array supports a form object, there is no restriction in using it with the language. For more information about the element zero, see the **Using the element zero of an array** section.

Arrays are 4D variables. Like any variable, an array has a scope and follows the rules of the 4D language, though with some unique differences. For more information, see the **Arrays and the 4D Language** and **Arrays and Pointers** sections.

Arrays are language objects; you can create and use arrays that will never appear on the screen. Arrays are also user interface objects. For more information about the interaction between arrays and form objects, see the **Arrays and Form Objects** section.

Arrays are designed to hold reasonable amounts of data for a short period of time. However, because arrays are held in memory, they are easy to handle and quick to manipulate. For details, see the **Arrays and Memory** section.

## Creating Arrays

You create an array with one of the array declaration commands described in this chapter. The following table lists the array declaration commands:

| Command | Creates or resizes an array of |
|---|---|
| **ARRAY INTEGER** | 2-byte Integer values |
| **ARRAY LONGINT** | 4-byte Integer values |
| **ARRAY REAL** | Real values |
| **ARRAY TEXT** | Text values (up to 2 GB of text per element) (*) |
| **_o_ARRAY STRING** | Text values (obsolete) (*) |
| **ARRAY DATE** | Date values |
| **ARRAY BOOLEAN** | Boolean values |
| **ARRAY PICTURE** | Pictures values |
| **ARRAY POINTER** | Pointer values |
| **ARRAY OBJECT** | Language objects |
| **ARRAY BLOB** | BLOBs |
| **ARRAY TIME** | Times |

Each array declaration command can create or resize one-dimensional or two-dimensional arrays. For more information about two-dimensional arrays, see the **Two-dimensional Arrays** section.

(*) There is no difference between Text and String arrays. The *strLen* parameter of the **_o_ARRAY STRING** command is ignored. It is recommended to use Text arrays. The **_o_ARRAY STRING** command is only kept for compatibility reasons.

The following line of code creates (declares) an Integer array of 10 elements:

```
ARRAY INTEGER(aiAnArray;10)
```

Then, the following code resizes that same array to 20 elements:

```
ARRAY INTEGER(aiAnArray;20)
```

Then, the following code resizes that same array to no elements:

```
ARRAY INTEGER(aiAnArray;0)
```

You reference the elements in an array by using curly braces ({…}). A number is used within the braces to address a particular element; this number is called the **element number**. The following lines put five names into the array called *atNames* and then display them in alert windows:

```
ARRAY TEXT(atNames;5)
atNames{1}:="Richard"
atNames{2}:="Sarah"
atNames{3}:="Sam"
atNames{4}:="Jane"
atNames{5}:="John"
For($vlElem;1;5)
   ALERT("The element #"+String($vlElem)+" is equal to: "+atNames{$vlElem})
End for
```

Note the syntax *atNames{$vlElem}*. Rather than specifying a numeric literal such as *atNames{3}*, you can use a numeric variable to indicate which element of an array you are addressing.

Using the iteration provided by a loop structure (**For...End for**, **Repeat...Until** or **While...End while**), compact pieces of code can address all or part of the elements in an array.

## Arrays and other areas of the 4D language

There are other 4D commands that can create and work with arrays. More particularly:

- To work with arrays and selection of records, use the commands **SELECTION RANGE TO ARRAY**, **SELECTION TO ARRAY**, **ARRAY TO SELECTION** and **DISTINCT VALUES**.
- Objects of the List box type are based on arrays; several commands of the “List box” theme work with arrays, for instance **LISTBOX INSERT ROWS**.
- You can create graphs and charts on series of values stored in tables and arrays. For more information, see the **GRAPH** command.
- The **LIST TO ARRAY** and **ARRAY TO LIST** commands.
- Many commands can build arrays in one call, for example: **FONT LIST**, **WINDOW LIST**, **VOLUME LIST**, **FOLDER LIST**, **DOCUMENT LIST**, **GET SERIAL PORT MAPPING**, **SAX GET XML ELEMENT**, etc.

# Arrays and Form Objects

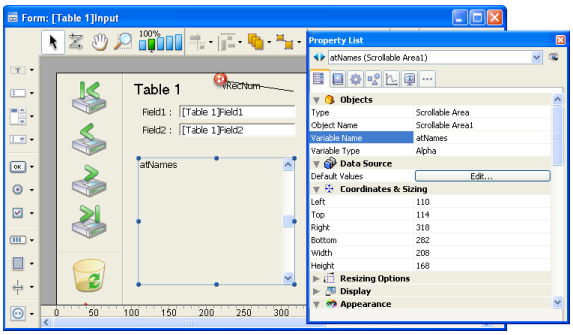
Arrays are language objects—you can create and use arrays that will never appear on the screen. However, arrays are also user interface objects. The following types of **Form Objects** are supported by arrays:

- Pop-up/Drop-down List
- Combo Box
- Scrollable Area (obsolete starting with 4D v13)
- Tab Control
- List box

While you can predefine these objects in the Design Environment Form Editor using the Default Values button of the Property List window (except for the List box) , you can also define them programmatically using the arrays commands. In both cases, the form object is supported by an array created by you or 4D.

When using these objects, you can detect which item within the object has been selected (or clicked) by testing the array for its **selected element**. Conversely, you can select a particular item within the object by setting the selected element for the array.

When an array is used to support a form object, it has then a dual nature; it is both a language object and a user interface object. For example, when designing a form, you create a scrollable area:



The name of the associated variable, in this case *atNames*, is the name of the array you use for creating and handling the scrollable area.

**Notes**:

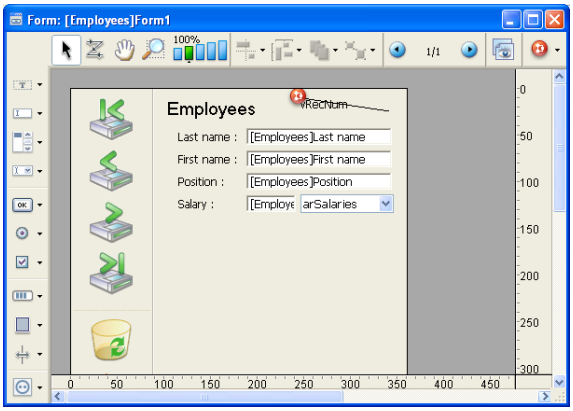
- The **selected element** of the array is stored internally in an Integer type variable. As a result, it is not possible to use it with arrays containing more than 32,767 elements (however, such a large number of elements is also not suitable for display as a form object).
- You cannot display two-dimensional arrays or pointer arrays.
- The management of **List box** type objects (which may contain several arrays) entails many specific aspects. These particularities are covered in the **Managing List Box Objects** section.

## Example: Creating a drop-down list

The following example shows how to fill an array and display it in a drop-down list. An array *arSalaries* is created using the **ARRAY REAL** command. It contains all the standard salaries paid to people in a company. When the user chooses an element from the drop-down list, the *[Employees]Salary* field is assigned the value chosen.

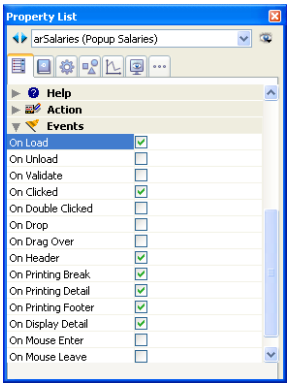
### Create the arSalaries drop-down list on a form

Create a drop-down list and name it *arSalaries*. The name of the drop-down list should be the same as the name of the array.

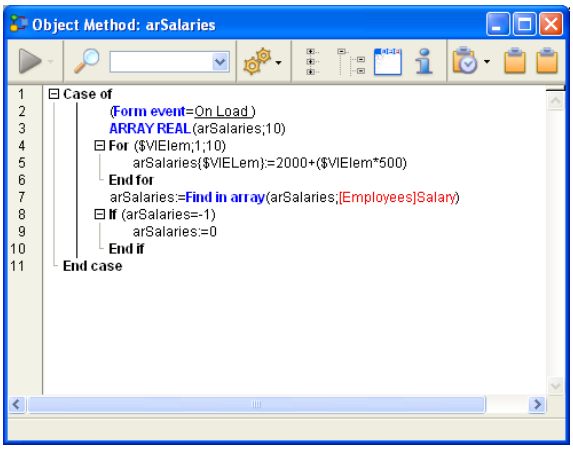


### Initializing the array

Initialize the array *arSalaries* using the On Load event for the object. To do so, remember to enable that event in the **Property List** window, as shown:



Click the **Object Method** button and create the method, as follows:



The lines:

```
ARRAY REAL(arSalaries;10)
For($vlElem;1;10)
   arSalaries{$vlElem}:=2000+($vlElem*500)
End for
```

create the numeric array 2500, 3000... 7000, corresponding to the annual salaries $30,000 up to $84,000, before tax.

The lines:

```
arSalaries:=Find in array(arSalaries;[Employees]Salary)
If(arSalaries=-1)
   arSalaries:=0
End if
```

handle both the creation of a new record or the modification of existing record.

- If you create a new record, the field *[Employees]Salary* is initially equal to zero. In this case, **Find in array** does not find the value in the array and returns -1. The test *If (arSalaries=-1)* resets *arSalaries* to zero, indicating that no element is selected in the drop-down list.

- If you modify an existing record, **Find in array** retrieves the value in the array and sets the selected element of the drop-down list to the current value of the field. If the value for a particular employee is not in the list, the test *If (arSalaries=-1)* deselects any element in the list.

**Note:** For more information about the **array selected element**, read the next section.

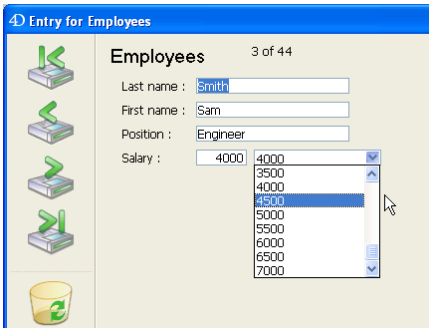
### Reporting the selected value to the [Employees]Salary field

To report the value selected from the drop-down list *arSalaries*, you just need to handle the On Clicked event to the object. The element number of the selected element is the value of the array *arSalaries* itself. Therefore, the expression *arSalaries{arSalaries}* returns the value chosen in the drop-down list.

Complete the method for the object *arSalaries* as follows:

```
Case of
   :(Form event=On Load)
      ARRAY REAL(arSalaries;10)
      For($vlElem;1;10)
         arSalaries{$vlElem}:=2000+($vlElem*500)
      End for
      arSalaries:=Find in array(arSalaries;[Employees]Salary)
      If(arSalaries=-1)
         arSalaries:=0
      End if
   :(Form event=On Clicked)
      [Employees]Salary:=arSalaries{arSalaries}
End case
```

The drop-down list looks like this:



The following section describes the common and basic operations you will perform on arrays while using them as form objects.

## Getting the size of the array

You can obtain the current size of the array by using the **Size of array** command. Using the previous example, the following line of code would display 5:

```
ALERT("The size of the array atNames is: "+String(Size of array(atNames)))
```

## Reordering the elements of the array

You can reorder the elements of the array using the **SORT ARRAY** command or of several arrays using the **MULTI SORT ARRAY** command. Using the previous example, and provided the array is shown as a scrollable area:

a. Initially, the area would look like the list on the left.

b. After the execution of the following line of code:

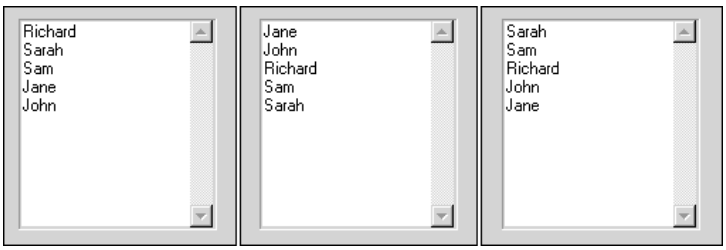
```
SORT ARRAY(atNames;>)
```

the area would look like the list in the middle.

c. After the execution of the following line of code:

```
SORT ARRAY(atNames;<)
```

the area would look like the list on the right.



## Adding or deleting elements

You can add, insert, or delete elements using the commands **APPEND TO ARRAY**, **INSERT IN ARRAY** and **DELETE FROM ARRAY**.

## Handling clicks in the array: testing the selected element

Using the previous example, and provided the array is shown as a scrollable area, you can handle clicks in this area as follows:

```
 //atNames scrollable area object method
Case of
   :(Form event=On Load)
 //Initialize the array (as shown further above)
      ARRAY TEXT(atNames;5)
 // ...
   :(Form event=On Unload)
 //We no longer need the array
      CLEAR VARIABLE(atNames)

   :(Form event=On Clicked)
      If(atNames#0)
         vtInfo:="You clicked on: "+atNames{atNames}
      End if
   :(Form event=On Double Clicked)
      If(atNames#0)
         ALERT("You double clicked on: "+atNames{atNames}
      End if
End case
```

**Note**: The events must be activated in the properties of the object.

While the syntax *atNames{$vlElem}* allows you to work with a particular element of the array, the syntax *atNames* returns the element number of the selected element within the array. Thus, the syntax *atNames{atNames}* means "the value of the selected element in the array *atNames*." If no element is selected, *atNames* is equal to 0 (zero), so the test **If (atNames#0)** detects whether or not an element is actually selected.

## Setting the selected element

In a similar fashion, you can programmatically change the selected element by assigning a value to the array.

### Examples

```
 //Selects the first element (if the array is not empty)
atNames:=1

 //Selects the last element (if the array is not empty)
atNames:=Size of array(atNames)

 //Deselects the selected element (if any) then no element is selected
atNames:=0

If((0<atNames)&(atNames<Size of array(atNames))
 //If possible, selects the next element to the selected element
   atNames:=atNames+1
End if
```

```
If(1<atNames)
 //If possible, selects the previous element to the selected element
   atNames:=atNames-1
End if
```

## Looking for a value in the array

The **Find in array** command searches for a particular value within an array. Using the previous example, the following code will select the element whose value is “Richard,” if that is what is entered in the request dialog box:

```
$vsName:=Request("Enter the first name:")
If(OK=1)
   $vlElem:=Find in array(atNames;$vsName)
   If($vlElem>0)
      atNames:=$vlElem
   Else
      ALERT("This is no "+$vsName+" in that list of first names.")
   End if
End if
```

Pop-up menus, drop-down lists, scrollable areas, and tab controls can be usually handled in the same manner. Obviously, no additional code is required to redraw objects on the screen each time you change the value of an element, or add or delete elements.

**Note**: To create and use tab controls with icons and enabled and disabled tabs, you must use a hierarchical list as the supporting object for the tab control. For more information, see the example for the **Count tasks** command.

## Handling combo boxes

While you can handle pop-up menus, drop-down lists, scrollable areas, and tab controls with the algorithms described in the previous section, you must handle combo boxes differently.

A combo box is actually a text enterable area to which is attached a list of values (the elements from the array). The user can pick a value from this list, and then edit the text. So, in a combo box, the notion of selected element does not apply.

With combo boxes, there is never a selected element. Each time the user selects one of the values attached to the area, that value is put into the element zero of the array. Then, if the user edits the text, the value modified by the user is also put into that element zero.

### Example

```
  ` asColors Combo Box object method
Case of
   :(Form event=On Load)
      ARRAY STRING(31;asColors;3)
      asColors{1}:="Blue"
      asColors{2}:="White"
      asColors{3}:="Red"
   :(Form event=On Clicked)
      If(asColors{0}#"")
  ` The object automatically changes its value
  ` Using the On Clicked event with a Combo Box
  ` is required only when additional actions must be taken
      End if
   :(Form event=On Data Change)
  ` Find in array ignores element 0, so returns -1 or >0
      If(Find in array(asColors;asColors{0})<0)
  ` Entered value is not one the values attached to the object
  ` Add the value to the list for next time
         APPEND TO ARRAY(asColors;asColors{0})
      Else
  ` Entered value is among the values attached to the object
      End if
End case
```

# Arrays and the 4D Language

Arrays are 4D variables. Like any variable, an array has a scope and follows the rules of the 4D language, though with some unique differences.

## Local, process and interprocess arrays

You can create and work with local, process, and interprocess arrays. Examples:

```
ARRAY INTEGER($aiCodes;100) ` Creates local array of 100 2-byte Integer values
ARRAY INTEGER(aiCodes;100) ` Creates process array of 100 2-byte Integer values
ARRAY INTEGER(◊aiCodes;100) ` Creates interprocess array of 100 2-byte Integer values
```

The scope of these arrays is identical to the scope of other local, process, and interprocess variables:

### Local arrays

A local array is declared when the name of the array starts with a dollar sign ($).

The scope of a local array is the method in which it is created. The array is cleared when the method ends. Local arrays with the same name in two different methods can have different types, because they are actually two different variables with different scopes.

When you create a local array within a form method, within an object method, within or a project method called as subroutine by the two previous type of method, the array is created and cleared each time the form or object method is invoked. In other words, the array is created and cleared for each form event. Consequently, you cannot use local arrays in forms, neither for display nor printing.

As with local variables, it is a good idea to use local arrays whenever possible. In doing so, you tend to minimize the amount of memory necessary for running your application.

### Process arrays

A process array is declared when the name of the array starts with a letter.

The scope of a process array is the process in which it is created. The array is cleared when the process ends or is aborted. A process array automatically has one instance created per process. Therefore, the array is of the same type throughout the processes. However, its contents are particular to each process.

### Interprocess arrays

An interprocess array is declared when the name of the array starts with <> (on Windows and Macintosh) or with the diamond sign, Option-Shift-V on a US keyboard (on Macintosh only).

The scope of an interprocess array consists of all processes during a working session. They should be used only to share data and transfer information between processes.

**Tip**: When you know in advance that an interprocess array will be accessed by several processes that could possible conflict, protect the access to that array with a semaphore. For more information, see the example for the **Semaphore** command.

**Note**: You can use process and interprocess arrays in forms to create form objects such as scrollable areas, drop-down lists, and so on.

## Passing an Array as parameter

You can pass an array as parameter to a 4D command or to the routine of a 4D Plug-in. On the other hand, you cannot pass an array as parameter to a user method. The alternative is to pass a pointer to the array as parameter to the method. For details, see the **Arrays and Pointers** section.

## Assigning and array to another array

Unlike text or string variables, you cannot assign one array to another. To copy (assign) an array to another one, use **COPY ARRAY**.

## Arrays and Pointers

---

You can pass an array as parameter to a 4D command or to the routine of a 4D Plug-in. On the other hand, you cannot pass an array as parameter to a user method. The alternative is to pass a pointer to the array as parameter to the method.

You can pass process and interprocess, process or local arrays as parameters.

Here are some examples.

- Given this example:

```
If((0<atNames)&(atNames<Size of array(atNames))
  ` If possible, selects the next element to the selected element
   atNames:=atNames+1
End if
```

If you need to do the same thing for 50 different arrays in various forms, you can avoid writing the same thing 50 times, by using the following project method:

```
  ` SELECT NEXT ELEMENT project method
  ` SELECT NEXT ELEMENT ( Pointer )
  ` SELECT NEXT ELEMENT ( -> Array )

C_POINTER($1)

If((0<$1->)&($1-><Size of array($1->))
   $1->:=$1->+1 ` If possible, selects the next element to the selected element
End if
```

Then, you can write:

```
SELECT NEXT ELEMENT(->atNames)
  ` ...
SELECT NEXT ELEMENT(->asZipCodes)
  ` ...
SELECT NEXT ELEMENT(->alRecordIDs)
  ` ... and so on
```

- The following project method returns the sum of all the elements of a numeric array (Integer, Long Integer, or real):

```
  ` Array sum
  ` Array sum ( Pointer )
  ` Array sum ( -> Array )

C_REAL($0)

$0:=0
For($vlElem;1;Size of array($1->))
   $0:=$0+$1->{$vlElem}
End for
```

**Note:** Since 4D v13, you can just use the **Sum** function to calculate the sum of the elements of a number array.

Then, you can write:

```
$vlSum:=Array sum(->arSalaries)
  ` ...
$vlSum:=Array sum(->aiDefectCounts)
  ` ..
$vlSum:=Array sum(->alPopulations)
```

- The following project method capitalizes of all the elements of a string or text array:

```
  ` CAPITALIZE ARRAY
  ` CAPITALIZE ARRAY ( Pointer )
  ` CAPITALIZE ARRAY ( -> Array )

For($vlElem;1;Size of array($1->))
   If($1->{$vlElem}#"")
      $1->{$vlElem}:=Uppercase($1->{$vlElem}≤1≥)+Lowercase(Substring($1->{$vlElem};2))
   End if
End for
```

Then, you can write:

```
CAPITALIZE ARRAY(->atSubjects)
  ` ...
CAPITALIZE ARRAY(->asLastNames)
```

The combination of arrays, pointers, and looping structures, such as **For...End for**, allows you to write many useful small project methods for handling arrays.

## Using the element zero of an array

---

An array always has an element zero. While element zero is not shown when an array supports a form object, there is no restriction(*) in using it with the language.

One example of the use of element zero is the case of the combo box discussed in the **Arrays and Form Objects** section.

Here is another example: you want to execute an action only when you click on an element other than the previously selected element. To do this, you must keep track of each selected element. One way to do this is to use a process variable in which you maintain the element number of the selected element. Another way is to use the element zero of the array:

```
  ` atNames scrollable area object method
Case of
   :(Form event=On Load)
  ` Initialize the array (as shown further above)
      ARRAY TEXT(atNames;5)
  ` ...
  ` Initialize the element zero with the number
  ` of the current selected element in its string form
  ` Here you start with no selected element
      atNames{0}:="0"

   :(Form event=On Unload)
  ` We no longer need the array
      CLEAR VARIABLE(atNames)

   :(Form event=On Clicked)
      If(atNames#0)
         If(atNames#Num(atNames{0}))
            vtInfo:="You clicked on: "+atNames{atNames}+" and it was not selected before."
            atNames{0}:=String(atNames)
         End if
      End if
   :(Form event=On Double Clicked)
      If(atNames#0)
         ALERT("You double clicked on: "+atNames{atNames}
      End if
End case
```

(*) However, there is one exception: in an array type **List Box**, the zero element is used internally to store the previous value of an element being edited, so it is not possible to use it in this particular context.

## Two-dimensional Arrays

---

Each of the array declaration commands can create or resize one-dimensional or two-dimensional arrays. Example:

```
ARRAY TEXT(atTopics;100;50) ` Creates a text array composed of 100 rows of 50 columns
```

Two-dimensional arrays are essentially language objects; you can neither display nor print them.

In the previous example:

- *atTopics* is a two-dimensional array
- *atTopics{8}{5}* is the 5th element (5th column...) of the 8th row
- *atTopics{20}* is the 20th row and is itself a one-dimensional array
- **Size of array***(atTopics)* returns 100, which is the number of rows
- **Size of array***(atTopics{17})* returns 50, which the number of columns for the 17th row

In the following example, a pointer to each field of each table in the database is stored in a two-dimensional array:

```
C_LONGINT($vlLastTable;$vlLastField)
C_LONGINT($vlFieldNumber)
 ` Create as many rows (empty and without columns) as there are tables
$vlLastTable:=Get last table number
ARRAY POINTER(<>apFields;$vlLastTable;0) `2D array with X rows and zero columns
 ` For each table
For($vlTable;1;$vlLastTable)
   If(Is table number valid($vlTable))
      $vlLastField:=Get last field number($vlTable)
 ` Give value of elements
      $vlColumnNumber:=0
      For($vlField;1;$vlLastField)
         If(Is field number valid($vlTable;$vlField))
            $vlColumnNumber:=$vlColumnNumber+1
 `Insert a column in a row of the table underway
            INSERT IN ARRAY(<>apFields{$vlTable};$vlColumnNumber;1)
 `Assign the "cell" with the pointer
            <>apFields{$vlTable}{$vlColumnNumber}:=Field($vlTable;$vlField)
         End if
      End for
   End if
End for
```

Provided that this two-dimensional array has been initialized, you can obtain the pointers to the fields for a particular table in the following way:

```
 ` Get the pointers to the fields for the table currently displayed at the screen:
COPY ARRAY(◊apFields{Table(Current form table)};$apTheFieldsIamWorkingOn)
 ` Initialize Boolean and Date fields
For($vlElem;1;Size of array($apTheFieldsIamWorkingOn))
   Case of
      :(Type($apTheFieldsIamWorkingOn{$vlElem}->)=Is date)
         $apTheFieldsIamWorkingOn{$vlElem}->:=Current date
      :(Type($apTheFieldsIamWorkingOn{$vlElem}->)=Is Boolean)
         $apTheFieldsIamWorkingOn{$vlElem}->:=True
   End case
End for
```

**Note**: As this example suggests, rows of a two-dimensional arrays can be the same size or different sizes.

## Arrays and Memory

---

Unlike the data you store on disk using tables and records, an array is always held in memory in its entirety.

For example, if all US zip codes were entered in the *[Zip Codes]* table, it would contain about 100,000 records. In addition, that table would include several fields: the zip code itself and the corresponding city, county, and state. If you select only the zip codes from California, the 4D database engine creates the corresponding selection of records within the *[Zip Codes]* table, and then loads the records only when they are needed (i.e., when they are displayed or printed). In order words, you work with an ordered series of values (of the same type for each field) that is partially loaded from the disk into the memory by the database engine of 4D.

Doing the same thing with arrays would be prohibitive for the following reasons:

- In order to maintain the four information types (zip code, city, county, state), you would have to maintain four large arrays in memory.
- Because an array is always held in memory in its entirety, you would have to keep all the zip codes information in memory throughout the whole working session, even though the data is not always in use.
- Again, because an array is always held in memory in its entirety, each time the database is started and then quit, the four arrays would have to be loaded and then saved on the disk, even though the data is not used or modified during the working session.

**Conclusion**: Arrays are intended to hold reasonable amounts of data for a short period of time. On the other hand, because arrays are held in memory, they are easy to handle and quick to manipulate.

However, in some circumstances, you may need to work with arrays holding hundreds or thousands of elements. The following table lists the formulas used to calculate the amount of memory used for each array type:

| Array Type | Formula for determining Memory Usage in Bytes |
|---|---|
| Boolean | (31+number of elements)¥8 |
| Date | (1+number of elements) * 6 |
| String | (1+number of elements) * (Sum of the size of each text) |
| Integer | (1+number of elements) * 2 |
| Long Integer | (1+number of elements) * 4 |
| Picture | (1+number of elements) * 4 + Sum of the size of each picture |
| Pointer | (1+number of elements) * 16 |
| Real | (1+number of elements) * 8 |
| Text | (1+number of elements) * (Sum of the size of each text) |
| Two-dimensional | (1+number of elements) * 12 + Sum of the size of each array |

**Notes**:

- The size of a text in memory is calculated using this formula: ((Length + 1) * 2)
- A few additional bytes are required to keep track of the selected element, the number of elements, and the array itself.

When working with very large arrays, the best way to handle full memory situations is to surround the creation of the arrays with an **ON ERR CALL** project method. Example:

```
  ` You are going to run a batch operation the whole night
  ` that requires the creation of large arrays. Instead of risking
  ` occurrences of errors in the middle of the night, put
  ` the creation of the arrays at the beginning of the operation
  ` and test the errors at this moment:
gError:=0 ` Assume no error
ON ERR CALL("ERROR HANDLING") ` Install a method for catching errors
ARRAY STRING(63;asThisArray;50000) ` Roughly 3125K in ASCII mode
ARRAY REAL(arThisAnotherArray;50000) ` 488K
ON ERR CALL("") ` No longer need to catch errors
If(gError=0)
  ` The arrays could be created
  ` and let's pursue the operation
Else
```

```
      ALERT("This operation requires more memory!")
   End if
    ` Whatever the case, we no longer need the arrays
   CLEAR VARIABLE(asThisArray)
   CLEAR VARIABLE(arThisAnotherArray)
```

The ***ERROR HANDLING*** project method is listed here:

```
    ` ERROR HANDLING project method
   gError:=Error ` Just return the error code
```

# APPEND TO ARRAY

APPEND TO ARRAY ( array ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ➡ | Array to which an element will be appended |
| value | Expression | ➡ | Value to append |

## Description

The **APPEND TO ARRAY** command adds a new element at the end of *array* and assigns *value* to the element. In interpreted mode, if *array* does not exist, the command creates it with regard to the type of *value*.

This command works with all kind of arrays: string, number, Boolean, date, pointer and picture.

The type of *value* must match the array type, otherwise the syntax error 54 “Argument types are incompatible” is generated. The following values will, however, be accepted:

- A string *array* (Text or String) accepts any *value* of the Text or String type.
- A number *array* (Integer, Longint or Real) accepts any *value* of the Integer, Longint, Real or Time type.

## Example

The following code:

```
INSERT IN ARRAY($myarray;Size of array($myarray)+1)
$myarray{Size of array($myarray)}:=$myvalue
```

... can be replaced with:

```
APPEND TO ARRAY($myarray;$myvalue)
```

# ARRAY BLOB

ARRAY BLOB ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ➡ | Name of array |
| size | Longint | ➡ | Number of array elements or Number of arrays if size2 is specified |
| size2 | Longint | ➡ | Number of 2D array elements |

## Description

The **ARRAY BLOB** command creates and/or resizes an array of Blob type elements in memory.

The *arrayName* parameter is the name of the array.

The *size* parameter is the number of array elements.

The *size2* parameter is optional. If you pass it, this command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* the number of columns in each array. Each row in a two-dimensional array can be processed both as an element and an array. This means that when you work with the first dimension of a two-dimensional array, you can insert and remove entire arrays using other commands in this theme.

When you apply the **ARRAY BLOB** command to an existing array:

- If you enlarge its size, existing elements are not changed and new elements are initialized to an empty BLOB (**BLOB size**= 0).
- If you reduce its size, elements at the "bottom" of the array are deleted and lost.

## Example 1

This example creates a process array containing 100 BLOB-type elements:

```
ARRAY BLOB(arrBlob;100)
```

## Example 2

This example creates a local array of 100 rows each containing 50 BLOB-type elements:

```
ARRAY BLOB($arrBlob;100;50)
```

## Example 3

This example creates a local array of 100 rows each containing 50 BLOB-type elements. The *$vByteValue* variable receives the 10th byte of the BLOB placed in the 7th column and the 5th row of the BLOB array:

```
C_INTEGER($vByteValue)
ARRAY BLOB($arrValues;100;50)
...
$vByteValue:=$arrValues{5}{7}{9}
```

# ARRAY BOOLEAN

ARRAY BOOLEAN ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Description

The **ARRAY BOOLEAN** command creates and/or resizes an array of *Boolean* elements in memory.

The *arrayName* parameter is the name of the array.

The *size* parameter is the number of elements in the array.

The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying **ARRAY BOOLEAN** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to False.
- If you reduce the array size, the last elements deleted from the array are lost.

**Tip:** In some contexts, an alternative to using Boolean arrays is using an Integer array where each element “means true” if different from zero and “means false” if equal to zero.

## Example 1

This example creates a process array of 100 *Boolean* elements:

```
ARRAY BOOLEAN(abValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 *Boolean* elements:

```
ARRAY BOOLEAN($abValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 *Boolean* elements and sets each even element to True:

```
ARRAY BOOLEAN(◊abValues;50)
For($vlElem;1;50)
   ◊abValues{$vlElem}:=(($vlElem%2)=0)
End for
```

# ARRAY DATE

ARRAY DATE ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ➡ | Name of the array |
| size | Longint | ➡ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ➡ | Number of columns in a two-dimensional array |

## Description

The **ARRAY DATE** command creates and/or resizes an array of *Date* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to the null date (!00/00/00!).
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 Date elements:

```
ARRAY DATE(adValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 Date elements:

```
ARRAY DATE($adValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 Date elements, and sets each element to the current date plus a number of days equal to the element number:

```
ARRAY DATE(◊adValues;50)
For($vlElem;1;50)
   ◊adValues{$vlElem}:=Current date+$vlElem
End for
```

# ARRAY INTEGER

ARRAY INTEGER ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Description

The **ARRAY INTEGER** command creates and/or resizes an array of 2-byte *Integer* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying **ARRAY INTEGER** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to 0.
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 2-byte *Integer* elements:

```
ARRAY INTEGER(aiValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 2-byte *Integer* elements:

```
ARRAY INTEGER($aiValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 2-byte *Integer* elements, and sets each element to its element number:

```
ARRAY INTEGER(◊aiValues;50)
For($vlElem;1;50)
   ◊aiValues{$vlElem}:=$vlElem
End for
```

# ARRAY LONGINT

ARRAY LONGINT ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Description

The **ARRAY LONGINT** command creates and/or resizes an array of 4-byte *Longint* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

When applying **ARRAY LONGINT** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to 0.
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 4-byte Long Integer elements:

```
ARRAY LONGINT(alValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 4-byte Long Integer elements:

```
ARRAY LONGINT($alValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 4-byte Long Integer elements and sets each element to its element number:

```
ARRAY LONGINT(◊alValues;50)
For($vlElem;1;50)
   ◊alValues{$vlElem}:=$vlElem
End for
```

# ARRAY OBJECT

ARRAY OBJECT ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ➡ | Name of array |
| size | Longint | ➡ | Number of array elements or Number of arrays if size2 is specified |
| size2 | Longint | ➡ | Number of 2D array elements |

## Description

The **ARRAY OBJECT** command creates and/or resizes an array of language Object type elements in memory.

The *arrayName* parameter is the name of the array. You can use any name that conforms to 4D conventions.

The *size* parameter is the number of array elements.

The *size2* parameter is optional. If you pass it, this command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* the number of columns in each array. Each row in a two-dimensional array can be processed both as an element and an array. This means that when you work with the first dimension of a two-dimensional array, you can insert and remove entire arrays using other commands in the "Arrays" theme.

When you apply the **ARRAY OBJECT** command to an existing array:

- If you enlarge its size, existing elements are not changed and new elements are undefined. You can test whether an element is defined using the **OB Is defined** command.
- If you reduce its size, elements at the "bottom" of the array are deleted and lost.

## Example 1

Creation of a process array of 100 Object-type elements:

```
ARRAY OBJECT(arrObjects;100)
```

## Example 2

Creation of a local array of 100 rows each containing 50 Object-type elements:

```
ARRAY OBJECT($arrObjects;100;50)
```

## Example 3

Creation and filling of a local object array:

```
C_OBJECT($Children;$ref_richard;$ref_susan;$ref_james)
ARRAY OBJECT($arrayChildren;0)
OB SET($ref_richard;"name";"Richard";"age";7)
APPEND TO ARRAY($arrayChildren;$ref_richard)
OB SET($ref_susan;"name";"Susan";"age";4)
APPEND TO ARRAY($arrayChildren;$ref_susan)
OB SET($ref_james;"name";"James";"age";3)
APPEND TO ARRAY($arrayChildren;$ref_james)
 // $arrayChildren{1} -> {"name":"Richard","age":7}
 // $arrayChildren{2} -> {"name":"Susan","age":4}
 // $arrayChildren{3} -> {"name":"James","age":3}
```

# ARRAY PICTURE

ARRAY PICTURE ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array, or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Description

The **ARRAY PICTURE** command creates and/or resizes an array of *Picture* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to empty pictures. This means that **Picture size** applied to one of these elements will return *0*.
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 *Picture* elements:

```
ARRAY PICTURE(agValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 *Picture* elements:

```
ARRAY PICTURE($agValues;100;50)
```

## Example 3

This example creates an interprocess array of *Picture* elements and loads each picture into one of the elements of the array. The array's size is equal to the number of *'PICT'* resources available to the database. The array's resource name starts with *"User Intf/"*:

```
RESOURCE LIST("PICT";$aiResIDs;$asResNames)
ARRAY PICTURE(◊agValues;Size of array($aiResIDs))
$vlPictElem:=0
For($vlElem;1;Size of array(◊agValues))
   If($asResNames{$vlElem}="User Intf/@")
      $vlPictElem:=$vlPictElem+1
      GET PICTURE RESOURCE("PICT";$aiResIDs{$vlElem};$vgPicture)
      ◊agValues{$vlPictElem}:=$vgPicture
   End if
End for
ARRAY PICTURE(◊agValues;$vlPictElem)
```

# ARRAY POINTER

ARRAY POINTER ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ➡ | Name of the array |
| size | Longint | ➡ | Number of elements in the array, or Number of rows if size2 is specified |
| size2 | Longint | ➡ | Number of columns in a two-dimensional array |

## Description

The **ARRAY POINTER** command creates or resizes an array of *Pointer* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the firt dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying **ARRAY POINTER** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to null *pointer*. This means that **Nil** applied to one of these elements will return True.
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 *Pointer* elements:

```
ARRAY POINTER(apValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 *Pointer* elements:

```
ARRAY POINTER($apValues;100;50)
```

## Example 3

This example creates an interprocess array of *Pointer* elements and sets each element pointing to the table whose number is the same as the element. The size of the array is equal to the number of tables in the database. In the case of a deleted table, the row will return **Nil**.

```
ARRAY POINTER(◊apValues;Get last table number)
For($vlElem;1;Size of array(◊apValues);1;-1)
   If(Is table number valid($vlElem))
      ◊apValues{$vlElem}:=Table($vlElem)
   End if
End for
```

# ARRAY REAL

ARRAY REAL ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Description

The **ARRAY REAL** command creates and/or resizes an array of *Real* elements in memory.

- The arrayName parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying **ARRAY REAL** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to 0.
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 Real elements:

```
ARRAY REAL(arValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 Real elements:

```
ARRAY REAL($arValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 Real elements and sets each element to its element number:

```
ARRAY REAL(◊arValues;50)
For($vlElem;1;50)
   ◊arValues{$vlElem}:=$vlElem
End for
```

# ARRAY TEXT

ARRAY TEXT ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ➡ | Name of the array |
| size | Longint | ➡ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ➡ | Number of columns in a two-dimensional array |

## Description

The **ARRAY TEXT** command creates and/or resizes an array of *Text* elements in memory.

- The *arrayName* parameter is the name of the array.
- The *size* parameter is the number of elements in the array.
- The *size2* parameter is optional; if *size2* is specified, the command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* specifies the number of columns in each array. Each row in a two-dimensional array can be treated as both an element and an array. This means that while working with the first dimension of the array, you can use other array commands to insert and delete entire arrays in a two-dimensional array.

While applying **ARRAY TEXT** to an existing array:

- If you enlarge the array size, the existing elements are left unchanged, and the new elements are initialized to "" (empty string).
- If you reduce the array size, the last elements deleted from the array are lost.

## Example 1

This example creates a process array of 100 *Text* elements:

```
ARRAY TEXT(atValues;100)
```

## Example 2

This example creates a local array of 100 rows of 50 *Text* elements:

```
ARRAY TEXT($atValues;100;50)
```

## Example 3

This example creates an interprocess array of 50 *Text* elements and sets each element to the value “Element #” followed by its element number:

```
ARRAY TEXT(◊atValues;50)
For($vlElem;1;50)
   ◊atValues{$vlElem}:="Element #"+String($vlElem)
End for
```

# ARRAY TIME

ARRAY TIME ( arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrayName | Array | ⇒ | Name of array |
| size | Longint | ⇒ | Number of array elements or Number of arrays if size2 is specified |
| size2 | Longint | ⇒ | Number of 2D array elements |

## Description

The **ARRAY TIME** command creates and/or resizes an array of Time type elements in memory.

**Reminder:** In 4D, times can be processed as numeric values. In 4D versions prior to v14, you had to combine a longint array with a display format in order to manage an array of times.

The *arrayName* parameter is the name of the array.

The *size* parameter is the number of array elements.

The *size2* parameter is optional. If you pass it, this command creates a two-dimensional array. In this case, *size* specifies the number of rows and *size2* the number of columns in each array. Each row in a two-dimensional array can be processed both as an element and an array. This means that when you work with the first dimension of a two-dimensional array, you can insert and remove entire arrays using other commands in this theme.

When you apply the **ARRAY TIME** command to an existing array:

- If you enlarge its size, existing elements are not changed and new elements are initialized to the null time value (00:00:00).
- If you reduce its size, elements at the "bottom" of the array are deleted and lost.

When you apply **SELECTION TO ARRAY** or **SELECTION RANGE TO ARRAY** to a Time type field, note that they only create a Time type array if the array has not already been defined as another type, such as Longint for example.

## Example 1

This example creates a process array containing 100 Time-type elements:

```
ARRAY TIME(arrTimes;100)
```

## Example 2

This example creates a local array of 100 rows each containing 50 Time-type elements:

```
ARRAY TIME($arrTimes;100;50)
```

## Example 3

Since time arrays accept numeric values, the following code is valid:

```
ARRAY TIME($arrTimeValues;10)
$CurTime:=Current time+1
APPEND TO ARRAY($arrTimeValues;$CurTime)
$Found:=Find in array($arrTimeValues;$CurTime)
```

# ARRAY TO LIST

ARRAY TO LIST ( array ; list {; itemRefs} )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ➡ | Array from which to copy array elements |
| list | String, ListRef | ➡ | Name or reference of list into which to copy array elements |
| itemRefs | Array | ➡ | Numeric array of item reference numbers |

## Description

The **ARRAY TO LIST** command creates or replaces the hierarchical list or the choice list (created in the List editor) that is specified in *list* using the elements of the array *array.*

In the *list* parameter, you can either pass a choice list (string) or a hierarchical list reference (*ListRef*). In the latter case, this list must have already been created previously (for example using the **New list** command) in order for this command to work.

The optional *itemRefs* parameter, if specified, must be a numeric array synchronized with the array *array*. Each element, then, indicates the list item reference number for the corresponding element in *array*. If you omit this parameter, 4D automatically sets the list item reference numbers to 1, 2... N.

**Compatibility Note:** The **ARRAY TO LIST** command must be used with caution because of the following limitations:

- This command only lets you set first-level items of the list.
- When you use this command with a choice list, it modifies the structure of the application (lists are saved in the structure file), so any modifications made locally are lost when the structure file is updated in production.
- This command cannot be used in a component with a choice list because they are loaded with their structure as read only.

You can use **ARRAY TO LIST** to build a list based on the elements of an array. However, to free yourself from these restrictions and make full use of the lists of values, we recommend using the commands of the **Hierarchical Lists** theme.

## Example

The following example copies the array *atRegions* to the list called “Regions:”

```
ARRAY TO LIST(atRegions;"Regions")
```

## Example

You want to put the distinct values of a field into a list, for example to create a hierarchical pop-up menu. You can write:

```
ALL RECORDS([Company])
DISTINCT VALUES([Company]country;$arrCountries)
CountryList:=New list
ARRAY TO LIST($arrCountries;CountryList)
```

## Error management

An error *-9957* is generated when **ARRAY TO LIST** is applied to a list that is currently being edited in the Design environment List Editor. You can catch this error using an **ON ERR CALL** project method.

# ARRAY TO SELECTION

ARRAY TO SELECTION {( array ; aField {; array2 ; aField2 ; ... ; arrayN ; aFieldN}{; *} )}

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array to copy to the selection |
| aField | Field | ⇐ | Field to receive the array data |
| * | Operator | ⇒ | Await execution |

## Description

The **ARRAY TO SELECTION** command copies one or more arrays into a selection of records. All fields listed must belong to the same table.

If a selection exists at the time of the call, the elements of the array are put into the records, based on the order of the array and the order of the records. If there are more elements than records, new records are created. The records, whether new or existing, are automatically saved.

**Note:** Since it can create new records, this command does not take a table's read-only state (if any) into account (see **Record Locking**).

All the arrays must have the same number of elements. If the arrays are of different sizes, a syntax error is generated.

This command does the reverse of **SELECTION TO ARRAY**. However, the **ARRAY TO SELECTION** command does not allow fields from different tables, including related tables, even when an automatic relation exists.

When you pass the * parameter, 4D does not execute the corresponding statement line immediately but instead stores it in memory; this way you can stack several lines ending with an *. All of these lines awaiting execution are executed by one final **ARRAY TO SELECTION** statement that does not have the * parameter. For this reason, the command can now be called without any parameters.
As with the **QUERY** command, this lets you break up a complex statement into a set of lines, which is easier to read and to maintain. You can also insert intermediary statements.

**WARNING:** Use **ARRAY TO SELECTION** with caution, because it overwrites information in existing records. If a record is locked by another process during the execution of **ARRAY TO SELECTION**, that record is not modified. Any locked records are put into the process set called *LockedSet*. After **ARRAY TO SELECTION** has executed, you can test the set *LockedSet* to see if any records were locked.

**Note**: This command does not take into account the read-only/read-write state of the table containing the field.

**4D Server:** The command is optimized for 4D Server. Arrays are sent by the client machine to the server, and the records are modified or created on the server machine. As such a request is handled synchronously, the client machine must wait for the operation to be completed successfully. In the multi-user or multi-process environment, any records that are locked will not be overwritten.

## Example 1

In the following example, the two arrays *asLastNames* and *asCompanies* place data in the *[People]* table. The values from the array *asLastNames* area placed in the field *[People]Last Name* and the values from the array *asCompanies* are placed in the field *[People]Company*:

```
ARRAY TO SELECTION(asLastNames;[People]Last Name;asCompanies;[People]Company)
```

## Example 2

This example duplicates a selection of records:

```
ARRAY TEXT(a1;0)
ARRAY TEXT(a2;0)
ARRAY TEXT(a3;0)
ARRAY TEXT(a4;0)

ALL RECORDS([Table_1])
For($i;1;Get last field number(1))
```

```
   $p:=Get pointer("a"+String($i))
   SELECTION TO ARRAY(Field(1;$i)->;$p->;*)
  // Deferred building of arrays
End for
SELECTION TO ARRAY //Execution of statements

REDUCE SELECTION([Table_1];0)
For($i;1;Get last field number(1))
   $p:=Get pointer("a"+String($i))
   ARRAY TO SELECTION($p->;Field(1;$i)->;*)
  // Building selection
End for
ARRAY TO SELECTION //Execution of statements
```

# BOOLEAN ARRAY FROM SET

BOOLEAN ARRAY FROM SET ( booleanArr {; set} )

| Parameter | Type | | Description |
|---|---|---|---|
| booleanArr | Boolean array | ⇦ | Array to indicate if a record is in the set or not |
| set | String | ⇨ | Name of the set or UserSet if this parameter is omitted |

## Description

The **BOOLEAN ARRAY FROM SET** command fills an array of Booleans indicating if each record in the table is or is not in *set*.

The elements in the array are ordered in the order in which the records are created in the table (absolute record numbers). If N is the number of records in the table, element 0 of the array corresponds to record number 0, element 1 of the array corresponds to record number 1, etc.

Each element of the array is:

- **True** if the corresponding record belongs to the set.
- **False** if the corresponding record does not belong to the set.

**Warning:** The total number of elements in the *booleanArr* array is not significant. For structural reasons, this number can be different from the number of records actually present in the table. Possible extra elements are set to **False**.

If you don't pass the *set* parameter, the command will use *UserSet* in the current process.

# COPY ARRAY

COPY ARRAY ( source ; destination )

| Parameter | Type | | Description |
|---|---|---|---|
| source | Array | ⇨ | Array from which to copy |
| destination | Array | ⇦ | Array to which to copy |

## Description

The **COPY ARRAY** command creates or overwrites the destination array *destination* with the exact contents, size, and type of the source array *source*.

The *source* and *destination* arrays can be local, process, or interprocess arrays. When copying arrays, the scope of the array does not matter.

**Note:** In compiled mode, the *destination* array must be of the same type as the *source* array.

## Example

The following example fills the array named C. It then creates a new array, named D, of the same size as C and with the same contents:

```
ALL RECORDS([People]) ` Select all records in People
SELECTION TO ARRAY([People]Company;C) ` Move company field data into array C
COPY ARRAY(C;D) ` Copy the array C to the array D
```

# Count in array

Count in array ( array ; value ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array where count should occur |
| value | Expression | ⇒ | Value to count |
| Function result | Longint | ⇐ | Number of instances found |

## Description

The **Count in array** command returns the number of times *value* is found in *array*.

This command can be used with the following array types: Text, Alpha, number, Date, Pointer and Boolean. The *array* and *value* parameters must be the same type or compatible.

If no element in *array* matches *value*, the command returns 0.

## Example

The following example allows displaying the number of selected lines in a list box:

```
 //tBList is the name of a List box column array
ALERT(String(Count in array(tBList;True))+" line(s) selected in the list box")
```

# DELETE FROM ARRAY

DELETE FROM ARRAY ( array ; where {; howMany} )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array from which to delete elements |
| where | Longint | ⇒ | Element at which to begin deletion |
| howMany | Longint | ⇒ | Number of elements to delete, or 1 element if omitted |

## Description

The **DELETE FROM ARRAY** command deletes one or more elements from *array*. Elements are deleted starting at the element specified by *where*.

The *howMany* parameter is the number of elements to delete. If *howMany* is not specified, then one element is deleted. The size of the array shrinks by *howMany*.

## Example 1

The following example deletes three elements, starting at element 5:

```
DELETE FROM ARRAY(anArray;5;3)
```

## Example 2

The following example deletes the last element from an array, if it exists:

```
$vlElem:=Size of array(anArray)
If($vlElem>0)
   DELETE FROM ARRAY(anArray;$vlElem)
End if
```

# DISTINCT ATTRIBUTE PATHS

DISTINCT ATTRIBUTE PATHS ( objectField ; pathArray )

| Parameter | Type | | Description |
|---|---|---|---|
| objectField | Field | ⇒ | Indexed object field |
| pathArray | Text array | ⇐ | Array to receive list of distinct paths |

## Description

The **DISTINCT ATTRIBUTE PATHS** command returns the list of distinct paths found in the indexed object field you passed in *objectField* for the current selection of the table to which this field belongs.

In *objectField*, you must pass an Object type field that is indexed; otherwise, an error is returned.

After the call, the size of *pathArray* is equal to the number of distinct paths found in the selection. Paths to nested object attributes are returned using the standard dot notation, for example "company.address.number". Keep in mind that object attribute names are case-sensitive. The command does not change the current selection or the current record.

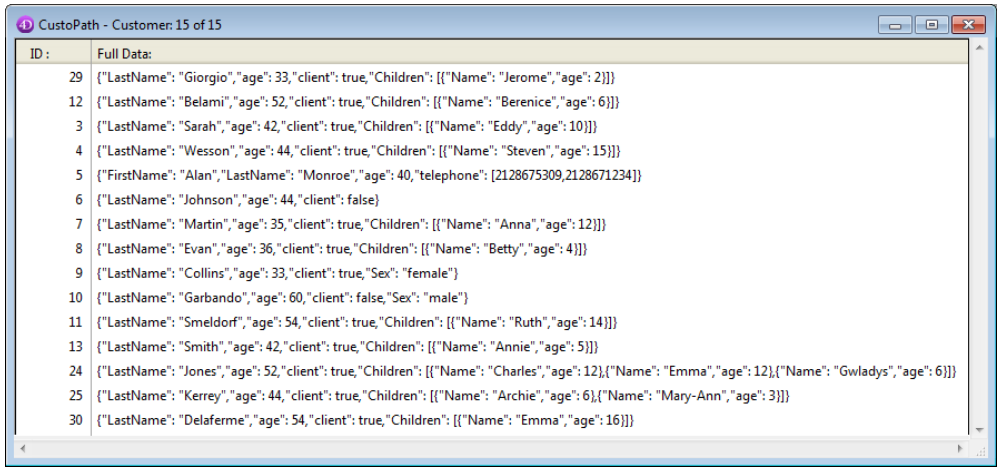
In *pathArray*, the list of distinct paths is returned in alphabetical (diacritic) order.

**Notes:**

- Records with an undefined value in the *objectField* are not taken into account.
- Attribute paths created during a transaction are taken into account by the command. It is important to note that these paths are kept in the index of the object field even if the transation has been canceled.

## Example

Your database contains a [Customer]full_Data (indexed) object field with 15 records:



If you execute this code:

```
ARRAY TEXT(aTPaths;0)
ALL RECORDS([Customer])
DISTINCT ATTRIBUTE PATHS([Customer]full_Data;aTPaths)
```

The *aTPaths* array receives the following elements:

| Element | Value |
| --- | --- |
| 1 | "age" |
| 2 | "Children" |
| 3 | "Children[]" |
| 4 | "Children[].age" |
| 5 | "Children[].Name" |
| 6 | "Children.length" |
| 7 | "client" |
| 8 | "FirstName" |
| 9 | "LastName" |
| 10 | "Sex" |
| 11 | "telephone" |
| 12 | "telephone[]" |
| 13 | "telephone.length" |

**Note:** "length" is a *virtual property* that is automatically available for all array type attributes. It provides the size of the array, i.e. the number of elements, and can be used in queries. For more information, please refer to the **Using the .length virtual property** paragraph.

# DISTINCT ATTRIBUTE VALUES

DISTINCT ATTRIBUTE VALUES ( objectField ; path ; valuesArray )

| Parameter | Type | | Description |
|---|---|---|---|
| objectField | Field | ➡ | Object field from which to get the list of distinct attribute values |
| path | Text | ➡ | Path of attribute whose distinct values you want to get |
| valuesArray | Text array, Longint array, Boolean array, Date array, Time array | ⬅ | Distinct values in attribute path |

## Description

The **DISTINCT ATTRIBUTE VALUES** command creates and populates the *valuesArray* with non-repeated (unique) values coming from the *path* attribute in the *objectField* field for the current selection of the table to which this field belongs. Note that *objectField* must be of the Object type, otherwise an error is returned. The command can be used with indexed or non-indexed fields.

Pass a valid attribute path in *path*. Use the standard dot notation to define paths to nested attributes, for example "company.address.number". Keep in mind that object attribute names are case-sensitive.

The array you passed in *valuesArray* must be of the same type as the values stored in the attribute *path*. Values must be scalar and can be of the Text, number, Boolean, Date, or Time type (pointers, objects, BLOBs or images are not supported). Make sure that all field attribute values are of the same type; otherwise, an error is returned. For example, if the *path* attribute contains "Monday" in one record and 10125 in another record, an error will be returned.

If the command is called from within a transaction, records created during the transaction are taken into account.

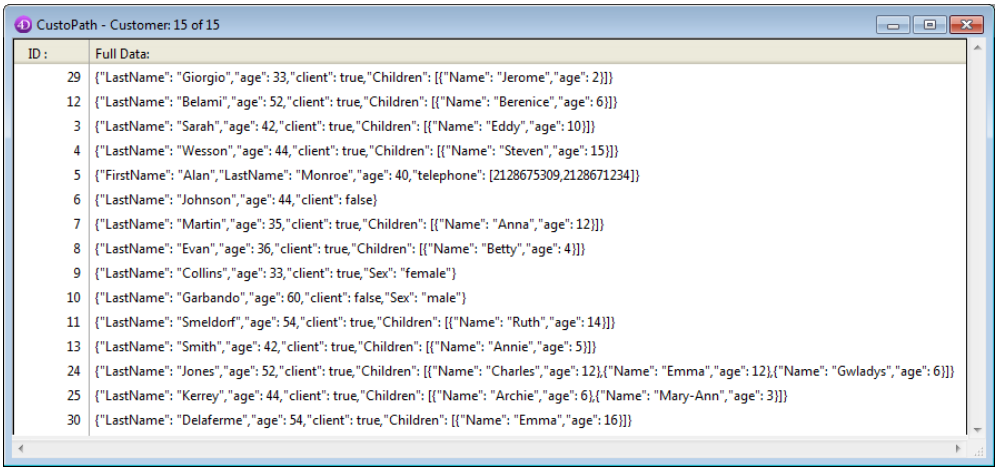
After the call, the size of the array is equal to the number of distinct values found in the selection. The command does not change the current selection or the current record.

### Using the .length virtual property

You can use the "length" virtual property with this command. It is automatically available for all attributes of the array type, and provides the size of the array, i.e. the number of elements it contains. This property is designed to be used in queries (see **QUERY BY ATTRIBUTE**). You can also use it with the **DISTINCT ATTRIBUTE VALUES** command to get the different array sizes for an attribute.

## Example

Your database contains a [Customer]full_Data object field with 15 records:



If you execute this code:

```
ARRAY LONGINT(aLAges;0)
ARRAY LONGINT(aLAgesChild;0)
ARRAY LONGINT(aLChildNum;0)
ALL RECORDS([Customer])
 //get the distinct values for the "age" attribute
DISTINCT ATTRIBUTE VALUES([Customer]full_Data;"age";aLAges)
```

```
 //get the distinct values for the "age" attribute within the "Children" array
DISTINCT ATTRIBUTE VALUES([Customer]full_Data;"Children[].age";aLAgesChild)
 //get the distinct numbers of children by using the length virtual property
DISTINCT ATTRIBUTE VALUES([Customer]full_Data;"Children.length";aLChildNum)
```

The *aLAges* array receives the following elements:

| Element | Value |
|---|---|
| 1 | 33 |
| 2 | 35 |
| 3 | 36 |
| 4 | 40 |
| 5 | 42 |
| 6 | 44 |
| 7 | 52 |
| 8 | 54 |
| 9 | 60 |

The *aLAgesChild* array receives the following elements:

| Element | Value |
|---|---|
| 1 | 2 |
| 2 | 3 |
| 3 | 4 |
| 4 | 5 |
| 5 | 6 |
| 6 | 10 |
| 7 | 12 |
| 8 | 14 |
| 9 | 15 |
| 10 | 16 |

The *aLChildNum* array receives the following elements:

| Element | Value |
|---|---|
| 1 | 1 |
| 2 | 2 |
| 3 | 3 |

# DISTINCT VALUES

DISTINCT VALUES ( aField ; array {; countArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ➡ | Indexable field to use for data |
| array | Array | ⬅ | Array to receive field data |
| countArray | Longint array, Real array | ⬅ | Array to receive count of each value |

## Description

The **DISTINCT VALUES** command creates and populates the array *array* with non-repeated (unique) values coming from the field *aField* for the current selection of the table to which the field belongs and, optionally, returns the number of occurrences of each value in the *countArray* parameter.

You can pass to **DISTINCT VALUES** any **indexable** field, that is, whose type supports indexing without necessarily being indexed.
However, executing this command on unindexed fields will be slower. Also note that, in this case, the command loses the current record.

**DISTINCT VALUES** browses and retains the non-repeated values present only in the currently selected records.

**Note:** When the **DISTINCT VALUES** command is called during a transaction (that has not yet finished), it **will take** into account records created during that transaction.

The array used by **DISTINCT VALUES** must be of the same type as the field passed as first parameter, otherwise the array is retyped. There is one exception to this rule: if the field is of the Picture type (and is associated with a keyword index), the corresponding array must be of the Text type.

After the call, the size of the array is equal to the number of distinct values found in the selection. The command does not change the current selection or the current record. The **DISTINCT VALUES** command uses the index of the field, so the elements in *array* are returned sorted in ascending order. If this is the order you need, you do not need to call **SORT ARRAY** after using **DISTINCT VALUES**.

**Note:** When **DISTINCT VALUES** is executed with a text or picture field associated with a keyword index, the command fills the array with the keywords of the index. Unlike other types of data, the values returned differ according to the existence of the index. In the case of a Text field, the keyword index is always taken into account, even when the field is also associated with a standard index. If the Text or Picture field is not associated with a keyword index, the array is returned empty.

The command accepts a *countArray* array as an optional parameter. When it is passed, this array returns, for each non-repeated value in *aField*, the number of occurrences detected in the current selection. The *countArray* array is automatically sized to the number of elements in *array*. For example, for a selection that contains three records with field values "A", "B", and "A", *array* will contain {A;B} and *countArray* will contain {2;1}. You can pass either a Longint array or a Real array in *countArray*.

**Note:** The *countArray* parameter is not supported for text or picture fields that are associated with keyword indexes (in this context, it is returned empty).

**WARNING: DISTINCT VALUES** can create large arrays depending on the size of the selection and the number of different values in the records. Arrays reside in memory, therefore it is a good idea to test the result after the completion of the command. To do so, test the size of the resulting array or cover the call to the command, using an **ON ERR CALL** project method.

**4D Server:** The command is optimized for 4D Server. The array is created and the values are calculated on the server machine; the array is then sent, in its entirety, to the client.

**Note:** This command does not support Object type fields.

## Example 1

The following example creates a list of cities from the current selection and tells the user the number of cities in which the firm has stores:

```
ALL RECORDS([Retail Outlets]) ` Create a selection of records
DISTINCT VALUES([Retail Outlets]City;asCities)
```

```
ALERT("The firm has stores in "+String(Size of array(asCities))+" cities.")
```

## Example 2

You want to get a complete list of keywords contained in the keyword index for the "Pictures" field:

```
ALL RECORDS([PICTURES])
ARRAY TEXT(<>_MyKeywords;10)
DISTINCT VALUES([PICTURES]Photos;<>_MyKeywords)
```

## Example 3

To compute statistics, you want to sort the number of distinct values in a field in descending order:

```
ARRAY TEXT($_issue_type;0)
ARRAY LONGINT($_issue_type_instance;0)
DISTINCT VALUES([Issue]iType;$_issue_type;$_issue_type_instances)
SORT ARRAY($_issue_type_instances;$_issue_type;<)
```

# Find in array

Find in array ( array ; value {; start} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ➡ | Array to search |
| value | Expression | ➡ | Value of same type to search in the array |
| start | Longint | ➡ | Element at which to start searching |
| Function result | Longint | ↩ | Number of the first element in array that matches value |

## Description

The **Find in array** command returns the number of the first element in *array* that matches *value*.

**Find in array** can be used with Text, String, Numeric, Date, Pointer, and Boolean arrays. The *array* and *value* parameters must be of the same type.

If no match is found, **Find in array** returns -1.

If *start* is specified, the command starts searching at the element number specified by *start*. If *start* is not specified, the command starts searching at element 1.

## Example 1

The following project method deletes all empty elements from the string or text array whose pointer is passed as parameter:

```
  ` CLEAN UP ARRAY project method
  ` CLEAN UP ARRAY ( Pointer )
  ` CLEAN UP ARRAY ( -> Text or String array )

C_POINTER($1)
Repeat
   $vlElem:=Find in array($1->;"")
   If($vlElem>0)
      DELETE FROM ARRAY($1->;$vlElem)
   End if
Until($vlElem<0)
```

After this project method is implemented in a database, you can write:

```
ARRAY TEXT(atSomeValues;...)
  ` ...
  ` Do plenty of things with the array
  ` ...
  ` Eliminate empty string elements
CLEAN UP ARRAY(->atSomeValues)
```

## Example 2

The following project method selects the first element of an array whose pointer is passed as the first parameter that matches the value of the variable or field whose pointer is passed as parameter:

```
  ` SELECT ELEMENT project method
  ` SELECT ELEMENT ( Pointer ; Pointer)
  ` SELECT ELEMENT ( -> Text or String array ; -> Text or String variable or field )

$1->:=Find in array($1->;$2->)
If($1->=-1)
   $1->:=0 ` If no element was found, set the array to no selected element
End if
```

After this project method is implemented in a database, you can write:

```
   ` asGender pop-up menu object method
Case of
   :(Form event=On Load)
      SELECT ELEMENT(->asGender;->[People]Gender)

End case
```

**Note:** This example uses the **selected element** of the array. Keep in mind that the selected element is not meaningful if the array contains more than 32,767 elements (see **Arrays and Form Objects**). In this case, you need to use a longint variable to store the result of **Find in array**.

# Find in sorted array

Find in sorted array ( array ; value ; > or < {; posFirst {; posLast}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array to search |
| value | Expression | ⇒ | Value (same type as array) to search for in the array |
| > or < | Operator | ⇒ | > if array is sorted in ascending order, < if it is sorted in descending order |
| posFirst | Longint | ⇐ | Position of its first occurrence if the value is found; otherwise position where the value should be inserted |
| posLast | Longint | ⇐ | Position of its last occurrence if the value is found; otherwise same as posFirst |
| Function result | Boolean | ⇐ | True if at least one element in array matches the value, False otherwise |

## Description

The **Find in sorted array** command returns **true** if at least one element in the sorted *array* matches the *value*, and optionally returns position(s) of matched element(s). Unlike **Find in array**, **Find in sorted array** only works with a sorted *array* and provides information about the position of occurrences, which allows you to insert elements if necessary.

The *array* must be already sorted and must match the ordering specified by the *> or <* parameter (i.e. the "greater than" symbol for ascending order and the "lower than" symbol for descending order). The **Find in sorted array** command will take advantage of the sort and use a *binary search* algorithm, which is much more efficient for large arrays (for more information, please refer to the binary search algorithm page on Wikipedia). However, if the array is not properly sorted, the result may be incorrect.

The command will ignore the sort indication and behave like a standard **Find in array** (sequential search, returning -1 for *posFirst* and *posLast* if the *value* is not found) in any of the following cases:

- if the array type cannot be sorted (e.g. pointer arrays),
- if the array is of type boolean (not accurate),
- if the database is not Unicode (compatibility mode) and the array is a string or text array,
- when searching in a text array for a string that includes a wildcard ('@') at the beginning or in the middle of the string (using a binary search with such a wildcard character is not possible because matching elements may be non-contiguous in the array).

In case the command returns **False**, the value returned in *posFirst* can be passed to **INSERT IN ARRAY** to insert the *value* into the array while keeping the array sorted. This sequence is faster than inserting a new item at the end of the array and then calling **SORT ARRAY** to move it to the right place.

The value returned in *posLast* can be combined with the value returned in *posFirst* to iterate on each element of the array matching the *value* (with a **For...End for** loop) or to find the number of occurrences (as would be found by **Count in array**, but faster).

## Example 1

You want to insert a value, if necessary, while keeping the array sorted:

```
C_LONGINT($pos)
If(Find in sorted array($array ;$value ;>;$pos)
   ALERT("Found at pos "+String($pos))
Else
   INSERT IN ARRAY($array ;$pos)
   $array{$pos}:=$value
End if
```

## Example 2

You want to find the number of occurrences of strings starting with "test" and create a string that concatenates all these elements:

```
C_LONGINT($posFirst ;$posLast)
C_TEXT($output)
```

```
If(Find in sorted array($array ;"test@";>;$posFirst ;$posLast))
   $output:="Found "+String($posLast-$posFirst+1)+" results :¥n"
End if
For($i ;$posFirst ;$posLast)
   $output:=$output+$array{$i}+"¥n"
End for
```

# INSERT IN ARRAY

INSERT IN ARRAY ( array ; where {; howMany} )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Name of the array |
| where | Longint | ⇒ | Where to insert the elements |
| howMany | Longint | ⇒ | Number of elements to be inserted, or 1 element if omitted |

## Description

The **INSERT IN ARRAY** command inserts one or more elements into the array *array*. The new elements are inserted before the element specified by *where*, and are initialized to the empty value for the array type. All elements beyond *where* are consequently moved within the array by an offset of one or the value you pass in *howMany*.

If *where* is greater than the size of the array, the elements are added to the end of the array.

The *howMany* parameter is the number of elements to insert. If *howMany* is not specified, then one element is inserted. The size of the array grows by *howMany*.

## Example 1

The following example inserts five new elements, starting at element 10:

```
INSERT IN ARRAY(anArray;10;5)
```

## Example 2

The following example appends an element to an array:

```
$vlElem:=Size of array(anArray)+1
INSERT IN ARRAY(anArray;$vlElem)
anArray{$vlElem}:=...
```

# LIST TO ARRAY

LIST TO ARRAY ( list ; array {; itemRefs} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | String, ListRef | ⇒ | Name or Reference of list from which to copy the first level items |
| array | Array | ⇐ | Array to which to copy the list items |
| itemRefs | Array | ⇐ | List item reference numbers |

## Description

The **LIST TO ARRAY** command creates or overrides the array *array* with the first level items of the list or choice list designated by *list*.

In the list parameter, you can pass either the name of a choice list (string), or a reference to a hierarchical list (*ListRef*).

If you do not set the array as an Alpha or Text type beforehand, **LIST TO ARRAY** creates a new Text array by default.

**Note:** In compiled mode, the *array* must have been defined previously and cannot be retyped.

The optional *itemRefs* parameter (a numeric array) returns the list item reference numbers.

You can use **LIST TO ARRAY** to build an array based on the first level items of a list. However, this command does not allow you to work with any of the list's child items. When working with hierarchical lists, we recommend that you use the hierarchical lists commands, in particular **Load list**.

## Example 1

The following example copies the items of a list called Regions into an array called *atRegions*:

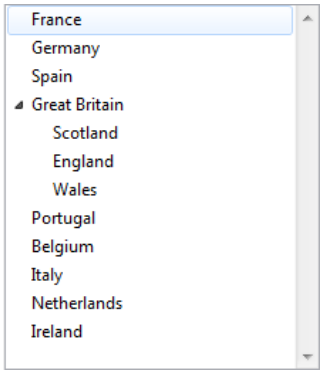
```
LIST TO ARRAY("Regions";atRegions)
```

## Example 2

Given a hierarchical list created as follows:

```
myList2:=New list
APPEND TO LIST(myList2;"Scotland";1)
APPEND TO LIST(myList2;"England";2)
APPEND TO LIST(myList2;"Wales";3)
myList1:=New list
APPEND TO LIST(myList1;"France";1)
APPEND TO LIST(myList1;"Germany";2)
APPEND TO LIST(myList1;"Spain";3)
APPEND TO LIST(myList1;"Great Britain";4;myList2;True)
APPEND TO LIST(myList1;"Portugal";5)
APPEND TO LIST(myList1;"Belgium";6)
APPEND TO LIST(myList1;"Italy";7)
APPEND TO LIST(myList1;"Netherlands";8)
APPEND TO LIST(myList1;"Ireland";9)
```

This list can be represented as:



If you execute the following statement:

```
LIST TO ARRAY(myList1;$MyArray)
```

...you get

```
$MyArray{1}="France"
$MyArray{2}="Germany"
$MyArray{3}="Spain"
$MyArray{4}="Great Britain"
$MyArray{5}="Portugal"
...
```

# LONGINT ARRAY FROM SELECTION

LONGINT ARRAY FROM SELECTION ( aTable ; recordArray {; selection} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table of the current selection |
| recordArray | Longint array | ⇐ | Array of record numbers |
| selection | String | ⇒ | Name of the named selection or the current selection if this parameter is omitted |

## Description

The **LONGINT ARRAY FROM SELECTION** command fills the *recordArray* array with the (absolute) record numbers that are in *selection*.

If you do not pass the *selection* parameter, the command will use the current selection of *aTable*.

**Note:** The array element number 0 is initialized to -1.

## Example

You want to retrieve the numbers of the records in the current selection:

```
ARRAY LONGINT($_arrRecNum;0) //mandatory for compiled mode
LONGINT ARRAY FROM SELECTION([Clients];$_arrRecNum)
```

# MULTI SORT ARRAY

MULTI SORT ARRAY ( array {; sort}{; array2 ; sort2 ; ... ; arrayN ; sortN} )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array(s) to be sorted |
| sort | Operator | ⇒ | ">" to sort by increasing order or "<" to sort by decreasing order If omitted no sort |

MULTI SORT ARRAY ( ptrArrayName ; sortArrayName )

| Parameter | Type | | Description |
|---|---|---|---|
| ptrArrayName | Pointer array | ⇒ | Array of array pointers |
| sortArrayName | Longint array | ⇒ | Sort order array (1 = sort by increasing order, -1 = sort by decreasing order, 0 = synchronization with previous sorts) |

## Description

The **MULTI SORT ARRAY** command enables you to carry out a multi-level sort on a set of arrays.

This command accepts two different syntaxes.

- **First syntax: MULTI SORT ARRAY (array{; sort}{; array2; sort2; ...; arrayN; sortN})**

This syntax is the simplest; it lets you directly pass the names of the synchronized arrays where you want to apply a multi-criteria sort.

You can pass an unlimited number of pairs (*array;> or <*) and/or only arrays. All the arrays passed as parameters are sorted in a synchronized manner.

You can pass arrays of any type except for Pointer or Picture arrays. You can sort an element of a two-dimensional array (i.e. *a2DArray{$vlThisElement}*), but you cannot sort the 2D array itself (i.e. *a2DArray*).

To use the contents of an array as sort criteria, pass the *sort* parameter. The value of the parameter (> or <) determines the order (ascending or descending) in which the array will be sorted. If the *sort* parameter is omitted, the contents of the array are not used as sort criteria.

**Note:** Keep in mind that at least one sort criterion must be passed in order for the command to work. If no sort criterion is set, an error is generated.

The sort levels are determined by the order in which the arrays are passed to the command: the position of an array with a sort criterion in the syntax determines its sort level.

- **Second syntax: MULTI SORT ARRAY (ptrArrayName; sortArrayName)**

This syntax, more complex, is also invaluable for generic developments (for example, you can create a generic method for sorting arrays of all types, or yet again, create the equivalent of a generic **SORT ARRAY** command).

The *ptrArrayName* parameter contains the name of an array of array pointers; each element of this array is a pointer designating an array to be sorted. The sorts are performed in the order of the array pointers defined by *ptrArrayName*.
**Warning:** all the arrays pointed to by *ptrArrayName* must have the same number of elements.

**Note:** *ptrArrayName* can be an array of local ($ptrArrayName), process (ptrArrayName) or inter-process (<>ptrArrayName) pointers. Conversely, the elements of this array must point to process or inter-process arrays only.

The *sortArrayName* parameter contains the name of an array in which each element indicates the sorting order (-1, 0 or 1) of the element of the corresponding array of pointers:
-1 = Sort by decreasing order.
0 = The array is not used as a sorting criterion but must be sorted according to the other sorts.
1 = Sort by increasing order.

**Note:** You cannot sort arrays of the Pointer or Picture type. You can sort an element of a two-dimensional array (i.e. a2DArray{$vlThisElement}), but you cannot sort the 2D array itself (i.e. a2DArray).

For each element of the *ptrArrayName* array, there must be a corresponding element of the *sortArrayName* array. Both arrays must therefore have exactly the same number of elements.

## Example 1

The following example uses the first syntax: it creates four arrays and sorts them by city (ascending order) then by salary (descending order) with the last two arrays, *names_array* and *telNum_array*, being synchronized according to the previous sort criteria:

```
ALL RECORDS([Employees])
SELECTION TO ARRAY([Employees]City;cities;[Employees]Salary;salaries;[Employees]Name;
names;[Employees]TelNum;telNums)
MULTI SORT ARRAY(cities;>;salaries;<;names;telNums)
```

If you want for the names array to be used as the third sort criteria, just add > or < after the *names_array* parameter. Note that the syntax:

```
MULTI SORT ARRAY(cities;>;salaries;names;telNums)
```

is equivalent to:

```
SORT ARRAY(cities;salaries;names;telNums;>)
```

## Example 2

The following example uses the second syntax: it creates four arrays and sorts them by city (increasing order) and company (decreasing order); the last two arrays, names_Array and telNum_Array, being synchronized according to previous sort criteria:

```
ALL RECORDS([Employees])
SELECTION TO ARRAY([Employees]City;cities;[Employees]Company;companies;[Employees]Name;
names;[Employees]TelNum;telNums)
ARRAY POINTER(pointers_Array;4)
ARRAY LONGINT(sorts_Array;4)
pointers_Array{1}:=->cities
sorts_Array{1}:=1
pointers_Array{2}:=->companies
sorts_Array{2}:=-1
pointers_Array{3}:=->names
sorts_Array{3}:=0
pointers_Array{4}:=->telNums
sorts_Array{4}:=0
MULTI SORT ARRAY(pointers_Array;sorts_Array)
```

If you want the array of names be used as a third sort criterion, you need to assign the value 1 to the sorts_Array{3} element. Or else, if you want the arrays to be sorted only by the city criterion, assign the value 0 to the sorts_Array{2}, sorts_Array{3} and sorts_Array{4} elements. In this way, you obtain an identical result to **SORT ARRAY***(cities;companies;names;telNums;>)*.

# SELECTION RANGE TO ARRAY

SELECTION RANGE TO ARRAY ( start ; end {; aField | aTable ; array} {; aField | aTable2 ; array2 ; ... ; aField | aTableN ; arrayN} )

| Parameter | Type | | Description |
|---|---|---|---|
| start | Longint | ➡ | Selected record number where data retrieval starts |
| end | Longint | ➡ | Selected record number where data retrieval ends |
| aField \| aTable | Field, Table | ➡ | Field to use for retrieving data or Table to use for retrieving record numbers |
| array | Array | ⬅ | Array to receive field data or record numbers |

## Description

**SELECTION RANGE TO ARRAY** creates one or more arrays and copies data from the fields or record numbers from the current selection into the arrays.

Unlike **SELECTION TO ARRAY**, which applies to the current selection in its entirety, **SELECTION RANGE TO ARRAY** only applies to the range of selected records specified by the parameters *start* and *end*.

The command expects you to pass in *start* and *end* the selected record numbers complying with the formula *1 <= start <= end <= Records in selection ([...])*.

If you pass *1 <= start = end < Records in selection ([...])*, you will load fields or get the record number from the record whose selected record is *start = end*.

If you pass incorrect selected record numbers, the command does the following:

- If *end > Records in selection ([...])*, it returns values from the selected record specified by *start* to the last selected record.
- If *start > end*, it returns values from the record whose selected record is *start* only.
- If both parameters are inconsistent with the size of the selection, it returns empty arrays.

Like **SELECTION TO ARRAY**, the **SELECTION RANGE TO ARRAY** command applies to the selection for the table specified in the first parameter.

Also like **SELECTION TO ARRAY**, **SELECTION RANGE TO ARRAY** can perform the following:

- Load values from one or several fields.
- Load Record numbers using the syntax *...;[table];Array;...*
- Load values from related fields, if there is a Many to One automatic relation between the tables or if you have previously called **SET AUTOMATIC RELATIONS** to change manual Many to One relations to automatic. In both cases, values can be loaded from tables through several levels of Many to One relations.

Each array is typed according to the field type.

When you apply **SELECTION RANGE TO ARRAY** to a Time type field, it is important to note that they only create a Time type array if the array has not already been defined as another type. For example, in the following context, the *myArray* array remains a Longint type array:

```
ARRAY LONGINT(myArray;0)
SELECTION TO ARRAY([myTable]myTimeField;myArray)
```

If you load record numbers, they are copied into a Long Integer array.

**Note:** You can call the **SELECTION RANGE TO ARRAY** command with just the *start* and *end* parameters. You use this special syntax to launch, on a limited selection, the execution of a deferred series of **SELECTION TO ARRAY** commands using the * parameter (see example 4).

**4D Server**: **SELECTION RANGE TO ARRAY** is optimized for 4D Server. Each array is created on the server and then sent, in its entirety, to the client machine.

**WARNING: SELECTION RANGE TO ARRAY** can create large arrays, depending on the range you specify in *start* and *end,* and on the type and size of the data you are loading. Arrays reside in memory, so it is a good idea to test the result after the command is completed. To do so, test the size of each resulting array or cover the call to the command, using an **ON ERR CALL** project method.

If the command is successful, the size of each resulting array is equal to *(end-start)+1*, except if the *end* parameter exceeded the number of records in the selection. In such a case, each resulting array contains *(Records in selection([...])-start)+1* elements.

## Example 1

The following code addresses the first 50 records from the current selection for the *[Invoices]* table. It loads the values from the *[Invoices]Invoice ID* field and the *[Customers]Customer ID* related field.

```
SELECTION RANGE TO ARRAY(1;50;[Invoices]Invoice ID;alInvoID;[Customers]Customer ID;alCustID)
```

## Example 2

The following code addresses the last 50 records from the current selection for the *[Invoices]* table. It loads the record numbers of the *[Invoices]* records as well as those of the *[Customers]* related records:

```
lSelSize:=Records in selection([Invoices])
SELECTION RANGE TO ARRAY(lSelSize-49;lSelSize;[Invoices];alInvRecN;[Customers];alCustRecN)
```

## Example 3

The following code process, in sequential “chunks”of 1000 records, a large selection that could not be downloaded in its entirety into arrays:

```
lMaxPage:=1000
lSelSize:=Records in selection([Phone Directory])
For($lPage ;1;1+((lSelSize-1)¥lMaxPage))
  ` Load the values and/or record numbers
   SELECTION RANGE TO ARRAY(1+(lMaxPage*($lPage-1));lMaxPage*$lPage;...;...;...;...;...;...)
  ` Do something with the arrays
End for
```

## Example 4

Use the first 50 current records of the [Invoices] table to load various arrays, in deferred execution:

```
 // Deferred statements
SELECTION TO ARRAY([Invoices]InvoiceRef;arrLInvRef;*)
SELECTION TO ARRAY([Invoices]Date;arrDInvDate;*)
SELECTION TO ARRAY([Clients]ClientRef;arrLClientRef;*)
 // Execution of deferred statements
SELECTION RANGE TO ARRAY(1;50)
```

# SELECTION TO ARRAY

SELECTION TO ARRAY {( aField | aTable ; array {; aField ; array {; aField2 ; array2 ; ... ; aFieldN ; arrayN}}{; *})}

| Parameter | Type | | Description |
|---|---|---|---|
| aField \| aTable | Field, Table | ➡ | Field to use for retrieving data or Table to use for retrieving record numbers |
| array | Array | ⬅ | Array to receive field data or record numbers |
| aField | Field | ➡ | Field to retrieve in array |
| array | Array | ⬅ | Array to receive field data |
| * | Operator | ➡ | Await execution |

## Description

The **SELECTION TO ARRAY** command creates one or more arrays and copies data in the fields or record numbers from the current selection into the arrays.

The command **SELECTION TO ARRAY** applies to the selection for the table designated by the first parameter (table name or field name). **SELECTION TO ARRAY** can perform the following:

- Load values from one or several fields.
- Load Record numbers from the table using the syntax *[table];array*
- Load values from related fields, provided that there is a Many to One automatic relation between the tables or provided that you have previously called **SET AUTOMATIC RELATIONS** to make manual Many to One relations automatic. In both cases, values are loaded from tables through several levels of Many to One relations.

Each array is typed according to the field type.

When you apply **SELECTION TO ARRAY** to a Time type field, it is important to note that they only create a Time type array if the array has not already been defined as another type. For example, in the following context, the *myArray* array remains a Longint type array:

```
ARRAY LONGINT(myArray;0)
SELECTION TO ARRAY([myTable]myTimeField;myArray)
```

If you load record numbers, they are copied into a Long Integer array.

When you pass the * parameter, 4D does not execute the corresponding statement line immediately but instead stores it in memory; this way you can stack several lines ending with an *. All of these lines awaiting execution are executed by one final **SELECTION TO ARRAY** statement that does not have the * parameter. For this reason, the command can now be called without any parameters. In this case, array types are verified when the final line (without the * parameter) is executed.
As with the **QUERY** command, this lets you break up a complex statement into a set of lines, which is easier to read and to maintain. You can also insert intermediary statements or build an array within a loop (see example 2 of the **ARRAY TO SELECTION** command).

**4D Server:** The **SELECTION TO ARRAY** command is optimized for 4D Server. Each array is created on the server and then sent, in its entirety, to the client machine.

**WARNING:** The **SELECTION TO ARRAY** command can create large arrays, depending on the size of the current selection and on the type and size of the data you are loading. Arrays reside in memory, so it is a good idea to test the result after the command is completed. To do so, test the size of each resulting array or cover the call to the command, using an **ON ERR CALL** project method.

**Note:** After a call to **SELECTION TO ARRAY**, the current selection and current record remain the same, but the current record is no longer loaded. If you need to use the values of the fields in the current record, use the **LOAD RECORD** command after the **SELECTION TO ARRAY** command.

## Example 1

In the following example, the *[People]* table has an automatic relation to the [Company] table. The two arrays *asLastName* and *asCompanyAddr* are sized according to the number of records selected in the *[People]* table and will contain information from both tables:

```
SELECTION TO ARRAY([People]Last Name;asLastName;[Company]Address;asCompanyAddr)
```

## Example 2

The following example returns the *[Clients]* record numbers in the array *alRecordNumbers* and the *[Clients]Names* field values in the array *asNames*:

```
SELECTION TO ARRAY([Clients];alRecordNumbers;[Clients]Names;asNames)
```

The same example can be written:

```
SELECTION TO ARRAY([Clients];alRecordNumbers;*)
SELECTION TO ARRAY([Clients]Names;asNames;*)
SELECTION TO ARRAY
```

# Size of array

Size of array ( array ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Array whose size is returned |
| Function result | Longint | ⇐ | Returns the number of elements in array |

## Description

The **Size of array** command returns the number of elements in *array*.

## Example 1

The following example returns the size of the array *anArray*:

```
vlSize:=Size of array(anArray) ` vlSize gets the size of anArray
```

## Example 2

The following example returns the number of rows in a two-dimensional array:

```
vlRows:=Size of array(a2DArray) ` vlRows gets the size of a2DArray
```

## Example 3

The following example returns the number of columns for a row in a two-dimensional array:

```
vlColumns:=Size of array(a2DArray{10}) ` vlColumns gets the size of a2DArray{10}
```

# SORT ARRAY

SORT ARRAY ( array {; array2 ; ... ; arrayN}{; > or <} )

| Parameter | Type | | Description |
|---|---|---|---|
| array | Array | ⇒ | Arrays to sort |
| > or < | Operator | ⇒ | ">" to sort in Ascending order, or "<" to sort in Descending order, or Ascending order if omitted |

## Description

The **SORT ARRAY** command sorts one or more arrays into ascending or descending order.

**Note:** You cannot sort *Pointer* or *Picture* arrays. You can sort the elements of a two-dimensional array (i.e., *a2DArray{$vlThisElem}*) but you cannot sort the two-dimensional array itself (i.e., *a2DArray*).

The last parameter specifies whether to sort *array* in ascending or descending order. The “greater than” symbol (>) indicates an ascending sort; the “less than” symbol (<) indicates a descending sort. If you do not specify the sorting order, then the sort is ascending.

If more than one array is specified, the arrays are sorted following the sort order of the first array; no multi-level sorting is performed here. Instead you can use the **MULTI SORT ARRAY** command when you want to sort synchronized arrays.

## Example 1

The following example creates two arrays and then sorts them by company:

```
ALL RECORDS([People])
SELECTION TO ARRAY([People]Name;asNames;[People]Company;asCompanies)
SORT ARRAY(asCompanies;asNames;>)
```

However, because **SORT ARRAY** does not perform multi-level sorts, you will end up with people’s names in random order within each company. To sort people by name within each company, you would write:

```
ALL RECORDS([People])
ORDER BY([People];[People]Company;>;[People]Name;>)
SELECTION TO ARRAY([People]Name;asNames;[People]Company;asCompanies)
```

## Example 2

You display the names from a *[People]* table in a floating window. When you click on buttons present in the window, you can sort this list of names from A to Z or from Z to A. As several people may have the same name, you also can use a *[People]ID number* field, which is indexed unique. When you click in the list of names, you will retrieve the record for the name you clicked. By maintaing a synchronized and hidden array of ID numbers, you are sure to access the record corresponding to the name you clicked:

```
  ` asNames array object method
Case of
   :(Form event=On Load)
      ALL RECORDS([People])
      SELECTION TO ARRAY([People]Name;asNames;[People]ID number;alIDs)
      SORT ARRAY(asNames;alIDs;>)
   :(Form event=On Unload)
      CLEAR VARIABLE(asNames)
      CLEAR VARIABLE(alIDs)
   :(Form event=On Clicked)
      If(asNames#0)
  ` Use the array alIDs to get the right record
         QUERY([People];[People]ID Number=alIDs{asNames})
  ` Do something with the record
      End if
End case
```

```
  ` bA2Z button object method
  ` Sort the arrays in ascending order and keep them synchronized
SORT ARRAY(asNames;alIDs;>)

  ` bZ2A button object method
  ` Sort the arrays in descending order and keep them synchronized
SORT ARRAY(asNames;alIDs;<)
```

# TEXT TO ARRAY

TEXT TO ARRAY ( varText ; arrText ; width ; fontName ; fontSize {; fontStyle {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| varText | Text | ⇒ | Original text to be divided |
| arrText | Text array | ⇐ | Array containing the text divided into words or lines |
| width | Longint | ⇒ | Maximum width of string (in pixels) |
| fontName | Text | ⇒ | Name of font |
| fontSize | Longint | ⇒ | Size of font |
| fontStyle | Longint | ⇒ | Style of font |
| * | Operator | ⇒ | If passed = interpret text as multistyle |

## Description

The **TEXT TO ARRAY** command transforms a text variable into a text array. The original varText text (styled or not) is divided and each part becomes an element of the *arrText* array that is returned by the command. This command can be used for example to fill pages or columns with text of a set size.

The original text is divided into "words" based on a line size defined by the command parameters and which takes any styles used into account.

In the *varText* parameter, you pass the text to be divided into array elements. This text may or may not be multistyle. Some parameters are ignored when the text is multistyle.

In the *arrText* parameter, you pass the name of the array to be filled by the divided text.

In the *width* parameter, you pass a size in pixels indicating the maximum line length to measure when dividing the text. For the entire text, the command evaluates the maximum number of words that can "fit" into this width based on the graphic attributes of the text (font, style).

- If it is multistyle text, the styles of the original text are taken into account and the following parameters are ignored if they are passed. In this case, the lines of text in the resulting array keep their original styles (so that they can be printed one by one through a text or string variable for example).
- If it is raw text (no styles), you must pass all the parameters so that the command is able to calculate the length of the lines.

Each array element must contain at least one word. If the *width* passed is too small for the dividing rule to be strictly respected, the array is filled as close as possible according to the parameters and the OK variable is set to 0. For example, if you pass a width of 3 pixels, it is probable that most of the words will be bigger than this length. In this case, the OK variable is set to 0.
This also means that the theoretical maximum size of the array returned is equal to the number of words found in *varText*.

In the *fontName* and *fontSize* parameters, you pass the font name and size with which *varText* must be evaluated by the command in order to divide it. These parameters are mandatory in the case of raw text.

In the *fontStyle* parameter, you pass one or more constants from the **Font Styles** theme:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

This parameter is optional; when it is omitted, the Plain style is used.

The optional * parameter, if passed, forces the *fontName*, *fontSize* and/or *fontStyle* parameters to be taken into account for multistyle text when these parameters are not defined in the original text. However, if these parameters are defined in the original text, then the parameters passed to the command are ignored in all cases.

## Example 1

We want to divide a multistyle text into lines with a maximum size of 200 pixels:

```
TEXT TO ARRAY(theText;TextArray;200;"Arial";20;Plain;*)
 // the Arial, 20, and Normal attributes are only taken into account if they are not defined in the text
```

## Example 2

We want to divide raw text into lines with a maximum size of 350 pixels in Bodoni Bold font, size 14. Since the command does not work correctly if the font is not available, it is important to check for its presence:

```
ARRAY TEXT($FontList;0)
FONT LIST($FontList)
$Font:="Bodoni"
$p:=Find in array($FontList;$Font)
If($p>0)
   TEXT TO ARRAY(theText;TextArray;350;"Bodoni";14;Bold)
Else
 // use another font
End if
```

## Example 3

Multistyle text must be printed without any styles in Arial Normal font, size 12 with a maximum width of 600 pixels:

```
 // we transform the multistyle text into raw text
$RawText:=OBJECT Get plain text(vText)
 // we fill the array
TEXT TO ARRAY($RawText;TextArray;600;"Arial";12)
```

## Example 4

You need to print in a 400-pixel wide area, a text with a maximum of 80 lines and using the largest font possible (without exceeding 24 points). You can write:

```
ARRAY TEXT(TextArray;0)
$Size:=24
Repeat
   TEXT TO ARRAY($RawText;TextArray;400;"Arial";$Size)
   $Size:=$Size-1
   $n:=Size of array(TextArray)
Until($n<=80)
```

# _o_ARRAY STRING

_o_ARRAY STRING ( strLen ; arrayName ; size {; size2} )

| Parameter | Type | | Description |
|---|---|---|---|
| strLen | Longint | ⇒ | Length of string (1... 255) |
| arrayName | Array | ⇒ | Name of the array |
| size | Longint | ⇒ | Number of elements in the array or Number of rows if size2 is specified |
| size2 | Longint | ⇒ | Number of columns in a two-dimensional array |

## Compatibility note

The operation of the **_o_ARRAY STRING** command is strictly identical to that of the **ARRAY TEXT** command (the *strLen* parameter is ignored). It is now recommended to use **ARRAY TEXT** exclusively in your 4D developments.

# Backup

- On Backup Shutdown Database Method
- On Backup Startup Database Method
- BACKUP
- CHECK LOG FILE
- GET BACKUP INFORMATION
- GET RESTORE INFORMATION
- INTEGRATE MIRROR LOG FILE
- Log File
- LOG FILE TO JSON
- New log file
- RESTORE
- SELECT LOG FILE
- *_o_INTEGRATE LOG FILE*

# On Backup Shutdown Database Method

---

The **On Backup Shutdown Database Method** is called every time a database backup ends. The reasons for the stoppage of a backup can be the end of the copy, user interruption or an error.
This concerns all 4D environments: 4D (all modes), 4D Server as well as 4D applications compiled and merged with 4D Volume Desktop.

The **On Backup Shutdown Database Method** allows verifying that the backup was executed correctly. It receives, in the *$1* parameter, a value representing the status of the backup once completed:

- If the backup was executed correctly, *$1* equals 0.
- If the backup was interrupted by the user or following an error, *$1* is different from 0.
  - If the backup was stopped by the **On Backup Startup Database Method** (*$0* # 0), *$1* gets the value actually returned in the *$0* parameter. This allows you to implement a customized error management system.
  - If the backup was stopped due to an error, the error code is returned in *$1*.

  In any case, you can get information about the error using the **GET BACKUP INFORMATION** command.

**Note**: You must declare the *$1* parameter (longint) in the database method:

```
C_LONGINT($1)
```

It is important to note that in the case of an error during backup (disk full, support unavailable, etc.), the information related to the error is only displayed in the 4D Server monitor or in the MSC, and copied into the backup log. No alert dialog box appears and the *error* variable is not modified. If you want to be able to notify the administrator that an error has occurred, particularly in the context of an application running in client/server mode, you will need to use the **On Backup Shutdown Database Method**.

## On Backup Startup Database Method

---

The **On Backup Startup Database Method** is called every time a database backup is about to start (manual backup, scheduled automatic backup, or using the **BACKUP** command).
This concerns all 4D environments: 4D (all modes), 4D Server and databases merged with 4D Volume Desktop.

The **On Backup Startup Database Method** allows verifying that the backup started. In this method, you should return a value that authorizes or refuses the backup in the $0 parameter:

- If $0 = 0, the backup can be launched.
- If $0 # 0, the backup is not authorized. The operation is cancelled and an error is returned. You can get the error using the **GET BACKUP INFORMATION** command.

You can use this database method to verify backup execution conditions (user, date of the last backup, etc.).

**Note:** You must declare the *$0* parameter (longint) in the database method:

```
C_LONGINT($0)
```

# BACKUP

BACKUP
Does not require any parameters

## Description

The **BACKUP** command starts the backup of the database using the current backup settings. No confirmation dialog is displayed; however, a progress bar appears on screen.

Backup settings are set in the Database Settings ("Preferences" in 4D v11 SQL). They are also stored in the Backup.XML file located in the subfolder Preferences/Backup of the database.

The **BACKUP** command calls the **On Backup Startup Database Method** at the beginning of its execution and the **On Backup Shutdown Database Method** at the end of its execution.
Because of this mechanism, the command should not be called from one of these database methods.

**4D Server:** When called from a client machine, **BACKUP** is considered as a stored procedure; it is still executed on the server.

## System variables and sets

If the backup is performed correctly, the system variable OK is set to 1; otherwise, it is set to 0.

## Error management

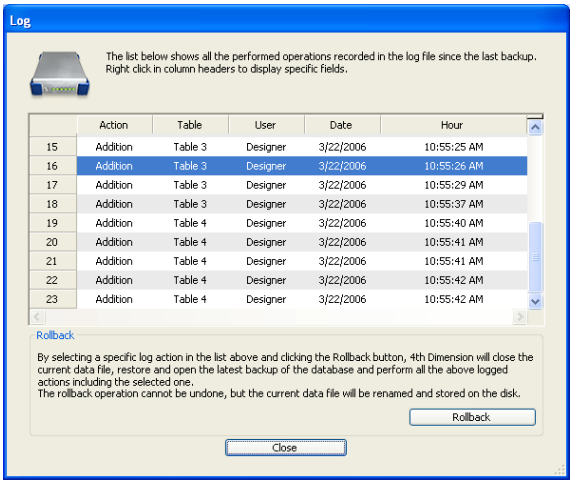
If an incident occurs during backup, information about the incident is written in the backup log and the top-level error is sent only to the **On Backup Shutdown database method**. It is therefore particularly important to use this database method in order to be able to manage back-up related errors using programming.

# CHECK LOG FILE

CHECK LOG FILE
Does not require any parameters

## Description

The **CHECK LOG FILE** command displays the dialog box for viewing the current log file of the database (which can also be accessed via the Maintenance Security Center window):



This dialog box includes the **Rollback** button that can be used to cancel operations carried out on the data of the database. For more information about this dialog box, please refer to the Design Reference manual of 4D.

**Note:** Since the rollback function is relatively powerful, it is recommended that access to the **CHECK LOG FILE** command be restricted to the database administrators.

This command can only be used in the context of single-user applications. More particularly, it allows access to the rollback function from 4D Volume Desktop applications (applications with no Design mode). If it is called within a client/server application, the command has no effect and the error 1421 is returned.

## Error Handling

- If this command is executed in a database operating without a log file, it does nothing and the error 1403 is returned.
- If this command is executed in a client/server database, it does nothing and the error 1421 is returned.
  You can intercept these errors using an error-handling method installed with the **ON ERR CALL** command.

# GET BACKUP INFORMATION

GET BACKUP INFORMATION ( selector ; info1 ; info2 )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ➡ | Type of information to get |
| info1 | Longint, Date | ⬅ | Value 1 of the selector |
| info2 | Time, String | ⬅ | Value 2 of the selector |

## Description

The **GET BACKUP INFORMATION** command gets information related to the last backup performed on the database data.

Pass the type of information to get in *selector*. You can use one of the following constants, placed in the "**Backup and Restore**" theme:

| Constant | Type | Value |
|---|---|---|
| Last backup date | Longint | 0 |
| Last backup status | Longint | 2 |
| Next backup date | Longint | 4 |

The type and content of the *info1* and *info2* parameters depend on the value of *selector*.

- If *selector* = 0 (Last Backup Date), *info1* returns the date and *info2* the time of the last backup.
- If *selector* = 2 (Last Backup Status), *info1* returns the number and *info2* the text of the status of the last backup.
- If *selector* = 4 (Next Backup Date), *info1* returns the date and *info2* the time of the next scheduled backup.

# GET RESTORE INFORMATION

GET RESTORE INFORMATION ( selector ; info1 ; info2 )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ➡ | Type of information to get |
| info1 | Longint, Date | ⬅ | Value 1 of the selector |
| info2 | String, Time | ⬅ | Value 2 of the selector |

## Description

The **GET RESTORE INFORMATION** command gets information related to the last automatic database restore.

Pass the type of information to get in *selector*. You can use one of the following constants, placed in the "**Backup and Restore**" theme:

| Constant | Type | Value |
|---|---|---|
| Last restore date | Longint | 0 |
| Last restore status | Longint | 2 |

The type and content of the *info1* and *info2* parameters depend on the value of *selector*.

- If *selector* = 0 (Last Restore Date), *info1* returns the date and *info2* the time of the last automatic database restore.
- If *selector* = 2 (Last Restore Status), *info1* returns the number and *info2* the text of the status of the last automatic database restore.

**Note:** This command does not take manual database restores into account.

# INTEGRATE MIRROR LOG FILE

INTEGRATE MIRROR LOG FILE ( pathName ; operationNum {; mode {; errObject}} )

| Parameter | Type | | Description |
|---|---|---|---|
| pathName | Text | ➡ | Name or pathname of the log file to be integrated |
| operationNum | Real variable | ➡ | Number of last operation integrated or -2 to integrate the whole file |
| | | ⬅ | New number of last operation integrated |
| mode | Longint | ➡ | 0=strict mode (default mode), 1=auto repair mode |
| errObject | Object variable | ⬅ | Missed operation(s) |

## Description

**Preliminary note:** This command only works with 4D Server. It can only be executed via the **Execute on server** command or in a stored procedure.

The **INTEGRATE MIRROR LOG FILE** integrates the log file designated by *pathName* into a 4D Server database, after the *operationNum* operation. The command accepts to integrate any log file into the database, even if it does not correspond to the the data file. This command is specifically intended for use in the context of a mirror database.

**Note:** Since 4D v14, it is possible to use a log file as part of a "mirror" database: the "Use Log File" option can now be checked in the Database Settings of a 4D Server used as a logical mirror, thus allowing the implementation of a series of cascading mirror servers (see the **Setting up a logical mirror** section in the 4D Server manual).

Unlike the existing **_o_INTEGRATE LOG FILE** command, at the end of its execution **INTEGRATE MIRROR LOG FILE** does not replace the current log file with the integrated one: the current log file of the database continues to be used. Accordingly, any changes made during integration are saved in the current log file.

In *pathName*, you pass an absolute or relative path to the database folder. If you pass an empty string in this parameter, a standard open file dialog box appears so that you can specify the file to be integrated. If this dialog box is canceled, no file is integrated and the *OK* system variable is set to 0.

In the *operationNum* variable, you pass the number of the last operation integrated, so that integration begins at the next operation. After integration, the value of the *operationNum* variable is updated with the number of the last operation integrated. You must save this variable and then reuse it directly as the *operationNum* parameter for the next integration operation. This allows you to follow on with subsequent log file integrations using **INTEGRATE MIRROR LOG FILE**. Pass -2 in the variable to integrate all the operations in the log file.

***Compatibility note:*** *In versions of 4D prior to v15 R4, the operationNum parameter was optional; however, from now on, if the operationNum parameter is omitted, an error is generated. To restore the original functioning of your former code, you can just pass -2 in the operationNum parameter variable.*

In *mode*, you pass the integration mode you want to activate. You can use one of the following constants found in the "**Backup and Restore**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Auto repair mode | Longint | 1 | Use flexible mode with auto-repair actions and fill the *errObject* parameter (if any) |
| Strict mode | Longint | 0 | Use strict integration mode (default) |

- Strict mode: In this mode, as soon as an error occurs during integration, it stops and you have to use the MSC in order to trace the error. This secure mode is used by default and is recommended in most cases.
- Auto repair mode: In this mode, when a non-critical error occurs, it is bypassed and integration continues. If you passed the *errObject* parameter, each error is logged and can be analyzed afterwards.
  Cases of non-critical errors are:
  - The log requests to add a record, but this record already exists in the data.
    Repair action: 4D updates the record.
  - The log requests to update a record, but this record does not yet exist.
    Repair action: 4D adds the record.
  - The log requests to delete a record, but this record does not exist.
    Repair action: 4D does nothing.

**Note**: In strict mode (default mode), integration will stop at the first error encountered. In this case, if you want to continue with the integration you will need to use the MSC.

When one of these anomalies occurs in auto-repair mode, the record concerned is automatically "repaired" and the related operation is logged in the *errObject* parameter. After execution is completed, the *errObject* parameter lists all the repaired records. It contains a single object array named "operations" built as follows:

```
{"operations":
    [
        {
            "operationType":24,
            "operationName":"Create record",
            "operationNumber":2,
            "contextID":48,
            "timeStamp":"2015-07-10T07:53:02.413Z",
            "dataLen":24,
            "recordNumber":0,
            "tableID":"F4CXXXXX",
            "tableName":"Customers",
            "fields": {
                "1": 9,
                "2": "test value",
                "3": "2003-03-03T00:00:00.000Z",
                "4": "BlobPath: Table 1/Field 4/Data_9ACB28F1A2744FDFA5822B22F18B2E12.png",
                "8": "BlobID: 2"
              }
        },
        {...}
    ]
```

**Warning:** The auto-repair mode must be used in specific cases since it bypasses 4D's internal data integrity checking features. It can be used, for example, when an intermediary log file has been lost or corrupted and you want to recover as many operations as possible. In any case, you need to pay particular attention to data integrity when using this mode.

The actual list of available properties depends on the operation type (i.e.: create record, delete record, modify record, create Blob, etc.). Here are the main properties:

- *operationType*: internal code for the operation
- *operationName*: kind of operation, for example "create record," "modify record"
- *operationNumber*: internal number of operation in the log file
- *contextID*: ID of execution context; the context is detailed in the *extraData* section
- *timeStamp*: timestamp of operation in the log file
- *dataLen*: internal size of data
- *recordNumber*: internal record number
- *tableID*: internal ID of the table
- *tableName*: name of the table
- *fields*: object containing the list of field numbers along with their values. All fields in the table are logged.
  In case of Blob or picture values, different information is provided based on their storage location:
  - If the Blob or picture is stored inside the data file, the property will be "BlobID:"+ an internal Blob number, for example: "BlobID:1"
  - If the Blob or picture is stored outside the data file, the property will be "BlobPath:" + the path for the data, for example: "BlobPath: Table 1/Field 6/Data_EE12D091535F9748BCE62EDE972A4BA2.jpg"
- *extraData*: user context data, including user name and ID, task name and ID, host machine name, and client version.
- *sequenceNumber*: current number within auto-increment sequence.
- *primaryKey*: primary key value.

## Example

You want to integrate a log file on the mirror server in auto-repair mode:

```
 //to be executed on the server
C_OBJECT($err)
C_LONGINT($num) //-2 to integrate all operations
INTEGRATE MIRROR LOG FILE("c:¥¥mirror¥¥logNew.journal";$num;Auto repair mode;$err)
```

## System variables and sets

If the integration is carried out correctly, the system variable OK is set to 1; otherwise, it is set to 0.

# Log File

Log File -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ➲ | Long name of the database log file |

## Description

The **Log File** command returns the long name (i.e. the complete pathname of the file, including its name) of the current log file of the open database.

If the database is operating without a log file, the command returns an empty string and the system variable OK is set to 0.

If the database operates with a log file, the system variable OK is set to 1. The pathname returned by the command is expressed with the syntax of the current platform.

**WARNING:** If you execute this command from a 4D Client machine, only the log file name is returned, not the long name

## System variables and sets

- If the database is operating without a log file, the system variable OK is set to 0; otherwise, it is set to 1.
- If for some reason the log file becomes unavailable during a working session, error 1274 is generated and 4D Server does not allow users to write data anymore. When the log file is available again, it is necessary to do a backup.

# LOG FILE TO JSON

LOG FILE TO JSON ( destFolderPath {; maxSize {; logPath {; fieldAtt}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| destFolderPath | Text | ⇒ | Path of the saved file destination folder |
| maxSize | Longint | ⇒ | Maximum size of JSON file to create (bytes) |
| logPath | Text | ⇒ | Pathname of log file to export; use current log file if omitted |
| fieldAtt | Longint | ⇒ | Field description attribute: 1 = use number (default), 2 = use name |

## Description

The **LOG FILE TO JSON** command saves the current log file, or any specified log file, in JSON format.

Once a log (binary file) is saved in JSON, its contents can be read and interpreted by the database administrator or any user in order to analyze database events, for example.

In *destFolderPath*, pass the path of the folder where you want to store the JSON file. This file is named **JournalExport.json**.

By default, the maximum size of the exported JSON file is 10 MB. When this size is reached, the file is closed and a new file is created. Limiting the size of each JSON file reduces memory requirements for analyzing the files. You can change the maximum size for the exported file by setting a value (in bytes) in the *maxSize* parameter. Passing 0 resets to the default size. Passing a negative value removes any size limit.

By default, if the *logPath* parameter is omitted, the command saves the current log file. If you want to export a specific log file, pass its path in the *logPath* parameter. The log file must be a file with the ".journal" extension. If you want to export an archived log file (".4bl" extension), you need to convert it beforehand using the**RESTORE** command. You can pass an empty string ("") to display the standard open file dialog box, allowing the user to select the log file to save. The selected log file path is returned in the **Document** system variable.

**Note:** When the command saves the current log file, the database is not locked. New operations can be executed while the file is being written on disk - these operations will not be included in the saved file.

When you export the current log file, the *fieldAtt* parameter allows you to define how fields will be described in the exported attribute: by number (default), or by name. You can pass one of the following constants, found in the "**Backup and Restore**" constant theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Field attribute with name | Longint | 2 | Fields are identified by their name. Example: {"LastName":"Jones"} |
| Field attribute with number | Longint | 1 | Fields are identified by their number (default if omitted). Example: {"5":"Jones"}. |

**Note:** When you export an external log file, fields are always identified by their number.

The saved JSON file contains all the operations recorded in the log, in the form of an array of JSON objects. Each object contains several properties describing the operation. Example:

```
[
   {
      "operationType":25,
      "operationName":"Modify record",
      "operationNumber":45,
      "contextID":37,
      "timeStamp":"2015-06-11T09:13:17.138Z",
      "dataLen":42,
      "recordNumber":4,
      "tableID":"5AFA15123F991C43B6ACF8B46A914BD0",
      "tableName":"elem",
      "fields": {
            "1": "primkey5",
            "2": -5,
            "5": "data 25"
        },
      "primaryKey": "8"
   },
   {
      "operationType":23,
```

```
      "operationName":"Save seqnum",
      "operationNumber":46,
      "contextID":37,
      "timeStamp":"2015-06-11T09:13:17.138Z",
      "sequenceNumber":23,
      "tableID":"5AFA15123F991C43B6ACF8B46A914BD0",
      "tableName":"elem"
   },
   {
      "operationType":24,
      "operationName":"Create record",
      "operationNumber":47,
      "contextID":37,
      "timeStamp":"2015-06-11T09:13:17.138Z",
      "dataLen":570,
      "recordNumber":7,
      "tableID":"5AFA15123F991C43B6ACF8B46A914BD0",
      "tableName":"elem",
      "fields": {
            "1": 9,
            "2": "test value",
            "3": "2003-03-03T00:00:00.000Z",
            "4": "BlobPath: Table 1/Field 4/Data_9ACB28F1A2744FDFA5822B22F18B2E12.png",
            "8": "BlobID: 2"
      },
      "extraData": {
          "task_id": 1,
          "user_name": "Vanessa Smith",
          "user4d_id": 1,
          "host_name": "iMac-VSmith-0833",
          "task_name": "Application process",
          "client_version": -1610541776
      },
      "primaryKey": "9"
   }
]
```

**Note:** If you passed Field attribute with name in the *fieldAtt* parameter, the "fields" object would look like this:

```
...
      "fields": {
            "ID": 9,
            "Field_2": "test value",
            "Date_Field": "2003-03-03T00:00:00.000Z",
            "Field_4": "BlobPath: Table 1/Field 4/Data_9ACB28F1A2744FDFA5822B22F18B2E12.png",
            "Field_8": "BlobID: 2"
      },...
```

The actual list of available properties depends on the operation type (i.e.: create record, delete record, modify record, create Blob, etc.). Here are the main properties:

- *operationType*: internal code for the operation
- *operationName*: kind of operation, for example "create record," "modify record"
- *operationNumber*: internal number of operation in the log file
- *contextID*: ID of execution context; the context is detailed in the *extraData* section
- *timeStamp*: timestamp of operation in the log file
- *dataLen*: internal size of data
- *recordNumber*: internal record number
- *tableID*: internal ID of the table
- *tableName*: name of the table
- *fields*: object containing the list of field numbers (or field names) along with their values. Any fields with a modified value are logged.
  In case of Blob or picture values, different information is provided based on their storage location:
  - If the Blob or picture is stored inside the data file, the property will be "BlobID:"+ an internal Blob number, for example: "BlobID:1"

    - If the Blob or picture is stored outside the data file, the property will be "BlobPath:" + the path for the data, for example: "BlobPath: Table 1/Field 6/Data_EE12D091535F9748BCE62EDE972A4BA2.jpg"
- *extraData*: user context data, including user name and ID, task name and ID, host machine name, and client version.
- *sequenceNumber*: current number within auto-increment sequence.
- *primaryKey*: primary key value.

## Example

You want to save the current log file in JSON:

```
LOG FILE TO JSON("c:¥¥4Dv15¥¥ExportLogs")
```

You want to save a specific log file in JSON with field names:

```
LOG FILE TO JSON("c:¥¥4Dv15¥¥ExportLogs";0;"c:¥¥4Dv15¥¥Backup¥¥old_myDB.journal";Field attribute with name)
```

## System variables and sets

The **LOG FILE TO JSON** command modifies the value of the OK and Document variables: if the JSON file was correctly saved, OK is set to 1 and Document contains the pathname of the file. If you passed "" in the *logPath* parameter and the user canceled the file selection dialog box, OK is set to 0 and Document contains an empty string. If the user selected an invalid file, OK is set to 0 and Document contains the file path.

# New log file

New log file -> Function result

| Parameter | Type | Description |
| --- | --- | --- |
| Function result | Text | Full pathname of closed log file |

## Description

**Preliminary note:** This command only works with 4D Server. It can only be executed via the **Execute on server** command or in a stored procedure.

The **New log file** command closes the current log file, renames it and creates a new one with the same name in the same location as the previous one. This command is meant to be used for setting up a backup system using a logical mirror (see the section "**Setting up a logical mirror**" in the 4D Server Reference Manual).

The command returns the full pathname (access path + name) of the log file being closed (called the "segment"). This file is stored in the same location as the current log file (specified on the Configuration page in the Backup theme of the Preferences). The command does not carry out any processing (compression, segmentation) on the saved file. No dialog box appears.

The file is renamed with the current backup numbers of the database and of the log file, as shown in the following example: *DatabaseName[BackupNum-LogBackupNum].journal*. For instance:

- If the MyDatabase.4DD database has been saved 4 times, the last backup file will be named *MyDatabase[0004].4BK*. The name of the first "segment" of the log file will therefore be *MyDatabase[0004-0001].journal*.
- If the MyDatabase.4DD database has been saved 3 times and the log file has been saved 5 times since, the name of the 6th backup of the log file will be *MyDatabase[0003-0006].journal*.

## Error management

In the event of an error, the command generates a code that can be intercepted using the **ON ERR CALL** command.

# RESTORE

RESTORE {( archivePath {; destFolderPath} )}

| Parameter | Type | | Description |
|---|---|---|---|
| archivePath | Text | ⇒ | Pathname of archive to restore |
| destFolderPath | Text | ⇒ | Pathname of destination folder |

## Description

The **RESTORE** command can be used to restore the file(s) included in a 4D archive. This command is useful as part of custom interfaces for managing backups.

If you do not pass the *archivePath* parameter, the command displays an open file dialog box so that the user can select the archive to restore.

The *archivePath* parameter lets you indicate the pathname of the archive file to be restored. This pathname must be expressed with the system syntax. You can pass an absolute pathname or a pathname relative to the database structure file. In this case (if the *destFolderPath* parameter is omitted), the standard restore dialog box appears with the archive pre-selected, so that the user can designate the destination folder. When the procedure is completed, a warning dialog box appears and the folder containing the restored elements is displayed.

You can also pass the *destFolderPath* parameter with the pathname of the destination folder of the restored elements. This pathname must be expressed with the system syntax. You can pass an absolute pathname or a pathname relative to the database structure file. If you pass this parameter, a preconfigured restore dialog box appears so that only the user can launch or cancel the restore procedure. When the procedure is completed, the window is simply reclosed without displaying any additional information.

The **RESTORE** command modifies the value of the *OK* and *Document* variables: if the restore was carried out correctly, *OK* is set to 1 and *Document* contains the path of the restoration folder. If the user cancels the restoration dialog box, interrupts the restoration or if an error occurs, *OK* is set to 0 and *Document* contains an empty string. You can intercept the error using a method installed via the **ON ERR CALL** command.

**Note:** In a 4D application that is compiled and merged with 4D Volume Desktop, the **RESTORE** command causes the display of a standard open file dialog box that lists by default any files having the “4BK” extension.

# SELECT LOG FILE

SELECT LOG FILE ( logFile )

| Parameter | Type | | Description |
|---|---|---|---|
| logFile | Operator, String | ⇒ | Name of the log file or "*" for closing the current log file |

## Description

The **SELECT LOG FILE** command creates, or closes the log file according to the value you pass in *logFile*.

**Note:** Calling **SELECT LOG FILE** is the same as selecting/deselecting the **Use Log File** option on the **Backup/Configuration** page of the application Preferences.

In *logFile*, pass the name or the full pathname of the log file to be created. If you only pass a name, the file will be created in the "Logs" folder of the database located next to the database structure file.

If you pass an empty string in *logFile*, **SELECT LOG FILE** presents an Save File dialog box, allowing the user to choose the name and location of the log file to be created. If the file is created correctly, the *OK* variable is set to 1. Otherwise, if the user clicks Cancel or if the log file could not be created, **OK** is set to 0.

**Note:** The new log file is not generated immediately after execution of the command, but rather after the next backup (the parameter is kept in the data file and will be taken into account even if the database is closed in the meantime). You can call the **BACKUP** command to trigger the creation of the log file.

If you pass *"*"* in *logFile*, **SELECT LOG FILE** closes the current log file for the database. The *OK* variable is set to 1 when the log file is closed.

If you use **SELECT LOG FILE** to create a log file when a full backup has not yet been performed and the data file already contains records, 4D then generates an error *-4447,* which you can intercept with an **ON ERR CALL** method.

## System variables and sets

OK is set to 1 if the log file is correctly created, or closed.

## Error management

An error -4447 is generated if the operation cannot be performed because the database needs to be backed up. You can intercept the error with an **ON ERR CALL** method.

# _o_INTEGRATE LOG FILE

_o_INTEGRATE LOG FILE ( pathName )

| Parameter | Type | | Description |
|---|---|---|---|
| pathName | Text | ⇨ | Name or pathname of the log file to be integrated |

## Compatibility note

The **_o_INTEGRATE LOG FILE** command is declared obsolete in 4D beginning with version 16 and is kept only for compatibility reasons. 4D's backup feature using a logical mirror is now based solely on the **INTEGRATE MIRROR LOG FILE** command, which has been optimized and provides greater flexibility.

# BLOB

- BLOB Commands
- BLOB PROPERTIES

- INTEGER TO BLOB
- LIST TO BLOB
- LONGINT TO BLOB
- REAL TO BLOB
- SET BLOB SIZE
- TEXT TO BLOB
- VARIABLE TO BLOB

# BLOB Commands

## Definition

4D supports the BLOB (Binary Large OBjects) data type.

You can define BLOB fields, BLOB variables and BLOB arrays:

- To create a BLOB field, select BLOB in the **Field type** drop-down-list within the **Field Properties** window.
- To create a BLOB variable, use the compiler declaration command **C_BLOB**. You can create local, process, and interprocess variables of type BLOB.
- To create a BLOB array, use the **ARRAY BLOB** command.

Within 4D, a BLOB is a contiguous series of variable length bytes, which can be treated as one whole object or whose bytes can be addressed individually. A BLOB can be empty (null length) or can contain up to 2147483647 bytes (2 GB).

## BLOBs and Memory

A BLOB is loaded into memory in its entirety. A BLOB variable or BLOB array is held and exists in memory only. A BLOB field is loaded into memory from the disk, like the rest of the record to which it belongs.

Like the other field types that can retain a large amount of data (such as the Picture field type), BLOB fields are not duplicated in memory when you modify a record. Consequently, the result returned by the commands **Old** and **Modified** is not significant when applied to a BLOB field.

## Displaying BLOBs

A BLOB can retain any type of data, so it has no default representation on the screen. If you display a BLOB field or variable in a form, it will always appear blank, whatever its contents.

## BLOB fields

You can use BLOB fields to store any kind of data, up to 2 GB. You cannot index a BLOB field, so you must use a formula in order to search records on values stored in a BLOB field.

## Parameter passing, Pointers and function results

4D BLOBs can be passed as parameters to 4D commands or plug-in routines that expect a BLOB parameters. BLOBS can also be passed as parameters to a user method or be returned as a function result.

To pass a BLOB to your own methods, you can also define a pointer to the BLOB and pass the pointer as parameter.

Examples:

```
  ` Declare a variable of type BLOB
C_BLOB(anyBlobVar)
  ` The BLOB is passed as parameter to a 4D command
SET BLOB SIZE(anyBlobVar;1024*1024)
  ` The BLOB is passed as parameter to an external routine
$errCode:=Do Something With This BLOB(anyBlobVar)
  ` The BLOB is passed as a parameter to a method that returns a BLOB
C_BLOB(retrieveBlob)
retrieveBlob:=Fill_Blob(anyBlobVar)
  ` A pointer to the BLOB is passed as parameter to a user method
COMPUTE BLOB(->anyBlobVar)
```

**Note for Plug-in developers**: A BLOB parameter is declared as “&O” (the letter “O”, not the digit “0”).

## Assignment

You can assign BLOBs to each other.

Example:

```
  ` Declare two variables of type BLOB
C_BLOB(vBlobA;vBlobB)
  ` Set the size of the first BLOB to 10K
SET BLOB SIZE(vBlobA;10*1024)
  ` Assign the first BLOB to the second one
vBlobB:=vBlobA
```

However, no operator can be applied to BLOBs; there is no expression of type BLOB.

## Addressing BLOB contents

You can address each byte of a BLOB individually using the curly brackets symbols *{...}*. Within a BLOB, bytes are numbered from *0* to *N-1*, where *N* is the size of the BLOB. Example:

```
  ` Declare a variable of type BLOB
C_BLOB(vBlob)
  ` Set the size of the BLOB to 256 bytes
SET BLOB SIZE(vBlob;256)
  ` The loop below initializes the 256 bytes of the BLOB to zero
For(vByte;0;BLOB size(vBlob)-1)
   vBlob{vByte}:=0
End for
```

Because you can address all the bytes of a BLOB individually, you can actually store whatever you want in a BLOB field or variable.

## BLOBs 4D commands

4D provides the following commands for working BLOBS:

- **SET BLOB SIZE** resizes a BLOB field or variable.
- **BLOB size** returns the size of a BLOB.
- **DOCUMENT TO BLOB** and **BLOB TO DOCUMENT** enable you to load and write a whole document to and from a BLOB (optionally, the data and resource forks on Macintosh).
- **VARIABLE TO BLOB** and **BLOB TO VARIABLE** as well as **LIST TO BLOB** and **BLOB to list** allow you to store and retrieve 4D variables in BLOBs.
- **COMPRESS BLOB**, **EXPAND BLOB** and **BLOB PROPERTIES** allow you to work with compressed BLOBs
- The commands **BLOB to integer**, **BLOB to longint**, **BLOB to real**, **BLOB to text**, **INTEGER TO BLOB**, **LONGINT TO BLOB**, **REAL TO BLOB** and **TEXT TO BLOB** enable you to manipulate any structured data coming from disk, resources, OS, and so on.
- **DELETE FROM BLOB**, **INSERT IN BLOB** and **COPY BLOB** allow quick handling of large chunks of data within BLOBs.
- **ENCRYPT BLOB** and **DECRYPT BLOB** allow you to encrypt and decrypt data in a 4D database.

These commands are described in this chapter.

In addition:

- **C_BLOB** declares a variable of type BLOB. Refer to the **Compiler** chapter for more information.
- **ARRAY BLOB** creates or resizes a BLOB type array (refer to the **Arrays** section).
- **GET PASTEBOARD DATA** and **APPEND DATA TO PASTEBOARD** enable you to deal with any data type stored in the pasteboard. Refer to the **Managing Pasteboards** section for more information.
- **GET RESOURCE** and **_o_SET RESOURCE** enable you to work with any type stored of resource stored on disk. Refer to the **Resources** chapter for more information.
- **WEB SEND BLOB** enable you to send any type of data to a Web browser. Refer to the **Web Server** chapter for more information.
- **PICTURE TO BLOB**, **BLOB TO PICTURE** and **PICTURE TO GIF** allow you to open and convert pictures. Refer to the **Pictures** chapter for more information.
- **GENERATE ENCRYPTION KEYPAIR** and **GENERATE CERTIFICATE REQUEST** are encryption commands used by the SSL (Secured Socket Layer) secured connection protocol. Refer to the **Using TLS Protocol** section for more information.

# BLOB PROPERTIES

BLOB PROPERTIES ( blob ; compressed {; expandedSize {; currentSize}} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB for which to get information |
| compressed | Longint | ⇐ | 0 = BLOB is not compressed, 1 = Compact compression, 2 = Fast compression, -1 = GZIP Best compression, -2 = GZIP Fast compression |
| expandedSize | Longint | ⇐ | Size of BLOB (in bytes) when not compressed |
| currentSize | Longint | ⇐ | Current size of BLOB (in bytes) |

## Description

The **BLOB PROPERTIES** command returns information about the BLOB *blob*.

The *compressed* parameter returns a value indicating if and how the BLOB is compressed. You can compare this value with the following constants, found in the **BLOB** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Compact compression mode | Longint | 1 | Compressed as much as possible (at the expense of the speed of compression and decompression operations). Default method. |
| Fast compression mode | Longint | 2 | Compressed as fast as possible (and will be decompressed as fast as possible), at the expense of the compression ratio (the compressed BLOB will be bigger). |
| GZIP best compression mode | Longint | -1 | Most compact GZIP compression |
| GZIP fast compression mode | Longint | -2 | Fastest GZIP compression |
| Is not compressed | Longint | 0 | No compression |

Whatever the compression status of the BLOB, the *expandedSize* parameter returns the size of the BLOB when it is not compressed.

The parameter *currentSize* returns the current size of the BLOB. If the BLOB is compressed, you will usually obtain *currentSize* less than *expandedSize*. If the BLOB is not compressed, you will always obtain *currentSize* equal to *expandedSize*.

## Example 1

See examples for the commands **COMPRESS BLOB** and **EXPAND BLOB**.

## Example 2

After a BLOB has been compressed, the following project method obtains the percentage of space saved by the compression:

```
   ` Space saved by compression project method
   ` Space saved by compression (Pointer {; Pointer } ) -> Long integer
   ` Space saved by compression ( -> BLOB {; -> savedBytes } ) -> Percentage

C_POINTER($1;$2)
C_LONGINT($0;$vlCompressed;$vlExpandedSize;$vlCurrentSize)

BLOB PROPERTIES($1->;$vlCompressed;$vlExpandedSize;$vlCurrentSize)
If($vlExpandedSize=0)
   $0:=0
   If(Count parameters>=2)
```

```
      $2->:=0
   End if
Else
   $0:=100-(($vlCurrentSize/$vlExpandedSize)*100)
   If(Count parameters>=2)
      $2->:=$vlExpandedSize-$vlCurrentSize
   End if
End if
```

After this method has been added to your application, you can use it this way:

```
  ```
COMPRESS BLOB(vxBlob)
$vlPercent:=Space saved by compression(->vxBlob;->vlBlobSize)
ALERT("The compression saved "+String(vlBlobSize)+" bytes, so "+String($vlPercent;"#0%")+
" of space.")
```
```

# BLOB size

BLOB size ( blob ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB field or variable |
| Function result | Longint | ⇐ | Size in bytes of the BLOB |

## Description

**BLOB size**returns the size of *blob* expressed in bytes.

## Example

The line of code adds 100 bytes to the BLOB *myBlob*:

```
SET BLOB SIZE(BLOB size(myBlob)+100)
```

# BLOB TO DOCUMENT

BLOB TO DOCUMENT ( document ; blob {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Name of the document |
| blob | BLOB | ⇒ | New contents for the document |
| * | Operator | ⇒ | On Macintosh only: Resource fork is written if * is passed; otherwise, Data fork is written |

## Description

**BLOB TO DOCUMENT** rewrites the whole contents of *document* using the data stored in *blob*. You can pass the name of a document in *document*. If the *document* does not exist, the command creates it. If you pass the name of an existing document, make sure that it is not already open, otherwise an error is generated. If you want to let the user choose the document, use the commands **Open document** or **Create document** and use the process variable *document* (see example).

**Notes regarding Macintosh:**

- Macintosh documents can be composed of two forks: the Data fork and the Resource fork. By default, the command **BLOB TO DOCUMENT** rewrites the Data fork of the document. To rewrite the Resource fork of the document instead, pass the optional * parameter. On Windows, the optional * parameter is ignored.
- The documents generated by this command do not have a "type". If you want to create a document with a type, you must use the **SET DOCUMENT TYPE** command.

## Example

You write an Information System that enables you to quickly store and retrieve documents. In a data entry form, you create a button which allows you to save a document that will contain the data previously loaded into a BLOB field. The method for this button could be:

```
$vhDocRef:=Create document("") ` Save the document of your choice
If(OK=1) ` If a document has been created
   CLOSE DOCUMENT($vhDocRef) ` We don't need to keep it open
   BLOB TO DOCUMENT(Document;[YourTable]YourBLOBField) ` Write the document contents
   If(OK=0)
   ` Handle error
   End if
End if
```

## System variables and sets

OK is set to 1 if the document is correctly written, otherwise OK is set to 0 and an error is generated.

## Error Handling

- If you try to rewrite a document that does not exist or that is already open by another process or application, the appropriate File Manager error is generated.
- The disk space may be insufficient for writing the new contents of the document.
- I/O errors can occur while writing the document.

In all cases, you can trap the error using an **ON ERR CALL** interruption method.

# BLOB to integer

BLOB to integer ( blob ; byteOrder {; offset} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB from which to get the integer value |
| byteOrder | Longint | ➡ | 0 Native byte ordering 1 Macintosh byte ordering 2 PC byte ordering |
| offset | Variable | ➡ | Offset within the BLOB (expressed in bytes) |
| | | ⬅ | New offset after reading |
| Function result | Integer | ↩ | 2-byte Integer value |

## Description

The **BLOB to integer** command returns a 2-byte Integer value read from the BLOB *blob*.

The *byteOrder* parameter fixes the byte ordering of the 2-byte Integer value to be read. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Macintosh byte ordering | Longint | 1 |
| Native byte ordering | Longint | 0 |
| PC byte ordering | Longint | 2 |

**Note regarding Platform Independence:** If you exchange BLOBs between Macintosh and PC platforms, it is up to you to manage byte swapping issues when using this command.

If you specify the optional *offset* variable parameter, the 2-byte Integer value is read at the offset (starting from zero) within the BLOB. If you do not specify the optional *offset* variable parameter, the first two bytes of the BLOB are read.

**Note:** You should pass an offset (in bytes) value between *0* (zero) and the size of the BLOB minus 2. If you do not do so, an error -111 is generated.

After the call, the variable is incremented by the number of bytes read, Therefore, you can reuse that same variable with another BLOB reading command to read another value.

## Example

The following example reads 20 Integer values from a BLOB, starting at the offset 0x200:

```
$vlOffset:=0x200
For($viLoop;0;19)
   $viValue:=BLOB to integer(vxSomeBlob;PC byte ordering;$vlOffset)
   ` Do something with $viValue
End for
```

# BLOB to list

BLOB to list ( blob {; offset} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB containing a hierarchical list |
| offset | Longint | ➡ | Offset within the BLOB (expressed in bytes) |
| | | ⬅ | New offset after reading |
| Function result | ListRef | ↩ | Reference to newly created list |

## Description

The **BLOB to list** command creates a new hierarchical list with the data stored within the BLOB *blob* at the byte offset (starting at zero) specified by *offset* and returns a List Reference number for that new list.

The BLOB data must be consistent with the command. Typically, you will use BLOBs that you previously filled out using the command **LIST TO BLOB**.

If you do not specify the optional *offset* parameter, the list data is read starting from the beginning of the BLOB. If you deal with a BLOB in which several variables or lists have been stored, you must pass the *offset* parameter and, in addition, you must pass a numeric variable. Before the call, set this numeric variable to the appropriate offset. After the call, that same numeric variable returns the offset of the next variable stored within the BLOB.

After the call, if the hierarchical list has been successfully created, the OK variable is set to 1. If the operation could not be performed, the OK variable is set to 0; for example, if there was not enough memory.

**Note regarding Platform Independence: BLOB to list** and **LIST TO BLOB** use a 4D internal format for handling lists stored in BLOBs. As a benefit, you do not need to worry about byte swapping between platforms when using these two commands. In other words, a BLOB created on Windows using those two commands can be reused on Macintosh and vice-versa.

## Example

In this example, the form method for a data entry form extracts a list from a BLOB field before the form appears on the screen, and stores it back to the BLOB field if the data entry is validated:

```
   ` [Things To Do];"Input" Form Method

Case of

   :(Form event=On Load)
      hList:=BLOB to list([Things To Do]Other Crazy Ideas)
      If(OK=0)
         hList:=New list
      End if

   :(Form event=On Unload)
      CLEAR LIST(hList;*)

   :(bValidate=1)
      LIST TO BLOB(hList;[Things To Do]Other Crazy Ideas)

End case
```

## System variables and sets

The OK variable is set to 1 if the list has been successfully created, otherwise it is set to 0.

# BLOB to longint

BLOB to longint ( blob ; byteOrder {; offset} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB from which to get the Long Integer value |
| byteOrder | Longint | ➡ | 0 = Native byte ordering, 1 = Macintosh byte ordering, 2 = PC byte ordering |
| offset | Variable | ➡ | Offset within the BLOB (expressed in bytes) |
| | | ⬅ | New offset after reading |
| Function result | Longint | ↩ | 4-byte Long Integer value |

## Description

The **BLOB to longint** command returns a 4-byte Long Integer value read from the BLOB *blob*.

The *byteOrder* parameter fixes the byte ordering of the 4-byte Long Integer value to be read. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Macintosh byte ordering | Longint | 1 |
| Native byte ordering | Longint | 0 |
| PC byte ordering | Longint | 2 |

**Note regarding Platform Independence:** If you exchange BLOBs between Macintosh and PC platforms, it is up to you to manage byte swapping issues while using this command.

If you specify the optional *offset* variable parameter, the 4-byte Long Integer is read at the offset (starting from zero) within the BLOB. If you do not specify the optional *offset* variable parameter, the first four bytes of the BLOB are read.

**Note:** You should pass an offset value between *0* (zero) and the size of the BLOB minus 4. If you do not do so, an error -111 is generated.

After the call, the variable is incremented by the number of bytes read. Therefore, you can reuse that same variable with another BLOB reading command to read another value.

## Example

The following example reads 20 Long Integer values from a BLOB, starting at the offset 0x200:

```
$vlOffset:=0x200
For($viLoop;0;19)
   $vlValue:=BLOB to longint(vxSomeBlob;PC byte ordering;$vlOffset)
   ` Do something with $vlValue
End for
```

# BLOB to real

BLOB to real ( blob ; realFormat {; offset} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB from which to get the Real value |
| realFormat | Longint | ➡ | 0=Native real format, 1=Extended real format, 2=Macintosh Double real format, 3=Windows Double real format |
| offset | Variable | ➡ | Offset within the BLOB (expressed in bytes) |
| | | ⬅ | New offset after reading |
| Function result | Real | ↩ | Real value |

## Description

The **BLOB to real** command returns a Real value read from the BLOB *blob*.

The *realFormat* parameter fixes the internal format and byte ordering of the Real value to be read. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Extended real format | Longint | 1 |
| Macintosh double real format | Longint | 2 |
| Native real format | Longint | 0 |
| PC double real format | Longint | 3 |

**Note regarding Platform Independence:** If you exchange BLOBs between Macintosh and PC platforms, it is up to you to manage real formats and byte swapping issues while using this command.

If you specify the optional *offset* variable parameter, the Read value is read at the offset (starting from zero) within the BLOB. If you do not specify the optional *offset* variable parameter, the first 8 or 10 bytes of the BLOB are read.

**Note:** You should pass an offset value between *0* (zero) and the size of the BLOB minus 8 or 10. If you do not do so, an error -111 is generated.

After the call, the variable is incremented by the number of bytes read. Therefore, you can reuse that same variable with another BLOB reading command to read another value.

## Example

The following example reads 20 Real values from a BLOB, starting at the offset 0x200:

```
$vlOffset:=0x200
For($viLoop;0;19)
   $vrValue:=BLOB to real(vxSomeBlob;PC byte ordering;$vlOffset)
   ` Do something with $vrValue
End for
```

# BLOB to text

BLOB to text ( blob ; textFormat {; offset {; textLength}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB from which to get the text |
| textFormat | Longint | ⇒ | Format and character set of text |
| offset | Variable | ⇒ | Offset within the BLOB (expressed in bytes) |
| | | ⇐ | New offset after reading |
| textLength | Longint | ⇒ | Number of characters to be read |
| Function result | Text | ⇐ | Text extracted |

## Description

The **BLOB to text** command returns a Text value read from the BLOB *blob*.

The *textFormat* parameter fixes the internal format and character set of the text value to be read. In databases created beginning with version 11, 4D uses the Unicode character set (UTF8) by default for managing text. For the sake of compatibility, this command can be used to "force" conversion using the Mac Roman character set (used in previous versions of 4D). The character set is chosen via the *textFormat* parameter. To do this, pass one of the following constants (found in the **BLOB** theme) in the *textFormat* parameter:

| Constant | Type | Value |
|---|---|---|
| Mac C string | Longint | 0 |
| Mac Pascal string | Longint | 1 |
| Mac text with length | Longint | 2 |
| Mac text without length | Longint | 3 |
| UTF8 C string | Longint | 4 |
| UTF8 text with length | Longint | 5 |
| UTF8 text without length | Longint | 6 |

**Notes:**

- The "UTF8" constants can only be used when the application runs in Unicode mode.
- The "Mac" constants cannot work with texts greater than 32 KB.
- If you want to work with character sets other than UTF8, use the **Convert to text** command.

For more information about these constants and the formats they represent, please refer to the description of the **TEXT TO BLOB** command.

**WARNING:** The number of characters to be read is determined by the *textFormat* parameter, EXCEPT for the formats Mac Text without length and UTF8 Text without length, for which you need to specify the number of characters to be read in the *textLength* parameter. For the other formats, *textLength* is ignored and you can omit it.

If you specify the optional *offset* variable parameter, the Text value is read at the offset (starting from zero) within the BLOB. If you do not specify the optional *offset* variable parameter, the beginning of the BLOB is read according to the value you pass in *textFormat*. Note that you must pass the *offset* variable parameter when you are reading text without length.

**Note:** You should pass an offset value between *0* (zero) and the size of the BLOB minus the size of the text to be read. If you do not do so, the function result is unpredictable.

After the call, the variable is incremented by the number of bytes read. Therefore, you can reuse that same variable with another BLOB reading command to read another value.

# BLOB TO VARIABLE

BLOB TO VARIABLE ( blob ; variable {; offset} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB containing 4D variables |
| variable | Variable | ⇐ | Variable to write with BLOB contents |
| offset | Longint | ⇒ | Position of variable within BLOB |
| | | ⇐ | Position of following variable within BLOB |

## Description

The **BLOB TO VARIABLE** command rewrites the variable *variable* with the data stored within the BLOB *blob* at the byte offset (starting at zero) specified by *offset*.

The BLOB data must be consistent with the destination variable. Typically, you will use BLOBs that you previously filled out using the command **VARIABLE TO BLOB**.

If you do not specify the optional *offset* parameter, the variable data is read starting from the beginning of the BLOB. If you deal with a BLOB in which several variables have been stored, you must pass the *offset* parameter and, in addition, you must pass a numeric variable. Before the call, set this numeric variable to the appropriate offset. After the call, that same numeric variable returns the offset of the next variable stored within the BLOB.

**Note: BLOB TO VARIABLE** supports object variables of the **C_OBJECT** type. For more information, refer to the **VARIABLE TO BLOB** command.

After the call, if the variable has been successfully rewritten, the OK variable is set to 1. If the operation could not be performed, the OK variable is set to 0; for example, if there was not enough memory.

**Note regarding Platform Independence: BLOB TO VARIABLE** and **VARIABLE TO BLOB** use a 4D internal format for handling variables stored in BLOBs. As a benefit, you do not need to worry about byte swapping between platforms while using these two commands. In other words, a BLOB created on Windows using either of these commands can be reused on Macintosh, and vice-versa.

## Example

See the examples for the **VARIABLE TO BLOB** command.

## System variables and sets

The OK variable is set to 1 if the variable has been successfully rewritten, otherwise it is set to 0.

# COMPRESS BLOB

COMPRESS BLOB ( blob {; compression} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB to compress |
| compression | Longint | ➡ | If not omitted: 1, compress as compact as possible 2, compress as fast as possible |

## Description

The **COMPRESS BLOB** command compresses the BLOB *blob* using a compression algorithm. This command only compresses BLOB whose size is over 255 bytes.

The optional *compression* parameter allows to set the way the BLOB will be compressed. You can pass one of the following constants, placed in the **BLOB** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Compact compression mode | Longint | 1 | Compressed as much as possible (at the expense of the speed of compression and decompression operations). Default method. |
| Fast compression mode | Longint | 2 | Compressed as fast as possible (and will be decompressed as fast as possible), at the expense of the compression ratio (the compressed BLOB will be bigger). |
| GZIP best compression mode | Longint | -1 | Most compact GZIP compression |
| GZIP fast compression mode | Longint | -2 | Fastest GZIP compression |

If you pass another value or if you omit the *compression* parameter, compression mode 1 is used (compact internal compression).

**Note:** This command only compresses BLOBs that are greater than or equal to 255 bytes.

After the call, the OK variable is set to 1 if the BLOB has been successfully compressed. If the compression could not be performed, the OK variable is set to 0. If the compression could not be performed because of a lack of memory or because the actual size of the blob is less than 255 bytes, no error is generated and the method resumes its execution.
In any other cases (i.e. the BLOB is damaged), the error -10600 is generated. This error can be trapped using the **ON ERR CALL** command.

After a BLOB has been compressed, you can expand it using the **EXPAND BLOB** command.

To detect if a BLOB has been compressed, use the **BLOB PROPERTIES** command.

**WARNING:** A compressed BLOB is still a BLOB, so there is nothing to stop you from modifying its contents. However, if you do so, the **EXPAND BLOB** command will not be able to decompress the BLOB properly.

## Example 1

This example tests if the BLOB *vxMyBlob* is compressed, and, if it is not, compresses it:

```
BLOB PROPERTIES(vxMyBlob;$vlCompressed;$vlExpandedSize;$vlCurrentSize)
If($vlCompressed=Is not compressed)
   COMPRESS BLOB(vxMyBlob)
End if
```

Note however, that if you apply **COMPRESS BLOB** to an already compressed BLOB, the command detects it and does nothing.

## Example 2

This example allows you to select a document and then compress it:

```
$vhDocRef :=Open document("")
If(OK=1)
   CLOSE DOCUMENT($vhDocRef)
   DOCUMENT TO BLOB(Document;vxBlob)
   If(OK=1)
      COMPRESS BLOB(vxBlob)
      If(OK=1)
         BLOB TO DOCUMENT(Document;vxBlob)
      End if
   End if
End if
```

## Example 3

Sending of raw HTTP data compressed with GZIP:

```
COMPRESS BLOB($blob;GZIP Best compression mode)
C_TEXT($vEncoding)
$vEncoding:="Content-encoding: gzip"
WEB SET HTTP HEADER($vEncoding)
WEB SEND RAW DATA($blob ;*)
```

## System variables and sets

The OK variable is set to 1 if the BLOB has been successfully compressed; otherwise, it is set to 0.

# COPY BLOB

COPY BLOB ( srcBLOB ; dstBLOB ; srcOffset ; dstOffset ; len )

| Parameter | Type | | Description |
|---|---|---|---|
| srcBLOB | BLOB | ⇒ | Source BLOB |
| dstBLOB | BLOB | ⇒ | Destination BLOB |
| srcOffset | Longint | ⇒ | Source position for the copy |
| dstOffset | Longint | ⇒ | Destination position for the copy |
| len | Longint | ⇒ | Number of bytes to be copied |

## Description

The **COPY BLOB** command copies the number of bytes specified by *len* from the BLOB *srcBLOB* to the BLOB *dstBLOB*.

The copy starts at the position (expressed relative to the beginning of the source BLOB) specified by *srcOffset* and takes place at the position (expressed relative to the beginning of the destination BLOB) specified by *dstOffset*.

**Note:** The destination BLOB can be resized if necessary.

# DECRYPT BLOB

DECRYPT BLOB ( toDecrypt ; sendPubKey {; recipPrivKey} )

| Parameter | Type | | Description |
|---|---|---|---|
| toDecrypt | BLOB | ⇒ | Data to decrypt |
| | | ⇐ | Decrypted data |
| sendPubKey | BLOB | ⇒ | Sender's public key |
| recipPrivKey | BLOB | ⇒ | Recipient's private key |

## Description

The **DECRYPT BLOB** command decrypts the content of the BLOB *toDecrypt* using the sender's public key *sendPubKey* and, optionally, the recipient's private key *recipPrivKey*.

The BLOB containing the sender's public key is passed in the *sendPubKey* parameter. This key has been generated by the sender using the **GENERATE ENCRYPTION KEYPAIR** command and it has to be sent to the recipient.

The BLOB containing the recipient's private key can be passed in the optional parameter *recipPrivKey*. In this case, the recipient has to generate a pair of encryption keys with the **GENERATE ENCRYPTION KEYPAIR** command and has to send his/her public key to the sender. The keypair-based encryption system guarantees that the message has been encrypted by the sender only and it can be decrypted by the recipient only. For more information about the keypair-based encryption system, refer to the routine **ENCRYPT BLOB**.

The command **DECRYPT BLOB** offers a checksum functionality in order to avoid any BLOB content modification (deliberate or not). If the encrypted BLOB is damaged or modified, the command will do nothing and an error will be returned.

## Example

Refer to the examples given for the **ENCRYPT BLOB** command.

# DELETE FROM BLOB

DELETE FROM BLOB ( blob ; offset ; len )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB from which to delete bytes |
| offset | Longint | ⇒ | Starting offset where bytes will be deleted |
| len | Longint | ⇒ | Number of bytes to be deleted |

## Description

The **DELETE FROM BLOB** command deletes the number of bytes specified by *len* from the BLOB *blob* at the position specified by *offset* (expressed relative to the beginning of the BLOB). The BLOB then becomes *len* bytes smaller.

# DOCUMENT TO BLOB

DOCUMENT TO BLOB ( document ; blob {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Name of the document |
| blob | BLOB | ⇒ | BLOB field or variable to receive the document |
| | | ⇐ | Document contents |
| * | Operator | ⇒ | On Macintosh only: Resource fork is loaded if * is passed otherwise Data fork is loaded |

## Description

**DOCUMENT TO BLOB** loads the whole contents of *document* into *blob*. You must pass the name of an existing document that is not already open, otherwise an error will be generated. To let the user choose the document to be loaded into the BLOB, use the command **Open document** and the process variable *document* (see Example).

**Note regarding Macintosh:** Macintosh documents can be composed of two forks: the Data fork and the Resource fork. By default, the command **DOCUMENT TO BLOB** loads the Data fork of the document. To load the Resource fork of the document instead, pass the optional * parameter. On Windows, the optional * parameter is ignored. Note that the 4D environment provides the equivalent of Mac OS resource forks on Windows. For example, the data fork of a 4D database is stored in a file with the file extension .4DB; the resource fork is stored in a file with the same name and the file extension .RSR. On Windows, if you write a 4D application with the data fork and resource fork stored in BLOBs, you just need to access the file corresponding to the fork with which you want to work.

## Example

You write an Information System that enables you to quickly store and retrieve documents. In a data entry form, you create a button that allows you to load a document into a BLOB field. The method for this button could be:

```
$vhDocRef:=Open document("") ` Select the document of your choice
If(OK=1) ` If a document has been chosen
   CLOSE DOCUMENT($vhDocRef) ` We don't need to keep it open
   DOCUMENT TO BLOB(Document;[YourTable]YourBLOBField) ` Load the document
   If(OK=0)
   ` Handle error
   End if
End if
```

## System variables and sets

OK is set to 1 if the document is correctly loaded, otherwise OK is set to 0 and an error is generated.

## Error Handling

- If you try to load (into a BLOB) a document that does not exist or that is already open by another process or application, the appropriate File Manager error is generated.
- An I/O error can occur if the document is locked, located on a locked volume, or if there is problem in reading the document.
- If there is not enough memory to load the document, an error -108 is generated.

In each case, you can trap the error using an **ON ERR CALL** interruption method.

# ENCRYPT BLOB

ENCRYPT BLOB ( toEncrypt ; sendPrivKey {; recipPubKey} )

| Parameter | Type | | Description |
|---|---|---|---|
| toEncrypt | BLOB | ⇒ | Data to encrypt |
| | | ⇐ | Encrypted data |
| sendPrivKey | BLOB | ⇒ | Sender's private key |
| recipPubKey | BLOB | ⇒ | Recipient's public key |

## Description

The **ENCRYPT BLOB** command encrypts the content of the *toEncrypt* BLOB with the sender's private key *sendPrivKey*, as well as optionally the recipient's public key *recipPubKey*. These keys should be generated by the command **GENERATE ENCRYPTION KEYPAIR** (within the "Secured Protocol" theme).

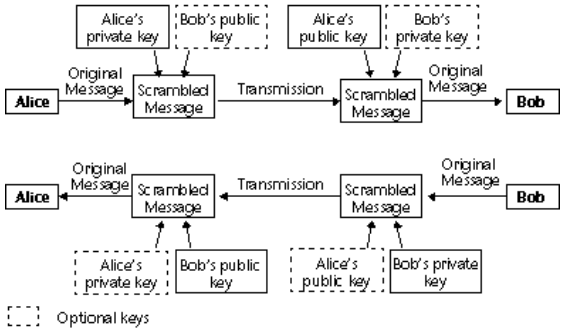
**Note:** This command uses the SSL protocol algorithm and encryption features. To be able to use this command, make sure that the components necessary to the SSL protocol are installed properly on your machine — even though you do not want to use SSL for 4D Web server connections. For detailed information on this protocol, please refer to section **Using TLS Protocol**.

- If one key is used for the encryption (the sender's private key), only people in possession of the public key will be able to read the information. This system guarantees that the sender himself has encrypted the information.
- The simultaneous use of the sender's private key and recipient's public key guarantees that only one recipient will be able to read the information.

The BLOB containing the keys has a PKCS internal format. This standard cross platform format allows exchanging or handling keys simply by copy-pasting in an Email or a text file.

Once the command has been run, the *toEncrypt* BLOB contains the encrypted data that will be decrypted only with the **DECRYPT BLOB** command, with the sender's public key passed as parameter.
Moreover, if the optional recipient's public key has been used to encrypt the information, the recipient's private key will also be necessary for decrypting.

**Encryption principle with public and private keys for message exchange between two people, "Alice" and "Bob":**



**Note:** The cipher contains a checksum functionality in order to avoid any BLOB content modification (deliberately or not). Consequently, an encrypted BLOB should not be modified otherwise it might not be decrypted.

### Optimizing Encryption Commands

Data encryption slows down the execution of your applications, especially if a pair of keys is used. However, you can consider the following optimization tips:

- Depending on the current available memory, the command will execute in "synchronous" or "asynchronous" mode. The asynchronous mode is faster, since it does not freeze the other processes. This mode is automatically used if the available memory is at least twice the size of the data to encrypt.
  Otherwise, for security reasons, the synchronous mode is used. This mode is slower since it freezes the other processes.
- Regarding large BLOBs, you can encrypt only a small "strategic" part of the BLOB in order to reduce the size of data to be processed as well as the processing time.

## Example

- **Using a single key**

A company wants to keep the data stored in a 4D database private. It has to regularly send these information to its subsidiaries through files, via the Internet.

1) The company generates a pair of keys with the command **GENERATE ENCRYPTION KEYPAIR**:

```
 `Method GENERATE_KEYS_TXT
C_BLOB($BPublicKey;$BPrivateKey)
GENERATE ENCRYPTION KEYPAIR($BPrivateKey;$BPublicKey)
BLOB TO DOCUMENT("PublicKey.txt";$BPublicKey)
BLOB TO DOCUMENT("PrivateKey.txt";$BPrivateKey)
```

2) The company keeps the private key and sends a copy of the document containing the public key to each subsidiary. For maximum security, the key should be copied on a disk handed over to the subsidiaries.

3) Then the company copies the private information (stored in the text field, for example) in BLOBs which will be encrypted with the private key:

```
 `Method ENCRYPT_INFO
C_BLOB($vbEncrypted;$vbPrivateKey)
C_TEXT($vtEncrypted)

$vtEncrypted:=[Private]Info
VARIABLE TO BLOB($vtEncrypted;$vbEncrypted)
DOCUMENT TO BLOB("PrivateKey.txt";$vbPrivateKey)
If(OK=1)
   ENCRYPT BLOB($vbEncrypted;$vbPrivateKey)
   BLOB TO DOCUMENT("Update.txt";$vbEncrypted)
End if
```

4) The update files can be sent to the subsidiaries (though a non-secured channel such as the Internet). If a third person gets hold of the encrypted file, he will not be able to decrypt it without the public key.

5) Each subsidiary can decrypt the document with the public key:

```
 `Method DECRYPT_INFO
C_BLOB($vbEncrypted;$vbPublicKey)
C_TEXT($vtDecrytped)
C_TIME($vtDocRef)

ALERT("Please select an encrypted document.")
$vtDocRef:=Open document("") `Select Update.txt
If(OK=1)
   CLOSE DOCUMENT($vtDocRef)
   DOCUMENT TO BLOB(Document;$vbEncrypted)
   DOCUMENT TO BLOB("PublicKey.txt";$vbPublicKey)
   If(OK=1)
      DECRYPT BLOB($vbEncrypted;$vbPublicKey)
      BLOB TO VARIABLE($vbEncrypted;$vtDecrypted)
      CREATE RECORD([Private])
      [Private]Info:=$vtDecrypted
      SAVE RECORD([Private])
   End if
End if
```

- **Using keypairs**

A company wants to use the Internet to exchange information. Each subsidiary receives private information and also sends information to the corporate office. Consequently there are two requirements:
- The recipient only should be able to read the message,
- The recipient must have proof that the message was sent by the sender himself.

1) The corporate office and each subsidiary generate their own key pairs (with the ***GENERATE_KEYS_TXT*** method).

2) The private key is kept secret by both sides. Each subsidiary sends its public key to the corporate office who, in its turn, sends its public key too. This key transfer does not need to be done through a secured channel as the public key is not enough to decrypt the message.

3) To encrypt the information to send, the subsidiary or the corporate house executes the ***ENCRYPT_INFO_2*** method which uses the sender's private key and the recipient's public key to encrypt the information:

```
 `Method ENCRYPT_INFO_2
C_BLOB($vbEncrypted;$vbPrivateKey;$vbPublicKey)
C_TEXT($vtEncrypt)
C_TIME($vtDocRef)

$vtEncrypt:=[Private]Info
VARIABLE TO BLOB($vtEncrypt;$vbEncrypted)
 ` Your own private key is loaded...
DOCUMENT TO BLOB("PrivateKey.txt";$vbPrivateKey)
If(OK=1)
 ` ...and the recipient' s public key
   ALERT("Please select the recipient' s public key.")
   $vhDocRef:=Open document("") `Public key to load
   If(OK=1)
      CLOSE DOCUMENT($vtDocRef)
      DOCUMENT TO BLOB(Document;$vbPublicKey)
 `BLOB encryption with the two keys as parameters
      ENCRYPT BLOB($vbEncrypted;$vbPrivateKey;$vbPublicKey)
      BLOB TO DOCUMENT("Update.txt";$vbEncrypted)
   End if
End if
```

4) The encrypted file can then be sent to the recipient via the Internet. If a third person gets hold of it, he or she will not be able to decrypt the message, even if he or she has the public keys as the recipient's private key will also be required.

5) Each recipient can decrypt the document by using his/her own private key and the sender's public key:

```
 `Method DECRYPT_INFO_2
C_BLOB($vbEncrypted;$vbPublicKey;$vbPrivateKey)
C_TEXT($vtDecrypted)
C_TIME($vhDocRef)

ALERT("Please select the encrypted document.")
$vhDocRef:=Open document("") `Select the Update.txt file
If(OK=1)
   CLOSE DOCUMENT($vhDocRef)
   DOCUMENT TO BLOB(Document;$vbEncrypted)
 `Your own private key is loaded
   DOCUMENT TO BLOB("PrivateKey.txt";$vbPrivateKey)
   If(OK=1)
 ` ...and the sender' s public key
      ALERT("Please select the sender' s public key.")
      $vhDocRef:=Open document("") `Public key to load
      If(OK=1)
         CLOSE DOCUMENT($vhDocRef)
         DOCUMENT TO BLOB(Document;$vbPublicKey)
 `Decrypting the BLOB with two keys as parameters
         DECRYPT BLOB($vbEncrypted;$vbPublicKey;$vbPrivateKey)
         BLOB TO VARIABLE($vbEncrypted;$vtDecrypted)
         CREATE RECORD([Private])
         [Private]Info:=$vtDecrypted
         SAVE RECORD([Private])
      End if
   End if
End if
```

# EXPAND BLOB

EXPAND BLOB ( blob )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB to expand |

## Description

The **EXPAND BLOB** command expands the BLOB *blob* that was previously compressed using the **COMPRESS BLOB** command.

After the call, the OK variable is set to 1 if the BLOB has been expanded. If the expansion could not be performed, the OK variable is set to 0.

If the expansion could not be performed because of a lack of memory, no error is generated and the method resumes its execution.
In any other case (i.e. the BLOB has not been compressed or is damaged), the error -10600 is generated. This error can be trapped using the **ON ERR CALL** command.

To check if a BLOB has been compressed, use the **BLOB PROPERTIES** command.

## Example 1

This example tests if the BLOB *vxMyBlob* is compressed and, if so, expands it:

```
BLOB PROPERTIES(vxMyBlob;$vlCompressed;$vlExpandedSize;$vlCurrentSize)
If($vlCompressed#Is not compressed)
   EXPAND BLOB(vxMyBlob)
End if
```

## Example 2

This example allows you to select a document and then expand it, if it is compressed:

```
$vhDocRef :=Open document("")
If(OK=1)
   CLOSE DOCUMENT($vhDocRef)
   DOCUMENT TO BLOB(Document;vxBlob)
   If(OK=1)
      BLOB PROPERTIES(vxBlob;$vlCompressed;$vlExpandedSize;$vlCurrentSize)
      If($vlCompressed#Is not compressed)
         EXPAND BLOB(vxBlob)
         If(OK=1)
            BLOB TO DOCUMENT(Document;vxBlob)
         End if
      End if
   End if
End if
```

## System variables and sets

The OK variable is set to 1 if the BLOB has been successfully expanded, otherwise it is set to 0.

# INSERT IN BLOB

INSERT IN BLOB ( blob ; offset ; len {; filler} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB into which bytes will be inserted |
| offset | Longint | ⇒ | Starting position where bytes will be inserted |
| len | Longint | ⇒ | Number of bytes to be inserted |
| filler | Longint | ⇒ | Default byte value (0x00..0xFF) 0x00 if omitted |

## Description

The **INSERT IN BLOB** command inserts the number of bytes specified by *len* into the BLOB *blob* at the position specified by *offset*. The BLOB then becomes *len* bytes larger.

If you do not specify the optional *filler* parameter, the bytes inserted into the BLOB are set to *0x00*. Otherwise, the bytes are set to the value you pass in *filler* (modulo 256 — 0..255).

Before the call, you pass in the *offset* parameter the position of the insertion relative to the beginning of the BLOB.

# INTEGER TO BLOB

INTEGER TO BLOB ( entier ; blob ; ordreOctet {; offset | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| entier | Longint | ⇒ | Integer value to write into the BLOB |
| blob | BLOB | ⇒ | BLOB to receive the Integer value |
| ordreOctet | Longint | ⇒ | 0 Native byte ordering 1 Macintosh byte ordering 2 PC byte ordering |
| offset \| * | Variable, Operator | ⇒ | Offset expressed in bytes within the BLOB or * to append the value |
| | | ⇐ | New offset after writing if not * |

## Description

The **INTEGER TO BLOB** command writes the 2-byte Integer value *integer* into the BLOB *blob*.

The *byteOrder* parameter fixes the byte ordering of the 2-byte Integer value to be written. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Macintosh byte ordering | Longint | 1 |
| Native byte ordering | Longint | 0 |
| PC byte ordering | Longint | 2 |

**Note regarding Platform Independence:** If you exchange BLOBs between the Macintosh and PC platforms, it is up to you to manage byte swapping issues when using this command.

If you specify the * optional parameter, the 2-byte Integer value is appended to the BLOB and the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of Integer, Long Integer, Real or Text values (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter or the *offset* variable parameter, the 2-byte Integer value is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

If you pass the *offset* variable parameter, the 2-byte Integer value is written at the byte offset (starting from zero) within the BLOB. No matter where you write the 2-byte Integer value, the size of the BLOB is increased according to the location you passed (plus up to 2 bytes, if necessary). Newly allocated bytes, other than the ones you are writing, are initialized to zero.

After the call, the *offset* variable parameter is returned, incremented by the number of bytes that have been written. Therefore, you can reuse that same variable with another BLOB writing command to write another value.

## Example 1

After executing this code:

```
INTEGER TO BLOB(0x0206;vxBlob;Native byte ordering)
```

- The size of *vxBlob* is 2 bytes
- On PowerPC platform: *vxBLOB{0}* = *$02* and *vxBLOB{1}* = *$06*
- On Intel platform: *vxBLOB{0}* = *$06* and *vxBLOB{1}* = *$02*

## Example 2

After executing this code:

```
INTEGER TO BLOB(0x0206;vxBlob;Macintosh byte ordering)
```

- The size of *vxBlob* is 2 bytes
- On all platforms *vxBLOB{0}* = *$02* and *vxBLOB{1}* = *$06*

## Example 3

After executing this code:

```
INTEGER TO BLOB(0x0206;vxBlob;PC byte ordering)
```

- The size of *vxBlob* is 2 bytes
- On all platforms *vxBLOB{0}* = *$06* and *vxBLOB{1}* = *$02*

## Example 4

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
INTEGER TO BLOB(0x0206;vxBlob;PC byte ordering;*)
```

- The size of *vxBlob* is 102 bytes
- On all platforms *vxBLOB{100}* = *$06* and *vxBLOB{101}* = *$02*
- The other bytes of the BLOB are left unchanged

## Example 5

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
vlOffset:=50
INTEGER TO BLOB(518;vxBlob;Macintosh byte ordering;vlOffset)
```

- The size of *vxBlob* is 100 bytes
- On all platforms *vxBLOB{50}* = *$02* and *vxBLOB{51}* = *$06*
- The other bytes of the BLOB are left unchanged
- The variable *vlOffset* has been incremented by 2 (and is now equal to 52)

# LIST TO BLOB

LIST TO BLOB ( list ; blob {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | Hierarchical list to store in the BLOB |
| blob | BLOB | ⇒ | BLOB to receive the Hierarchical list |
| * | Operator | ⇒ | * to append the value |

## Description

The **LIST TO BLOB** command stores the hierarchical list *list* in the BLOB *blob*.

If you specify the * optional parameter, the hierarchical list is appended to the BLOB and the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of variables or lists (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter, the hierarchical list is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

Wherever the hierarchical list is stored, the size of the BLOB will be increased if necessary according to the specified location (plus up to the size of the list if necessary). Modified bytes (other than the ones you set) are reset to 0 (zero).

**WARNING:** If you use a BLOB for storing lists, you must later use the command **BLOB to list** for reading back the contents of the BLOB, because lists are stored in BLOBs using a 4D internal format.

After the call, if the list has been successfully stored, the OK variable is set to 1. If the operation could not be performed, the OK variable is set to 0; for example, if there was not enough memory.

**Note regarding Platform Independence: LIST TO BLOB** and **BLOB to list** use a 4D internal format for handling lists stored in BLOBs. As a benefit, you do not need to worry about byte swapping between platforms when using these two commands. In other words, a BLOB created on Windows using those commands can be reused on Macintosh, and vice-versa.

## Example

See example for the command **BLOB to list**.

# LONGINT TO BLOB

LONGINT TO BLOB ( longInt ; blob ; byteOrder {; offset | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| longInt | Longint | ➡ | Long Integer value to write into the BLOB |
| blob | BLOB | ➡ | BLOB to receive the Long Integer value |
| byteOrder | Longint | ➡ | 0 Native byte ordering 1 Macintosh byte ordering 2 PC byte ordering |
| offset \| * | Variable, Operator | ➡ | Offset within the BLOB (expressed in bytes) or * to append the value |
| | | ⬅ | New offset after writing if not * |

## Description

The **LONGINT TO BLOB** command writes the 4-byte Long Integer value *integer* into the BLOB *blob*.

The *byteOrder* parameter fixes the byte ordering of the 4-byte Long Integer value to be written. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Macintosh byte ordering | Longint | 1 |
| Native byte ordering | Longint | 0 |
| PC byte ordering | Longint | 2 |

**Note regarding Platform Independence:** If you exchange BLOBs between Macintosh and PC platforms, it is up to you to manage byte swapping issues while using this command.

If you specify the * optional parameter, the 4-byte Long Integer value is appended to the BLOB and the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of Integer, Long Integer, Real or Text values (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter nor the *offset* variable parameter, the 4-byte Long Integer value is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

If you pass the *offset* variable parameter, the 4-byte Long Integer value is written at the offset (starting from zero) within the BLOB. No matter where you write the 4-byte Long Integer value, the size of the BLOB is increased according to the location you passed (plus up to 4 bytes, if necessary). New allocated bytes, other than the ones you are writing, are initialized to zero.

After the call, the *offset* variable parameter is returned, incremented by the number of bytes that have been written. Therefore, you can reuse that same variable with another BLOB writing command to write another value.

## Example 1

After executing this code:

```
LONGINT TO BLOB(0x01020304;vxBlob;Native byte ordering)
```

- The size of *vxBlob* is 4 bytes
- On PowerPC platform: *vxBLOB{0}=$01*, *vxBLOB{1}=$02*, *vxBLOB{2}=$03*, *vxBLOB{3}=$04*
- On Intel platform: *vxBLOB{0}=$04*, *vxBLOB{1}=$03*, *vxBLOB{2}=$02*, *vxBLOB{3}=$01*

## Example 2

After executing this code:

```
LONGINT TO BLOB(0x01020304;vxBlob;Macintosh byte ordering)
```

- The size of *vxBlob* is 4 bytes
- On all platforms *vxBLOB{0}=$01*, *vxBLOB{1}=$02*, *vxBLOB{2}=$03*, *vxBLOB{3}=$04*

## Example 3

After executing this code:

```
LONGINT TO BLOB(0x01020304;vxBlob;PC byte ordering)
```

- The size of *vxBlob* is 4 bytes
- On all platforms *vxBLOB{0}=$04*, *vxBLOB{1}=$03*, *vxBLOB{2}=$02*, *vxBLOB{3}=$01*

## Example 4

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
LONGINT TO BLOB(0x01020304;vxBlob;PC byte ordering;*)
```

- The size of *vxBlob* is 104 bytes
- On all platforms *vxBLOB{100}=$04*, *vxBLOB{101}=$03*, *vxBLOB{102}=$02*, *vxBLOB{103}=$01*
- The other bytes of the BLOB are left unchanged

## Example 5

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
vlOffset:=50
LONGINT TO BLOB(0x01020304;vxBlob;Macintosh byte ordering;vlOffset)
```

- The size of *vxBlob* is 100 bytes
- On all platforms *vxBLOB{50}=$01*, *vxBLOB{51}=$02*, *vxBLOB{52}=$03*, *vxBLOB{53}=$04*
- The other bytes of the BLOB are left unchanged
- The variable *vlOffset* has been incremented by 4 (and is now equal to 54)

# REAL TO BLOB

REAL TO BLOB ( real ; blob ; realFormat {; offset | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| real | Real | ➡ | Real value to write into the BLOB |
| blob | BLOB | ➡ | BLOB to receive the Real value |
| realFormat | Longint | ➡ | 0 Native real format 1 Extended real format 2 Macintosh Double real format 3 Windows Double real format |
| offset \| * | Variable, Operator | ➡ | Offset within the BLOB (expressed in bytes) or * to append the value |
| | | ⬅ | New offset after writing if not * |

## Description

The **REAL TO BLOB** command writes the Real value *real* into the BLOB *blob*.

The *realFormat* parameter fixes the internal format and byte ordering of the Real value to be written. You pass one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Extended real format | Longint | 1 |
| Macintosh double real format | Longint | 2 |
| Native real format | Longint | 0 |
| PC double real format | Longint | 3 |

**Platform Independence Note:** If you exchange BLOBs between Macintosh and PC platforms, it is up to you to manage real formats and byte swapping issues when using this command.

If you specify the * optional parameter, the Real value is appended to the BLOB; the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of Integer, Long Integer, Real or Text values (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter or the *offset* variable parameter, the Real value is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

If you pass the *offset* variable parameter, the Real value is written at the offset (starting from zero) within the BLOB. No matter where you write the Real value, the size of the BLOB is increased according to the location you passed (plus up to 8 or 10 bytes, if necessary). New allocated bytes, other than the ones you are writing, are initialized to zero.

After the call, the *offset* variable parameter is returned, incremented by the number of bytes that have been written. Therefore, you can reuse that same variable with another BLOB writing command to write another value.

## Example 1

After executing this code:

```
C_REAL(vrValue)
vrValue:=...
REAL TO BLOB(vrValue;vxBlob;Native real format)
```

- On all platforms, the size of *vxBlob* is 8 bytes

## Example 2

After executing this code:

```
C_REAL(vrValue)
vrValue:=...
REAL TO BLOB(vrValue;vxBlob;Extended real format)
```

- On all platforms, the size of *vxBlob* is 10 bytes

## Example 3

After executing this code:

```
C_REAL(vrValue)
vrValue:=...
REAL TO BLOB(vrValue;vxBlob;Macintosh double real format) ` or Windows double real format
```

- On all platforms, the size of *vxBlob* is 8 bytes

## Example 4

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
C_REAL(vrValue)
vrValue:=...
INTEGER TO BLOB(vrValue;vxBlob;PC double real format) ` or Macintosh double real format
```

- On all platforms, the size of *vxBlob* is 8 bytes

## Example 5

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
REAL TO BLOB(vrValue;vxBlob;Extended real format;*)
```

- On all platforms, the size of *vxBlob* is 110 bytes
- On all platforms, the real value is stored at the bytes #100 to #109
- The other bytes of the BLOB are left unchanged

## Example 6

After executing this code:

```
SET BLOB SIZE(vxBlob;100)
C_REAL(vrValue)
vrValue:=...
vlOffset:=50
REAL TO BLOB(vrValue;vxBlob;PC double real format;vlOffset) ` or Macintosh double real format
```

- On all platforms, the size of *vxBlob* is 100 bytes
- On all platforms, the real value is stored in the bytes #50 to #57
- The other bytes of the BLOB are left unchanged
- The variable *vlOffset* has been incremented by 8 (and is now equal to 58)

# SET BLOB SIZE

SET BLOB SIZE ( blob ; size {; filler} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB field or variable |
| size | Longint | ➡ | New size of the BLOB |
| filler | Longint | ➡ | ASCII code of filler character |

## Description

**SET BLOB SIZE** resizes the BLOB *blob* according to the value passed in *size*.

If you want to allocate new bytes to a BLOB and want to have those bytes initialized to a specific value, pass the value (0..255) into the *filler* optional parameter.

## Example 1

When you are through with a large process or interprocess BLOB, it is good idea to free the memory it occupies. To do so, write:

```
SET BLOB SIZE(aProcessBLOB;0)
SET BLOB SIZE(◊anInterprocessBLOB;0)
```

## Example 2

The following example creates a BLOB of 16K filled of 0xFF:

```
C_BLOB(vxData)
SET BLOB SIZE(vxData;16*1024;0xFF)
```

## Error Handling

If you cannot resize a BLOB due to insufficient memory, the error -108 is generated. You can trap this error using an **ON ERR CALL** interruption method.

# TEXT TO BLOB

TEXT TO BLOB ( text ; blob {; textFormat {; offset | *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ➡ | Text to write into the BLOB |
| blob | BLOB | ➡ | BLOB to receive the text |
| textFormat | Longint | ➡ | Format and character set of text |
| offset \| * | Variable, Operator | ➡ | Offset within the BLOB (expressed in bytes) or * to append the value |
| | | ⬅ | New offset after writing if not * |

## Description

The **TEXT TO BLOB** command writes the Text value *text* into the BLOB *blob*.

The *textFormat* parameter can be used to set the internal format and the character set of the text value to be written. To do this, pass one of the following constants (found in the "**BLOB**" theme) in the *textFormat* parameter:

| Constant | Type | Value |
|---|---|---|
| Mac C string | Longint | 0 |
| Mac Pascal string | Longint | 1 |
| Mac text with length | Longint | 2 |
| Mac text without length | Longint | 3 |
| UTF8 C string | Longint | 4 |
| UTF8 text with length | Longint | 5 |
| UTF8 text without length | Longint | 6 |

If you omit the *textFormat* parameter, by default 4D uses the Mac C string format. In databases created beginning with version 11, 4D works by default with the Unicode character set (UTF8) for managing text, so it is recommended to use this character set.

**Notes:**

- The "UTF8" constants can only be used when the application runs in Unicode mode.
- The "Mac" constants cannot work with texts greater than 32 KB.
- If you want to work with character sets other than UTF8, use the **CONVERT FROM TEXT** command.

The following table describes each of these formats:

| Text format | Description and Examples | |
|---|---|---|
| C string | The text is ended by a NULL character (ASCII code $00). | |
| | *UTF8* | "" --> $00 |
| | | "Café" --> $43 61 66 C3 A9 00 |
| | *Mac* | "" --> $00 |
| | | "Café" --> $43 61 66 8E 00 |
| Pascal string | The text is preceded by a 1-byte length. | |
| | *UTF8* | - |
| | | - |
| | *Mac* | "" --> $00 |
| | | "Café" --> $04 43 61 66 8E |
| Text with length | The text is preceded by a 4-byte (UTF8) or 2-byte (Mac) length. | |
| | *UTF8* | "" --> $00 00 00 00 |
| | | "Café" --> $00 00 00 05 43 61 66 C3 A9 |
| | *Mac* | "" --> $00 00 |
| | | "Café" --> $00 04 43 61 66 8E |
| Text without length | The text is composed only of its characters. | |
| | *UTF8* | "" --> No data |
| | | "Café" --> $43 61 66 C3 A9 |
| | *Mac* | "" --> No data |
| | | "Café" --> $43 61 66 8E |

If you specify the * optional parameter, the Text value is appended to the BLOB; the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of Integer, Long Integer, Real or Text values (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter nor the *offset* variable parameter, the Text value is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

If you pass the *offset* variable parameter, the Text value is written at the offset (starting from zero) within the BLOB. No matter where you write the Text value, the size of the BLOB is, increased according to the location you passed (plus up to the size of the text, if necessary). New allocated bytes, other than the ones you are writing, are initialized to zero.

After the call, the *offset* variable parameter is returned, incremented by the number of bytes that have been written. Therfore, you can reuse that same variable with another BLOB writing command to write another value.

## Example

After executing this code:

```
SET BLOB SIZE(vxBlob;0)
C_TEXT(vtValue)
vtValue:="Café" ` Length of vtValue is 4 bytes
TEXT TO BLOB(vtValue;vxBlob;Mac C string) ` Size of BLOB becomes 5 bytes
TEXT TO BLOB(vtValue;vxBlob;Mac Pascal string) ` Size of BLOB becomes 5 bytes
TEXT TO BLOB(vtValue;vxBlob;Mac text with length) ` Size of BLOB becomes 6 bytes
TEXT TO BLOB(vtValue;vxBlob;Mac text without length) ` Size of BLOB becomes 4 bytes
TEXT TO BLOB(vtValue;vxBlob;UTF8 C string) ` Size of BLOB becomes 6 bytes
TEXT TO BLOB(vtValue;vxBlob;UTF8 text with length) ` Size of BLOB becomes 9 bytes
TEXT TO BLOB(vtValue;vxBlob;UTF8 text without length) ` Size of BLOB becomes 5 bytes
```

# VARIABLE TO BLOB

VARIABLE TO BLOB ( variable ; blob {; offset | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ➡ | Variable to store in the BLOB |
| blob | BLOB | ➡ | BLOB to receive the variable |
| offset \| * | Variable, Operator | ➡ | Offset within the BLOB (expressed in bytes) or * to append the value |
| | | ⬅ | New offset after writing if not * |

## Description

The **VARIABLE TO BLOB** command stores the variable *variable* in the BLOB *blob*.

If you specify the * optional parameter, the variable is appended to the BLOB and the size of the BLOB is extended accordingly. Using the * optional parameter, you can sequentially store any number of variables or lists (see other BLOB commands) in a BLOB, as long as the BLOB fits into memory.

If you do not specify the * optional parameter or the *offset* variable parameter, the variable is stored at the beginning of the BLOB, overriding its previous contents; the size of the BLOB is adjusted accordingly.

If you pass the *offset* variable parameter, the variable is written at the offset (starting from zero) within the BLOB. No matter where you write the variable, the size of the BLOB is increased according to the location you passed (plus the size of the variable, if necessary). Newly allocated bytes, other than the ones you are writing, are initialized to zero.

After the call, the *offset* variable parameter is returned, incremented by the number of bytes that have been written. Therefore, you can reuse that same variable with another BLOB writing command to write another variable or list.

**VARIABLE TO BLOB** accepts any type of variable (including other BLOBs), except the following:

- Pointer
- Array of pointers

Note that:

- if you store a Long Integer variable that is a reference to a hierarchical list (ListRef), **VARIABLE TO BLOB** stores the Long Integer variable, not the list. To store and retrieve hierarchical lists in and from a BLOB, use the **LIST TO BLOB** and **BLOB to list** commands.
- if you pass a **C_OBJECT** object in the *variable* parameter, the command places it in the BLOB as JSON in UTF-8. If the object contains pointers, their dereferenced values are stored in the BLOB, not the pointers themselves.

**WARNING:** If you use a BLOB for storing variables, you must later use the command **BLOB TO VARIABLE** for reading back the contents of the BLOB, because variables are stored in BLOBs using a 4D internal format.

After the call, if the variable has been successfully stored, the OK variable is set to 1. If the operation could not be performed, the OK variable is set to 0; for example, there was not enough memory.

**Note regarding Platform Independence: VARIABLE TO BLOB** and **BLOB TO VARIABLE** use a 4D internal format for handling variables stored in BLOBs. As a benefit, you do not need to worry about byte swapping between platforms while using these two commands. In other words, a BLOB created on Windows using either of these commands can be reused on Macintosh, and vice-versa.

## Example 1

The two following project methods allow you to quickly store and retrieve arrays into and from documents on disk:

```
  ` SAVE ARRAY project method
  ` SAVE ARRAY ( String ; Pointer )
  ` SAVE ARRAY ( Document ; -> Array )
C_STRING(255;$1)
C_POINTER($2)
C_BLOB($vxArrayData)
VARIABLE TO BLOB($2->;$vxArrayData) ` Store the array into the BLOB
COMPRESS BLOB($vxArrayData) ` Compress the BLOB
BLOB TO DOCUMENT($1;$vxArrayData) ` Save the BLOB on disk
```

```
   ` LOAD ARRAY project method
   ` LOAD ARRAY ( String ; Pointer )
   ` LOAD ARRAY ( Document ; -> Array )
C_STRING(255;$1)
C_POINTER($2)
C_BLOB($vxArrayData)
DOCUMENT TO BLOB($1;$vxArrayData) ` Load the BLOB from the disk
EXPAND BLOB($vxArrayData) ` Expand the BLOB
BLOB TO VARIABLE($vxArrayData;$2->) ` Retrieve the array from the BLOB
```

After these methods have been added to your application, you can write:

```
ARRAY STRING(...;asAnyArray;...)
` ...
SAVE ARRAY($vsDocName;->asAnyArray)
` ...
LOAD ARRAY($vsDocName;->asAnyArray)
```

## Example 2

The two following project methods allow you to quickly store and retrieve any set of variables into and from a BLOB:

```
 //STORE VARIABLES INTO BLOB project method
 //STORE VARIABLES INTO BLOB ( Pointer { ; Pointer ... { ; Pointer } } )
 //STORE VARIABLES INTO BLOB ( BLOB { ; Var1 ... { ; Var2 } } )
C_POINTER($1)
C_LONGINT($vlParam)

SET BLOB SIZE($1->;0)
For($vlParam;2;Count parameters)
   VARIABLE TO BLOB($1->;$1->;*)
End for

 //RETRIEVE VARIABLES FROM BLOB project method
 //RETRIEVE VARIABLES FROM BLOB ( Pointer { ; Pointer ... { ; Pointer } } )
 //RETRIEVE VARIABLES FROM BLOB ( BLOB { ; Var1 ... { ; Var2 } } )
C_POINTER($1)
C_LONGINT($vlParam;$vlOffset)

$vlOffset:=0
For($vlParam;2;Count parameters)
   BLOB TO VARIABLE($1->;$1->;$vlOffset)
End for
```

After these methods have been added to your application, you can write:

```
STORE VARIABLES INTO BLOB(->vxBLOB;->vgPicture;->asAnArray;->alAnotherArray)
 // ...
RETRIEVE VARIABLES FROM BLOB(->vxBLOB;->vgPicture;->asAnArray;->alAnotherArray)
```

## System variables and sets

The OK variable is set to 1 if the variable has been successfully stored, otherwise it is set to 0.

# Boolean

- Boolean Commands
- False
- Not
- True

## Boolean Commands

4D includes Boolean functions, are used for Boolean calculations:

```
True
False
Not
```

### Example

This example sets a *Boolean* variable based on the value of a button. It returns True in *myBoolean* if the *myButton* button was clicked and False if the button was not clicked. When a button is clicked, the button variable is set to 1.

```
If(myButton=1) ` If the button was clicked
   myBoolean:=True ` myBoolean is set to True
Else ` If the button was not clicked,
   myBoolean:=False ` myBoolean is set to False
End if
```

The previous example can be simplified into one line.

```
myBoolean:=(myButton=1)
```

# False

False -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | False |

## Description

**False** returns the Boolean value False.

## Example

The following example sets the variable *vbOptions* to False:

```
vbOptions:=False
```

# Not

Not ( boolean ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| boolean | Boolean | ⇒ | Boolean value to negate |
| Function result | Boolean | ⇒ | Opposite of Boolean |

## Description

The **Not** function returns the negation of *boolean*, changing True to False or False to True.

## Example

This example first assigns True to a variable, then changes the variable value to False, and then back to True.

```
vResult:=True ` vResult is set to True
vResult:=Not(vResult) ` vResult is set to False
vResult:=Not(vResult) ` vResult is set to True
```

# True

True -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True |

## Description

**True** returns the Boolean value True.

## Example

The following example sets the variable *vbOptions* to True:

```
vbOptions:=True
```

# Cache Management

4D integrates a built-in data cache scheme for accelerating I/O operations. The fact that data modifications are, for some time, present in the data cache and not on the disk is transparent to your coding. For example, if you issue a **QUERY** call, the 4D database engine integrates the data cache in the query operation.

The database cache manager has been fully rewritten in 4D v16, allowing it to take advantage of 64-bit environments. Automatically enabled and optimized, it can however be dynamically configured or analyzed with the commands from this theme.

Note also that a Cache flush periodicity selector can be used with the **SET DATABASE PARAMETER** and **Get database parameter** commands.

- Cache info New 16.0
- FLUSH CACHE Updated 16.0
- Get cache size New 16.0
- GET MEMORY STATISTICS Updated 16.0
- SET CACHE SIZE New 16.0

# Cache info

Cache info {{ dbFilter )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| dbFilter | Object | ⇒ | Defines list of attributes to be returned (filtered per DB) |
| Function result | Object | ⇐ | Information about cache |

## 64-bit only

This command only works in 4D 64-bit versions.

## Description

The **Cache info** command returns an object that contains detailed information about the current cache contents (used memory, loaded tables and indexes, etc.)

**Note:** This command only works in local mode (4D Server and 4D); it must not be used from 4D in remote mode.

By default, returned information refers to the running database only. The optional *dbFilter* object parameter allows you to specify the scope of the command:

- pass the "dbFilter" attribute with the "All" value to get cache information about all running databases, including components.
- pass the "dbFilter" attribute with a "" (empty string) value to get information about the current database only (equivalent to omitting the *dbFilter* parameter).

The **Cache info** command returns a single object that contains all the relevant information about the cache. The returned object has the following basic structure:

```
{
   "maxMem": Maximum cache size (real),
   "usedMem": Current cache size (real),
   "objects": [...] Array of objects currently loaded in cache
}
```

Elements of the *objects* array are root objects (tables, indexes, Blobs, etc.) which are currently loaded in the cache. Each element contains specific attributes that describe its current status. For more information about advanced interpretation of this data, please contact your local Technical Service department.

## Example

You want to get cache information for the current database:

```
C_OBJECT($cache)
$cache:=Cache info
```

You want to get cache information for the database and all opened components:

```
C_OBJECT($dbFilter)
OB SET($dbFilter;"dbFilter";"All")
$cache:=Cache info($dbFilter)
```

# FLUSH CACHE

FLUSH CACHE {( size | * )}

| Parameter | Type | | Description |
|---|---|---|---|
| size \| * | Real, Operator | ⇒ | * to completely free cache memory, or number of bytes to free in cache |

## Description

The **FLUSH CACHE** command immediately saves the data buffers to disk. All changes that have been made to the database are stored on disk.

By default, the current cache memory is left untouched, which means that its data continues to be used for subsequent reading accesses. Optionally, you can pass a parameter to modify its contents:

- pass * to save the cache and free up entire cache memory.
- pass a *size* value to save the cache and free up only the *size* number of bytes from the cache.

**Note:** Passing a parameter to this command is reserved for testing purposes. For performance reasons, it is not recommended to free up the cache in the production environment.

In normal cases, you should not call this command, as 4D saves data modifications on a regular basis. The **Flush Cache every X Seconds (Minutes)** option on the **Database/Memory page** of the Database Settings, which specifies how often to save, is typically used to control cache flushing. We recommend using the default value of 20 seconds. Note also that the Cache flush periodicity parameter can be set and read using the **SET DATABASE PARAMETER** and **Get database parameter** commands.

# Get cache size

Get cache size -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Real |  | Size of database cache in bytes |

## Description

The **Get cache size** command returns the current database cache size in bytes.

**Note:** This command only works in local mode (4D Server and 4D); it must not be used from 4D in remote mode.

## Example

See example for **SET CACHE SIZE** command.

# GET MEMORY STATISTICS

GET MEMORY STATISTICS ( infoType ; arrNames ; arrValues ; arrCount )

| Parameter | Type | | Description |
|---|---|---|---|
| infoType | Longint | ⇨ | Selector of information to get |
| arrNames | Text array | ⇦ | Information titles |
| arrValues | Real array | ⇦ | Information values |
| arrCount | Real array | ⇦ | Number of objects concerned (if available) |

## Description

The **GET MEMORY STATISTICS** command recovers information related to the use of the data cache by 4D. This information can be used to analyze the functioning of the application.

In the *infoType* parameter, pass a value indicating the type of information that you want to obtain:

- 1 = General memory information. This information is also available via the Runtime Explorer: size of physical, virtual, free and used memory, stack memory and free stack memory, etc.
- 2 = Summary of database cache occupancy statistics (4D 32-bit only).

**Compatibility Note:** Value 2 is deprecated for 4D 64-bit versions. For these versions, we recommend using the **Cache info** command to get cache statistics.

After the command has been executed, the statistics are provided in the *arrNames*, *arrValues* and *arrCount* arrays. For more information about advanced interpretation of this data, please contact your local Technical Service department.

# SET CACHE SIZE

SET CACHE SIZE ( size {; minFreeSize} )

| Parameter | Type | | Description |
|---|---|---|---|
| size | Real | ⇒ | Size of database cache in bytes |
| minFreeSize | Real | ⇒ | Minimum number of bytes to release when cache is full |

## 64-bit only

This command only works in 4D 64-bit versions.

## Description

The **SET CACHE SIZE** command sets the database cache size dynamically and, optionally, sets the mininum byte size at which to start to free memory.

**Note:** This command only works in local mode (4D Server and 4D); it cannot be used in 4D remote mode.

In *size*, pass the new size for the database cache in bytes. This new size is applied dynamically when the command is executed.

In *minFreeSize*, pass the minimum size of memory to release from the database cache when the engine needs to make space in order to allocate an object to it (value in bytes). The purpose of this option is to reduce the number of times that data is released from the cache in order to obtain better performance.
By default, if this option is not used, 4D unloads at least 10% of the cache when space is needed. If your database works with a large cache, it could be advantageous to use a fixed size that does not depend on the cache size. You can adjust this setting according to the size of the blocks of data being handled in your database.

## Example

You want to add 100 MB to the current database cache size. You can write:

```
C_REAL($currentCache)
$currentCache:=Get cache size
 // current cache size is, for example, 419430400
SET CACHE SIZE($currentCache+10000000)
 // current cache size is now 519430400
```

# Communications

- GET SERIAL PORT MAPPING
- RECEIVE BUFFER
- RECEIVE PACKET
- RECEIVE RECORD
- RECEIVE VARIABLE
- SEND PACKET
- SEND RECORD
- SEND VARIABLE
- SET CHANNEL
- SET TIMEOUT
- USE CHARACTER SET

# GET SERIAL PORT MAPPING

GET SERIAL PORT MAPPING ( numArray ; nameArray )

| Parameter | Type | | Description |
|---|---|---|---|
| numArray | Longint array | ⇐ | Array of port numbers |
| nameArray | String array | ⇐ | Array of port names |

## Description

The **GET SERIAL PORT MAPPING** command returns two arrays, *numArray* and *nameArray*, containing the serial port numbers and the serial port names of the current machine.

This command is useful under Mac OS X, where the operating system dynamically allocates the port number when using a USB serial adapter. You can address any extended serial port using its name (static), regardless of its actual number.

**Note:** This command does not return meaningful values with standard ports. If you want to address a standard port, you must pass its value (0 or 1) directly using the **SET CHANNEL** command (former operation of 4D).

## Example

This project method can be used to address the same serial port (without protocol), regardless of the number that has been assigned to it:

```
ARRAY TEXT($arrPortNames;0)
ARRAY LONGINT($arrPortNums;0)
C_LONGINT($vPortNum;$vFinalPortNum)

 `Find out the current numbers of the serial ports
GET SERIAL PORT MAPPING($arrPortNums;$arrPortNames)
$vPortNum:=Find in array($arrPortNames;vPortName)
 ` vPortName contains the name of the port to be used: it may come from a dialog box,
 ` a value stored in a field, etc.
If(arrPortNums{$vPortNum}=0)
   $vFinalPortNum:=0 `special case under Mac OS X
Else
   $vFinalPortNum:=arrPortNums{$vPortNum}+100
End if
SET CHANNEL($vFinalPortNum;params) `params contains the communication parameters
... `Carry out the desired operations
SET CHANNEL(11) `Closing of port
```

# RECEIVE BUFFER

RECEIVE BUFFER ( receiveVar )

| Parameter | Type | | Description |
|---|---|---|---|
| receiveVar | Text variable | ➡ | Variable to receive data |

## Description

**RECEIVE BUFFER** reads the serial port that was previously opened with **SET CHANNEL**. The serial port has a buffer that fills with characters until a command reads from the buffer. **RECEIVE BUFFER** gets the characters from the serial buffer, put them into *receiveVar* then clears the buffer. If there are no characters in the buffer, then *receiveVar* will contain nothing.

**On Windows**

The Windows serial port buffer is limited in size to 10 Kbytes. This means that the buffer can overflow. When it is full and new characters are received, the new characters replace the oldest characters. The old characters are lost; therefore, it is essential that the buffer is read quickly when new characters are received.

**On Mac OS**

The Mac OS X serial port buffer capacity is, in theory, unlimited (depending on the available memory). If the buffer is full and new characters are received, the new characters replace the oldest characters. The old characters are lost; therefore, it is essential that the buffer is read quickly when new characters are received.

**RECEIVE BUFFER** is different from **RECEIVE PACKET** in that it takes whatever is in the buffer and then immediately returns. **RECEIVE PACKET** waits until it finds a specific character or until a given number of characters are in the buffer.

During the execution of **RECEIVE BUFFER**, the user can interrupt the reception by pressing **Ctrl-Alt-Shift** (Windows) or **Command-Option-Shift** (Macintosh). This interruption generates an error -9994 that you can catch with an error-handling method installed using **ON ERR CALL**.

## Example

The project method ***LISTEN TO SERIAL PORT*** uses **RECEIVE BUFFER** to get text from the serial port and accumulate it into a an interprocess variable:

```
  ` LISTEN TO SERIAL PORT
  ` Opening the serial port
SET CHANNEL(201;Speed 9600+Data bits 8+Stop bits one+Parity none)
<>IP_Listen_Serial_Port:=True
While(<>IP_Listen_Serial_Port)
   RECEIVE BUFFER($vtBuffer)
   If((Length($vtBuffer)+Length(<>vtBuffer))>MAXTEXTLEN)
      <>vtBuffer:=""
   End if
   <>vtBuffer:=<>vtBuffer+$Buffer
End while
```

At this point, any other process can read the interprocess *◊vtBuffer* to work with the data coming from the serial port.

To stop listening to the serial port, just execute:

```
  ` Stop listening to the serial port
◊IP_Listen_Serial_Port:=False
```

Note that access to the interprocess *◊vtBuffer* variable should be protected by a semaphore, so that processes will not conflict. See the command **Semaphore** for more information.

# RECEIVE PACKET

RECEIVE PACKET ( {docRef ;} receiveVar ; stopChar | numBytes )

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ⇒ | Document reference number, or Current channel (serial port or document) |
| receiveVar | Text variable, BLOB variable | ⇒ | Variable to receive data |
| stopChar \| numBytes | String, Longint | ⇒ | Character(s) at which to stop receiving, or Number of bytes to receive |

## Description

**RECEIVE PACKET** reads characters from a serial port or from a document.

If *docRef* is specified, this command retrieves data from a document opened using **Open document**, **Create document** or **Append document**. If *docRef* is omitted, this command retrieves data from the serial port or the document opened using **SET CHANNEL**.

Whatever the source, the characters read are returned in *receiveVar*, which must be a Text, String or BLOB variable. If the characters have been sent by the **SEND PACKET** command, the type must correspond to that of the packet sent.

**Notes:**

- When the package received is of the BLOB type, the command does not take into account any character set defined by the **USE CHARACTER SET** command. The BLOB is returned without any modification.
- When the package received is of the Text type, the **RECEIVE PACKET** command supports Byte Order Marks (BOMs). In this case, if the current character set is of the Unicode type (UTF-8, UTF-16 or UTF-32), 4D attempts to identify a BOM among the first bytes received. If one is detected, it is filtered out of the *receiveVar* variable and 4D uses the character set that it defines instead of the current character set.

To read a particular number of characters, pass this number in *numBytes*. If the *receiveVar* variable is of the Text type, in a single call you can read up to 2 GB of text (theoretical value).

To receive data until a particular string (composed of one or more characters) is encountered, pass this string in *stopChar* (the string is not returned in *receiveVar*).

In this case, if the character string specified by *stopChar* is not found:

- When **RECEIVE PACKET** is reading a document, it will stop reading at the end of the document.
- When **RECEIVE PACKET** is reading from a serial port, it will attempt to wait indefinitely until the timeout (if any) has elapsed (see **SET TIMEOUT**) or until the user interrupts the reception (see below).

During execution of **RECEIVE PACKET**, the user can interrupt the reception by pressing **Ctrl-Alt-Shift** (Windows) or **Command-Option-Shift** (Macintosh). This interruption generates an error -9994 that you can catch with an error-handling method installed using **ON ERR CALL**. Usually, you will only have to handle interruption of a reception when communicating over a serial port.

When reading a document, the first **RECEIVE PACKET** begins reading at the beginning of the document. The reading of each subsequent packet begins at the character following the last byte read.

**Note:** This command is useful for document opened with **SET CHANNEL**. On the other hand, for a document opened with **Open document**, **Create document** or **Append document**, you can use the **Get document position** and **SET DOCUMENT POSITION** commands to get and change the location in the document where the next writing (**SEND PACKET**) or reading (**RECEIVE PACKET**) will occur.

When attempting to read past the end of a file, **RECEIVE PACKET** will return with the data read up to that point and the variable OK will be set to 1. Then, the next **RECEIVE PACKET** will return an empty string and set the OK variable to zero.

## Example 1

The following example reads 20 characters from a serial port into the variable *getTwenty*:

```
RECEIVE PACKET(getTwenty;20)
```

## Example 2

The following example reads data from the document referenced by the variable *myDoc* into the variable *vData*. It reads until it encounters a carriage return:

```
RECEIVE PACKET(myDoc;vData;Char(Carriage return))
```

## Example 3

The following example reads data from the document referenced by the variable *myDoc* into the variable *vData*. It reads until it encounters the *</TD>* (end of table cell) HTML tag:

```
RECEIVE PACKET(myDoc;vData;"</TD>")
```

## Example 4

The following example reads data from a document into fields. The data is stored as fixed-length fields. The method calls a subroutine to strip any trailing spaces (spaces at the end of the string). The subroutine follows the method:

```
$vhDocRef :=Open document("";"TEXT") ` Open a TEXT document
If(OK=1) ` If the document was opened
   Repeat ` Loop until no more data
      RECEIVE PACKET($vhDocRef;$Var1;15) ` Read 15 characters
      RECEIVE PACKET($vhDocRef;$Var2;15) ` Do same as above for second field
      If(($Var1#"")|($Var2#"")) ` If at least one of the fields is not empty
         CREATE RECORD([People]) ` Create a new record
         [People]First :=Strip($Var1) ` Save the first name
         [People]Last :=Strip($Var2) ` Save the last name
         SAVE RECORD([People]) ` Save the record
      End if
   Until(OK=0)
   CLOSE DOCUMENT($vhDocRef) ` Close the document
End if
```

The spaces at the end of the data are stripped by the following method, called **Strip**:

```
For($i;Length($1);1;-1) ` Loop from end of string to start
   If($1≤$i≥#" ") ` If it is not a space…
      $i :=-$i  ` Force the loop to end
   End if
End for
$0:=Delete string($1;-$i;Length($1)) ` Delete the spaces
```

## System variables and sets

After a call to **RECEIVE PACKET**, the OK system variable is set to 1 if the packet is received without error. Otherwise, the OK system variable is set to 0.

# RECEIVE RECORD

RECEIVE RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table into which to receive the record, or Default table, if omitted |

## Description

**RECEIVE RECORD** receives a record into *table* from the serial port or document opened by the **SET CHANNEL** command. The record must have been sent with **SEND RECORD**. When you execute **RECEIVE RECORD**, a new record is automatically created for *table*. If the record is received correctly, you must then use **SAVE RECORD** to save the new record.

The complete record is received. This means that pictures and BLOBs stored in or with the record are also received.

**Important:** When records are being sent and received using **SEND RECORD** and **RECEIVE RECORD**, the source table structure and the destination table structure must be compatible. If they are not, 4D will convert values according to the table definitions when **RECEIVE RECORD** is executed.

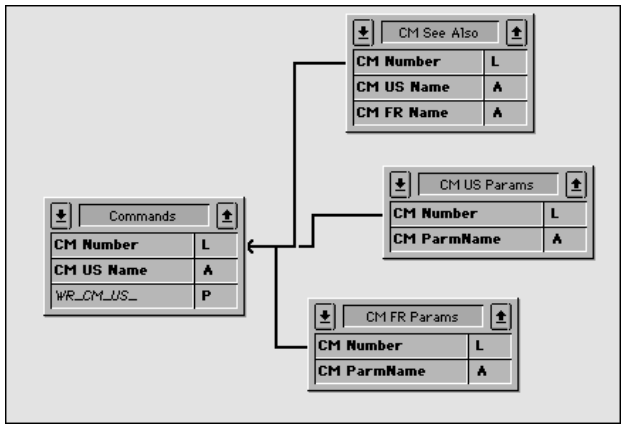
**Notes:**

1. If you receive a record from a document using this command, the document must have been opened using the **SET CHANNEL** command. You cannot use **RECEIVE RECORD** with a document opened with **Open document**, **Create document** or **Append document**.
2. During the execution of **RECEIVE RECORD**, the user can interrupt the reception by pressing **Ctrl-Alt-Shift** (Windows) or **Command-Option-Shift** (Macintosh). This interruption generates an error -9994 that you can catch with an error-handling method installed using **ON ERR CALL**. Usually, you only need to handle the interruption of a reception while communicating over a serial port.

## Example

A combined use of **SEND VARIABLE**, **SEND RECORD**, **RECEIVE VARIABLE** and **RECEIVE RECORD** is ideal for archiving data or for exchanging data between identical single-user databases used in different places. You can exchange data between 4D databases using the import/export commands such as **EXPORT TEXT** and **IMPORT TEXT**. However, if your data contains graphics and/or related tables, using **SEND RECORD** and **RECEIVE RECORD** is far more convenient.

For instance, consider a documentation system based on 4D and 4D Write. Since several writers in different locations wordwide work on it, we need a simple way to exchange data between the different databases. Here is a simplified view of the database structure:



The table *[Commands]* contains the description of each command or topic. The tables *[CM US Params]* and *[CM FR Params]* respectivily contain the parameter list for each command in English and in French. The table *[CM See Also]* contains the commands listed as reference (See Also section) for each command. Exchanging documentation between databases therefore consists in sending the *[Commands]* records and their related records. To do so, we use **SEND RECORD** and **RECEIVE RECORD**. In addition, we use **SEND VARIABLE** and **SEND RECORD** in order to mark the import/export document with tags.

Here is the (simplified) project method for exporting the documentation:

```
 // CM_EXPORT_SEL project method
 // This method works with the current selection of the [Commands] table

SET CHANNEL(12;"") // Let's the user create an open a channel document
If(OK=1)
 //  Tag the document with a variable that indicates its contents
 //  Note: the BUILD_LANG process variable indicates if US (English) or FR (French) data is sent
   $vsTag:="4DV6COMMAND"+BUILD_LANG
   SEND VARIABLE($vsTag)
 //  Send a variable indicationg how many [Commands] are sent
   $vlNbCmd:=Records in selection([Commands])
   SEND VARIABLE($vlNbCmd)
   FIRST RECORD([Commands])
 //  For each command
   For($vlCmd;1;$vlNbCmd)
 //  Send the [Commands] record
      SEND RECORD([Commands])
 //  Select all the related records
      RELATE MANY([Commands])
 //  Depending on the language, send a variable indicating
 //  the number of parameters that will follow
      Case of
         :(BUILD_LANG="US")
            $vlNbParm:=Records in selection([CM US Params])
         :(BUILD_LANG="FR")
            $vlNbParm:=Records in selection([CM FR Params])
      End case
      SEND VARIABLE($vlNbParm)
 //  Send the parameter records (if any)
      For($vlParm;1;$vlNbParm)
         Case of
            :(BUILD_LANG="US")
               SEND RECORD([CM US Params])
               NEXT RECORD([CM US Params])
            :(BUILD_LANG="FR")
               SEND RECORD([CM FR Params])
               NEXT RECORD([CM FR Params])
         End case
      End for
 //  Send a variable indicating how many  “See Also”  will follow
      $vlNbSee:=Records in selection([CM See Also])
      SEND VARIABLE($vlNbSee)
 //  Send the [See Also] records (if any)
      For($vlSee;1;$vlNbSee)
         SEND RECORD([CM See Also])
         NEXT RECORD([CM See Also])
      End for
 // Go to the next [Commands] record and continue the export
      NEXT RECORD([Commands])
   End for
   SET CHANNEL(11) // Close the document
End if
```

Here is the (simplified) project method for importing the documentation:

```
 // CM_IMPORT_SEL project method

SET CHANNEL(10;"") // Let's user open an existing document
If(OK=1) // If a document was open
   RECEIVE VARIABLE($vsTag) // Try receiving the expected tag variable
   If($vsTag="4DV6COMMAND@") // Did we get the right tag?
      $CurLang:=Substring($vsTag;Length($vsTag)-1) // Extract language from the tag
      If(($CurLang="US")|($CurLang="FR")) // Did we get a valid language
         RECEIVE VARIABLE($vlNbCmd) // How many commands are there in this document?
         If($vlNbCmd>0) // If at least one
            For($vlCmd;1;$vlNbCmd) // For each archived [Commands] record
 // Receive the record
               RECEIVE RECORD([Commands])
 // Call a subroutine that saves the new record or copies its values
```

```
    // into an already existing record
                CM_IMP_CMD($CurLang)
    // Receive the number of parameters (if any)
                RECEIVE VARIABLE($vlNbParm)
                If($vlNbParm>=0)
    // Call a subroutine that calls RECEIVE RECORD then saves the new records
    // or copies them into already existing records
                   CM_IMP_PARM($vlNbParm;$CurLang)
                End if
    // Receive the number of  “See Also”  (if any)
                RECEIVE VARIABLE($vlNbSee)
                If($vlNbSee>0)
    // Call a subroutine that calls RECEIVE RECORD then saves the new records
    // or copies them into already existing records
                   CM_IMP_SEEA($vlNbSee;$CurLang)
                End if
             End for
          Else
             ALERT("The number of commands in this export document is invalid.")
          End if
       Else
          ALERT("The language of this export document is unkown.")
       End if
    Else
       ALERT("This document is NOT a Commands export document.")
    End if
    SET CHANNEL(11) // Close document
End if
```

Note that we do not test the OK variable while receiving the data nor try to catch the errors. However, because we stored variables in the document that describes the document itself, if these variables, once received, made sense, the probability for an error is very low. If for instance a user opens a wrong document, the first test stops the operation right away.

## System variables and sets

The OK system variable is set to 1 if the record is received. Otherwise, the OK system variable is set to 0.

# RECEIVE VARIABLE

RECEIVE VARIABLE ( variable )

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ⇨ | Variable in which to receive |

## Description

**RECEIVE VARIABLE** receives *variable*, which was previously sent by **SEND VARIABLE** from the document or serial port previously opened by **SET CHANNEL**.

In interpreted mode, if the variable does not exist prior to the call to **RECEIVE VARIABLE**, the variable is created, typed and assigned according to what has been received. In compiled mode, the variable must be of the same type as what is received. In both cases, the contents of the variable are replaced with what is received.

**Notes:**

1. If you receive a variable from a document using this command, the document must have been opened using the **SET CHANNEL** command. You cannot use **RECEIVE VARIABLE** with a document opened with **Open document**, **Create document** or **Append document**.
2. This command does not support array variables. If you want to send and receive arrays from a document or over a serial port, use the **BLOB Commands**.
3. During the execution of **RECEIVE VARIABLE**, the user can interrupt the reception by pressing **Ctrl-Alt-Shift** (Windows) or **Command-Option-Shift** (Macintosh). This interruption generates an error -9994 that you can catch with an error-handling method installed using **ON ERR CALL**. Usually, you only need to handle the interruption of a reception while communicating over a serial port.

## Example

See example for the **RECEIVE RECORD** command.

## System variables and sets

The OK system variable is set to 1 if the variable is received. Otherwise, the OK system variable is set to 0.

# SEND PACKET

SEND PACKET ( {docRef ;} packet )

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ⇒ | Document reference number, or Current channel (serial port or document) |
| packet | String, BLOB | ⇒ | String or BLOB to be sent |

## Description

**SEND PACKET** sends a packet to a serial port or to a document. If *docRef* is specified, the packet is written to the document referenced by *docRef*. If *docRef* is not specified, the packet is written to the serial port or document previously opened by the **SET CHANNEL** command.

A *packet* is just a piece of data, generally a string of characters.
You can also pass a BLOB in *packet*. This allows you to bypass the constraints related to encoding for characters sent in text mode (see example 2).

**Note:** When you pass a BLOB in *packet*, the command does not take into account any character set defined by the **USE CHARACTER SET** command. The BLOB is sent without any modification.

Before you use **SEND PACKET**, you must open a serial port or a document with **SET CHANNEL**, or open a document with one of the document commands.

When writing to a document, the first **SEND PACKET** begins writing at the beginning of the document unless the document was opened with **USE CHARACTER SET**. Until the document is closed, each subsequent packet is appended to any previously sent packets.

**Note:** This command is useful for a document opened with **SET CHANNEL**. On the other hand, for a document opened with **Open document**, **Create document** or **Append document**, you can use the commands **Get document position** and **SET DOCUMENT POSITION** to get and change the location in the document where the next writing (**SEND PACKET**) or reading (**RECEIVE PACKET**) will occur.

## Example 1

The following example writes data from fields to a document. It writes the fields as fixed-length fields. Fixed-length fields are always of a specific length. If a field is shorter than the specified length, the field is padded with spaces. (That is, spaces are added to make up the specified length.) Although the use of fixed-length fields is an inefficient method of storing data, some computer systems and applications still use them:

```
$vhDocRef :=Create document("") ` Create a document
If(OK=1) ` Was the document created?
   For($vlRecord;1;Records in selection([People])) ` Loop once for each record
   ` Send a packet. Create the packet from a string of 15 spaces containing the first name field
      SEND PACKET($vhDocRef;Change string(15*Char(SPACE);[People]First;1))
   ` Send a second packet. Create the packet from a string of 15 spaces containing the last name field
   ` This could be in the first SEND PACKET, but is separated for clarity
      SEND PACKET($vhDocRef;Change string(15*Char(SPACE);[People]Last;1))
      NEXT RECORD([People])
   End for
   ` Send a Char(26), which is used as an end-of-file marker for some computers
   SEND PACKET($vhDocRef;Char(SUB ASCII code))
   CLOSE DOCUMENT($vhDocRef) ` Close the document
End if
```

## Example 2

This example illustrates the sending and retrieval of extended characters via a BLOB in a document:

```
C_BLOB($send_blob)
C_BLOB($receive_blob)
TEXT TO BLOB("ázérty";$send_blob;UTF8 text without length)
SET BLOB SIZE($send_blob;16;255)
```

```
$send_blob{6}:=0
$send_blob{7}:=1
$send_blob{8}:=2
$send_blob{9}:=3
$send_blob{10}:=0
$vlDocRef:=Create document("blob.test")
If(OK=1)
   SEND PACKET($vlDocRef;$send_blob)
   CLOSE DOCUMENT($vlDocRef)
End if
$vlDocRef:=Open document(document)
If(OK=1)
   RECEIVE PACKET($vlDocRef;$receive_blob;65536)
   CLOSE DOCUMENT($vlDocRef)
End if
```

# SEND RECORD

SEND RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to send the current record, or Default table, if omitted |

## Description

**SEND RECORD** sends the current record of *aTable* to the serial port or document opened by the **SET CHANNEL** command. The record is sent with a special internal format that can be read only by **RECEIVE RECORD**. If no current record exists, **SEND RECORD** has no effect.

The complete record is sent. This means that pictures and BLOBs stored in or with the record are also sent.

**Important:** When records are being sent and received using **SEND RECORD** and **RECEIVE RECORD**, the source table structure and the destination table structure must be compatible. If they are not, 4D will convert values according to the table definitions when **RECEIVE RECORD** is executed.

**Note:** If you send a record to a document using this command, the document must have been opened using the **SET CHANNEL** command. You cannot use **SEND RECORD** with a document opened with **Open document**, **Create document** or **Append document**.

**Compatibility note:** Beginning with version 11 of 4D, this command no longer supports subtables.

## Example

See example for the **RECEIVE RECORD** command.

# SEND VARIABLE

SEND VARIABLE ( variable )

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ⇨ | Variable to send |

## Description

**SEND VARIABLE** sends *variable* to the document or serial port previously opened by **SET CHANNEL**. The variable is sent with a special internal format that can be read only by **RECEIVE VARIABLE**. **SEND VARIABLE** sends the complete variable (including its type and value).

**Notes:**

1. If you send a variable to a document using this command, the document must have been opened using the **SET CHANNEL** command. You cannot use **SEND VARIABLE** with a document opened with **Open document**, **Create document** or **Append document**.
2. This command does not support array variables. If you want to send and receive arrays from a document or over a serial port, use the **BLOB Commands**.

## Example

See example for the **RECEIVE RECORD** command.

# SET CHANNEL

SET CHANNEL ( port ; settings )

| Parameter | Type | | Description |
|---|---|---|---|
| port | Longint | ⇒ | Serial port number |
| settings | Longint | ⇒ | Serial port settings |

SET CHANNEL ( operation ; document )

| Parameter | Type | | Description |
|---|---|---|---|
| operation | Longint | ⇒ | Document operation to perform |
| document | String | ⇒ | Document name |

## Description

The **SET CHANNEL** command opens a serial port or a document. You can open only one serial port or one document at a time with this command. To close an opened serial port, pass **SET CHANNEL** (11).

**Historical Note:** This command was originally the first 4D command used for working with serial ports and documents on disks. Since that time, new commands have been added. Today, you will typically work with documents on disk using the commands **Open document**, **Create document** and **Append document**. With these commands, you can read and write characters to and from documents using **Create document** or **RECEIVE PACKET** (these commands work with **SET CHANNEL**, too). However, if you want to use the commands **SEND VARIABLE**, **RECEIVE VARIABLE**, **SEND RECORD** and **RECEIVE RECORD**, you must use **SET CHANNEL** to access the document on disk.

The description of **SET CHANNEL** is composed of two sections:

- Working with Serial Ports
- Working with Documents

## Working with Serial Ports: SET CHANNEL (port;settings)

The first form of the **SET CHANNEL** command opens a serial port, setting the protocol and other port information. Data can be sent with **SEND PACKET**, **SEND RECORD** or **SEND VARIABLE**, and received with **RECEIVE BUFFER**, **RECEIVE PACKET**, **RECEIVE VARIABLE** or **RECEIVE RECORD**.
The first parameter, *port*, selects the port and the protocol. You can address up to 99 serial ports (one at a time).
The following table lists the values for *port*:

| Value for port | Description |
|---|---|
| 0 | Printer port (Macintosh) or COM2 (PC) with no protocol |
| 1 | Modem port (Macintosh) or COM1 (PC) with no protocol |
| 20 | Printer port (Macintosh) or COM2 (PC) with sofware protocol such as XON/XOFF |
| 21 | Modem port (Macintosh) or COM1 (PC) with sofware protocol such as XON/XOFF |
| 30 | Printer port (Macintosh) or COM2 (PC) with hardware protocol such as RTS/CTS |
| 31 | Modem port (Macintosh) or COM1 (PC) with hardware protocol such as RTS/CTS |
| 101 to 199 | Serial communication with no protocol |
| 201 to 299 | Serial communication with software protocol such as XON/XOFF |
| 301 to 399 | Serial communication with hardware protocol such as RTS/CTS |

**Important:** The value you pass in *port* must refer to an existing serial COM port recognized by the operating system. For example, in order to be able to use the values 101, 103 and 125, the serial ports COM1, COM3 and COM25 must have been set up correctly.

### Note on serial ports

In a standard configuration Mac OS and Windows support two serial ports: on Mac OS, the modem port and the printer port; on Windows, the COM1 and COM2 ports. However, additional serial ports can be added by the use of extension boards. Originally, 4D only adressed two standard serial ports and it was only later that the support of additional ports was implemented. For compatibility reasons, both addressing systems were kept.

- If you want to address a standard serial port (printer/COM2 or modem/COM1), you can either pass in the *port* parameter one of the following values 0, 1, 20, 21, 30 and 31 (that corresponds to the old addressing method), or a value greater than 100 (please see the following explanation).
- If you want to address additional serial ports, you need to pass the value N+100 (where N is the value of the port to address). You may also consider adding 100 or 200 to the value mentioned above (N+100), if you want to select respectively a software or a hardware protocol.

### Example 1

If you want to use the printer/COM2 port with no protocol, you can use one of the following syntaxes:

```
SET CHANNEL(0;param)
```

or

```
SET CHANNEL(102;param)
```

### Example 2

If you want to use the modem/COM1 port with the XON/XOFF protocol, you can use one of the following syntaxes:

```
SET CHANNEL(21;param)
```

or

```
SET CHANNEL(201;param)
```

### Example 3

If you want to use the COM 25 port with the RTS/CTS protocol, you need to use the following syntax:

```
SET CHANNEL(325;param)
```

The *settings* parameter sets the speed, number of data bits, number of stop bits, and parity. You determine the value for *settings* by adding the speed, data bits, stop bits, and parity values as listed in the following table. For example, to set 1200 baud, 8 data bits, 1 stop bit, and no parity, you would add 94 + 3072 + 16384 + 0 = 19550. You would then use 19550 as the value of the *setup* parameter.

| | Value to accumulate in settings parameter | Description |
|---|---|---|
| Speed | 380 | 300 |
| (in baud) | 189 | 600 |
| | 94 | 1200 |
| | 62 | 1800 |
| | 46 | 2400 |
| | 30 | 3600 |
| | 22 | 4800 |
| | 14 | 7200 |
| | 10 | 9600 |
| | 4 | 19200 |
| | 2 | 28800 |
| | 1 | 38400 |
| | 0 | 57600 |
| | 1022 | 115200 |
| | 1021 | 230400 |
| Data bits | 0 | 5 |
| | 2048 | 6 |
| | 1024 | 7 |
| | 3072 | 8 |
| Stop bits | 16384 | 1 |
| | –32768 | 1.5 |
| | –16384 | 2 |
| Parity | 0 | None |
| | 4096 | Odd |
| | 12288 | Even |

**Tip:** The various numeric values to be accumulated and passed in *port* and *settings* (but not including the values for COM1...COM99) are available as predefined constants in the theme **Communications** within the Design environment Explorer windows. For COM1...COM99, use numeric literals.

## Working with Documents on Disk: SET CHANNEL(operation;document)

The second form of the **SET CHANNEL** command allows you to create, open, and close a document. Unlike the **System Documents** commands, it can open only one document at a time. The document can be read from or written to.

The *operation* parameter specifies the operation to be performed on the document specified by *document*. The following table lists the values of *operation* and the resulting operation with different values for *document*. The first column lists the allowed values for *operation*. The second column lists the allowed values for *document*. The third column lists the resulting operation.

For example, to display an Open File dialog box to open a text file, you would use the following line:

```
SET CHANNEL(13;"")
```

| Operation | Document | Result |
|---|---|---|
| 10 | String | Opens the document specified by String.<br>If the document doesn't exist, the document is opened and created. |
| 10 | "" (empty string) | Displays the Open File dialog box to open a file.<br>All file types are displayed. |
| 11 | none | Closes an open file. |
| 12 | "" (empty string) | Displays the Save File dialog box to create a new file. |
| 13 | "" (empty string) | Displays the Open File dialog box to open a file. Only text file types are displayed. |

All of the operations in this table set the *Document* system variable if appropriate. They also set the OK system variable to 1 if the operation was successful. Otherwise, the OK system variable is set to 0.

### Example 4

See examples for the **RECEIVE BUFFER**, **SET TIMEOUT** and **RECEIVE RECORD** commands.

# SET TIMEOUT

SET TIMEOUT ( seconds )

| Parameter | Type | | Description |
|---|---|---|---|
| seconds | Longint | ⇨ | Seconds until the timeout |

## Description

**SET TIMEOUT** specifies how much time a serial port command has to complete. If the serial port command does not complete within the specified time, *seconds*, the serial port command is canceled, an error -9990 is generated, and the OK system variable is set to 0. You can catch the error with an error-handling method installed using **ON ERR CALL**.

Note that the time is the total time allowed for the command to execute, not the time between characters received. To cancel a previous setting and stop monitoring serial port communication, use a setting of 0 for *seconds*.

The commands that are affected by the timeout setting are:

- **RECEIVE PACKET**
- **RECEIVE RECORD**
- **RECEIVE VARIABLE**

## Example

The following example sets the serial port to receive data. It then sets a time-out. The data is read with **RECEIVE PACKET**. If the data is not received in time, an error occurs:

```
SET CHANNEL(MacOS serial port;Speed 9600+Data bits 8+Stop bits one+Parity none) ` Open Serial Port
SET TIMEOUT(10) ` Set the timeout for 10 seconds
ON ERR CALL("CATCH COM ERRORS") ` Do not let the method being interrupted
RECEIVE PACKET(vtBuffer;Char(13)) ` Read until a carriage return is met
If(OK=0)
   ALERT("Error receiving data.")
Else
   [People]Name:=vtBuffer ` Save received data in a field
End if
ON ERR CALL("")
```

# USE CHARACTER SET

USE CHARACTER SET ( map {; mapInOut} )

| Parameter | Type | | Description |
|---|---|---|---|
| map | String, Operator | ⇒ | Name of character set to use, or * to reset to default character set |
| mapInOut | Longint | ⇒ | 0 = Output map 1 = Input map, If omitted, output map |

## Description

**USE CHARACTER SET** modifies the character set used by 4D during data transfer between the database and a document or a serial port for the current process. Transfer operations include the import and export of text, DIF, and SYLK files. A character map also works on data transferred with **SEND PACKET**, **RECEIVE PACKET** (for text type packets) and **RECEIVE BUFFER**. It has no effect on transfers of data done with **SEND RECORD**, **SEND VARIABLE**, **RECEIVE RECORD**, **SEND PACKET**, **RECEIVE PACKET** (for BLOB type packets) and **RECEIVE VARIABLE**.

The *map* parameter must correspond to the “IANA” name of the character set to be used, or to one of its aliases. For example, the names “iso-8859-1” or “utf-8” are both valid names, as well as the aliases “latin1” or “l1”. For more information about these names, please refer to the following address: *http://www.iana.org/assignments/character-sets*. Examples if IANA names are also provided in the description of the **CONVERT FROM TEXT** command.

If *mapInOut* is 0, the map is set for exporting. If *mapInOut* is 1, the map is set for importing. If you do not pass the *mapInOut* parameter, the export map is used by default.

When the * parameter is passed, the default character set is restored (import or export map depending on the value of *mapInOut*).
In 4D, the default character set is UTF-8.

## Example

The following example (Unicode mode) uses the UTF-16 character set to export a text, then the default character set is restored:

```
USE CHARACTER SET("UTF-16LE";0) ` Use the UTF-16 'Little Endian' character set
EXPORT TEXT([MyTable];"MyText") ` Export data through the map
USE CHARACTER SET(*;0) ` Restore the default character set
```

## System variables and sets

The OK system variable is set to 1 if the map is loaded correctly. Otherwise, it is set to 0.

# Compiler Commands

The integrated compiler of 4D translates your database applications into assembly level instructions. The advantages of the compiler are:

- **Speed:** Your database can run from 3 to 1,000 times faster.
- **Code checking:** Your database application is scanned for the consistency of code. Both logical and syntactical conflicts are detected.
- **Protection:** once your database is compiled, you can delete the interpreted code, Then, the compiled database is functionally identical to the original, except that the structure and procedures cannot be viewed or modified, deliberately or inadvertently.
- **Stand-alone double-clickable applications:** compiled databases can also be transformed into stand-alone applications (.EXE files) with their own icon.
- **Execution in preemptive mode**: only compiled code can be executed in a preemptive process.

For a description of the operation of the 4D compiler, refer to the Design Reference manual.

The commands in this theme relate to the use of the compiler. They enable you to normalize data types throughout your database. The **IDLE** command is specifically used in compiled databases.

| | | |
|---|---|---|
| **C_BLOB** | **C_REAL** | **C_TEXT** |
| **C_BOOLEAN** | **C_LONGINT** | **C_DATE** |
| **C_POINTER** | **C_PICTURE** | **C_TIME** |
| **C_OBJECT** | **IDLE** | |

**Compatibility note:** The obsolete **_o_C_GRAPH**, **_o_C_INTEGER** and **_o_C_STRING** commands must no longer be used.

These commands, except **IDLE**, declare variables and cast them as a specified data type. Declaring variables resolves ambiguities concerning a variable's data type. If a variable is not declared with one of these commands, the compiler attempts to determine a variable's data type. The data type of a variable used in a form is often difficult for the compiler to determine. Therefore, it is especially important that you use these commands to declare a variable used in a form.

**Note**: To save time, you can use the option for generating and updating typing methods (called "Compiler methods") found in the compiler window. This option automatically creates typing methods that take stock of and assign a type to all of the variables used in the database.

**Arrays** are variables that must follow the same rules as standard variables with respect to compilation. The array declaration commands are grouped together in the "**Arrays**" theme.

## General rules about writing code that will be compiled

- You must not give the same name to more than one method or variable. You cannot have a method with the same name as a variable.
- Variable indirection as used in 4D version 1 is not allowed. You cannot use alpha indirection, with the section symbol (§), to indirectly reference variables. Nor can you use numeric indirection, with the curly braces ({...}), for this purpose. Curly braces can only be used when accessing specific elements of an array that has been declared. However, you can use parameter indirection.
- You can't change the data type of any variable or array.
- You can't change a one-dimensional array to a two-dimensional array, or change a two-dimensional array to a one-dimensional array.
- You can't change the length of string variables or of elements in string arrays.
- Although the compiler will type the variable for you, you should specify the data type of a variable by using compiler directives where the data type is ambiguous, such as in a form.
- Another reason to explicitly type your variables is to optimize your code. This rule applies especially to any variable used as a counter. Use variables of a long integer data type for maximum performance.

- To clear a variable (initialize it to null), use **CLEAR VARIABLE** with the name of the variable. Do not use a string to represent the name of the variable in the **CLEAR VARIABLE** command.
- The **Undefined** function will always return *False*. Variables are always defined.
- Numeric operations on long integer and integer variables are usually much faster than operations on the default numeric type (real).
- If you have checked the "Can be run in preemptive processes" property for the method, the code must not call any thread-unsafe commands or other thread-unsafe methods.

These principles are detailed in the following sections:

- **Using Compiler Directives**, explains when and where to write compiler directives,
- **Typing Guide**, describes the different types of conflicts that may occur during the compilation of 4D databases,
- **Syntax Details**, provides additional information concerning several 4D commands,
- **Optimization Hints**, offers hints to accelerate the running of applications in compiled mode,
- **Writing a thread-safe method**.

## Example 1

The following are some basic variable declarations for the compiler:

```
C_BLOB(vxMyBlob) // The process variable vxMyBlob is declared as a variable of type BLOB
C_BOOLEAN(<>OnWindows) // The interprocess variable <>OnWindows is declared as a variable of type Boolean
C_DATE($vdCurDate) // The local variable $vdCurDate is declared as a variable of type Date
C_LONGINT(vg1;vg2;vg3) // The 3 process variables vg1, vg2 and vg3 are declared as variables of type longint
```

## Example 2

In the following example, the ***OneMethodAmongOthers*** project method declares 3 parameters:

```
// OneMethodAmongOthers Project Method
// OneMethodAmongOthers ( Real ; Date { ; Long } )
// OneMethodAmongOthers ( Amount ; Date { ; Ratio } )

C_REAL($1) // 1st parameter is of type Real
C_DATE($2) // 2nd parameter is of type Date
C_LONGINT($3) // 3rd parameter is of type Long Integer

// ...
```

## Example 3

In the following example, the *Capitalize* project method accepts a text parameter and returns a text result:

```
// Capitalize Project Method
// Capitalize ( Text ) -> Text
// Capitalize ( Source string ) -> Capitalized string

C_TEXT($0;$1)
$0:=Uppercase(Substring($1;1;1))+Lowercase(Substring($1;2))
```

## Example 4

In the following example, the project method ***SEND PACKETS*** accepts a time parameter followed by a variable number of text parameters:

```
` SEND PACKETS Project Method
` SEND PACKETS ( Time ; Text { ; Text2... ; TextN } )
` SEND PACKETS ( docRef ; Data { ; Data2... ; DataN } )
```

```
C_TIME($1)
C_TEXT(${2})
C_LONGINT($vlPacket)

For($vlPacket;2;Count parameters)
   SEND PACKET($1;${$vlPacket})
End for
```

## Example 5

In the following example, the ***COMPILER_Param_Predeclare28*** project method predeclares the syntax of other project methods for the compiler:

```
 // COMPILER_Param_Predeclare28 Project Method

C_REAL(OneMethodAmongOthers;$1) // OneMethodAmongOthers ( Real ; Integer { ; Long } )
C_DATE(OneMethodAmongOthers;$2) // ...
C_LONGINT(OneMethodAmongOthers;$3) // ...
C_TEXT(Capitalize;$0;$1) // Capitalize ( Text) -> Text
C_TIME(SEND PACKETS;$1) // SEND PACKETS ( Time ; Text { ; Text2... ; TextN } )
C_TEXT(SEND PACKETS;${2}) // ...
```

## Using Compiler Directives

### Data types of variables

4D has three categories of variables:

- Local variables,
- Process variables,
- Interprocess variables.

For more information about this point, refer to the **Variables** section. Process and interprocess variables are structurally the same for the compiler.

Since the compiler cannot determine the process in which the variable will be used, process variables should be used with more care than interprocess variables. All process variables are systematically duplicated when a new process begins. A process variable can have a different value in each process, but it has the same type for the entire database.

#### Types of Variables

All variables have a type. As described in the **Data Types** section, there are several different types of variables:

| |
|---|
| Boolean |
| Date |
| Longint |
| Graph |
| Time |
| Picture |
| Number (or Real) |
| Pointer |
| Text |
| BLOB |
| Object |

Here are the different types of arrays:

| |
|---|
| Boolean Array |
| Date Array |
| Integer Array |
| Longint Array |
| Picture Array |
| Real Array |
| Time Array |
| Object Array |
| Pointer Array |
| BLOB Array |
| Text Array |

**Notes:**
- The Object type is available since 4D v14.
- The former Alpha (fixed string) and Integer types are no longer used for variables. In existing code, they are automatically redirected to Text and Longint types.

#### Creation of the symbol table

In interpreted mode, a variable can have more than one data type. This is possible because the code is interpreted rather than compiled. 4D interprets each statement separately and comprehends its context. When you work in a compiled environment, the situation is different. While interpretation is performed line by line, the compilation process looks at a database in its entirety.

The compiler's approach is the following:

- The compiler systematically analyzes the objects in the database. The objects are database, project, form, trigger and object methods.
- The compiler scans the objects to determine the data type of each variable used in the database, and it generates the table of variables and methods (the symbol table).
- Once it has established the data types of all variables, the compiler translates (compiles) the database. However, it cannot compile the database unless it can determine the data type for each of the variables.

If the compiler comes across the same variable name and two different data types, it has no reason to favor any particular one. In other words, in order to type an object and give it a memory address, the compiler must know the precise identity of that object (i.e., its name and its data type). The compiler determines its size from the data type. For every compiled database, the compiler creates a map that lists, for each variable, its name (or identifier), its location (or memory address), and the space it occupies (indicated by its data type). This map is called the symbol table. An option in the Preferences lets you choose whether to generate this table in the form of a file during compilation.
This map is also used for the automatic generation of compiler methods.

### Variables typed by the compiler

If you want the compiler to check the typing of your variables or to type them itself, it is easy to place a compiler directive for this purpose. You can choose between two different possibilities, depending on your working methods:

- Either use the directive in the method in which the variable first appears, depending on whether it is a local, proces or interprocess variable. Be sure to use the directive the very first time you use the variable, in the first method to be executed. Keep in mind that during compilation, the compiler takes the methods in the order of their creation in 4D, and not in the order in which they are displayed in the Explorer.
- Or, if you are systematic in your approach, group all the process and interprocess variables with the different compiler directives in the **On Startup database method** or in a method called by the **On Startup database method**.
  For local variables, group the directives at the beginning of the method in which they appear.

### Default values

When variables are typed by means of a compiler directive, they receive a default value, which they will keep during the session as long as they have not been assigned.

The default value depends on the variable type and category, its execution context (interpreted or compiled), as well as, for compiled mode, the compilation options defined on the **Compiler page** of the Database settings:

- Process and interprocess variables are always set "to zero" (which means, depending on the case, "0", an empty string, an empty Blob, a Nil pointer, a blank date (00-00-00), etc.)
- Local variables are set:
  - in interpreted mode: to zero
  - in compiled mode, depending on the **Initialize local variables** option of the Database settings:
    - to zero when "to zero" is chosen,
    - to a set random value when "to a random value" is chosen (0x72677267 for numbers and times, always True for Booleans, the same as "to zero" for the others),
    - to a random value (for numbers) when "no" is chosen.

The following table illustrates these default values:

| Type | Interprocess | Process | Local interpreted | Local compiled "to zero" | Local compiled "random" | Local compiled "no" |
|---|---|---|---|---|---|---|
| Booleen | False | False | False | False | True | True (varies) |
| Date | 00-00-00 | 00-00-00 | 00-00-00 | 00-00-00 | 00-00-00 | 00-00-00 |
| Longint | 0 | 0 | 0 | 0 | 1919382119 | 909540880 (varies) |
| Graph | 0 | 0 | 0 | 0 | 1919382119 | 775946656 (varies) |
| Time | 00:00:00 | 00:00:00 | 00:00:00 | 00:00:00 | 533161:41:59 | 249345:34:24 (varies) |
| Picture | picture size=0 | picture size=0 | picture size=0 | picture size=0 | picture size=0 | picture size=0 |
| Real | 0 | 0 | 0 | 0 | 1.250753659382e+243 | 1.972748538022e-217 (varies) |
| Pointer | Nil=true | Nil=true | Nil=true | Nil=true | Nil=true | Nil=true |
| Text | "" | "" | "" | "" | "" | "" |
| Blob | Blob size=0 | Blob size=0 | Blob size=0 | Blob size=0 | Blob size=0 | Blob size=0 |
| Object | undefined | undefined | undefined | undefined | undefined | undefined |

## When to use compiler directives

Compiler directives are useful in two cases:

- The compiler is unable to determine the data type of a variable from its context,
- You do not want the compiler to determine a variable's type from its use.

Furthermore, using compiler directives allows you to reduce compilation time.

### Cases of ambiguity

Sometimes the compiler cannot determine the data type of a variable. Whenever it cannot make a determination, the compiler generates an appropriate error message.
There are three major causes that prevent the compiler from determining the data type: multiple data types, ambiguity on a forced deduction and the inability to determine a data type.

#### Multiple data types

If a variable has been retyped in different statements in the database, the compiler generates an error that is easy to fix. The compiler selects the first variable it encounters and arbitrarily assigns its data type to the next occurrence of the variable having the same name but a different data type.

Here is a simple example:

in method A,

```
Variable:=True
```

in method B,

```
Variable:="The moon is green"
```

If method A is compiled before method B, the compiler considers the statement *Variable:="The moon is green"* as a data type change in a previously encountered variable. The compiler notifies you that retyping has occurred. It generates an error for you to correct. In most cases, the problem can be fixed by renaming the second occurrence of the variable.

#### Ambiguity on a forced deduction

Sometimes, due to a sequence, the compiler can deduce that an object's type is not the proper type for it. In this case, you must explicitly type the variable with a compiler directive.

Here is an example using the default values for an active object:

In a form, you can assign default values for the following objects: combo boxes, pop-up menus, tab controls, drop-down lists, menu/drop-down lists and scrollable areas using the Edit button for the **Value List** (under the Entry Control theme of the Property List) (for more information, refer to the 4D Design Reference manual). The default values are automatically loaded into an array whose name is the same as the name of the object.

If the object is not used in a method, the compiler can deduce the type, without ambiguity, as a text array.

However, if a display initialization must be performed, the sequence could be:

```
Case of
   :(Form event=On Load)
      MyPopUp:=2
      ...
End case
```

In this case, the ambiguity appears--when parsing methods, the compiler will deduce a Real data type for the object MyPopUp. In this case, it is necessary to explicitly declare the array in the form method or in a compiler method:

```
Case of
   :(Form event=On Load)
      ARRAY TEXT(MyPopUp;2)
      MyPopUp:=2
      ...
End case
```

**Inability to determine a data type**

This case can arise when a variable is used without having been declared, within a context that does not provide information about its data type. Here, only a compiler directive can guide the compiler.
This phenomenon occurs primarily within four contexts:

- when pointers are used,
- when you use a command with more than one syntax,
- when you use a command having optional parameters of different data types,
- when you use a 4D method called via a URL.

*Pointers*

A pointer cannot be expected to return a data type other than its own.
Consider the following sequence:

```
Var1:=5.2(1)
Pointer:=->Var1(2)
Var2:=Pointer->(3)
```

Although (2) defines the type of variable pointed to by Pointer, the type of Var2 is not determined. During compilation, the compiler can recognize a pointer, but it has no way of knowing what type of variable it is pointing to. Therefore it cannot deduce the data type of Var2. A compiler directive is needed, for example *C_REAL(Var2)*.

*Multi-syntax commands*

When you use a variable associated with the function **Year of**, the variable can only be of the data type Date, considering the nature of this function. However, things are not always so simple. Here is an example:
The **GET FIELD PROPERTIES** command accepts two syntaxes:
**GET FIELD PROPERTIES**(tableNo;fieldNo;type;length;index)
**GET FIELD PROPERTIES**(fieldPointer;type;length;index)

When you use a multi-syntax command, the compiler cannot guess which syntax and parameters you have selected. You must use compiler directives to type variables passed to the command, if they are not typed according to their use elsewhere in the database.

*Commands with optional parameters of different data types*

When you use a command that contains several optional parameters of different data types, the compiler cannot determine which optional parameters have been used. Here is an example:
The **GET LIST ITEM** command accepts two optional parameters; the first as a Longint and the other as a Boolean.
The command can thus either be used as follows:
**GET LIST ITEM**(list;itemPos;itemRef;itemText;sublist;expanded)
or like this:
**GET LIST ITEM**(list;itemPos;itemRef;itemText;expanded)
You must use compiler directives to type optional variables passed to the command, if they are not typed according to their use elsewhere in the database.

*Methods called via URLs*

If you write 4D methods that need to be called via a URL, and if you do not use $1 in the method, you must explicitly

declare the text variable $1 with the following sequence:
**C_TEXT**($1)
In fact, the compiler cannot determine that the 4D method will be called via a URL.

### Reducing time needed to compile

If all the variables used in the database are explicitly declared, it is not necessary for the compiler to check the typing. In this case, you can set the options so that the compiler only executes the translation phase of the method. This saves at least 50% in compilation time.

### Optimizing code

You can speed up your methods by using compiler directives. For more details on this subject, refer to the **Optimization Hints** section. To give a simple example, suppose you need to increment a counter using a local variable. If you do not declare the variable, the compiler assumes that is a Real. If you declare it as a Longint, the compiled database will perform more efficiently. On a PC, for instance, a Real takes 8 bytes, but if you type the counter as a Longint, it only uses 4 bytes. Incrementing an 8-byte counter obviously takes longer than incrementing a 4-byte one.

## Where to place your compiler directives

Compiler directives can be handled in two different ways, depending on whether or not you want the compiler to type your variables.

### Typing variables

The compiler must respect the identification criteria of the variables.

There are two possibilities:

1) If the variables are not typed, the compiler can do it for you automatically. Whenever possible––as long as there is no ambiguity––the compiler determines a variable's type from the way it is used. For example, if you write:

```
V1:=True
```

the compiler determines that variable V1 is of data type Boolean.

By the same token, if you write:

```
V2:="This is a sample phrase"
```

the compiler determines that V2 is a Text type variable.

The compiler is also capable of establishing the data type of a variable in less straightforward situations:

```
V3:=V1 `V3 is of the same type as V1
V4:=2*V2 `V4 is of the same type as V2
```

The compiler also determines the data type of your variables according to calls to 4D commands and according to your methods. For example if you pass a Boolean type parameter and a Date type parameter to a method, the compiler assigns the Boolean type and the Date type to the local variables $1 and $2 in the called method.

When the compiler determines the data type by inference, unless indicated otherwise in the Preferences, it never assigns the limiting data types: Integer, Longint or String. The default type assigned by the compiler is always the widest possible. For example, if you write:

```
Number:=4
```

the compiler assigns the Real data type to Number, even though 4 happens to be an integer. In other words, the compiler does not rule out the possibility that, under other circumstances, the variable's value might be 4.5.
If it is appropriate to type a variable as Integer, Longint or String, you can do so using a compiler directive. It is to your advantage to do so, because these data types occupy less memory and performing operations on them is faster.

If you have already typed your variables and are sure that your typing is coherent and complete, you may explicitly ask the compiler not to redo this work, using the compilation Preferences. In case your typing was not complete and exhaustive, at the time of compilation, the compiler will return errors requesting you to make the necessary modifications.

2) The compiler directive commands enable you to explicitly declare the variables used in your databases.

They are used in the following manner:

```
C_BOOLEAN(Var)
```

Through such directives, you inform the compiler to create a variable Var that will be a Boolean.
Whenever an application includes compiler directives, the compiler detects them and thus avoids guesswork.

A compiler directive has priority over deductions made from assignments or use.

Variables declared with the compiler directive **_o_C_INTEGER** are actually the same as those declared by the directive **C_LONGINT**. They are, in fact, long integers between -2147483648 and +2147483647.

### Variables typed by the developer

If you do not want the compiler to check your typing, you must give it a code to identify the compiler directives.
The convention to follow is:
Compiler directives for the process and interprocess variables and the parameters should be placed in one or more methods, the names of which begin with the key word **Compiler**.
By default, the compiler lets you automatically generate five types of Compiler methods, which group together the directives for variables, arrays and method parameters (for more information about this point, refer to the Design Reference manual).

**Note:** The syntax for declaring these parameters is the following:
*Directive (methodName;parameter)*. This syntax is not executable in interpreted mode.

**Particular parameters**

- Parameters received by database methods
  If these parameters have not been explicitly declared, they are typed by the compiler. Nevertheless, if you declare them, the declaration must be done inside the database methods.
  This parameter declaration cannot be written in a Compiler method.
  Example: **On Web Connection Database Method** receives six parameters, $1 to $6, of the data type Text. At the beginning of the database method, you must write: **C_TEXT**($1;$2;$3;$4;$5;$6)

- Triggers
  The $0 parameter (Longint), which is the result of a trigger, is typed by the compiler if the parameter has not been explicitly declared. Nevertheless, if you want to declare it, you must do so in the trigger itself.
  This parameter declaration cannot be written in a Compiler method.

- Objects that accept the “On Drag Over” form event
  The $0 parameter (Longint), which is the result of the “On Drag Over” form event, is typed by the compiler if the parameter has not been explicitly declared. Nevertheless, if you want to decalre it, you must do so in the object method.
  This parameter declaration cannot be written in a Compiler method.
  **Note:** The compiler does not initialize the $0 parameter. So, as soon as you use the On Drag Over form event, you must initialize $0. For example:

```
C_LONGINT($0)
If(Form event=On Drag Over)
   $0:=0
   ...
   If($DataType=Is picture)
      $0:=-1
   End if
   ...
End if
```

## A certain liberty permitted by the compiler

Compiler directives remove any ambiguity concerning data types. Although a certain rigor is necessary, this does not necessarily mean that the compiler is intolerant of any and every inconsistency.
For example, if you assign a real value to a variable declared as an Integer, the compiler does not regard either assignment as a type conflict and assigns the corresponding values according to your directives. So, if you write:

```
C_LONGINT(vInteger)
vInteger:=2.6
```

The compiler does not regard it as a data type conflict that will prevent compilation; instead, the compiler simply rounds off to the closest integer value (3 instead of 2.6).

# Typing Guide

This section describes the main causes of typing conflicts on variables, as well as ways to avoid them.

## Conflicts on simple variables

Simple data type conflicts can be summarized as follows:

- conflict between two uses,
- conflict between use and a compiler directive,
- conflict resulting from implicit retyping,
- conflict between two compiler directives.

### Conflicts between two uses

The simplest data type conflict is one that stems from a single variable name designating two different objects. Suppose that, in an application, you write:

```
Variable:=5
```

and that elsewhere, in the same application, you write:

```
Variable:=True
```

This generates a data type conflict. The problem can be solved by renaming one of the variables.

### Conflict between use and a compiler directive

Suppose that, in an application, you write:

```
Variable:=5
```

and that elsewhere, in the same application, you write:

```
C_BOOLEAN(Variable)
```

Since the compiler scans the directives first, it will type Variable as Boolean, but when it finds the statement:

```
Variable:=5
```

it detects a data type conflict. You can solve the problem by renaming your variable or modifying the compiler directive.

Using variables of different data types in one expression creates inconsistencies. The compiler points out incompatibilities. Here is a simple example:

```
vBool:=True `The compiler infers that vBoolean is data type Boolean
C_LONGINT(<>vInteger) `Declaration of an Longint by a compiler directive
<>vInteger:=3 `Command compatible with the compiler directive
Var:=<>vInteger+vBool `Operation containing variables with incompatible data types
```

### Conflict stemming from implicit retyping

Some functions return variables of a very precise data type. Assigning the result of one of such variables to a variable already typed differently will cause a data type conflict if you are not careful.

For example, in an interpreted application, you can write:

```
IdentNo:=Request("Identification Number") `IdentNo is data type Text
If(Ok=1)
   IdentNo:=Num(IdentNo) `IdentNo is data type Real
```

```
   QUERY([Contacts]Id=IdentNo)
End if
```

In this example, you create a type conflict in the third line. The solution consists in controlling the behavior of the variable. In some cases, you must create an intermediate variable that uses a different name. In other cases, such as this, your method can be structured differently:

```
IdentNo:=Num(Request("Identification Number")) `IdentNo is data type Real
If(Ok=1)
   QUERY([Contacts]Id=IdentNo)
End if
```

### Conflict between two compiler directives

Declaring the same variable through two conflicting compiler directives constitutes a retyping. If, in the same database, you write:

```
C_BOOLEAN(Variable)
C_TEXT(Variable)
```

the compiler detects the conflict and reports an error in the error file. Typically, you can solve the problem by renaming one of the variables.

### Note concerning local variables

Data type conflicts involving local variables are identical to those in process or interprocess variables. The only difference is that there must be consistency only within a specified method.

For process and interprocess variables, conflicts occur at the general leve of teh database. For local variables, conflicts occur at the level of the method. For example, you cannot write in the same method:

```
$Temp:="Flowers"
```

and then

```
$Temp:=5
```

However, you can write:

```
$Temp:="Flowers"
```

in method M1, and:

```
$Temp:=5
```

in method M2, because the scope of local variables is the method itself and not the entire database.

## Conflicts in arrays

Conflicts concerning an array are never size-related. As in uncompiled databases, arrays are managed dynamically. The size of an array can vary throughout methods, and you do not have to declare a maximum size for an array.

Therefore, you can size an array to null, add or remove elements, or delete the contents.

You should follow these guidelines when writing a database intended for compilation:

- Do not change data types of array elements,
- Do not change the number of dimensions of an array,
- For a String array, do not change character-string length.

### Changing data types of array elements

If you declare an array as an Integer array, it must remain an integer array throughout the database. It can never contain, for example, Boolean type elements.

If you write:

```
ARRAY INTEGER(MyArray;5)
ARRAY BOOLEAN(MyArray;5)
```

the compiler cannot type MyArray.

Just rename one of the arrays.

### Changing the number of dimensions of an array

In an uncompiled database, you can change the number of dimensions in an array. When the compiler sets up the symbol table, one-dimensional arrays and two-dimensional arrays are managed differently.

Consequently, you cannot redeclare a one-dimensional array as two-dimensional, or vice versa.

Therefore, in the same database, you cannot have:

```
ARRAY INTEGER(MyArray1;10)
ARRAY INTEGER(MyArray1;10;10)
```

However, you can write the following statements in the same application:

```
ARRAY INTEGER(MyArray1;10)
ARRAY INTEGER(MyArray2;10;10)
```

The number of dimensions in an array cannot be changed in a database. However, you can change the size of an array. You can resize one array of a two-dimensional array and write:

```
ARRAY BOOLEAN(MyArray;5)
ARRAY BOOLEAN(MyArray;10)
```

**Note:** A two-dimensional array is, in fact, a set of several one-dimensional arrays. For more information, refer to the **Two-dimensional Arrays** section.

### Implicit retyping

When using commands such as **COPY ARRAY**, **LIST TO ARRAY**, **ARRAY TO LIST**, **SELECTION TO ARRAY**, **SELECTION RANGE TO ARRAY**, **ARRAY TO SELECTION**, or **DISTINCT VALUES**, you may change, voluntarily or not, the data types of elements, or the number of dimensions. You will thus find yourself in one of the situations previously mentioned.

The compiler generates an error message; the required correction is usually quite obvious. Examples of implicit array retyping are provided in the **Syntax Details** section.

### Local arrays

If you want to compile a database that uses local arrays (arrays only visible by the methods that created them), you must explicitly declare them in 4D before using them.

Explicitly declaring an array means using a command of the type **ARRAY REAL**, **ARRAY INTEGER**, etc.

For example, if a method creates a local integer array of 10 elements, you should have the following line in your method:

```
ARRAY INTEGER($MyArray;10)
```

## Typing of variables created in forms

Variables created in a form (e.g., buttons, drop-down list boxes, and so forth) are always process or interprocess variables.

In an interpreted database, the data type of such variables is not important. However, in compiled applications, it may have to be taken into consideration. The rules are, nevertheless, quite clear:

- You can type form variables using compiler directives, or
- The compiler assigns it a default type that can be set in the compilation Preferences (see the Design Reference manual).

### Variables considered by default as Real

The following form variables are typed as Real by default:

| |
|---|
| Check box |
| 3D check box |
| Button |
| Highlight button |
| Invisible button |
| 3D button |
| Picture button |
| Button grid |
| Radio button |
| 3D radio button |
| Radio picture |
| Picture menu |
| Hierarchical pop-up menu |
| Hierarchical list |
| Ruler |
| Dial |
| Thermometer |
| List box (selection type) |

**Note:** The Ruler, Dial and Thermometer form variables are always typed as Reals, even if you choose Long integer as the Default Button Type in the Preferences.

For one of these variables, the only data type conflict that could arise would be if the name of a variable were identical to that of another one located elsewhere in the database. In this case, rename the second variable.

### Plug-in area variable

A plug-in area is always a Longint. There can never be a data type conflict.
For a plug-in area, the only possible data type conflict that could arise would be if the name of a variable were identical to that of another one located elsewhere in the database. In this case, rename the second variable.

### 4D Write Pro area variable

4D Write Pro areas are always Object type variables. There cannot be any typing conflict, unless the same variable name is used in another part of the application.

### Variables considered by default as Text

These variables are of the following types:

| |
|---|
| Non-enterable variable |
| Enterable variable |
| Drop-down list |
| Menu/drop-down list |
| Scrollable area |
| Combo box |
| Pop-up Menu |
| Tab control |
| Web area |
| Column of (array type) list box. |

These variables are divided into two categories:
- simple variables (enterable and non-enterable variables)
- display variables (drop-down lists, menus/drop-down lists, scrollable areas, pop-up menus, combo boxes, tab controls and columns of list boxes).

- *Simple variables*
  Their default data type is Text. When used in methods or object methods, they are assigned the data type selected by you. There is no danger of conflict other than one resulting from assigning the same name to another variable.

- *Display variables*
  Some variables are used to display arrays in forms. If default values have been entered in the Form editor, you must

explicitly declare the corresponding variables using the Array Declaration commands (**ARRAY BOOLEAN**, **ARRAY TEXT**, etc.).

### List boxes

Each list box adds several variables in the forms. The default type of these variables depends on the type of list box:

| | Array type list boxes | Selection type list boxes |
|---|---|---|
| List box | Boolean array | Number (not used) |
| Column of list box | Text array | Dynamic typing |
| Header | Number | Number |
| Footer | Dynamic typing | Dynamic typing |
| Row control array | Boolean array (Longint array accepted) | - |
| Styles | Longint array | Longint |
| Font colors | Longint array | Longint |
| Background colors | Longint array | Longint |

Make sure that you identify and type these variables and arrays correctly in order to avoid generating conflicts during compilation.

## Pointers

When you use pointers in your database, you take advantage of a powerful and versatile 4D tool. The compiler preserves all the benefits of pointers.

A pointer can point to variables of different data types. Do not create a conflict by assigning different data types to a variable. Be careful not to change the data type of a variable to which a pointer refers.

Here is an example of this problem:

```
Variable:=5.3
Pointer:=->Variable
Pointer->:=6.4
Pointer->:=False
```

In this case, your dereferenced pointer is a Real variable. By assigning it a Boolean value, you create a data type conflict.

If you need to use pointers for different purposes in the same method, make sure that your pointers are defined:

```
Variable:=5.3
Pointer:=->Variable
Pointer->:=6.4
Bool:=True
Pointer:=->Bool
Pointer->:=False
```

A pointer is always defined in relation to the object to which it refers. That is why the compiler cannot detect data type conflicts created by pointers. In case of a conflict, you will get no error message while you are in the typing phase or in the compilation phase.

This does not mean that the compiler has no way to detect conflicts involving pointers. The compiler can verify your use of pointers when you check the **Range Checking** option in the compilation Preferences (see the Design Reference manual).

## Plug-in Commands

### General points

During compilation, the compiler analyzes the definitions of the plug-in commands used in the database, i.e. the number and type of parameters of these commands. There is no danger of confusion at the typing level if your calls are consistent with the declaration of the method.

Make sure that your plug-ins are installed in the *PlugIns* folder, in one of the locations authorized by 4D: next to the database structure file or next to the executable application (Windows) / in the software package (Mac OS). For compatibility reasons, it is still possible to use the *Win4DX* or *Mac4DX* folder next to the structure file. For more information, refer to the Installation Guide of 4D.

The compiler does not duplicate these files, but analyzes them to determine the proper declaration of their routines.
If your plug-ins are located elsewhere, the compiler will ask you to locate them during typing, via an Open file dialog box.

### Plug-in commands receiving implicit parameters

Certain plug-ins, for example 4D Write, implement commands that implicitly call 4D commands.

Take the example of 4D Write. The syntax for the **WR ON EVENT** command is:
***WR ON EVENT****(area;event;eventMethod)*

The last parameter is the name of the method that you have created in 4D. This method is called by 4D Write each time the event is received. It automatically receives the following parameters:

| Parameters | Type | Description |
|---|---|---|
| $0 | Longint | Function return |
| $1 | Longint | 4D Write area |
| $2 | Longint | Shift key |
| $3 | Longint | Alt key (Windows); Option key (Mac OS) |
| $4 | Longint | Ctrl key (Windows), Command key (Mac OS) |
| $5 | Longint | Type of event |
| $6 | Longint | Value depends on the Event parameter |

For the compiler to take these parameters into account, you must make sure that they have been typed, either by a compiler directive, or by their usage in the method. If they have been used procedurally, the usage has to be explicit enough to be able to deduce the type clearly.

## 4D components

4D can be used to create and work with components. A 4D component is a set of 4D objects representing one or more functionalities and grouped in a structure file (called the matrix database), that can be installed in different databases (called host databases).

A host database running in interpreted mode can use either interpreted or compiled components indifferently. It is possible to install both interpreted and compiled components in the same host database. On the other hand, a host database running in compiled mode cannot use interpreted components. In this case, only compiled components can be used.

An interpreted host database containing interpreted components can be compiled if it does not call any methods of the interpreted component. If this is not the case, a warning dialog box appears when you attempt to compile the application and compilation is not possible.

A naming conflict can occur when a shared project method of the component has the same name as a project method of the host database. In this case, when the code is executed in the context of the host database, the method of the host database is called. This means that it is possible to “mask” the method of the component with a custom method (for example, to obtain a different functionality). When the code is executed in the context of the component, the method of the component is called. This masking will be indicated by a warning in the event of compilation of the host database.

If two components share methods having the same name, an error is generated when the host database is compiled.

For more information about components, please refer to the Design Reference manual.

## Handling local variables $0…$N and parameter passing

The handling of local variables follows all the rules that have already been stated. As with all other variables, their data types cannot be altered while the method executes. In this section, we examine two instances that could lead to data type conflicts:

- When you actually require retyping. The use of pointers helps avoid data type conflicts.
- When you need to address parameters by indirection.

### Using pointers to avoid retyping

A variable cannot be retyped. However, it is possible to use a pointer to refer to variables of different data types.

As an example, consider a function that returns the memory size of a one-dimensional array. In all but two cases, the result is a Real; for Text arrays and Picture arrays, the memory size depends on values that cannot be expressed numerically (see the **Arrays and Memory** section).

For Text and Picture arrays, the result is returned as a string of characters. This function requires a parameter: a pointer to the array whose memory size we want to know.

There are two methods to carry out this operation:

- Work with local variables without worrying about their data types; in such case, the method runs only in interpreted mode.
- Use pointers, and proceed in interpreted or in compiled mode.

**MemSize function, only in interpreted mode (example for Macintosh)**

```
$Size:=Size of array($1->)
$Type:=Type($1->)
Case of
   :($Type=Real array)
      $0:=8+($Size*10) ` $0 is a Real
   :($Type=Integer array)
      $0:=8+($Size*2)
   :($Type=LongInt array)
      $0:=8+($Size*4)
   :($Type=Date array)
      $0:=8+($Size*6)
   :($Type=Text array)
      $0:=String(8+($Size*4))+("+Sum of text lengths") ` $0 is a Text
   :($Type=Picture array)
      $0:=String(8+($Size*4))+("+Sum of picture sizes") ` $0 is a Text
   :($Type=Pointer array)
      $0:=8+($Size*16)
   :($Type=Boolean array)
      $0:=8+($Size/8)
End case
```

In the above method, the data type of $0 changes according to the value of $1; therefore, it is not compatible with the compiler.

**MemSize function in interpreted and compiled modes (example for Macintosh)**

Here, the method is written using pointers:

```
$Size:=Size of array($1->)
$Type:=Type($1->)
VarNum:=0
Case of
   :($Type=Real array)
      VarNum:=8+($Size*10) ` VarNum is a Real
   :($Type=Integer array)
      VarNum:=8+($Size*2)
   :($Type=LongInt array)
      VarNum:=8+($Size*4)
   :($Type=Date array)
      VarNum:=8+($Size*6)
   :($Type=Text array)
      VarText:=String(8+($Size*4))+("+Sum of text lengths")
   :($Type=Picture array)
      VarText:=String(8+($Size*4))+("+Sum of picture sizes")
   :($Type=Pointer array)
      VarNum:=8+($Size*16)
   :($Type=Boolean array)
      VarNum:=8+($Size/8)
End case
If(VarNum#0)
   $0:=->VarNum
Else
   $0:=->VarText
End if
```

Here are the key differences between the two functions:

- In the first case, the function's result is the expected variable,
- In the second case, the function's result is a pointer to that variable. You simply dereference your result.

### Parameter indirection

The compiler manages the power and versatility of parameter indirection. In interpreted mode, 4D gives you a free hand with numbers and data types of parameters. You retain this freedom in compiled mode, provided that you do not introduce data type conflicts and that you do not use more parameters than you passed in the calling method.

To prevent possible conflicts, parameters addressed by indirection must all be of the same data type.

This indirection is best managed if you respect the following convention: if only some of the parameters are addressed by indirection, they should be passed after the others.

Within the method, an indirection address is formatted: ${$i}, where $i is a numeric variable. ${$i} is called a generic parameter.

As an example, consider a function that adds values and returns the sum formatted according to a format that is passed as a parameter. Each time this method is called, the number of values to be added may vary. We must pass the values as parameters to the method and the format in the form of a character string. The number of values can vary from call to call.

This function is called in the following manner:

```
Result:=MySum("##0.00";125,2;33,5;24)
```

In this case, the calling method will get the string “182.70”, which is the sum of the numbers, formatted as specified. The function's parameters must be passed in the correct order: first the format and then the values.

Here is the function, named MySum:

```
$Sum:=0
For($i;2;Count parameters)
   $Sum:=$Sum+${$i}
End for
$0:=String($Sum;$1)
```

This function can now be called in various ways:

```
Result:=MySum("##0.00";125,2;33,5;24)
Result:=MySum("000";1;18;4;23;17)
```

As with other local variables, it is not necessary to declare generic parameters by compiler directive. When required (in cases of ambiguity or for optimization), it is done using the following syntax:

```
C_LONGINT(${4})
```

This command means that all parameters starting from the fourth (included) will be addressed by indirection and will be of the data type Longint. $1, $2 and $3 can be of any data type. However, if you use $2 by indirection, the data type used will be the generic type. Thus, it will be of the data type Longint, even if for you it was, for instance, of the data type Real.

**Note**: The compiler uses this command in the typing phase. The number in the declaration has to be a constant and not a variable.

## Reserved variables and constants

Some 4D variables and constants are assigned a data type and an identity by the compiler. Therefore, you cannot create a new variable, method, function or plug-in command using any of these variables or constant names. You can test their values and use them as you do in interpreted mode.

### System variables

Here is a complete list of 4D **System Variables** with their data types.

| Variable | Type |
|---|---|
| OK | Longint |
| Document | Text |
| FldDelimit | Longint |
| RecDelimit | Longint |
| Error | Longint |
| Error method | Text |
| Error line | Longint |
| Error formula | Text |
| MouseDown | Longint |
| KeyCode | Longint |
| Modifiers | Longint |
| MouseX | Longint |
| MouseY | Longint |
| MouseProc | Longint |

### Quick report variables

When you create a calculated column in a report, 4D automatically creates a variable C1 for the first one, C2 for the second one, C3 and so forth. This is done transparently.
If you use these variables in methods, keep in mind that, like other variables, C1, C2, ... Cn cannot be retyped.

### 4D predefined constants

A complete list of the predefined constants in 4D can be found using the **List of constant themes**. 4D constants are also displayed in the Explorer in Design mode.

## Syntax Details

The compiler expects that the usual syntactic rules for 4D commands are followed. It does not require any special modifications for databases that will be compiled.

This section nevertheless provides certain reminders and specific details:

- Some commands that affect a variable's data type may lead, if you are not careful, to data type conflicts.
- Since certain commands use more than one kind of syntax or parameters, it is to your advantage to know which is the most appropriate one to select.

### Strings

#### Character code(character)

For commands operating on strings, only the **Character code** function requires special attention. In interpreted mode, you can pass either a non-empty string or an empty string to this function.
In compiled mode, you cannot pass an empty string.
If you pass an empty string, and if the argument passed to **Character code** is a variable, the compiler will not be able to detect an error in compilation.

### Communications

**SEND VARIABLE(variable)**
**RECEIVE VARIABLE(variable)**
These two commands are used for writing and receiving variables sent to disk. Variables are passed as parameters to these commands.

The parameter you pass must always be of the same data type. Suppose you want to send a list of variables to a file. To eliminate the risk of changing data types inadvertently, we recommend that you specify the data type of the variables being sent at the head of the list. This way, when you receive these variables, you will always begin by getting an indicator. Then, when you call **RECEIVE VARIABLE**, the transfer is managed by a *Case of* statement.

Example:

```
SET CHANNEL(12;"File")
If(OK=1)
   $Type:=Type([Client]Total_TO)
   SEND VARIABLE($Type)
   For($i;1;Records in selection)
      $Send_TO:=[Client]Total_TO
      SEND VARIABLE($Send_TO)
   End for
End if
SET CHANNEL(11)
SET CHANNEL(13;"MyFile")
If(OK=1)
   RECEIVE VARIABLE($Type)
   Case of
      :($Type=Is string var)
         RECEIVE VARIABLE($String)
    `Processing variable received
      :($Type=Is real)
         RECEIVE VARIABLE($Real)
    `Processing variable received
      :($Type=Is text)
         RECEIVE VARIABLE($Text)
    `Processing variable received
   End case
```

```
End if
SET CHANNEL(11)
```

## Structure access

**Field (field pointer)** or **(table number;field number)**
**Table(table pointer)** or **(table number)** or **(field pointer)**
These two commands return results of different data types, according to the parameters passed to them:

- If you pass a pointer to the **Table** function, the result returned is a number.
- If you pass a number to the **Table** function, the result returned is a pointer.

## Documents

Keep in mind that the document references returned by the **Open document**, **Append document** and **Create document** functions are of the data type Time.

## Math

**Mod (value;divider)**
The expression “25 modulo 3” can be written in two different ways in 4D:

```
Variable:=Mod(25;3)
```

or

```
Variable:=25%3
```

The compiler sees a difference between the two: **Mod** applies to all numerics, while the operator % applies only to Integers and Long Integers. If the operand of the % operator exceeds the range of the Long Integer data type, the returned result is likely to be wrong.

## Exceptions

**IDLE**
**ON EVENT CALL (Method{; ProcessName})**
**ABORT**

### ON EVENT CALL

The **IDLE** command has been added to 4D language to manage exceptions. This command should be used whenever you use the **ON EVENT CALL** command.

This command could be defined as an event management directive.
Only the kernel of 4D is able to detect a system event (mouse click, keyboard activity, and so forth). In most cases, kernel calls are initiated by the compiled code itself, in a way that is transparent to the user.

On the other hand, when 4D is waiting passively for an event--for example, in a waiting loop--it is clear that there will be no call.

***Example under Windows***

```
 `MouseClick Method
If(MouseDown=1)
   <>vTest:=True
   ALERT("Somebody clicked the mouse")
End if

 `Wait Method
<>vTest:=False
ON EVENT CALL("MouseClick")
While(<>vTest=False)
 `Event's waiting loop
End while
ON EVENT CALL("")
```

In this case, you would add the **IDLE** command in the following manner:

```
 `Wait Method
<>vTest:=False
ON EVENT CALL("MouseClick")
While(<>vTest=False)
   IDLE
 `Kernel call to sense an event
End while
ON EVENT CALL("")
```

### ABORT

Use this command only in error-handling project methods. It works exactly as it does in 4D, except in a method that has been called by one of the following commands: **EXECUTE FORMULA**, **APPLY TO SELECTION** or **_o_APPLY TO SUBSELECTION**. Try to avoid this situation.

## Arrays

Seven 4D commands are used by the compiler to determine the data type of an array. They are:

**COPY ARRAY(source;destination)**
**SELECTION TO ARRAY(field;array)**
**ARRAY TO SELECTION(array;field)**
**SELECTION RANGE TO ARRAY(start;end;field;array)**
**LIST TO ARRAY(list;array{; itemRefs})**
**ARRAY TO LIST(array;list{; itemRefs})**
**DISTINCT VALUES(field;array)**

### COPY ARRAY

The **COPY ARRAY** command accepts two array type parameters. If one of the array parameters is not declared elsewhere, the compiler determines the data type of the undeclared array from the data type of the declared one.
This deduction is performed in the two following cases:

- The array typed is the first parameter. The compiler assigns the data type of the first array to the second array.
- The declared array is the second parameter. Here, the compiler assigns the data type of the second array to the first array.

Since the compiler is strict about data types, **COPY ARRAY** can be performed only from an array of a certain data type to an array of the same type.
Consequently, if you want to copy an array of elements whose data types are similar, i.e., Integers, Long Integers and Reals, or Texts and Strings, or Strings with different lengths, you have to copy the elements one by one.

Suppose you want to copy elements from an Integer array to a Real array. You can proceed as follows:

```
$Size:=Size of array(ArrInt)
ARRAY REAL(ArrReal;$Size)
 `Set same size for Real array as the Integer array
For($i;1;$Size)
   ArrReal{$i}:=ArrInt{$i}
 `Copy each of the elements
End for
```

Remember that you cannot change the number of dimensions of an array during the process. If you copy a one-dimensional array into a two-dimensional array, the compiler generates an error message.

### SELECTION TO ARRAY, ARRAY TO SELECTION, DISTINCT VALUES, SELECTION RANGE TO ARRAY

As with 4D in interpreted mode, these four commands do not require the declaration of arrays. The undeclared array will be assigned the data type of the field specified in the command.

If you write:

```
SELECTION TO ARRAY([MyTable]IntField;MyArray)
```

the data type of MyArray would be an Integer array having one dimension (assuming that IntField is an integer field).

If the array has been declared, make sure that the field is of the same data type. Although Integer, Longint and Real are similar types, they are not equivalent.

On the other hand, in the case of Text and String data types, you have a little more latitude. By default, if an array was not previously declared and you apply a command that includes a String type field as a parameter, the default data type assigned to the array is Text. If the array was previously declared as String or Text, these commands will follow your directives.

The same is true for Text type fields--your directives have priority.

Remember that the **SELECTION TO ARRAY**, **SELECTION RANGE TO ARRAY**, **ARRAY TO SELECTION** and **DISTINCT VALUES** commands can only be used with a one-dimensional array.

The **SELECTION TO ARRAY** command also has a second syntax:
**SELECTION TO ARRAY**(table;array).

In this case, the MyArray variable will be an array of Longints. The **SELECTION RANGE TO ARRAY** command works in the same way.

### LIST TO ARRAY, ARRAY TO LIST

The **LIST TO ARRAY** and **ARRAY TO LIST** commands only concern two types of arrays:

- one-dimensional String arrays, and
- one-dimensional Text arrays.

### Using pointers in array-related commands

The compiler cannot detect a data type conflict if you use a dereferenced pointer as a parameter to an array-declaration command. If you write:

```
SELECTION TO ARRAY([Table]Field:Pointer->)
```

where Pointer-> stands for an array, the compiler cannot check whether the field type and array type are identical. It is up to you to prevent such conflicts; you should type the array referred to by the pointer.

The compiler issues a warning whenever it encounters an array declaration statement in which one of the parameters is a pointer. These messages can be helpful in detecting this type of conflict.

### Local arrays

If your database uses local arrays (arrays recognized only in the method in which they were created), it is necessary to declare them explicitly in 4D before using them.

To declare a local array, use one of the array commands such as **ARRAY REAL**, **ARRAY INTEGER**, etc.

For example, if a method creates a local Integer array with 10 elements, you need to declare the array before using it. Use the command:

```
ARRAY INTEGER($MyArray;10)
```

## Language

**Get pointer(varName)**
**Type (object)**
**EXECUTE FORMULA(statement)**
**TRACE**
**NO TRACE**

### Get pointer

**Get pointer** is a function that returns a pointer to the parameter that you passed to it. Suppose you want to initialize an array of pointers. Each element in that array points to a given variable. Suppose there are twelve such variables named V1, V2, ···V12. You could write:

```
ARRAY POINTER(Arr;12)
Arr{1}:=->V1
Arr{2}:=->V2

Arr{12}:=->V12
```

You could also write:

```
ARRAY POINTER(Arr;12)
For($i;1;12)
   Arr{$i}:=Get pointer("V"+String($i))
End for
```

At the end of this operation, you get an array of pointers where each element points to a variable Vi.

These two sequences can be compiled. However, if the variables V1 to V12 are not used explicitly elsewhere in the database, the compiler cannot type them. Therefore, they must be used or declared explicitly elsewhere.
Such explicit declaration may be performed in two ways:

- By declaring V1, V2, ···V12 through a compiler directive:

```
C_LONGINT(V1;V2;V3;V4;V5;V6;V7;V8;V9;V10;V11;V12)
```

- By assigning these variables in a method:

```
V1:=0
V2:=0

V12:=0
```

### Type (object)

Since each variable in a compiled database has only one data type, the **Type** function may seem to be of no use. However, it can be useful when you work with pointers. For example, you may need to know the data type of the variable to which a pointer refers; due to the flexibility of pointers, one cannot always be sure to what object it points.

### EXECUTE FORMULA

This command offers benefits in interpreted mode that are not carried over to compiled mode.

In compiled mode, a method name passed as a parameter to this command is interpreted. Therefore, you miss some of the advantages provided by the compiler, and your parameter's syntax cannot be checked.

Moreover, you cannot pass local variables as parameters to it.

**EXECUTE FORMULA** can be replaced by a series of statements. Two examples are given below.

Given the following sequence:

```
i:=FormFunc
EXECUTE FORMULA("FORM SET INPUT (Form"+String(i)+")")
```

It can be replaced by:

```
i:=FormFunc
VarForm:="Form"+String(i)
FORM SET INPUT(VarForm)
```

Below is another example:

```
$Num:=SelPrinter
EXECUTE FORMULA("Print"+$Num)
```

Here, **EXECUTE FORMULA** can be replaced with *Case of*:

```
Case of
   :($Num=1)
      Print1
   :($Num=2)
      Print2
   :($Num=3)
      Print3
End case
```

The **EXECUTE FORMULA** command can always be replaced. Since the method to be executed is chosen from the list of the database's project methods or the 4D commands, there is a finite number of methods. Consequently, it is always possible to replace **EXECUTE FORMULA** with either *Case of* or with another command. Furthermore, your code will execute faster.

### TRACE, NO TRACE

These two commands are used in the debugging process. They serve no purpose in a compiled database. However, you can keep them in your methods; they will simply be ignored by the compiler.

## Variables

**Undefined(variable)**
**SAVE VARIABLES(document;variable1{; variable2…})**
**LOAD VARIABLES(document;variable1{; variable2…})**
**CLEAR VARIABLE(variable)**

### Undefined

Considering the typing process carried out by the compiler, a variable can never be undefined in compiled mode. In fact, all the variables have been defined by the time compilation has been completed. The **Undefined** function therefore always returns **False**, whatever parameter it is passed.

**Note:** To know if your application is running in compiled mode, call the **Is compiled mode** command.

### SAVE VARIABLES, LOAD VARIABLES

In interpreted mode, you can check that the document exists by testing if one of the variables is undefined after performing a **LOAD VARIABLES**. This is no longer feasible in compiled databases, because the **Undefined** function always returns **False**.

This test can be performed in either interpreted or compiled mode by:

1. Initializing the variables that you will receive to a value that is not a legal value for any of the variables.
2. Comparing one of the received variables to the initialization value after **LOAD VARIABLES**.

The method can be written as follows:

```
Var1:="xxxxxx"
 `"xxxxxx" is a value that cannot be returned by LOAD VARIABLES
Var2:="xxxxxx"
Var3:="xxxxxx"
Var4:="xxxxxx"
LOAD VARIABLES("Document";Var1;Var2;Var3;Var4)
If(Var1="xxxxxx")
 `Document not found

Else
 `Document found

End if
```

### CLEAR VARIABLE

This routine uses two different syntaxes in interpreted mode:

**CLEAR VARIABLE**(variable)

**CLEAR VARIABLE**("a")

In compiled mode, the first syntax of **CLEAR VARIABLE**(variable) reinitializes the variable (set to null for a numeric; empty string for a character string or a text, etc.), since no variable can be undefined in compiled mode.

Consequently, **CLEAR VARIABLE** does not free any memory in compiled mode, except in four cases: Text, Picture, BLOB and Array type variables.

For an array, **CLEAR VARIABLE** has the same effect as a new array declaration where the size is set to null.

For an array MyArray whose elements are of the *Integer* type, **CLEAR VARIABLE**(MyArray) has the same effect as one of the following expressions:

```
ARRAY INTEGER(MyArray;0)
 `if it as a one-dimensional array
ARRAY INTEGER(MyArray;0;0)
 `if it is a two-dimensional array
```

The second syntax, **CLEAR VARIABLE**("a"), is incompatible with the compiler, since compilers access variables by address, not by name.

## Pointers with certain commands

### Pointers with certain commands

The following commands have one common feature: they accept an optional first parameter [Table], and the second parameter can be a pointer.

| | |
|---|---|
| ADD TO SET | LOAD SET |
| APPLY TO SELECTION | LOCKED BY |
| COPY NAMED SELECTION | ORDER BY |
| CREATE EMPTY SET | ORDER BY FORMULA |
| CREATE SET | FORM SET OUTPUT |
| CUT NAMED SELECTION | PAGE SETUP |
| DIALOG | Print form |
| EXPORT DIF | PRINT LABEL |
| EXPORT SYLK | QR REPORT |
| EXPORT TEXT | QUERY |
| GOTO RECORD | QUERY BY FORMULA |
| GOTO SELECTED RECORD | QUERY SELECTION |
| _o_GRAPH TABLE | QUERY SELECTION BY FORMULA |
| IMPORT DIF | REDUCE SELECTION |
| IMPORT SYLK | RELATE MANY |
| IMPORT TEXT | REMOVE FROM SET |
| FORM SET INPUT | |

In compiled mode, it is easy to return the optional [Table] parameter. However, when the first parameter passed to one of these commands is a pointer, the compiler does not know to what the pointer is referring; the compiler treats it as a table pointer.

Take the case of the **QUERY** command whose syntax is as follows:
**QUERY**({table{;formula{;*}}})

The first element of the *formula* parameter must be a field.

If you write :

```
QUERY(PtrField->=True)
```

the compiler will look for a symbol representing a field in the second element. When it finds the "=" sign, it will issue an error message, since it cannot identify the command with an expression that it knows how to process.

On the other hand, if you write:

```
QUERY(PtrTable->;PtrField->=True)
```

or

```
QUERY([Table];PtrField->=True)
```

you will avoid any possible ambiguity.

### Direct use of commands returning pointers

When using pointers, there is a particularity concerning commands where the first parameter [aTable] and second parameter are both optional. In this context, for internal reasons, the compiler does not allow a command that returns a pointer (for example **Current form table**) to be passed directly as a parameter (an error is generated).

This is the case, for example, of the **FORM SCREENSHOT** command. The following code works in interpreted mode but is rejected during compilation:

```
 //triggers a compilation error
FORM SCREENSHOT(Current form table->;$formName;$myPict)
```

In this case, you can just use an intermediate variable in order for this code to be validated by the compiler:

```
 //equivalent compilable code
C_POINTER($ptr)
$ptr:=Current form table
FORM SCREENSHOT($ptr->;$formName;$myPict)
```

## Constants

If you create your own 4DK# resources (constants), make sure that numerics are declared as Longints (L) or Reals (R) and character strings as Strings (S). Any other type will generate a warning.

# Optimization Hints

It is difficult to state a definitive “good-programming” method, but we wish to stress the advantages of well-structured programs. The capacity for structured programming in 4D can be a great help.

The compilation of a well-structured database can yield much better results than the same effort performed in a poorly-designed one. For instance, if you write a generic method to manage n object methods, you will get higher quality results in both interpreted and compiled modes than in a situation where n object methods comprise n times the same set of statements.

In other words, the quality of the programming does have an impact on the quality of the compiled code.

With practice, you can gradually improve your 4D code. Frequent use of the compiler gives you corrective feedback that enables you to reach instinctively for the most efficient solution.
In the meantime, we can offer some advice and a few tricks that will save you time in performing simple, recurring tasks.

## Using comments in code

Certain programming techniques may make your code less readable both for yourself or another person at a later time. Because of this, we encourage you to comment your methods with a lot of detail. In fact, while excessive comments have a tendency to slow down interpreted databases, they have absolutely no influence on the execution time in a compiled database.

## Using compiler directives to optimize code

Compiler directives can help you speed up your code considerably. When typing variables on the basis of their use, the compiler uses the data type with the largest scope possible so as not to penalize you. For example, if you do not type the variable defined by the statement: *Var:= 5*, the compiler will type it as Real, even if it could be declared an Integer.

### Numeric Variables

The compiler gives numeric variables (not typed by compiler directives) the default data type Real if the Database Settings are not set to anything else. But calculations performed on a Real are slower than on a Longint. If you know that a numeric variable will always be an integer, it is to your advantage to declare it through the compiler directive **C_LONGINT**.

For example, it is good practice to declare your loop counters as Integers.

Some 4D functions return Integers (e.g., **Character code**, **Int**, etc.). If you assign the result of one of these functions to an untyped variable of your database, the compiler types it as Real rather than as Integer. Remember to declare such variables with compiler directives whenever you are sure that they will not be used in a different context.

Here is a simple example of a function that returns a random value with a given range:

```
$0:=Mod(Random;($2-$1+1))+$1
```

It will always return an integer. Written this way, the compiler will type $0 as Real rather than Integer or Longint. It is preferable, therefore, to include a compiler directive in the method:

```
C_LONGINT($0)
$0:=Mod(Random;($2-$1+1))+$1
```

The parameter returned by the method will take less space in memory and will be much faster.

Here is another example. Suppose you typed two variables as Longint:

```
C_LONGINT($var1;$var2)
```

and a third non-typed variable receives the sum of the other two variables:

```
$var3:=$var1+$var2.
```

The compiler will type the third variable, $var3, as Real. You will have to explicitly declare it as Longint if you want the result to be a long integer.

**Note:** Be careful with the computation mode in 4D. In compiled mode, it is not the data type of the variable that receives the calculation which determines the computation mode, but rather the data types of the operands.

In the following example, the calculation is based on long integers:

```
C_REAL($var3)
C_LONGINT($var1;$var2)
$var1:=2147483647
$var2:=1
$var3:=$var1+$var2
```

$var3 is equal to −2147483648 in both compiled mode and interpreted mode.

However, in this example:

```
C_REAL($var3)
C_LONGINT($var1)
$var1:=2147483647
$var3:=$var1+1
```

for optimization reasons, the compiler considers the value 1 as an integer. In compiled mode, $var3 is equal to −2147483648 because the calculation is based on Longints. In interpreted mode, $var3 is equal to 2147483648 because the calculation is based on Reals.

Buttons are a specific case of a Real that can be declared as Longint.

### Strings

If you want to test the value of a character, make the comparison on its **Character code** value rather than on the character itself. The regular character comparison procedure considers all of the character's alternatives, such as diacritical marks.

## Various observations

### Two-dimensional arrays

The processing of two-dimensional arrays is better managed if the second dimension is larger than the first.

For example, an array declared as:

```
ARRAY INTEGER(Array;5;1000)
```

will be better managed than an array declared as:

```
ARRAY INTEGER(Array;1000;5)
```

### Fields

Whenever you need to perform several calculations on a field, you can improve performance by storing the value of that field in a variable and performing your calculations on the variable rather than the field. Consider the following method:

```
Case of
   :([Client]Dest="New York City")
      Transport:="Messenger"
   :([Client]Dest="Puerto Rico")
      Transport:="Air mail"
   :([Client]Dest="Overseas")
      Transport:="Express mail service"
   Else
      Transport:="Regular mail service"
End case
```

This method will take longer to execute than if it were written:

```
$Dest:=[Client]Dest
Case of
   :($Dest="New York City")
      Transport:="Messenger"
   :($Dest="Puerto Rico")
```

```
      Transport:="Air mail"
   :($Dest="Overseas")
      Transport:="Express mail service"
   Else
      Transport:="Regular mail service"
End case
```

### Pointers

As is the case with fields, it is faster to work with variables than with dereferenced pointers. Whenever you need to perform several calculations on a variable referenced by a pointer, you can save time by storing the dereferenced pointer in a variable.

For example, suppose you use a pointer, MyPtr, to refer to a field or to a variable. Then, you want to perform a set of tests on the value referenced by MyPtr. You could write:

```
Case of
   :(MyPtr->=1)
      Sequence 1
   :(MyPtr->=2)
      Sequence 2

End case
```

The set of tests would be performed faster if it were written:

```
Temp:=MyPtr->
Case of
   :(Temp=1)
      Sequence 1
   :(Temp=2)
      Sequence 2

End case
```

### Local variables

Use local variables wherever possible to structure you code. Using local variables has the following advantages:

- Local variables take less space when used in a database. They are created when the method in which they are used is entered, and they are destroyed when the method finishes executing.
- The code generated is optimized for local variables, especially for those of the type Longint. This is useful for counters in loops.

# Error messages

This section describes the different messages generated by the compiler. These messages are of several different types:

- warnings, that help you avoid common pitfalls;
- errors, that it is up to you to correct;
- range checking messages, generated within 4D.

## Warnings

These messages are generated throughout the compilation process. Each message is accompanied here with an example of the problem and, when necessary, an additional explanation.

Pointer in COPY ARRAY

```
COPY ARRAY(Pointer->;Array)
```

Pointer in SELECTION TO ARRAY

```
SELECTION TO ARRAY(Pointer->;MyArray)
SELECTION TO ARRAY([MyTable]MyField;Pointer->)
```

Pointer in ARRAY TO SELECTION

```
ARRAY TO SELECTION(Pointer->;[MyTable]MyField)
```

Pointer in LIST TO ARRAY

```
LIST TO ARRAY(List;Pointer->)
```

Pointer in ARRAY TO LIST

```
ARRAY TO LIST(Pointer->;List)
```

Pointer in an array declaration

```
ARRAY REAL(Pointer->;5)
```

The command **ARRAY REAL**(Array;Pointer->) does not generate this warning. The value of the dimension of an array does not have any influence on its type. In this example, the array referred to by the pointer must have been defined elsewhere.

Pointer in DISTINCT VALUES

```
DISTINCT VALUES(Pointer->;Array)
```

Using the function Undefined is not advised.

```
If(Undefined(Variable))
```

The **Undefined** function always returns *FALSE* in a compiled database.

This method is protected by a password.

An automatic action button does not have a name in the MyForm form on page X.
All of your buttons should have names to avoid conflicts.

Assumes that the pointer points to an alphanumeric expression.

```
Pointer->≤2≥:="a"
```

Assumes that the string index is numeric.

```
String≤Pointer->≥:="a"
```

Assumes that the array index is of type real.

```
ALERT(MyArray{Pointer->})
```

Missing parameter in the plug-in procedure call.

```
WR SET FONT(Area)
```

**Note:** You can enable and disable warnings individually using the following tags:
**//%W-warning_number** to disable a warning
**//%W+warning_number** to enable a warning
Enabling and disabling warnings in this way is effective for all the code parsed subsequently in the compilation plan. If you want to generally disable or enable warnings, you can just insert the appropriate tag in a method named "Compiler_xxx" since these methods are the first ones parsed by the compiler. For example, to disable the "Pointer in COPY ARRAY" warning, you can insert the "//%W-518.1" tag at the desired location.

## Error messages

These messages are generated throughout the compilation process. It is up to you to correct these errors in order to for the compiler to be able to generate a compiled database. Each message is accompanied here with an example of the problem and, when necessary, an additional explanation.

**Typing**

The type of the variable is not compatible with the operator. Cannot make an assignment with those types.

```
MyReal:=12.3
MyBoolean:=True
MyReal:=MyBoolean
```

Changing the number of dimensions of an array.

```
ARRAY TEXT(MyArray;5;5)
ARRAY TEXT(MyArray;5)
```

Typing conflict on the MyArray variable in the form.

```
ARRAY INTEGER(MyArray)
```

Declaring an array without dimensions.

```
ARRAY INTEGER(MyArray)
```

Variable expected.

```
COPY ARRAY(MyArray;"")
```

The type of Variable is unknown. This variable is used in the method M1.
The type of Variable cannot be determined. A compiler directive is necessary.

Invalid constant type

```
OK:="The weather is nice"
```

The method M1 is unknown.
The line contains a call to a method that does not exist or no longer exists.

Incorrect usage of a field.

```
MyDate:=Add to date(BooleanField;1;1;1)
```

The variable Variable is not a method.

```
Variable(1)
```

The variable Variable is not an array.

```
Variable{5}:=12
```

The result of the function is not compatible with the expression.

```
Text:="Number"+Num(i)
```

The types of the variables used in this expression are not compatible.

```
Integer:=MyDate*Text
```

Changing the type of the variable $i from type Fixed string to type Real.

```
$i:="3"
$($i):=5
```

The array index is not a number.

```
IntArray{"3"}:=4
```

Retyping the variable Variable from type Text to an array of type Text.

```
C_TEXT(Variable)
COPY ARRAY(TextArray;Variable)
```

Retyping of the variable Variable from type Text to type Real.

```
Variable:=Num(Variable)
```

Retyping the array MyBoolean from array of type Boolean to variable of type Real.

```
Variable:=MyBoolean
```

Retyping the array IntArray from array of type Integer to array of type Text.

```
ARRAY TEXT(IntArray;12)
```

if IntArray was declared elsewhere as an Integer array.

Trying to dereference a variable which is not of type Pointer.

```
Variable->:=5
```

if Variable is not of the type Pointer.

Retyping of the variable Var1 from type Text to type Number.

```
Var1:=3.5
```

Incorrect usage of a field.

```
Variable:=[MyTable]MyField
```

[MyTable]MyField is a Date field. Variable is of the type Number.

**Syntax**

The result of the function is not a pointer.

```
Variable:=Num("The weather is nice")->
```

It is not possible to dereference this function.

Syntax error.

```
If(Boolean)
End for
```

Too many opening curly brackets ({) .
The line contains more opening brackets than closing brackets.

Too many closing curly brackets (}).
The line contains more closing brackets than opening brackets.

Closing parenthesis ) expected.
The line contains more opening parentheses than closing parentheses.

Opening parenthesis ( expected.
The line contains more closing parentheses than opening parentheses.

Field expected.

```
If(Modified(Variable))
```

Opening curly bracket expected.

```
C_INTEGER($
```

Variable expected.

```
C_INTEGER([MyTable]MyField)
```

Constant number expected.

```
C_INTEGER($["3"])
```

Semicolon ; expected.

```
COPY ARRAY(Array1 Array2)
```

**Mac OS**

```
MyString≤3:="a"
```

Too many closing character reference symbols.

```
MyString3≥:="a"
```

**Windows**

```
MyString[[3:="a"
```

Too many closing character reference symbols.

```
MyString 3]]:="a"
```

Did not expect a subtable.

```
ARRAY TO SELECTION(Array;Subtable)
```

The argument of an IF statement must be a boolean.

```
If(Pointer)
```

Expression is too complex.
Divide your statement into several shorter statements.

Method is too complex.
Too many Case of...End case and/or If…End if structures.

Unknown field.
Your method, possibly copied from another database, contains •???• instead of a field name.

Unknown table.
Your method, possibly copied from another database, contains •???• instead of a table name.

Pointer to an incorrect expression.

```
Pointer:=->Variable+3
```

Incorrect usage of string index.

```
MyReal≤3≥or MyReal[[3]]
```

or

```
MyString≤Variable≥or MyString[[Variable]]
```

where Variable is not a Number variable.

**Parameters**

The result of this function cannot be passed as a parameter to this method or command.

```
MyMethod(Num(MyString))
```

if MyMethod expects a Boolean expression.

Too many parameters have been passed to this method.

```
DEFAULT TABLE(Table:Form)
```

This value cannot be passed as a parameter to this method or command.

```
MyMethod(3+2)
```

if MyMethod expects a Boolean expression.

Function result type conflict.

```
C_INTEGER($0)
$0:=False
```

Generic parameter type conflict.

```
C_INTEGER(${3})
For($i;3;5)
   ${$i}:=String($i)
End for
```

This 4D command does not require any parameters.

```
SHOW TOOL BAR(MyVar)
```

This 4D command requires at least one parameter.

```
DEFAULT TABLE
```

MyString cannot be passed as a parameter to that method.

```
MyMethod(MyString)
```

if MyMethod is expecting a Boolean parameter.

The type of the parameter $1 is different in the calling and in the called method.

```
Calculate("3+2")
```

with the directive **C_INTEGER**($1) in Calculate.

One of the parameters in COPY ARRAY is a variable.

```
COPY ARRAY(Variable;Array)
```

Retyping of the variable $1 from type Number to type Text.

```
$1:=String($1)
```

An array cannot be a parameter.

```
ReInit(MyArray)
```

To pass an array in a method, you need to pass a pointer to the array.

**Operators**

The type of the variable is not compatible with the operator.

```
Bool2:=Bool1+True
```

Addition cannot be performed on Boolean fields.

Did not expect the operator >.

```
QUERY(MyTable;[MyTable]MyField=0;>)
```

Cannot compare two variables of those types.

```
If(Number=Picture2)
```

Cannot negate this type of variable.

```
Boolean:=-False
```

**Plug-in Commands**

The plug-in command PExt does not seem to be correctly defined.

Not enough parameters were passed to this plug-in command.

Too many parameters were passed to this plug-in command.

The plug-in command Variable does not seem to be correctly defined.

**General Errors**

Two methods have the same name : Name.
To compile your database, all of the project methods must have different names.

Internal error # xx.
If this message appears, call 4D Technical Support and report the error number.

The variable Variable could not be typed. This variable is used in the method M1.
The Variable type cannot be determined. A compiler directive is necessary.

The original method is damaged.
The method is damaged in the original structure. Delete it or replace it.

Unknown 4D command.
The method is damaged.

Retyping the variable Variable in the form Form.
This message appears if you give, for example, the name OK to a variable of the type Graph in a form.

The name of the function Name is also the name of a variable in the form.
Rename either the function or the variable.

A method and a variable have the same name : Name.
Rename either the method or the variable.

A plug-in command and a variable have the same name : Name.
Rename either the plug-in command or the variable.

Cannot call a command that is not thread-safe from a method declared as thread-safe.
Modify the method so that it becomes thread-safe (do not use any command that is not thread-safe) or change the declaration property of the method in order to start a cooperative process

Cannot call 'MethodName' method that is not thread-safe from a method declared thread-safe.
Modify the method so that it becomes thread-safe or change the declaration property of the method in order to start a cooperative process

## Range-checking messages

These messages are generated in 4D while the compiled database is running. They are displayed in a specific error window.

The result is out of range.
If MyArray is a five-element array, this message appears if you try to access element 17 in the array.

Division by zero.

```
Var1:=0
Var2:=2
Var3:=Var2/Var1
```

Accessing a parameter that does not exist.
Using the $4 local variable when only three parameters have been passed to the current method.

The pointer is not properly initialized.

```
MyPointer->:=5
```

if MyPointer has not yet been initialized.

The destination string is smaller than the source.

```
C_STRING(MyString1;5)
C_STRING(MyString2;10)
MyString2:="Flowers"
MyString1:=MyString2
```

Invalid character reference.

```
i:=-30
MyString≤i≥:=MyString2 or MyString[[i]]:=MyString2
```

The parameter is an empty string.

```
MyString≤1≥:=""
MyString[[1]]:=""
```

Modulo by zero.

```
Var1:=0
Var2:=2
Var3:=Var2% Var1
```

Invalid parameters in an EXECUTE command.

```
EXECUTE FORMULA("MyMethod(MyAlpha)")
```

if MyMethod expects a parameter other than an Alphanumeric.

Pointer to an unknown variable.

```
MyPointer:=Get pointer("Variable")
MyPointer:="MyString"
```

if Variable does not appear explicitly in the database.

Attempting to retype by using a pointer.

```
Boolean:=Pointer->
```

if Pointer points to a field of type Integer.

Bad usage of a pointer or pointer to an unknown variable.

```
Character:=StringVar≤Pointer->≥
Character:=StringVar[[Pointer]]
```

if Pointer does not point to a Number.

# C_BLOB

C_BLOB ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

**C_BLOB** casts each specified variable as a BLOB variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess, or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_BLOB**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_BLOB**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the **Compiler Commands** section.

# C_BOOLEAN

C_BOOLEAN ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_BOOLEAN** command casts each specified variable as a Boolean variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess, or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_BOOLEAN**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_BOOLEAN**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_DATE

C_DATE ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_DATE** command casts each specified variable as a Date variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess, or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_DATE**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_DATE**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_LONGINT

C_LONGINT ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_LONGINT** command casts each specified variable as a Long Integer variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_LONGINT**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_LONGINT**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_OBJECT

C_OBJECT ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Name of method |
| variable | Variable | ⇒ | Name(s) of variable(s) or parameter(s) ${...} to declare |

## Description

The **C_OBJECT** command assigns the *Object* type to all the variables that are specified.

The *Object* type is supported by the 4D language starting with v14. Objects of this type are managed by the commands of the **Objects (Language)** theme.

You use the first syntax of the command (when the *method* parameter is not passed) to declare and type a process, interprocess or local variable. This syntax can be used in interpreted databases.

You use the second syntax of the command (when the *method* parameter is passed) to declare the method's result and/or parameters ($0, $1, $2, etc.) to the compiler in advance. You must use this syntax if you want to skip the variable typing phase in order to save time when the database is compiled.

**WARNING:** You cannot execute the second syntax in interpreted mode. For this reason, when you use this syntax, you should store it in a method (whose name must begin with "COMPILER") that is not executed in interpreted mode.

**Advanced use:** You can use the **C_OBJECT**(${...}) syntax to declare a variable number of parameters of the same type for a method as long as they are the last parameters of this method. For example, the declaration **C_OBJECT**(${5}) indicates to the compiler that beginning with the fifth parameter, the method can receive a variable number of parameters of this type.

## Example

Refer to the **Compiler Commands** section.

# C_PICTURE

C_PICTURE ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_PICTURE** command casts each specified variable as a Picture variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_PICTURE**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_PICTURE**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_POINTER

C_POINTER ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_POINTER** command casts each specified variable as a Pointer variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess, or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with "COMPILER."

**Advanced Tip:** The syntax **C_POINTER**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_POINTER**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_REAL

C_REAL ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_REAL** command casts each specified variable as a Real variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_REAL**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_REAL**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_TEXT

C_TEXT ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_TEXT** command casts each specified variable as a Text variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_TEXT**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_TEXT**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# C_TIME

C_TIME ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Description

The **C_TIME** command casts each specified variable as a Time variable.

The first form of the command, in which the optional *method* parameter is NOT passed, is used to declare and type any process, interprocess, or local variable.

**Note:** This form can be used in interpreted databases.

The second form of the command, in which the optional *method* parameter IS passed, is used to predeclare to the compiler the result and/or the parameters ($0, $1, $2 etc) for a method. Use this form of the command in order to skip the Typing variables phase while compiling a database, saving compilation time.

**WARNING:** The second form cannot be executed in interpreted mode. For this reason, if you are using this syntax, keep it in a method that is not executed in interpreted mode. The name of this method must start with “COMPILER.”

**Advanced Tip:** The syntax **C_TIME**(${...}) allows you to declare a variable number of parameters of the same type, under the condition that these are the last parameters for the method. For example, the declaration **C_TIME**(${5}) tells 4D and the compiler that starting with the fifth parameter, the method can receive a variable number of parameters of that type. For more information, see the **Count parameters** command.

## Examples

See examples in the section **Compiler Commands**.

# IDLE

IDLE
Does not require any parameters

## Description

The **IDLE** command is designed only for use with the compiler. This command is only used in compiled databases in which user-defined methods are written so that no calls are made back to the 4D engine. For example, if a method has a *For* loop in which no 4D commands are executed, the loop could not be interrupted by a process installed with **ON EVENT CALL**, nor could a user switch to another application. In this case, you should insert **IDLE** to allow 4D to trap events. If you do not want any interruptions, omit **IDLE**.

## Example

In the following example, the loop would never terminate in a compiled database without the call to **IDLE**:

```
  ` Do Something Project Method
ON EVENT CALL("EVENT METHOD")
◊vbWeStop:=False
MESSAGE("Processing..."+Char(13)+"Type any key to interrupt...")
Repeat
  ` Do some processing that doesn't involve a 4D command
   IDLE
Until(◊vbWeStop)
ON EVENT CALL("")
```

with:

```
  ` EVENT METHOD Project Method
If(Undefined(KeyCode))
   KeyCode:=0
End if
If(KeyCode#0)
   CONFIRM("Do you really want to stop this operation?")
   If(OK=1)
      ◊vbWeStop:=True
   End if
End if
```

# _o_C_GRAPH

_o_C_GRAPH ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | String | ⇒ | Name of method |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Compatibility note

Variables of the Graph area type are obsolete and no longer supported since 4D v14. You need to use picture variables (see **GRAPH**).

# _o_C_INTEGER

_o_C_INTEGER ( {method ;} variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ➡ | Optional name of method |
| variable | | ➡ | Name of variable(s) to declare |

## Preliminary Note

The **_o_C_INTEGER** command is still present in 4D for compatibility with old databases. In fact, 4D and the compiler retype Integers into Longints internally. For example:

```
_o_C_INTEGER($MyVar)
$TheType:=Type($MyVar) //$TheType = 9 (Is longint)
```

# _o_C_STRING

_o_C_STRING ( {method ;} size ; variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| method | Method | ⇒ | Optional name of method |
| size | Longint | ⇒ | Size of the string |
| variable | Variable | ⇒ | Name of variable(s) to declare |

## Compatibility note

The operation of the **_o_C_STRING** command is strictly identical to the **C_TEXT** command (the *size* parameter is ignored). It is now recommended to only use **C_TEXT** in your 4D developments.

# Data Entry

- ACCEPT
- ADD RECORD
- CANCEL
- DIALOG
- Modified
- MODIFY RECORD
- Old
- REJECT
- *_o_ADD SUBRECORD*
- *_o_MODIFY SUBRECORD*

# ACCEPT

ACCEPT
Does not require any parameters

## Description

The **ACCEPT** command is used in form or object methods (or in subroutines) to:

- accept a new or modified record or subrecord, for which data entry has been initiated using **ADD RECORD**, **MODIFY RECORD**, **_o_ADD SUBRECORD** or **_o_MODIFY SUBRECORD**.
- accept a form displayed with the **DIALOG** command.
- exit a form displaying a selection of records, using **DISPLAY SELECTION** or **MODIFY SELECTION**.

**ACCEPT** performs the same action as if a user had pressed the Enter key. After the form is accepted, the OK system variable is set to 1.

**ACCEPT** is commonly executed as a result of choosing a menu command. **ACCEPT** is also commonly used in the object method of a “no action” button.

It is also often used in the optional close box method for the **Open window** command. If there is a Control-menu box on a window, **ACCEPT** or **CANCEL** can be called, in the method to be executed, when the Control-menu box is double-clicked or the Close menu command is chosen.

**ACCEPT** cannot be queued up. In response to an event, executing two **ACCEPT** commands in a row from within a method would have the same effect as executing one.

# ADD RECORD

ADD RECORD ( {aTable}{;}{*} )

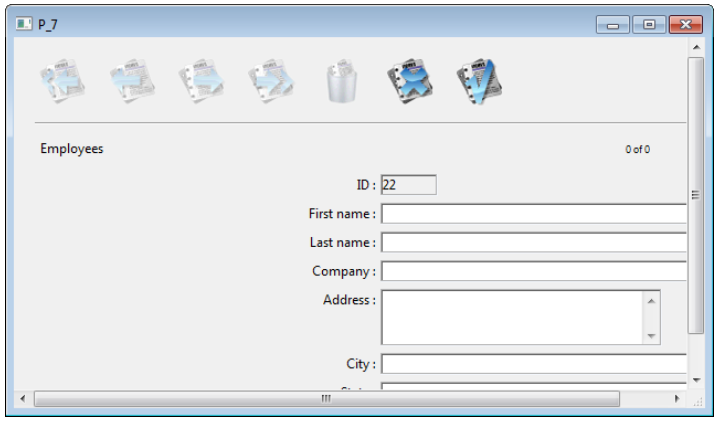
| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table to use for data entry, or Default table, if omitted |
| * | | ➡ | Hide scroll bars |

## Description

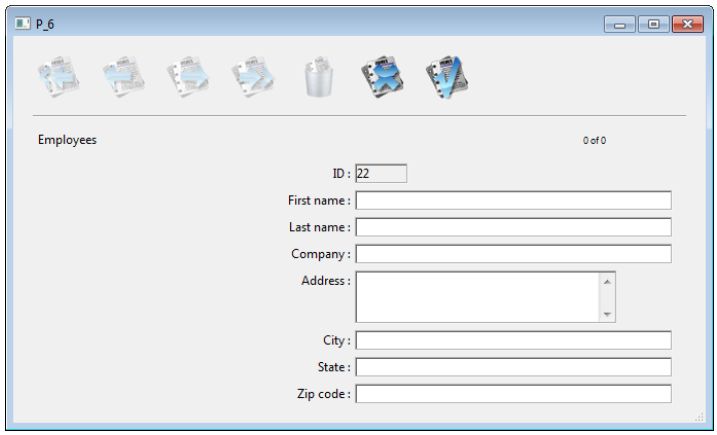
The **ADD RECORD** command lets the user add a new record to the database for the table *aTable* or for the default table, if you omit the *aTable* parameter.

**ADD RECORD** creates a new record, makes the new record the current record for the current process, and displays the current input form. In the Application environment, after the user has accepted the new record, the new record is the only record in the current selection.

The following figure shows a typical data entry form.



The form is displayed in the frontmost window of the process. The window has scroll bars and a size box. Specifying the optional * parameter causes the window to be drawn without scroll bars and the form window can no longer be reduced:



**ADD RECORD** displays the form until the user accepts or cancels the record. If the user is adding several records, the command must be executed once for each new record.

The record is saved (accepted) if the user clicks an Accept button or presses the Enter key (numeric keypad), or if the **ACCEPT** command is executed.

The record is not saved (canceled) if the user clicks a Cancel button or presses the cancel key combination (Ctrl-Period on Windows, Command-Period on Macintosh), or if the **CANCEL** command is executed.

**Note:** This command does not require *aTable* to be in read/write mode. It can be used even when the table is in read-only mode (see **Record Locking**).

After a call to **ADD RECORD**, OK is set to 1 if the record is accepted, to 0 if canceled.

**Note:** Even when canceled, the record remains in memory and can be saved if **SAVE RECORD** is executed before the current record pointer is changed.

## Example 1

The following example is a loop commonly used to add new records to a database:

```
FORM SET INPUT([Customers];"Std Input") ` Set input form for [Customers] table
Repeat ` Loop until the user cancels
   ADD RECORD([Customers];*) ` Add a record to the [Customers] table
Until(OK=0) ` Until the user cancels
```

## Example 2

The following example queries the database for a customer. Depending on the results of the search, one of two things may happen. If no customer is found, then the user is allowed to add a new customer with **ADD RECORD**. If at least one customer is found, the user is presented with the first record found, which can be modified with **MODIFY RECORD**:

```
READ WRITE([Customers])
FORM SET INPUT([Customers];"Input") ` Set the input form
vlCustNum:=Num(Request("Enter Customer Number:")) ` Get the customer number
If(OK=1)
   QUERY([Customers];[Customers]CustNo=vlCustNum) ` Look for the customer
   If(Records in selection([Customers])=0) ` If no customer is found…
      ADD RECORD([Customers]) ` Add a new customer
   Else
      If(Not(Locked([Customers])))
         MODIFY RECORD([Customers]) ` Modify the record
         UNLOAD RECORD([Customers])
      Else
         ALERT("The record is currently being used.")
      End if
   End if
End if
```

## System variables and sets

Accepting the record sets the OK system variable to 1; canceling it sets the OK system variable to 0. The OK system variable is set only after the record is accepted or canceled.

# CANCEL

CANCEL
Does not require any parameters

## Description

The **CANCEL** command is used in form or object methods (or in a subroutine) to:

- cancel a new or modified record or subrecord, for which data entry has been initiated using **ADD RECORD**, **MODIFY RECORD**, **_o_ADD SUBRECORD** or **_o_MODIFY SUBRECORD**.
- cancel a form displayed with the **DIALOG** command.
- exit a form displaying a selection of records, using **DISPLAY SELECTION** or **MODIFY SELECTION**.
- cancel the printing of a form that is about to be printed using the **Print form** command (see below).

In the context of data entry, **CANCEL** performs the same action as if the user had pressed the cancel key (**Esc**).

**CANCEL** is commonly executed as a result of a menu command being chosen. **CANCEL** is also commonly used in the object method of a “no action” button.

It is also often used in the optional close box method for the **Open window** command. If there is a Control-menu box on a window, **ACCEPT** or **CANCEL** can be called, in the method to be executed, when the Control-menu box is double-clicked or the **Close** menu command is chosen.

**CANCEL** cannot be queued up. Executing two **CANCEL** commands in a row from within a method in response to an event would have the same effect as executing only one.

Finally, this command can be used in the On Printing Detail form event, when using the **Print form** command. In this context, the **CANCEL** command suspends the printing of the form that is about to be printed, then resumes it on the next page. This mechanism can be used to manage form printing when there is a lack of space or if a page break is required.

**Note:** This operation differs from that of the **PAGE BREAK**(*) command that cancels ALL the forms waiting to be printed.

## Example

Refer to the example of the **SET PRINT MARKER** command.

## System variables and sets

When the **CANCEL** command is executed (form or printing cancelled), the system variable OK is set to 0.

# DIALOG

DIALOG ( {aTable ;} form {; *} )

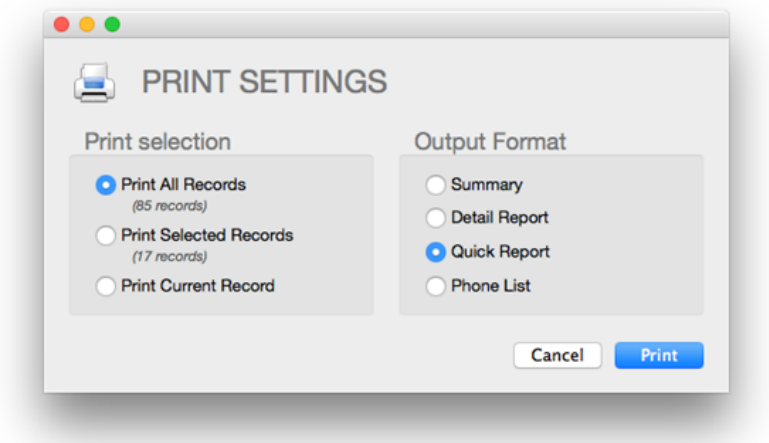
| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table owning the form or If omitted: default table or use of project form |
| form | String | ⇒ | Name of table or project form to display as dialog |
| * | Operator | ⇒ | Use the same process |

## Description

The **DIALOG** command presents the form *form* to the user. This command is often used to get information from the user through the use of variables, or to present information to the user, such as options for performing an operation.

It is common to display the form inside a modal window created with the **Open window** command.

Here is a typical example of a dialog:



Use **DIALOG** instead of **ALERT**, **CONFIRM** or **Request** when the information that must be presented or gathered is more complex than those commands can manage.

**Note:** In converted databases, it is possible to prohibit data entry in fields of dialog boxes (and thus limit data entry to variables only) using an option in the Preferences of 4D (Compatibility page). This restriction corresponds to the operation of former versions of 4D.

Unlike **ADD RECORD** or **MODIFY RECORD**, **DIALOG** does not use the current input form. You must specify the form (project form or table form) to be used in the *form* parameter. Also, the default button panel is not used if buttons are omitted. In this case, only the **Escape** (Windows) or **Esc** (Mac OS) key lets you exit the form.

The dialog is accepted if the user clicks an Accept button or presses the Enter key (numeric key pad), or if the **ACCEPT** command is executed.
Keep in mind that validation does not cause saving: if the dialog includes fields, you must explicitly call the **SAVE RECORD** command to save any data that has been modified.

The dialog is canceled if the user clicks a Cancel button or presses the cancel key (**Escape** on Windows, **Esc** on Macintosh), or if the **CANCEL** command is executed.

If you pass the optional * parameter, the form is loaded and displayed in the last open window of the current process and the command finishes it execution while leaving the active form on screen.
This form then reacts “normally” to user actions and is closed using a standard action or when 4D code related to the form (object method or form method) calls the **CANCEL** or **ACCEPT** command. If the current process terminates, the forms created in this way are automatically closed in the same way as if a **CANCEL** command had been called. This opening mode is particularly useful for displaying a floating palette with a document, without necessarily requiring another process.

**Notes:**

- You must create a window before calling the statement **DIALOG**(form;*); it is not possible to use the current dialog window in the process nor the window created by default for each process. Otherwise, the error -9909 is generated.
- When the * parameter is used, the window is closed automatically following a standard action or a call to the **CANCEL** or **ACCEPT** command. You do not have to manage the closing of the window itself.

## Example 1

The following example shows the use of **DIALOG** to specify search criteria. A custom form containing the variables *vName* and *vState* is displayed so the user can enter the search criteria.

```
Open window(10;40;370;220) ` Open a modal window
DIALOG("Search Dialog") ` Display a custom search dialog
CLOSE WINDOW ` No longer need the modal window
If(OK=1) ` If the dialog is accepted
   QUERY([Company];[Company]Name=vName;*)
   QUERY([Company];&;[Company]State=vState)
End if
```

## Example 2

The following example can be used to create a tool palette:

```
 `Display tool palette
$palette_window:=Open form window("tools";Palette form window)
DIALOG("tools";*) `Give back the control immediately
 `Display main document windowl
$document_window:=Open form window("doc";Plain form window)
DIALOG("doc")
```

## System variables and sets

After a call to **DIALOG**, if the dialog is accepted, OK is set to 1; if it is canceled, OK is set to 0.

# Modified

Modified ( aField ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Field to test |
| Function result | Boolean | ⇐ | True if the field has been assigned a new value, otherwise False |

## Description

**Modified** returns **True** if *field* has been programmatically assigned a value or has been edited during data entry. The **Modified** command must only be used in a form method (or a subroutine called by a form method).

Be careful, this command only returns a significant value within the same execution cycle. It is more particularly set to **False** for all the form events that correspond to the former **_o_During** execution cycle (On Clicked, On After Keystroke, etc.).

During data entry, a field is considered modified if the user has edited the field (whether or not the original value is changed) and then left it by going to another field or by clicking on a control. Note that just tabbing out of a field does not set **Modified** to True. The field must have been edited in order for **Modified** to be True.

When executing a method, a field is considered to be modified if it has been assigned a value (different or not).

**Note: Modified** always returns **True** after the execution of the **PUSH RECORD** and **POP RECORD** commands.

In all cases, use the **Old** command to detect whether the field value has actually been changed.

**Note:** Although **Modified** can be applied to any type of field, if you use it in combination with the **Old** command, be aware of the restrictions that apply to the **Old** command. For details, see the description of the **Old** command.

During data entry, it is usually easier to perform operations in object methods using the **Form event** command than to use **Modified** in form methods. Since an object method is sent an On Data Change event whenever a field is modified, the use of an object method is equivalent to using **Modified** in a form method.

**Note:** To operate properly, the **Modified** command is to be used only in a form method or in a method called by a form method.

## Example 1

The following example tests whether either the *[Orders]Quantity* field or the *[Orders]Price* field has changed. If either has been changed, then the *[Orders]Total* field is recalculated.

```
If((Modified([Orders]Quantity)|(Modified([Orders]Price))
   [Orders]Total :=[Orders]Quantity*[Orders]Price
End if
```

Note that the same thing could be accomplished by using the second line as a subroutine called by the object methods for the *[Orders]Quantity* field and the *[Orders]Price* field within the On Data Change form event.

## Example 2

You select a record for the table *[anyTable]*, then you call multiple subroutines that may modify the field *[anyTable]Important field,* but do not save the record. At the end of the main method, you can use the **Modified** command to detect whether you must save the record:

```
  ` Here the record has been selected as current record
  ` Then you perform actions using subroutines
DO SOMETHING
DO SOMETHING ELSE
DO NOT FORGET TO DO THAT
  ` ...
  ` And then you test the field to detect whether the record has to be saved
If(Modified([anyTable]Important field))
   SAVE RECORD([anyTable])
End if
```

# MODIFY RECORD

MODIFY RECORD ( {aTable}{;}{*} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to use for data entry, or Default table, if omitted |
| * | | ⇒ | Hide scroll bars |

## Description

The **MODIFY RECORD** command modifies the current record for the table *aTable* or for the default table if you omit the *aTable* parameter. **MODIFY RECORD** loads the record, if it is not already loaded for the current process, and displays the current input form. If there is no current record, then **MODIFY RECORD** does nothing. **MODIFY RECORD** does not affect the current selection.

The form is displayed in the frontmost window of the process. The window has scroll bars and a size box. Specifying the optional * parameter causes the window to be drawn without scroll bars or a size box.

To use **MODIFY RECORD**, the current record must have read-write access and should not be locked.
If the form contains buttons for moving within the selection of records, **MODIFY RECORD** lets the user click the buttons to modify records and move to other records.

The record is saved (accepted) if the user clicks an Accept button or presses the Enter key (numeric key pad), or if the **ACCEPT** command is executed.

The record is not saved (canceled) if the user clicks a Cancel button or presses the cancel key combination (Ctrl-Period on Windows, Command-Period on Macintosh), or if the **CANCEL** command is executed. Even when canceled, the record remains in memory and can be saved if **SAVE RECORD** is executed before the current record pointer is changed.

After a call to **MODIFY RECORD**, OK is set to 1 if the record is accepted, to 0 if canceled.

**Note:** Even when canceled, the record remains in memory and can be saved if **SAVE RECORD** is executed before the current record pointer is changed.

If you are using **MODIFY RECORD** and the user does not change any of the data in the record, the record is not considered to be modified, and accepting the record does not cause it to be saved again. Actions such as changing variables, checking check boxes, and selecting radio buttons do not qualify as modifications. Only changing data in a field, either through data entry or through a method, causes the record to be saved.

## Example

See example for the **ADD RECORD** command.

## System variables and sets

Accepting the record sets the OK system variable to 1; canceling it sets the OK system variable to 0. The OK system variable is set only after the record is accepted or canceled.

# Old

Old ( aField ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Field for which to return old value |
| Function result | Expression | ⇐ | Original field value |

## Description

The **Old** command returns the value held in *aField* before the field was programmatically assigned a value or modified in data entry.

Each time you change the current record for a table, 4D creates and maintains in memory a duplicated “image” of the new current record when it is loaded in memory. When modifying a record, you work with the actual image of the record, not this duplicated image. This image is then discarded when you change the current record again.

**Old** returns the value from the duplicated image. In other words, for an existing record, it returns the value of the field as it is stored on disk. If a record is new, **Old** returns the default empty value for *field* according to its type. For example, if *field* is an Alpha field, **Old** returns an empty string. If *field* is a numeric field, **Old** returns zero (0), and so on.

**Old** works on *aField* whether the field has been modified by a method or by the user during data entry. It can be applied to all field types.

To restore the original value of a field, assign it the value returned by **Old**.

**Note:** For technical reasons, in the case of Picture and BLOB type fields, the expression returned by **Old** cannot be used directly as a parameter for another command. It is necessary to pass the value via an intermediate variable. For example:

```
 `Do NOT write (causes a syntax error):
$size :=BLOB size(Old([theTable]theBlob)) `INCORRECT

 `Write:
$oldBLOB:=Old([theTable]theBlob)
$size :=BLOB size($oldBLOB) `CORRECT
```

# REJECT

REJECT {( aField )}

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ➡ | Field to reject |

## Description

**REJECT** has two forms. The first form has no parameters. It rejects the entire data entry and forces the user to stay in the form. The second form rejects only *aField* and forces the user to stay in the field.

**Note:** You should consider the built-in data validation tools before using this command.

The first form of **REJECT** prevents the user from accepting a record that is not complete. You can achieve the same result without using **REJECT** — you associate the Enter key with a No Action button and use the **ACCEPT** and **CANCEL** commands to accept or cancel the record, after the fields have been entered correctly. It is recommended that you use this second technique and do not use the first form of **REJECT**.

If you use the first form, you execute **REJECT** to prevent the user from accepting a record, usually because the record is not complete or has inaccurate entries. If the user tries to accept the record, executing **REJECT** prevents the record from being accepted; the record remains displayed in the form. The user must continue with data entry until the record is acceptable, or cancel the record.

The best place to put this form of **REJECT** is in the object method of an Accept button associated with the Enter key. This way, validation occurs only when the record is accepted, and the user cannot bypass the validation by pressing the Enter key.

The second form of **REJECT** is executed with the *field* parameter. In this case, the cursor stays in the field area, which forces the user to enter a correct value.
With this syntax, it is imperative that you call the **REJECT** command in the On Data Change form event.You need to put this syntax of the **REJECT** command either in the form method, or in the object method of the entry area. If you are using **REJECT** for the subform's Detail Form for a table, put it in the form method or object method for the Detail Form. This command has no effect on fields in subform areas.

You can use **HIGHLIGHT TEXT** to select the data in the field that is being rejected.

## Example 1

The following example is for a bank transaction record. It shows the first form of **REJECT** being used in an Accept button object method. The Enter key is set as an equivalent for the button. This means that even if the user presses the Enter key to accept the record, the button's object method will be executed. If the transaction is a check, then there must be a check number. If there is no check number, the validation is rejected:

```
Case of
   :(([Operation]Transaction="Check") & ([Operation]Check Number=""))  ` If it is a check with no number...
      ALERT("Please fill in the check number.")  ` Alert the user
      REJECT  ` Reject the entry
      GOTO OBJECT([Operation]Check Number)  ` Go to the check number field
End case
```

## Example 2

The following example is part of an object method for an *[Employees]Salary* field. The object method tests the *Employees]Salary* field and rejects the field if it is less than $10,000. You could perform the same operation by specifying a minimum value for the field in the form editor:

```
Case of
   :(Form event=On Data Change)
      If([Employees]Salary<10000)
         ALERT("Salary must be greater than $10,000")
         REJECT([Employees]Salary)
```

```
        End if
    End case
```

# _o_ADD SUBRECORD

_o_ADD SUBRECORD ( subtable ; form {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ➡ | Subtable to use for data entry |
| form | String | ➡ | Form to use for data entry |
| * | | ➡ | Hide scroll bars |

## Compatibility Note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_MODIFY SUBRECORD

_o_MODIFY SUBRECORD ( subtable ; form {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ➡ | Subtable to use for data entry |
| form | String | ➡ | Form to use for data entry |
| * | | ➡ | Hide scroll bars |

## Compatibility Note

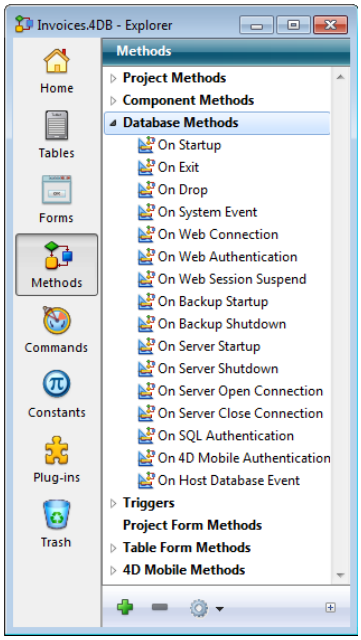
Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# Database Methods

- Database Methods
- On 4D Mobile Authentication database method
- On Backup Shutdown database method
- On Backup Startup database method
- On Drop database method
- On Exit database method
- On Host Database Event database method
- On Server Close Connection database method
- On Server Open Connection database method
- On Server Shutdown database method
- On Server Startup database method
- On SQL Authentication database method
- On Startup database method
- On System Event database method
- On Web Authentication database method
- On Web Close Process database method
- On Web Connection database method

# Database Methods

Database methods are methods that are automatically executed by 4D when a general session event occurs.



To create or open and edit a database method:

1. Open the **Explorer** window.
2. Select the **Methods** page.
3. Expand the **Database Methods** theme.
4. Double click on the method.

or:

1. Select the method.
2. Press Enter or Return.

You edit a database method in the same way as any other method.

You cannot call a database method from another method. Database methods are automatically invoked by 4D at certain points in a working session. The following table summarizes the execution of database methods:

| Database Method | 4D local | 4D Server | 4D remote |
|---|---|---|---|
| On Startup | Yes, Once | No | Yes, Once |
| On Exit | Yes, Once | No | Yes, Once |
| On Drop | Yes, Multiple | No | Yes, Multiple |
| On System Event | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Web Connection | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Web Authentication | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Web Session Suspend | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Backup Startup | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Backup Shutdown | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On Server Startup | No | Yes, Once | No |
| On Server Shutdown | No | Yes, Once | No |
| On Server Open Connection | No | Yes, Multiple | No |
| On Server Close Connection | No | Yes, Multiple | No |
| On SQL Authentication | Yes, Multiple | Yes, Multiple | Yes, Multiple |
| On 4D Mobile Authentication | Yes, Multiple | Yes, Multiple | Non |
| On Host Database Event | Yes, Multiple | Yes, Multiple | Yes, Multiple |

# On 4D Mobile Authentication database method

$1, $2, $3 -> On 4D Mobile Authentication database method -> $0

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Text | ⇦ | User name |
| $2 | Text | ⇦ | Password |
| $3 | Boolean | ⇦ | True = Digest mode, False = Basic mode |
| $0 | Boolean | ⇨ | True = request accepted, False = request rejected |

## Description

The **On 4D Mobile Authentication database method** provides you with a custom way of controlling the opening of 4D Mobile sessions (via REST) on 4D. This database method is mainly intended for filtering connections when setting up a connection between a Wakanda Server and 4D.

When the request to open a 4D Mobile session comes from Wakanda Server by means of the ***mergeOutsideCatalog()*** method (general case), the connection identifiers are provided in the header of the request. The **On 4D Mobile Authentication database method** is called so that you can evaluate these identifiers. You can use the list of users for the 4D database or you can use your own table of identifiers.

**Important:** When **On 4D Mobile Authentication database method** is defined (i.e. when it contains code), 4D fully delegates control of 4D Mobile requests to it: any setting made using the "Read/Write" menu on the Web/4D Mobile page of the Database Settings is ignored (see the *Design Reference* manual).

The database method receives two parameters (*$1* and *$2*) of the Text type and a Boolean (*$3*), passed by 4D, and returns a Boolean, *$0*. You must declare these parameters as follows:

```
 //On 4D Mobile Authentication database method
C_TEXT($1;$2)
C_BOOLEAN($0;$3)
... // Code for the method
```

*$1* contains the user name and *$2* the password used for the connection.

The password (*$2*) can be received either in clear or hashed form, depending mode used by the request. This mode is indicated by the *$3* parameter to enable you to perform the appropriate processing:

- If the password is sent in clear (Basic mode), *$3* returns **False**.
- If it is sent in hashed form (Digest mode), *$3* returns **True**.

When a 4D Mobile connection request comes from Wakanda Server, the password is always sent in hashed form.

You must check the identifiers of the 4D Mobile connection in the database method. Usually, you check the name and password using a custom user table. If the identifiers are valid, pass **True** in *$0*. The request is then accepted; 4D executes it and returns the result in JSON.
Otherwise, pass **False** in *$0*; in this case, the connection is rejected and the server returns an authentication error to the sender of the request.

If the user is referenced in the list of 4D users of the database, you can check the password directly by means of the following statement:

```
$0:=Validate password($1;$2;$3)
```

The **Validate password** command has been extended to accept a user name as first parameter as well as an optional parameter indicating whether the password is expressed in hashed form.

If you want to use your own list of users external to the 4D database list, you can save their passwords in hashed form using the same algorithm as that used by Wakanda Server when sending the connection request to the **On 4D Mobile Authentication database method** in *$2*. To hash a password using this method, you can write:

```
$HashedPasswd :=Generate digest($ClearPasswd ;4D digest)
```

The **Generate digest** command accepts 4D digest as a hashing algorithm, corresponding to the method used by 4D for its internal management of passwords.

## Example 1

This example only accepts the "admin" user with the password "123" that does not match a 4D user:

```
 //On 4D Mobile Authentication database method
C_TEXT($1;$2)
C_BOOLEAN($0;$3)
 //$1: user
 //$2: password
 //$3: digest mode
If($1="admin")
   If($3)
      $0:=($2=Generate digest("123";4D digest))
   Else
      $0:=($2="123")
   End if
Else
   $0:=False
End if
```

## Example 2

This example of the **On 4D Mobile Authentication database method** checks that the connection request comes from one of the two authorized Wakanda servers, saved in the users of the 4D database:

```
C_TEXT($1;$2)
C_BOOLEAN($0)
ON ERR CALL("4DMOBILE_error")
If($1="WAK1")|($1="WAK2")
   $0:=Validate password($1;$2;$3)
Else
   $0:=False
End case
```

# On Backup Shutdown database method

$1 -> On Backup Shutdown database method

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Longint | ⇦ | 0 = backup executed correctly; other value = error, interrupted by user or code returned by On Backup Startup |

---

The **On Backup Shutdown database method** is called every time a database backup ends. The reasons for the stoppage of a backup can be the end of the copy, user interruption or an error.
This concerns all 4D environments: 4D (all modes), 4D Server as well as 4D applications compiled and merged with 4D Volume Desktop.

The **On Backup Shutdown database method** allows verifying that the backup was executed correctly. It receives, in the *$1* parameter, a value representing the status of the backup once completed:

- If the backup was executed correctly, *$1* equals 0.
- If the backup was interrupted by the user or following an error, *$1* is different from 0.
  - If the backup was stopped by the **On Backup Startup Database Method** (*$0* # 0), *$1* gets the value actually returned in the *$0* parameter. This allows you to implement a customized error management system.
  - If the backup was stopped due to an error, the error code is returned in *$1*.

  In any case, you can get information about the error using the **GET BACKUP INFORMATION** command.

**Note**: You must declare the *$1* parameter (longint) in the database method:

```
C_LONGINT($1)
```

It is important to note that in the case of an error during backup (disk full, support unavailable, etc.), the information related to the error is only displayed in the 4D Server monitor or in the MSC, and copied into the backup log. No alert dialog box appears and the *error* variable is not modified. If you want to be able to notify the administrator that an error has occurred, particularly in the context of an application running in client/server mode, you will need to use the **On Backup Shutdown database method**.

# On Backup Startup database method

On Backup Startup database method -> $0

| Parameter | Type | | Description |
|---|---|---|---|
| $0 | Longint | ⮌ | 0 = backup can be launched; value other than 0 = backup not authorized |

---

The **On Backup Startup database method** is called every time a database backup is about to start (manual backup, scheduled automatic backup, or using the **BACKUP** command).
This concerns all 4D environments: 4D (all modes), 4D Server and databases merged with 4D Volume Desktop.

The **On Backup Startup database method** allows verifying that the backup started. In this method, you should return a value that authorizes or refuses the backup in the $0 parameter:

- If $0 = 0, the backup can be launched.
- If $0 # 0, the backup is not authorized. The operation is cancelled and an error is returned. You can get the error using the **GET BACKUP INFORMATION** command.

You can use this database method to verify backup execution conditions (user, date of the last backup, etc.).

**Note:** You must declare the *$0* parameter (longint) in the database method:

```
C_LONGINT($0)
```

# On Drop database method

On Drop database method
Does not require any parameters

---

The **On Drop database method** is available in local or remote 4D applications.

This database method is automatically executed in the case of objects being dropped in the 4D application outside of any form or windows, i.e.:

- In an empty area of the MDI window (Windows),
- On the 4D icon in the Dock (Mac OS) or on the system desktop.

Under Mac OS, you need to hold down the **Option**+**Command** keys during the drop in order for the database method to be called.

When a drop occurs on the 4D application icon on the desktop, the **On Drop database method** is only called when the application is already launched, except in the case of applications merged with 4D Desktop. In this case, the database method is called even when the application is not launched. This means that it is possible to define custom document signatures.

## Example

This example can be used to open a 4D Write document that is dropped outside of any form:

```
  `On Drop database method
droppedFile:=Get file from pasteboard(1)
If(Position(".4W7";droppedFile)=Length(droppedFile)-3)
   externalArea:=Open external window(100;100;500;500;0;droppedFile;"_4D Write")
   WR OPEN DOCUMENT(externalArea;droppedFile)
End if
```

# On Exit database method

On Exit database method
Does not require any parameters

---

The **On Exit database method** is called once when you quit a database.

This method is used in the following 4D environments:

- 4D in local mode
- 4D in remote mode
- 4D application compiled and merged with 4D VolumeDesktop

**Note**: The **On Exit database method** is NOT invoked by 4D Server.

The **On Exit database method** is automatically invoked by 4D; unlike project methods, you cannot call this database method yourself by programming. You can however execute it from the Method editor. You can also use subroutines.

A database can be exited if any of the following occur:

- The user selects the menu command **Quit** from the Design Environment **File** menu or from the Application environment (Quit standard action)
- A call to the **QUIT 4D** command is issued
- A 4D Plug-in issues a call to the **QUIT 4D** entry point

No matter how the exit from the database was initiated, 4D performs the following actions:

- If there is no **On Exit database method**, 4D aborts each running process one by one, without distinction. If the user is performing data entry, the records will be cancelled and not saved.
- If there is an **On Exit database method**, 4D starts executing this method within a newly created local process. You can therefore use this database method to inform other processes, via interprocess communication, that they must close (data entry) or stop executing. Note that 4D will eventually quit—the **On Exit database method** can perform all the cleanup or closing operations you want, but it cannot refuse the quit, and will at some point end.

The **On Exit database method** is the perfect place to:

- Stop processes automatically started when the database was opened
- Save (locally, on disk) Preferences or Settings to be reused at the beginning of the next session in the **On Startup database method**
- Perform any other actions that you want to be done automatically each time a database is exited

**Note:** Don't forget that the **On Exit database method** is a local/client process, so it cannot access the data file. Thus, if the **On Exit database method** performs a query or a sort, a 4D Client that is about to quit will "freeze" and actually will not quit. If you need to access data when a client quits the application, create a new global process from within the **On Exit database method**, which will be able to access the data file. In this case, be sure that the new process will terminate correctly before the end of the **On Exit database method** execution (by using interprocess variables, by example).

## Example

The following example covers all the methods used in a database that tracks the significant events that occur during a working session and writes a description in a text document called "Journal."

- The **On Startup database method** initializes the interprocess variable *◊vbQuit4D*, which tells all the use processes whether or not the database is being exited. It also creates the journal file, if it does not already exist.

```
` On Startup Database Method
C_TEXT(◊vtIPMessage)
C_BOOLEAN(◊vbQuit4D)
◊vbQuit4D:=False
```

```
If(Test path name("Journal")#Is a document)
   $vhDocRef:=Create document("Journal")
   If(OK=1)
      CLOSE DOCUMENT($vhDocRef)
   End if
End if
WRITE JOURNAL("Opening Session")
```

- The project method ***WRITE JOURNAL***, used as subroutine by the other methods, writes the information it receives, in the journal file:

```
  ` WRITE JOURNAL Project Method
  ` WRITE JOURNAL ( Text )
  ` WRITE JOURNAL ( Event description )
C_TEXT($1)
C_TIME($vhDocRef)

While(Semaphore("$Journal"))
   DELAY PROCESS(Current process;1)
End while
$vhDocRef:=Append document("Journal")
If(OK=1)
   PROCESS PROPERTIES(Current process;$vsProcessName;$vlState;$vlElapsedTime;$vbVisible)
   SEND PACKET($vhDocRef;String(Current date)+Char(9)+String(Current time)+Char(9)
   +String(Current process)+Char(9)+$vsProcessName+Char(9)+$1+Char(13))
   CLOSE DOCUMENT($vhDocRef)
End if
CLEAR SEMAPHORE("$Journal")
```

Note that the document is open and closed each time. Also note the use of a semaphore as “access protection” to the document—we do not want two processes trying to access the journal file at the same time.

- The ***M_ADD_RECORDS*** project method is executed when a menu item **Add Record** is chosen in the Application environment:

```
  ` M_ADD_RECORDS Project Method
SET MENU BAR(1)
Repeat
   ADD RECORD([Table1];*)
   If(OK=1)
      WRITE JOURNAL("Adding record #"+String(Record number([Table1]))+" in Table1")
   End if
Until((OK=0)|◊vbQuit4D)
```

This method loops until the user cancels the last data entry or exits the database.

- The input form for *[Table 1]* includes the treatment of the On Outside Call events. So, even if a process is in data entry, it can be exited smoothly, with the user either saving (or not saving) the current data entry:

```
  ` [Table1];"Input" Form Method
Case of
   :(Form event=On Outside Call)
      If(◊vtIPMessage="QUIT")
         CONFIRM("Do you want to save the changes made to this record?")
         If(OK=1)
            ACCEPT
         Else
            CANCEL
         End if
      End if
End case
```

- The *M_QUIT* project method is executed when **Quit** is chosen from the **File** menu in the Application environment:

```
  ` M_QUIT Project Method
$vlProcessID:=New process("DO_QUIT";32*1024;"$DO_QUIT")
```

The method uses a trick. When **QUIT 4D** is called, the command has an immediate effect. Therefore, the process from which the call is issued is in "stop mode" until the database is actually exited. Since this process can be one of the processes in which data entry occurs, the call to **QUIT 4D** is made in a local process that is started only for this purpose. Here is the *DO_QUIT* method:

```
  ` DO_QUIT Project Method
CONFIRM("Are you sure you want to quit?")
If(OK=1)
   WRITE JOURNAL("Quitting Database")
   QUIT 4D
  ` QUIT 4D has an immediate effect, any line of code below will never be executed
  ` ...
End if
```

- Finally, here is the **On Exit database method** which tells all open user processes "It's time to get out of here!" It sets *◊vbQuit4D* to *True* and sends interprocess messages to the user processes that are performing data entry:

```
  ` On Exit Database Method
◊vbQuit4D:=True
Repeat
   $vbDone:=True
   For($vlProcess;1;Count tasks)
      PROCESS PROPERTIES($vlProcess;$vsProcessName;$vlState;$vlElapsedTime;$vbVisible)
      If((((($vsProcessName="ML_@")|($vsProcessName="M_@")))&($vlState>=0))
         $vbDone:=False
         ◊vtIPMessage:="QUIT"
         BRING TO FRONT($vlProcess)
         CALL PROCESS($vlProcess)
         $vhStart:=Current time
         Repeat
            DELAY PROCESS(Current process;60)
         Until((Process state($vlProcess)<0)|((Current time-$vhStart)>=?00:01:00?))
      End if
   End for
Until($vbDone)
WRITE JOURNAL("Closing session")
```

**Note**: Processes that have names beginning with *"ML_..."* or *"M_..."* are started by menu commands for which the **Start a New Process** property has been selected. In this example, these are the processes started when the menu command **Add record** was chosen.

The test *(Current time-$vhStart)>=?00:01:00?* allows the database method to get out of the "waiting the other process" Repeat loop if the other process does not act immediately.
The following is a typical example of the Journal file produced by the database:

| | | | | |
|---|---|---|---|---|
| 2/6/03 | 15:47:25 | 1 | Main process | Opening Session |
| 2/6/03 | 15:55:43 | 5 | ML_1 | Adding record #23 in Table1 |
| 2/6/03 | 15:55:46 | 5 | ML_1 | Adding record #24 in Table1 |
| 2/6/03 | 15:55:54 | 6 | $DO_QUIT | Quitting Database |
| 2/6/03 | 15:55:58 | 7 | $xx | Closing session |

**Note**: The name *$xx* is the name of the local process started by 4D in order to execute the **On Exit database method**.

# On Host Database Event database method

$1 -> On Host Database Event database method

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Longint | ⇦ | Event code |

## Description

The **On Host Database Event database method** allows 4D components to execute code when the host database is opened and closed.

**Note:** For security reasons, in order to be able to call this database method, you must explicitly allow its execution in the host database. For more information about this point, refer to the *Design Reference* manual.

The **On Host Database Event database method** is executed automatically only in databases used as components of host databases (when it is authorized in the Settings of the host database). It is called when events related to the opening and closing of the host database occur.

To process an event, you must test the value of the *$1* parameter inside the method, and compare it with one of the following constants, available in the "**Database Events**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| On after host database exit | Longint | 4 | The **On Exit database method** of the host database has just finished running |
| On after host database startup | Longint | 2 | The **On Startup database method** of the host database just finished running |
| On before host database exit | Longint | 3 | The host database is closing. The **On Exit database method** of the host database has not yet been called.<br>The **On Exit database method** of the host database is not called while the **On Host Database Event database method** of the component is running |
| On before host database startup | Longint | 1 | The host database has just been started. The **On Startup database method** method of the host database has not yet been called.<br>The On Startup database method of the host database is not called while the **On Host Database Event database method** of the component is running |

This allows 4D components to load and save preferences or user states related to the operation of the host database.

## Example

Example of typical structure of an On Host Database Event database method:

```
 // On Host Database Event database method
C_LONGINT($1)
Case of
   :($1=On before host database startup)
 // put code here that you want to execute before the "On Startup" database method
 // of the host database
   :($1=On after host database startup)
 // put code here that you want to execute after the "On Startup"
 // database method of the host database
   :($1=On before host database exit)
 // put code here that you want to execute before the "On Exit"
 // database method of the host database
   :($1=On after host database exit)
 // put code here that you want to execute after the "On Exit"
 // database method of the host database
End case
```

# On Server Close Connection database method

$1, $2, $3 -> On Server Close Connection database method

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Longint | ⇦ | User ID number used internally by 4D Server to identify users |
| $2 | Longint | ⇦ | Connection ID number used internally by 4D Server to identify a connection |
| $3 | Longint | ⇦ | Obsolete: Always returns 0 but must be declared |

## Description

The **On Server Close Connection database method** is called once on the Server machine each time a 4D Client process ends.

As for the **On Server Open Connection database method**, 4D Server passes three Long Integer parameters to the **On Server Close Connection database method**. On the other hand, no result is expected by 4D Server.

The method must therefore be explicitly declared with three Long Integer parameters:

```
C_LONGINT($1;$2;$3)
```

This table details the information provided by the three parameters passed to the database method:

| Parameter | Description |
|---|---|
| $1 | User ID number used internally by 4D Server to identify users |
| $2 | Connection ID number used internally by 4D Server to identify a connection |
| $3 | Obsolete: Always returns 0 but must be declared |

The **On Server Close Connection database method** is the exact counterpoint to the **On Server Open Connection database method**. For more information and a description of the **4D Client processes**, see the description of this database method.

## Example

See the first example for **On Server Open Connection database method**.

# On Server Open Connection database method

$1, $2, $3 -> On Server Open Connection database method -> $0

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Longint | ⇦ | User ID number used internally by 4D Server to identify users |
| $2 | Longint | ⇦ | Connection ID number used internally by 4D Server to identify a connection |
| $3 | Longint | ⇦ | Obsolete: Always returns 0 (but must be declared) |
| $0 | Longint | ⇨ | 0 or omitted = connection accepted; other value = connection refused |

## When is the On Server Open Connection Database Method Called?

The **On Server Open Connection database method** is called once on the Server machine each time a connection process is started by a 4D remote workstation. The **On Server Open Connection database method** is NOT invoked by any 4D environment other than 4D Server.

The **On Server Open Connection database method** is called each time:

- a remote 4D connects (because the Application process starts)
- a remote 4D opens the Design environment (because the Design process starts)
- a remote 4D starts a global process (whose name does not begin with "$") which requires the creation of a cooperative process on the server **(*)**. This process can be created using the **New process** command, a menu command or using the Execute Method dialog box.

In each case with a remote 4D, several processes are started—One on the client machine and one or two others (as needed) on the server machine. On the client machine, the process executes code and send requests to 4D Server. On the server machine, the **4D Client Process** (preemptive process) maintains the database environment for the client process (i.e., current selections and locking of records for user processes) and replies to requests sent by the process running on the client machine. The **4D Client Database process** (cooperative process) is in charge of monitoring the corresponding 4D Client process.

**(*)** Beginning with 4D v13, for optimization purposes, the server processes (a preemptive process for access to the database engine and a cooperative process for access to the language) are only created when necessary when executing client-side code. For example, here are the details of a 4D code sequence running in a new client process:

```
 // global process begins without a new process on the server, like a local process.
CREATE RECORD([Table_1])
[Table_1]field1_1:="Hello world"
SAVE RECORD([Table_1]) // creation here of preemptive process on server
$serverTime:=Current time(*) // creation here of cooperative process on server
 // call to On Server Open Connection
```

**Important**: Web connections and SQL connections do not invoke the **On Server Open Connection database method**. When a Web browser connects to 4D Server, the **On Web Authentication Database Method** (if any) and/or the **On Web Connection database method** are invoked. When 4D Server receives an SQL query, the **On SQL Authentication database method** (if one exists) is called. For more information, see the description of this database method in the 4D Language Reference manual.

**Important**: When a Stored Procedure is started, the **On Server Open Connection database method** is NOT invoked. **Stored Procedures** are server processes, not 4D Client processes. They execute code on the Server machine, but do not reply to requests exchanged by a 4D client (or other clients) and 4D Server.

## How is the On Server Open Connection Database Method Called?

The **On Server Open Connection database method** is executed on the 4D Server machine within the 4D Client process that provoked the call to the method.

For example, if a remote 4D connects to a 4D Server interpreted database, the user process, the Design process and the client registration process (by default) for that client are started. The **On Server Open Connection database method** is therefore executed three times in a row—the first time within the Application process, the second time within the client registration process, and the third time within the Design process. If the three process are respectively the sixth, seventh

and eighth process to be started on the Server machine, and if you call **Current process** from within the **On Server Open Connection database method**, the first time **Current process** returns 6, the second time 7 and the third time 8.

Note that **On Server Open Connection database method** executes on the Server machine. It executes within the 4D Client process running on the Server machine, independent of the process running on the client side. In addition, at the moment when the method is invoked, the 4D Client process has not yet been named (**PROCESS PROPERTIES** will not at this point return the name of the 4D Client process).

The **On Server Open Connection database method** has no access to the process variable table of the process running on the Client side. This table resides on the Client machine, not on the Server machine.

When the **On Server Open Connection database method** accesses a process variable, it works with a private and dynamically created process variable table for the 4D Client process.

4D Server passes three Long Integer parameters to the **On Server Open Connection database method** and expects a Long Integer result. The method must therefore be explicitly declared with three Long Integer parameters as well as a Long Integer function result:

```
C_LONGINT($0;$1;$2;$3)
```

If you do not return a value in *$0*, thereby leaving the variable undefined or initialized to zero, 4D Server assumes that the database method accepts the connection. If you do not accept the connection, you return a non-null value in *$0*.

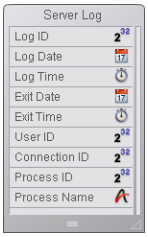
This table details the information provided by the three parameters passed to the database method:

| Parameter | Description |
|---|---|
| $1 | User ID number used internally by 4D Server to identify users |
| $2 | Connection ID number used internally by 4D Server to identify a connection |
| $3 | Obsolete: Always returns 0 but must be declared |

These ID numbers are not directly usable as sources of information to be passed as, for example, parameters to a 4D command. However, they provide a way to uniquely identify a 4D Client process between the **On Server Open Connection database method** and the **On Server Close Connection database method**. At any moment of a 4D Server session, the combination of these values is unique. By storing this information in an interprocess array or a table, the two database methods can exchange information. In the example at the end of this section, the two database methods use this information to store the date and time of the beginning and end of a connection in the same record of a table.

## Example 1

The following example shows how to maintain a log of the connections to the database using the **On Server Open Connection database method** and the **On Server Close Connection Database Method**. The *[Server Log]* table (shown below) is used to keep track of the connection processes:



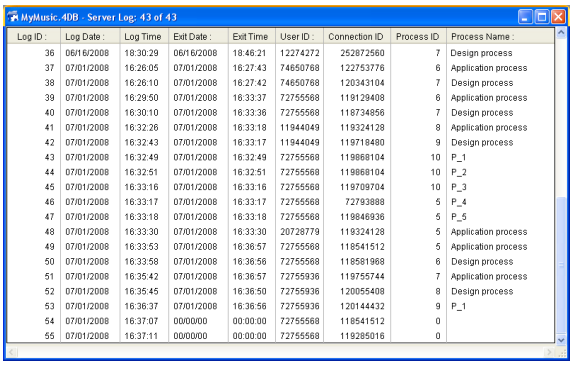
The information stored in this table is managed by the **On Server Open Connection database method** and the **On Server Close Connection Database Method** listed here:

```
  ` On Server Open Connection Database Method
C_LONGINT($0;$1;$2;$3)
  ` Create a [Server Log] record
CREATE RECORD([Server Log])
[Server Log]Log ID:=Sequence number([Server Log])
  ` Save the Log Date and Time
[Server Log]Log Date:=Current date
[Server Log]Log Time:=Current time
  ` Save the connection information
[Server Log]User ID:=$1
[Server Log]Connection ID:=$2
SAVE RECORD([Server Log])
  ` Returns no error so that the connection can continue
$0:=0

  ` On Server Close Connection Database Method
```

```
C_LONGINT($1;$2;$3)
  ` Retrieve the [Server Log] record
QUERY([Server Log];[Server Log]User ID=$1;*)
QUERY([Server Log]; & ;[Server Log]Connection ID=$2;*)
QUERY([Server Log]; & ;[Server Log]Process ID=0)
  ` Save the Exit date and time
[Server Log]Exit Date:=Current date
[Server Log]Exit Time:=Current time
  ` Save the process information
[Server Log]Process ID:=Current process
PROCESS PROPERTIES([Server Log]Process ID;$vsProcName;$vlProcState;$vlProcTime)
[Server Log]Process Name:=$vsProcName
SAVE RECORD([Server Log])
```

Here are some entries in the [Server Log] showing several remote connections:



MyMusic.4DB - Server Log: 43 of 43

| Log ID : | Log Date : | Log Time | Exit Date : | Exit Time | User ID : | Connection ID | Process ID | Process Name : |
|---|---|---|---|---|---|---|---|---|
| 36 | 06/16/2008 | 18:30:29 | 06/16/2008 | 18:46:21 | 12274272 | 252872560 | 7 | Design process |

| 48 | 07/01/2008 | 16:33:30 | 07/01/2008 | 16:33:30 | 20728779 | 119324128 | 5 | Application process |
| 49 | 07/01/2008 | 16:33:53 | 07/01/2008 | 16:36:57 | 72755568 | 118541512 | 5 | Application process |
| 50 | 07/01/2008 | 16:33:58 | 07/01/2008 | 16:36:56 | 72755568 | 118581968 | 6 | Design process |
| 51 | 07/01/2008 | 16:35:42 | 07/01/2008 | 16:36:57 | 72755936 | 119755744 | 7 | Application process |
| 52 | 07/01/2008 | 16:35:45 | 07/01/2008 | 16:36:50 | 72755936 | 120055408 | 8 | Design process |
| 53 | 07/01/2008 | 16:36:37 | 07/01/2008 | 16:36:56 | 72755936 | 120144432 | 9 | P_1 |
| 54 | 07/01/2008 | 16:37:07 | 00/00/00 | 00:00:00 | 72755568 | 118541512 | 0 | |
| 55 | 07/01/2008 | 16:37:11 | 00/00/00 | 00:00:00 | 72755568 | 119285016 | 0 | |

## Example 2

The following example prevents any new connection from 2 to 4 A.M.

```
  ` On Server Open Connection Database Method
C_LONGINT($0;$1;$2;$3)

If((?02:00:00?<=Current time)&(Current time<?04:00:00?))
   $0:=22000
Else
   $0:=0
End if
```

# On Server Shutdown database method

On Server Shutdown database method
Does not require any parameters

---

The **On Server Shutdown database method** is called once on the server machine when the current database is closed on 4D Server. The **On Server Shutdown database method** is NOT invoked by any 4D environment other than 4D Server.

To close the current database on the server, you can select the **Close Database...** menu command on the server. You can also choose the **Quit** command or call the **QUIT 4D** command within a stored procedure executed on the server.

When the exit from the database is initiated, 4D performs the following actions:

- If there is no **On Server Shutdown database method**, 4D Server aborts each running process one by one, without distinction.
- If there is an **On Server Shutdown database method**, 4D Server starts executing this method within a newly created local process. You can therefore use this database method to inform other processes, via interprocess communication, that they must stop executing. Note that 4D Server will eventually quit — the **On Server Shutdown database method** can perform all the cleanup or closing operations you want, but it cannot refuse the quit, and will at some point end.

The **On Server Shutdown database method** is the perfect place to:

- Stop store procedures automatically started when the database was opened.
- Save (locally, on disk) Preferences or Settings to be reused at the beginning of the next session in the **On Server Startup Database Method**.
- Perform any other actions that you want to be done automatically each time a database is exited.

**Warning:** If you use the **On Server Shutdown database method** to close stored procedures, keep in mind that the server quits once the **On Server Shutdown database method** (and not the stored procedures) is executed. If some stored procedures are still running at this point, they will be killed.
Consequently, if you want to make sure that the stored procedures are fully executed before being killed by the server, the **On Server Shutdown database method** should indicate to the stored procedures that they must end their execution (for example, using an interprocess variable) and should allow them to close (through a x seconds loop or another interprocess variable).

If you want code to be executed automatically on a client machine when a remote 4D stops connecting to the server, use the **On Exit database method**.

# On Server Startup database method

On Server Startup database method
Does not require any parameters

---

The **On Server Startup database method** is called once on the server machine when you open a database with 4D Server.The **On Server Startup database method** is NOT invoked by any 4D environment other than 4D Server.

The **On Server Startup database method** is the perfect place to:

- Initialize interprocess variables that you will use during the whole 4D Server session.
- Start **Stored Procedures** automatically when a database is opened.
- Load Preferences or Settings saved during the previous 4D Server session.
- Prevent the opening of the database if a condition is not met (i.e., missing system resources) by explicitly calling **QUIT 4D**.
- Perform any other actions that you want performed automatically each time a database is opened.

To automatically execute code on a client machine when a remote 4D connects to the server, use the **On Startup database method**.

**Note:** The **On Server Startup database method** is executed automatically, which means that no remote 4D can connect until the method has finished executing.

# On SQL Authentication database method

$1, $2, $3 -> On SQL Authentication database method -> $0

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Text | ⇦ | User name |
| $2 | Text | ⇦ | Password |
| $3 | Text | ⇦ | (Optional) IP address of client at origin of the request |
| $0 | Boolean | ⇨ | True = request accepted, False = request refused |

---

The **On SQL Authentication database method** can be used to filter requests sent to the integrated SQL server of 4D. This filtering can be based on the name and password as well as the (optional) IP address of the user. The developer can use their own table of users or that of the 4D users to evaluate the connection identifiers. Once the connection is authenticated, the **CHANGE CURRENT USER** command must be called in order to control access of requests within the 4D database.

When it exists, the **On SQL Authentication database method** is called automatically by 4D or 4D Server on each external connection to the SQL server. The internal system for managing 4D users is therefore not activated. The connection is only accepted if the database method returns **True** in $0 and if the **CHANGE CURRENT USER** command has been executed successfully. If one of these conditions is not met, the request is refused.

**Note**: The statement **SQL LOGIN**(**SQL_INTERNAL**;$user;$password) does not call the **On SQL Authentication database method** since it is an internal connection in this case.

The database method receives up to three parameters of the Text type, passed by 4D ($1, $2 and $3), and returns a Boolean, $0. Here is a description of these parameters:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | User name |
| $2 | Text | Password |
| $3 | Text | (optional) IP address of client at origin of the request(*) |
| $0 | Boolean | True = request accepted, False = request refused |

(*) 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

You must declare these parameters as follows:

```
  ` On Web Authentication database method

C_TEXT($1;$2;$3)
C_BOOLEAN($0)
  ` Code for method
```

The password ($2) is received as standard text.

You must check the identifiers of the SQL connection in the **On SQL Authentication database method**. For example, you can check the name and password using a custom table of users. If the identifiers are valid, pass **True** in $0 to accept the connection. Otherwise, pass **False** in $0; in this case, the connection is refused.

**Note:** If the **On SQL Authentication database method** does not exist, the connection is evaluated using the integrated user management system of 4D (if it is activated, in other words, if a password has been assigned to the Designer). If this system is not activated, users are connected with Designer access rights (free access).

If you have passed **True** in $0, you must then successfully call the **CHANGE CURRENT USER** command in the **On SQL Authentication database method** in order for the request to be accepted and for 4D to open an SQL session for the user.

The use of the **CHANGE CURRENT USER** command can be used to implement a virtual authentication system which has the double advantage of allowing the control of connection actions and of hiding the connection identifiers from the outside in the 4D SQL session.

This example of the **On SQL Authentication database method** checks whether the connection request comes from the internal network, validates the identifiers and then assigns access rights to the "sql_user" user for the SQL session.

```
C_TEXT($1;$2;$3)
C_BOOLEAN($0)
```

```
   `$1: user
   `$2: password
   `{$3: IP address of client}
ON ERR CALL("SQL_error")
If(checkInternalIP($3))
   `The checkInternalIP method checks whether the IP address is internal
   If($1="victor") & ($2="hugo")
      CHANGE CURRENT USER("sql_user";"")
      If(OK=1)
         $0:=True
      Else
         $0:=False
      End if
   Else
      $0:=False
   End if
Else
   $0:=False
End if
```

# On Startup database method

On Startup database method
Does not require any parameters

---

The **On Startup database method** is called once when you open a database.

This occurs in the following 4D environments:

- 4D in local mode
- 4D in remote mode (on the client side, after the connection has been accepted by 4D Server)
- 4D application compiled and merged with 4D Volume Desktop

**Note**: The **On Startup database method** is NOT invoked by 4D Server.

The **On Startup database method** is automatically invoked by 4D; unlike project methods, you cannot call this database method yourself by programming. You can however execute it from the Method editor. You can also use subroutines.

The **On Startup database method** is the perfect place to:

- Initialize interprocess variables that you will use during the whole working session.
- Start processes automatically when a database is opened.
- Load Preferences or Settings saved for this purpose during the previous working session.
- Prevent the opening of the database if a condition is not met (i.e., missing system resources) by explicitly calling **QUIT 4D**.
- Perform any other actions that you want to be performed automatically each time a database is opened.

However, we strongly recommend that you do NOT launch print jobs from the **On Startup database method**.

## Example

See the example in the **On Exit database method** section.

# On System Event database method

$1 -> On System Event database method

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Longint | ⇦ | Event code |

## Description

The **On System Event database method** is called each time a system event occurs. This concerns all 4D environments: 4D (all modes) and 4D Server, as well as 4D applications that are compiled and merged with 4D Volume Desktop.

To process an event, you must test the value of the $1 parameter within the method and compare it to one of the following constants, found in the **Database Events** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| On application background move | Longint | 1 | The 4D application moves to the background |
| On application foreground move | Longint | 2 | The 4D application moves to the foreground |

These events are generated when a 4D application changes level, irrespective of the user action initiating this change. For example:

- Clicking the window of the application or of another application,
- selecting it using the **Alt+Tab** (Windows) or **Command+Tab** (Mac OS) keyboard shortcut,
- Selecting the **Hide** command in the dock (Mac OS),
- Clicking the application icon in the dock or task bar,
- Clicking the minimize button of the main window (Windows).

It is absolutely necessary to declare the $1 parameter (longint) in the database method. The structure of the database method code is therefore:

```
 // On System Event database method

C_LONGINT($1)
Case of
   :($1=On application background move)
 //Do something
   :($1=On application foreground move)
 //Do something else
End case
```

# On Web Authentication database method

$1, $2, $3, $4, $5, $6 -> On Web Authentication database method -> $0

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Text | ⇦ | URL |
| $2 | Text | ⇦ | HTTP header + HTTP body |
| $3 | Text | ⇦ | IP address of browser |
| $4 | Text | ⇦ | IP address of the server |
| $5 | Text | ⇦ | User name |
| $6 | Text | ⇦ | Password |
| $0 | Boolean | ⇨ | True = request accepted, False = request refused |

## Description

The **On Web Authentication database method** is in charge of managing Web server engine access. It is called by 4D or 4D Server when a Web browser request requires the execution of a 4D method on the server (method called using a *4DACTION* URL, a *4DSCRIPT* tag, etc.).

This method receives six Text parameters: $1, $2, $3, $4, $5, and $6, and returns one Boolean parameter, $0. The description of these parameters is as follows:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | URL |
| $2 | Text | HTTP header + HTTP body (32 KB maximum) |
| $3 | Text | IP address of the Web client (browser) |
| $4 | Text | IP address of the server |
| $5 | Text | User name |
| $6 | Text | Password |
| $0 | Boolean | True = request accepted, False = request rejected |

You must declare these parameters as follows:

```
` On Web Authentication Database Method

C_TEXT($1;$2;$3;$4;$5;$6)
C_BOOLEAN($0)

` Code for the method
```

**Note:** All the On Web Authentication database method's parameters are not necessarily filled in. The information received by the database method depends on the options that you have previously selected in the Database Settings dialog box (please refer to the section **Connection Security**).

- **URL**

  The first parameter (*$1*) is the URL entered by the user in the location area of his or her Web browser, from which the host address has been removed.

  Let's take the example of an Intranet connection. Suppose that the IP address of your 4D Web Server machine is *123.4.567.89*. The following table shows the values of *$1* depending on the URL entered in the Web browser:

  | URL entered in Web browser Location area | Value of parameter $1 |
  |---|---|
  | 123.4.567.89 | / |
  | http://123.4.567.89 | / |
  | 123.4.567.89/Customers | /Customers |
  | http://123.4.567.89/Customers | /Customers |
  | http://123.4.567.89/Customers/Add | /Customers/Add |
  | 123.4.567.89/Do_This/If_OK/Do_That | /Do_This/If_OK/Do_That |

- **Header and Body of the HTTP request**

The second parameter (*$2*) is the header and the body of the HTTP request sent by the Web browser. Note that this information is passed to your **On Web Authentication database method** as it is. Its contents will vary depending on the nature of the Web browser which is attempting the connection.
If your application deals with this information, it is up to you to parse the header and the body.

**Notes:**

- For performance reasons, the size of data passing through the $2 parameter must not exceed 32 KB. Beyond this size, they are truncated by the 4D HTTP server.
- For more information about this parameter, please refer to the description of the **On Web Connection database method**.

- **Web client IP address**

  The $3 parameter receives the IP address of the browser's machine. This information can allow you to distinguish between Intranet and Internet connections.
  **Note:** 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

- **Server IP address**

  The $4 parameter receives the IP address used to call the Web server. 4D since version 6.5 allows for multi-homing, which allows you to exploit machines with more than one IP address. For more information, please refer to the section **Web Server Settings**

- **User Name and Password**

  The $5 and $6 parameters receive the user name and password entered by the user in the standard identification dialog box displayed by the browser. This dialog box appears for each connection, if a password management option has been selected in the Database Settings dialog box (see section **Connection Security**).

**Note:** If the user name sent by the browser exists in 4D, the $6 parameter (the user's password) is not returned for security reasons.

- **$0 parameter**

  The **On Web Authentication database method** returns a boolean in $0:
  - If $0 is **True**, the connection is accepted.
  - If $0 is **False**, the connection is refused.

The **On Web Connection database method** is only executed if the connection has been accepted by **On Web Authentication**.

**WARNING:** If no value is set to *$0* or if *$0* is not defined in the **On Web Authentication database method**, the connection is considered as accepted and the **On Web Connection database method** is executed.

**Notes :**

- Do not call any interface elements in the **On Web Authentication database method** (**ALERT**, **DIALOG**, etc.) because otherwise its execution will be interrupted and the connection refused. The same thing will happen if an error occurs during its processing.
- It is possible to prevent execution by *4DACTION* or *4DSCRIPT* for each project method via the "Available through 4D HTML tags and URLs (4DACTION...)" option in the Method properties dialog box. For more information about this point, please refer to the **Connection Security** section.

## On Web Authentication Database Method calls

The **On Web Authentication database method** is automatically called, regardless of the mode, when a request or processing requires the execution of a 4D method. It is also called when the Web server receives an invalid static URL (for example, if the static page requested does not exist).

The **On Web Authentication database method** is therefore called in the following cases:

- when 4D receives a URL beginning with *4DACTION/*
- when 4D receives a URL beginning with *4DCGI/*
- when 4D receives a URL beginning with *4DSYNC/*
- when 4D receives a URL requesting a static page that does not exist
- when 4D receives a root access URL and no home page has been set in the Database Settings or by means of the **WEB SET HOME PAGE** command

- when 4D processes a *4DSCRIPT* tag in a semi-dynamic page
- when 4D processes a *4DLOOP* tag based on a method in a semi-dynamic page.

**Compatibility note:** The database method is also called when 4D receives a URL beginning with *4DMETHOD/*. This URL is obsolete and is only kept for compatibility's sake.

Note that the **On Web Authentication database method** is NOT called when the server receives a URL requesting a valid static page.

## Example 1

Example of the **On Web Authentication database method** in BASIC mode:

```
 `On Web Authentication Database Method
C_TEXT($5;$6;$3;$4)
C_TEXT($user;$password;$BrowserIP;$ServerIP)
C_BOOLEAN($4Duser)
ARRAY TEXT($users;0)
ARRAY LONGINT($nums;0)
C_LONGINT($upos)
C_BOOLEAN($0)

$0:=False

$user:=$5
$password:=$6
$BrowserIP:=$3
$ServerIP:=$4

 `For security reasons, refuse names that contain @
If(WithWildcard($user)|WithWildcard($password))
   $0:=False
 `The WithWildcard method is described below
Else
 `Check to see if it's a 4D user
   GET USER LIST($users;$nums)
   $upos:=Find in array($users;$user)
   If($upos >0)
      $4Duser:=Not(Is user deleted($nums{$upos}))
   Else
      $4Duser:=False
   End if

   If(Not($4Duser))
 `It is not a user defined 4D, look in the table of Web users
      QUERY([WebUsers];[WebUsers]User=$user;*)
      QUERY([WebUsers]; & [WebUsers]Password=$password)
      $0:=(Records in selection([WebUsers])=1)
   Else
      $0:=True
   End if
End if
 `Is this an intranet connection?
If(Substring($BrowserIP;1;7)#"192.100.")
   $0:=False
End if
```

## Example 2

Example of the **On Web Authentication database method** in DIGEST mode:

```
 `On Web Authentication Database Method
C_TEXT($1;$2;$5;$6;$3;$4)
C_TEXT($user)
C_BOOLEAN($0)
$0:=False
$user:=$5
```

```
   `For security reasons, refuse names that contain @
If(WithWildcard($user))
   $0:=False
   `The WithWildcard method is described below
Else
   QUERY([WebUsers];[WebUsers]User=$user)
   If(OK=1)
      $0:=Validate Digest Web Password($user;[WebUsers]password)
   Else
      $0:=False `User does not exist
   End if
End if
```

The ***WithWildcard*** method is as follows:

```
   `WithWildcard Method
   `WithWildcard ( String ) -> Boolean
   `WithWildcard ( Name ) -> Contains a Wilcard character

C_INTEGER($i)
C_BOOLEAN($0)
C_TEXT($1)

$0:=False
For($i;1;Length($1))
   If(Character code(Substring($1;$i;1))=Character code("@"))
      $0:=True
   End if
End for
```

# On Web Close Process database method

On Web Close Process database method
Does not require any parameters

---

The **On Web Close Process database method** is called by the 4D Web server each time a Web session is about to be closed. A session can be closed in the following cases:

- when the maximum number of simultaneous sessions is reached (100 by default, modifiable using the **WEB SET OPTION** command), and 4D needs to create new ones (4D automatically kills the process of the oldest inactive session),
- when the maximum period of inactivity for the session process is reached (480 minutes by default, modifiable using the **WEB SET OPTION** command),
- when the **WEB CLOSE SESSION** command is called.

When this database method is called, the context of the session (variables and selections generated by the user) is still valid. This means that you can save data related to the session in order to be able to use them again subsequently, more specifically using the **On Web Connection Database Method**.

**Note:** In the context of a 4D Mobile session (which can generate several processes), the **On Web Close Process database method** is called for each Web process that is closed, allowing you to save all types of data (variables, selection, etc.) generated by the 4D Mobile session process.

An example of the **On Web Close Process database method** is provided in the **Web Sessions Management** section.

## On Web Connection database method

$1, $2, $3, $4, $5, $6 -> On Web Connection database method

| Parameter | Type | | Description |
|---|---|---|---|
| $1 | Text | ⇐ | URL |
| $2 | Text | ⇐ | HTTP header + HTTP body |
| $3 | Text | ⇐ | IP address of browser |
| $4 | Text | ⇐ | IP address of the server |
| $5 | Text | ⇐ | User name |
| $6 | Text | ⇐ | Password |

---

The **On Web Connection database method** can be called in the following cases:

- the Web server receives a request beginning with the *4DCGI* URL.
- the Web server receives an invalid request.

For more information, refer to the paragraph “On Web Connection Database Method calls” below.

**Compatibility note**: The database method is also called when a context is created in contextual mode (obsolete mode that could be used in converted 4D databases).

The request should have been previously accepted by the **On Web Authentication database method** (if it exists) and the Web server must be launched.

The **On Web Connection database method** receives six text parameters that are passed by 4D. The contents of these parameters are as follows:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | URL |
| $2 | Text | HTTP header + HTTP body (up to 32 kb limit) |
| $3 | Text | IP address of the Web client (browser) |
| $4 | Text | IP address of the server |
| $5 | Text | User name |
| $6 | Text | Password |

You must declare these parameters as follows:

```
` On Web Connection Database Method

C_TEXT($1;$2;$3;$4;$5;$6)

` Code for the method
```

- **URL extra data**

  The first parameter (*$1*) is the URL entered by the user in the location area of his or her Web browser, from which the host address has been removed.
  Let’s take the example of an Intranet connection. Suppose that the IP address of your 4D Web Server machine is *123.4.567.89*. The following table shows the values of *$1* depending on the URL entered in the Web browser:

| URL entered in Web browser Location area | Value of parameter $1 |
|---|---|
| 123.4.567.89 | / |
| http://123.4.567.89 | / |
| 123.4.567.89/Customers | /Customers |
| http://123.4.567.89/Customers | /Customers |
| http://123.4.567.89/Customers/Add | /Customers/Add |
| 123.4.567.89/Do_This/If_OK/Do_That | /Do_This/If_OK/Do_That |

  Note that you are free to use this parameter at your convenience. 4D simply ignores the value passed beyond the host

part of the URL.
For example, you can establish a convention where the value *"/Customers/Add"* means "go directly to add a new record in the *[Customers]* table." By supplying the Web users of your database with a list of possible values and/or default bookmarks, you can provide shortcuts to the different parts of your application. This way, Web users can quickly access resources of your Web site without going through the whole navigation path each time they make a new connection to your database.

**WARNING:** In order to prevent a user from reentering a database with a bookmark created during a previous session, 4D intercepts any URL that corresponds to one of the standard 4D URLs.

- **Header of the HTTP request followed by the HTTP body**
  The second parameter (*$2*) is the header and the body of the HTTP request sent by the Web browser. Note that this information is passed to your **On Web Connection database method** as it is. Its contents will vary depending on the nature of the Web browser which is attempting the connection.
  With Safari running on Mac OS, you may receive a header similar to this:

```
GET /favicon.ico HTTP/1.1
Referer: http://123.45.67.89/4dcgi/test
User-Agent: Mozilla/5.0 (Macintosh; U; Intel Mac OS X; fr-fr) AppleWebKit/523.10.3 (KHTML, like Gecko) Version/3.0.4
Safari/523.10
Cache-Control: max-age=0
Accept: */*
Accept-Language: fr-fr
Accept-Encoding: gzip, deflate
Connection: keep-alive
Host: 123.45.67.89
```

  With Microsoft Internet Explorer 8 running on Windows, you may receive a header similar to this:

```
GET / HTTP/1.1
Accept: image/jpeg, application/x-ms-application, image/gif, application/xaml+xml, image/pjpeg, application/x-ms-xbap,
application/vnd.ms-powerpoint, application/vnd.ms-excel, application/msword, */*
Accept-Language: fr-FR
User-Agent: Mozilla/4.0 (compatible; MSIE 8.0; Windows NT 6.1; Trident/4.0; SLCC2; .NET CLR 2.0.50727; .NET CLR
3.5.30729; .NET CLR 3.0.30729; Media Center PC 6.0; .NET4.0C)
Accept-Encoding: gzip, deflate
Host: 123.45.67.89
Connection: Keep-Alive
```

  If your application deals with this information, it is up to you to parse the header and the body.
  **Note:** For performance reasons, the size of these data cannot be more than 32 KB. Beyond this, they are truncated by the 4D HTTP server.

- **IP address of the Web client**
  The *$3* parameter receives the IP address of the browser's machine. This information can allow you to distinguish between Intranet and Internet connections.
  **Note:** 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

- **IP address of the server**
  The *$4* parameter receives the IP address to which the HTTP request was sent. 4D allows for multi-homing, which allows you to exploit machines with more than one IP address. For more information, please refer to the section **Web Server Settings**.

- **User Name and Password**
  The *$5* and *$6* parameters receive the user name and password entered by the user in the standard identification dialog box displayed by the browser. This dialog box appears for each connection, if the **Use Passwords** option has been selected in the Database Settings dialog box (see section **Connection Security**).

**Note:** If the user name sent by the browser exists in 4D, the *$6* parameter (the user's password) is not returned for security reasons.

## On Web Connection Database Method Calls

The **On Web Connection database method** can be used as the entry point for the 4D Web server, either using the special *4DCGI* URL, or using customized command URLs.

**Warning:** Calling a 4D command that displays an interface element (**DIALOG**, **ALERT**, etc.) ends the method processing.

The **On Web Connection database method** is therefore called in the following cases:

- When 4D receives the */4DCGI* URL. The database method is called with the */4DCGI/<action>* URL in *$1*.
- When a Web page is called with a URL of type *<path>/<file>* is not found. The database method is called with the URL (*).
- When a Web page is called with a URL of type *<file>/* and no home page has been defined by default. The database method is called with the URL (*).

(*) In this particular cases, the URL received in *$1* does NOT start with the "/" character.

# Date and Time

- Add to date
- Current date
- Current time
- Date
- Day number
- Day of
- Milliseconds
- Month of
- SET DEFAULT CENTURY
- Tickcount
- Time
- Time string
- Year of

# Add to date

Add to date ( date ; years ; months ; days ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| date | Date | ➡ | Date to which to add days, months, and years |
| years | Longint | ➡ | Number of years to add to the date |
| months | Longint | ➡ | Number of months to add to the date |
| days | Longint | ➡ | Number of days to add to the date |
| Function result | Date | ⮌ | Resulting date |

## Description

The **Add to date** command adds *years*, *months,* and *days* to the date you pass in *aDate*, then returns the result.

Although you can use the **Date Operators** to add days to a date, **Add to date** allows you to quickly add months and years without having to deal with the number of days per month or leap years (as you would when using the + date operator).

## Example

```
 ` This line calculates the date in one year, same day
$vdInOneYear:=Add to date(Current date;1;0;0)

 ` This line calculates the date next month, same day
$vdNextMonth:=Add to date(Current date;0;1;0)

 ` This line does the same thing as $vdTomorrow:=Current date+1
$vdTomorrow:=Add to date(Current date;0;0;1)
```

# Current date

Current date {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Returns the current date from the server |
| Function result | Date | ⇐ | Current date |

## Description

The **Current date** command returns the current date as kept by the system clock.

**4D Server:** If you use the asterisk (*) parameter when executing this function on a 4D Client machine, it returns the current date from the server.

## Example 1

The following example displays an alert box containing the current date:

```
ALERT("The date is "+String(Current date)+".")
```

## Example 2

If you write an application for the international market, you may need to know if the version of 4D that you run works with dates formatted as MM/DD/YYYY (US version) or DD/MM/YYYY (French version). This is useful to know for customizing data entry fields.

The following project method allows you to do so:

```
  ` Sys date format global function
  ` Sys date format -> String
  ` Sys date format -> Default 4D data format

C_STRING(31;$0;$vsDate;$vsMDY;$vsMonth;$vsDay;$vsYear)
C_LONGINT($1;$vlPos)
C_DATE($vdDate)

  ` Get a Date value where the month, day and year values are all different
$vdDate:=Current date
Repeat
   $vsMonth:=String(Month of($vdDate))
   $vsDay:=String(Day of($vdDate))
   $vsYear:=String(Year of($vdDate)%100)
   If(($vsMonth=$vsDay)|($vsMonth=$vsYear)|($vsDay=$vsYear))
      vOK:=0
      $vdDate:=$vdDate+1
   Else
      vOK:=1
   End if
Until(vOK=1)
$0:="" ` Initialize function result
$vsDate:=String($vdDate)
$vlPos:=Position("/";$vsDate) ` Find the first / separator in the string ..
$vsMDY:=Substring($vsDate;1;$vlPos-1) ` Extract the first digits from the date
$vsDate:=Substring($vsDate;$vlPos+1) ` Eliminate the first digits as well as the first / separator
Case of
   :($vsMDY=$vsMonth) ` The digits express the month
      $0:="MM"
   :($vsMDY=$vsDay) ` The digits express the day
      $0:="DD"
   :($vsMDY=$vsYear) ` The digits express the year
      $0:="YYYY"
```

```
End case
$0:=$0+"/" ` Start building the function result
$vlPos:=Position("/";$vsDate) ` Find the second separator in the string ../..
$vsMDY:=Substring($vsDate;1;$vlPos-1) ` Extract the next digits from the date
$vsDate:=Substring($vsDate;$vlPos+1) ` Reduce the string to the last digits from the date
Case of
   :($vsMDY=$vsMonth) ` The digits express the month
      $0:=$0+"MM"
   :($vsMDY=$vsDay) ` The digits express the day
      $0:=$0+"DD"
   :($vsMDY=$vsYear) ` The digits express the year
      $0:=$0+"YYYY"
End case
$0:=$0+"/" ` Pursue building the function result
Case of
   :($vsDate=$vsMonth) ` The digits express the month
      $0:=$0+"MM"
   :($vsDate=$vsDay) ` The digits express the day
      $0:=$0+"DD"
   :($vsDate=$vsYear) ` The digits express the year
      $0:=$0+"YYYY"
End case
 ` At this point $0 is equal to MM/DD/YYYY or DD/MM/YYYY or...
```

# Current time

Current time {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Returns the current time from the server |
| Function result | Time | ⇒ | Current time |

## Description

The **Current time** command returns the current time from the system clock.

The current time is always between *00:00:00* and *23:59:59*. Use **String** or **Time string** to obtain the string form of the time expression returned by **Current time**.

**4D Server:** If you use the asterisk (*) parameter when executing this function on a 4D Client machine, it returns the current time from the server.

## Example 1

The following example shows you how to time the length of an operation. Here, ***LongOperation*** is a method that needs to be timed:

```
$vhStartTime:=Current time ` Save the start time
LongOperation ` Perform the operation
ALERT("The operation took "+String(Current time-$vhStartTime)) ` Display how long it took
```

## Example 2

The following example extracts the hours, minutes, and seconds from the current time:

```
$vhNow:=Current time
ALERT("Current hour is: "+String($vhNow¥3600))
ALERT("Current minute is: "+String(($vhNow¥60)%60))
ALERT("Current second is: "+String($vhNow%60))
```

# Date

Date ( dateString ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| dateString | String | ➡ | String representing the date to be returned |
| Function result | Date | ⮌ | Date |

## Description

The **Date** command evaluates *dateString* and returns a date.

The *dateString* parameter format must follow either the ISO date format or the regional settings defined at the system level.

**ISO date format**

The string must be formatted as follows: "YYYY-MM-DD**T**HH:MM:SS", for example "2013-11-20T10:20:00". In this case, **Date** evaluates the *dateString* parameter correctly, whatever the current language settings. Decimal seconds, preceded by a period, are supported (e.g.: "2013-11-20T10:20:00.9854").

If the *dateString* format does not precisely fit this ISO schema, then the date is evaluated as a short date format based on the regional settings of the system.

**Note :** Starting with 4D v14, it is recommended to use the "YYYY-MM-DDTHH:MM:SS**Z**" format, compliant with the ISO standard and allowing to express the time zone.

**Regional settings**

When the *dateString* does not match the ISO format, the regional settings defined in the operating system for a short date are used for the evaluation. For example, in the US version of 4D, by default the date must be in the order MM/DD/YY (month, day, year). The month and day can be one or two digits. The year can be two or four digits. If the year is two digits, then **Date** considers whether the date belongs to the 21st or 20th century based on the value entered. By default, the pivotal value is 30:

- If the value is greater than or equal to 30, 4D considers the century to be the 20th and adds 19 to the beginning of the value.
- If the value is less than 30, 4D considers the century to be the 21st and adds 20 to the beginning of the value.

This mechanism can be configured using the **SET DEFAULT CENTURY** command.

The following characters are valid date separators: slash (/), space, period (.), comma (,), and dash (-).

If you pass an invalid date (such as "13/35/94" or "aa/12/94") in *dateString*, **Date** returns a null date (!00/00/00!). It is your responsibility to verify that *dateString* is a valid date.

## Example 1

The following example uses a request box to prompt the user for a date. The string entered by the user is converted to a date and stored in the *reqDate* variable:

```
vdRequestedDate:=Date(Request("Please enter the date:";String(Current date)))
If(OK=1)
   ` Do something with the date now stored in vdRequestedDate
End if
```

## Example 2

The following example returns the string "12/25/94" as a date:

```
vdDate:=Date("12/25/94")
```

## Example 3

Date evaluation based on a date in ISO format:

```
$vtDateISO:="2013-06-05T20:00:00"
$vDate:=Date($vtDateISO)
 //$vDate represents June 5th, 2013 regardless of the system language
```

# Day number

Day number ( aDate ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aDate | Date | ➡ | Date for which to return the number |
| Function result | Longint | ⮌ | Number representing the weekday on which date falls |

## Description

The **Day number** command returns a number representing the weekday on which *aDate* falls.

**Note: Day number** returns *2* for null dates.

4D provides the following predefined constants, found in the "**Days and Months**" theme:

| Constant | Type | Value |
|---|---|---|
| Sunday | Longint | 1 |
| Monday | Longint | 2 |
| Tuesday | Longint | 3 |
| Wednesday | Longint | 4 |
| Thursday | Longint | 5 |
| Friday | Longint | 6 |
| Saturday | Longint | 7 |

**Note: Day number** returns a value between 1 and 7. To get the day number within the month for a date, use the command **Day of**.

## Example

The following example is a function that returns the current day as a string:

```
$viDay :=Day number(Current date) ` $viDay gets the current day number
Case of
   :($viDay =1)
      $0:="Sunday"
   :($viDay =2)
      $0:="Monday"
   :($viDay =3)
      $0:="Tuesday"
   :($viDay =4)
      $0:="Wednesday"
   :($viDay =5)
      $0:="Thursday"
   :($viDay =6)
      $0:="Friday"
   :($viDay =7)
      $0:="Saturday"
End case
```

# Day of

Day of ( date ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| date | Date | ➡ | Date for which to return the day |
| Function result | Longint | ⮌ | Day of the month of date |

## Description

The **Day of** command returns the day of the month of *aDate*.

**Note: Day of** returns a value between 1 and 31. To get the day of the week for a date, use the command **Day number**.

## Example 1

The following example illustrates the use of **Day of**. The results are assigned to the variable *vResult*. The comments describe what is put in *vResult*:

```
vResult:=Day of(!12/25/92!) ` vResult gets 25
vResult:=Day of(Current date) ` vResult gets day of current date
```

## Example 2

See the example for the **Current date** command.

# Milliseconds

Milliseconds -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | | Number of milliseconds elasped since the machine was started |

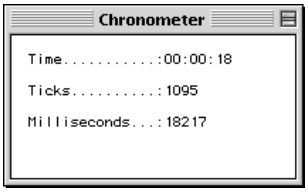
## Description

**Milliseconds** returns the number of milliseconds (1000th of a second) elapsed since the machine was started.

## Example

The following code displays the “Chronometer” window for one minute:

```
Open window(100;100;300;200;0;"Chronometer")
$vhTimeStart:=Current time
$vlTicksStart:=Tickcount
$vrMillisecondsStart:=Milliseconds
Repeat
   GOTO XY(2;1)
   MESSAGE("Time..........:"+String(Current time-$vhTimeStart))
   GOTO XY(2;3)
   MESSAGE("Ticks.........:"+String(Tickcount-$vlTicksStart))
   GOTO XY(2;5)
   MESSAGE("Milliseconds...:"+String(Milliseconds-$vrMillisecondsStart))
Until((Current time-$vhTimeStart)>=?00:01:00?)
CLOSE WINDOW
```



# Month of

Month of ( aDate ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aDate | Date | ⇒ | Date for which to return the month |
| Function result | Longint | ⇐ | Number indicating the month of date |

## Description

The **Month of** command returns the month of *aDate*.

**Note: Month of** returns the number of the month, not the name (see Example 1).

To compare the value returned by this function, 4D provides the following predefined constants, found in the "**Days and Months**" theme:

| Constant | Type | Value |
|---|---|---|
| January | Longint | 1 |
| February | Longint | 2 |
| March | Longint | 3 |
| April | Longint | 4 |
| May | Longint | 5 |
| June | Longint | 6 |
| July | Longint | 7 |
| August | Longint | 8 |
| September | Longint | 9 |
| October | Longint | 10 |
| November | Longint | 11 |
| December | Longint | 12 |

## Example 1

The following example illustrates the use of **Month of**. The results are assigned to the variable *vResult*. The comments describe what is put in *vResult*:

```
vResult:=Month of(!12/25/92!) ` vResult gets 12
vResult:=Month of(Current date) ` vResult gets month of current date
```

## Example 2

See example for the **Current date** command.

# SET DEFAULT CENTURY

SET DEFAULT CENTURY ( century {; pivotYear} )

| Parameter | Type | | Description |
|---|---|---|---|
| century | Longint | ⇒ | Default century (minus one) for entry of date with two-digit year |
| pivotYear | Longint | ⇒ | Pivot year for entry of date with two-digit year |

## Description

The **SET DEFAULT CENTURY** command specifies the default century and the pivot year used by 4D when you enter a date with only two digits for the year.

The pivot year value defines the way 4D will interpret data entry of a date with a two-digit year:

- If the year is greater than or equal to the pivot year, 4D uses the current default century.
- If the year is less than the pivot year, 4D uses the next century (relative to the current default).

By default, 4D sets the century to be the 20th century and uses 30 as pivot year. For example:

- 01/25/97 means January 25, 1997.
- 01/25/30 means January 25, 1930.
- 01/25/29 means January 25, 2029.
- 01/25/07 means January 25, 2007.

To change this default, execute the command. The effect of the command is immediate. You can pass a new default century only, or a new default century and a pivot year.

If you pass only a new default century minus one in *century*, 4D will interpret data entry of a date with a two-digit year as belonging to this century.
For example, after the call:

```
SET DEFAULT CENTURY(20) ` Switch to 21st century for default century
```

- 01/25/97 means January 25, 2097
- 01/25/07 means January 25, 2007

In addition, you can specify the optional *pivotYear* parameter.
For example, after this call, in which the pivot year is 1995:

```
SET DEFAULT CENTURY(19;95) ` Switch to 21st century for default century if year is less than 95
```

- 01/25/97 means January 25, 1997
- 01/25/07 means January 25, 2007

**Note:** This command only affects how 4D interprets dates entered with a two-digit year.
In all cases:

- 01/25/1997 means January 25, 1997
- 01/25/2097 means January 25, 2097
- 01/25/1907 means January 25, 1907
- 01/25/2007 means January 25, 2007

This command only affects data entry. It has no effect on date storage, computation, and so on.

# Tickcount

Tickcount -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of ticks (60th of a second) elapsed since the machine was started |

## Description

**Tickcount** returns the number of ticks (60th of a second) elapsed since the machine was started.

**Note: Tickcount** returns a value of type Long Integer.

## Example

See example for the command **Milliseconds**.

# Time

Time ( timeValue ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| timeValue | String, Longint | ⇒ | Value to return as a time |
| Function result | Time | ⇐ | Time specified by timeValue |

## Description

The **Time** command returns a time expression equivalent to the time specified in the *timeValue* parameter.

The *timeValue* parameter can contain either:

- a string containing a time expressed in one of the standard time formats of 4D corresponding to the language of your system (for more information, refer to the description of the **String** command).
- a longint that represents the number of seconds elapsed since 00:00:00.

## Example 1

The following example displays an alert box with the message “1:00 P.M. = 13 hours 0 minute”:

```
ALERT("1:00 P.M. = "+String(Time("13:00:00");Hour Min))
```

## Example 2

You can express any numerical value as a time:

```
vTime:=Time(10000)
 //vTime is 02:46:40
vTime2:=Time((60*60)+(20*60)+5200)
 //vTime2 is 02:46:40
```

# Time string

Time string ( seconds ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| seconds | Longint, Time | ⇒ | Seconds from midnight |
| Function result | String | ⇐ | Time as a string in 24-hour format |

## Description

The **Time string** command returns the string form of the time expression you pass in *seconds*.

The string is in the *HH:MM:SS* format.

If you go beyond the number of seconds in a day (86,400), **Time string** continues to add hours, minutes, and seconds. For example, **Time string** (86401) returns 24:00:01.

**Note:** If you need the string form of a time expression in a variety of formats, use **String**.

## Example

The following example displays an alert box with the message, “46800 seconds is 13:00:00.”

```
ALERT("46800 seconds is "+Time string(46800))
```

# Year of

Year of ( date ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| date | Date | ⇒ | Date for which to return the year |
| Function result | Longint | ⇐ | Number indicating the year of date |

## Description

The **Year of** command returns the year of *aDate*.

## Example 1

The following example illustrates the use of **Year of**. The results are assigned to the variable *vResult*.

```
vResult:=Year of(!12/25/92!) ` vResult gets 1992
vResult:=Year of(!12/25/1992!) ` vResult gets 1992
vResult:=Year of(!12/25/1892!) ` vResult gets 1892
vResult:=Year of(!12/25/2092!) ` vResult gets 2092
vResult:=Year of(Current date) ` vResult gets year of current date
```

## Example 2

See example for the command **Current date**.

# Design Object Access

- Design Object Access Commands
- Current method path
- FORM GET NAMES
- METHOD Get attribute
- METHOD GET ATTRIBUTES
- METHOD GET CODE
- METHOD GET COMMENTS
- METHOD GET FOLDERS
- METHOD GET MODIFICATION DATE
- METHOD GET NAMES
- METHOD Get path
- METHOD GET PATHS
- METHOD GET PATHS FORM
- METHOD OPEN PATH
- METHOD RESOLVE PATH
- METHOD SET ACCESS MODE
- METHOD SET ATTRIBUTE
- METHOD SET ATTRIBUTES
- METHOD SET CODE
- METHOD SET COMMENTS

# Design Object Access Commands

With 4D, you can access the contents of methods in your applications by programming. This source toolkit facilitates the integration into your applications of code control tools and more particularly version control systems (VCS). It also lets you implement advanced systems for code documentation, for building a custom explorer or for organizing scheduled backups of the code saved as disk files.

The following principles are implemented:

- Each method and form in a 4D application has its own address in the form of a pathname. For example, the trigger method for table 1 can be found at "[trigger]/table_1". Each object pathname is unique in an application.
  **Note:** To ensure the uniqueness of pathnames, 4D no longer lets you create objects with the same name on different form pages. In databases converted from versions prior to 4D v13, the MSC detects these duplicate names.
- You can access objects in the 4D application using the commands of this theme, for example **METHOD GET NAMES** or **METHOD GET PATHS**.
- Most of the commands in this theme work in both interpreted and compiled mode. However, commands that modify properties or access contents executable from methods can only be used in interpreted mode (see the table below).
- You can use all the commands of this theme with 4D in local or remote mode.
  However, keep in mind that you cannot use certain commands in compiled mode: the purpose of this theme is to create custom development support tools. You must not use these commands to dynamically change the functioning of a database that is running. For example, you cannot use **METHOD SET ATTRIBUTE** to change a method attribute according to the status of the current user.
- When a command of this theme is called from a component by default it accesses the component objects. In this case, to access objects of the host database, you just pass a * as the last parameter. Note that in this context, this syntax is only possible for commands that modify objects (such as **METHOD SET ATTRIBUTE**), because components are always executed in read-only mode.

## Use in compiled mode

For reasons related to the principle of the compilation process, only certain commands in this theme can be used in compiled mode. The following table indicates the available of the commands in compiled mode:

| Command | Can be used in compiled mode |
|---|---|
| Current method path | Yes |
| FORM GET NAMES | Yes |
| METHOD Get attribute | Yes |
| METHOD GET ATTRIBUTES | Yes |
| METHOD GET CODE | No (*) |
| METHOD GET COMMENTS | Yes |
| METHOD GET FOLDERS | Yes |
| METHOD GET MODIFICATION DATE | Yes |
| METHOD GET NAMES | Yes |
| METHOD Get path | Yes |
| METHOD GET PATHS | Yes |
| METHOD GET PATHS FORM | Yes |
| METHOD OPEN PATH | No (*) |
| METHOD RESOLVE PATH | Yes |
| METHOD SET ACCESS MODE | Yes |
| METHOD SET ATTRIBUTE | No (*) |
| METHOD SET ATTRIBUTES | No (*) |
| METHOD SET CODE | No (*) |
| METHOD SET COMMENTS | No (*) |

(*) The error -9762 "The command cannot be executed in a compiled database." is generated when the command is executed in compiled mode.

## Creation of pathnames

By default, no file is created on disk by 4D. However, pathnames generated for objects are compatible with the file management of the operating system; they can generate files directly on disk using your own import/export methods.

More specifically, forbidden characters such as ":" are encoded in method names. Generated files may be integrated automatically in a version control system.
Here are the encoded characters:

| Character | Encoding |
|---|---|
| " | %22 |
| * | %2A |
| / | %2F |
| : | %3A |
| < | %3C |
| > | %3E |
| ? | %3F |
| \| | %7C |
| ¥ | %5C |
| % | %25 |

**Examples:**
*Form?1* is encoded *Form%3F1*
*Button/1* is encoded *Button%2F1*

# Current method path

Current method path -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Text | ➲ | Full internal pathname of the method being executed |

## Description

The **Current method path** command returns the internal pathname of the database method, trigger, project method, form method or object method being executed.

**Note:** In the context of 4D macro-commands, the <*method_path*> tag is replaced in the code by the full pathname of the method being executed.

# FORM GET NAMES

FORM GET NAMES ( {aTable ;} arrNames {; filter {; marker}}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table reference |
| arrNames | Text array | ⇐ | Array of form names |
| filter | Text | ⇒ | Name filter |
| marker | Longint | ⇒ | Marker for minimum version to return |
| | | ⇐ | New value |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **FORM GET NAMES** command fills the *arrNames* array with the names of forms in the application.

If you pass the *aTable* parameter, the command returns the names of the table forms associated with this table. If you omit this parameter, the command returns the names of the database project forms.

You can limit this list of forms by passing a comparison string in the *filter* parameter: in this case, only forms whose names match the filter are returned. You can use the @ character in order to specify "starts with", "ends with" or "contains" type filters. If you pass an empty string, the *filter* parameter is ignored.

You can also limit the list of forms using the optional *marker* parameter, which allows you to limit forms returned in *arrNames* to those that were modified after a given time. As part of a version control system, this parameter lets you update only forms that were modified since the last backup.
This principle works as follows: 4D internally maintains a counter of database resource modifications. Since forms are resources, each time a form is created or saved, this counter is incremented. If you pass the *marker* parameter, the command returns, in *arrNames*, only forms corresponding to marker values that are greater than or equal to that of the *marker*. In addition, if you pass a variable in *marker*, the command returns the new value of the modification counter, i.e., the highest one, in this variable. You can then save this value and use it in the next call of the **FORM GET NAMES** command to retrieve only new or modified forms.

If the command is executed from a component, it returns by default the names of the component project forms. If you pass the * parameter, the array contains the forms of the host database.

**Note:** Forms placed in the trash are not listed.

## Example

Examples of typical use:

```
 // List all the project forms of the database
FORM GET NAMES(arr_Names)

 // List forms of the [Employees] table
FORM GET NAMES([Employees] ;arr_Names)

 // List "input" forms of the [Employees] table
FORM GET NAMES([Employees] ;arr_Names;"input_@")

 // List specific project forms of the database
FORM GET NAMES(arr_Names;"dialogue_@")

 // List all project forms in database that were modified since the last synchronization
 // vMarker contains a numeric value
FORM GET NAMES(arr_Names;"";vMarker)

 // List table forms from a component
 // A pointer is necessary because the table name is unknown
FORM GET NAMES(tablePtr->;arr_Names;*)
```

# METHOD Get attribute

METHOD Get attribute ( path ; attribType {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text | ⇒ | Path of project method |
| attribType | Longint | ⇒ | Type of attribute to get |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |
| Function result | Boolean | ⇐ | True = attribute selected; otherwise False |

## Description

The **METHOD Get attribute** command returns the value of the *attribType* attribute for the project method designated by the *path* parameter. This command only works with project methods. If you pass an invalid *path*, an error is generated.

In the *attribType* parameter, pass a value indicating the type of attribute to get. You can use the following constants, found in the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute executed on server | Longint | 8 | Corresponds to the "Execute on server" option |
| Attribute invisible | Longint | 1 | Corresponds to the "Invisible" option |
| Attribute published SOAP | Longint | 3 | Corresponds to the "Offered as a Web Service" option |
| Attribute published SQL | Longint | 7 | Corresponds to the "Available through SQL" option |
| Attribute published Web | Longint | 2 | Corresponds to the "Available through 4D HTML tags and URLs (4DACTION...)" option |
| Attribute published WSDL | Longint | 4 | Corresponds to the "Published in WSDL" option |
| Attribute shared | Longint | 5 | Corresponds to the "Shared by components and host database" option |

If the command is executed from a component, it applies by default to the component methods. If you pass the * parameter, it accesses the methods of the host database.

The command returns **True** when an attribute is selected and **False** if it is deselected.

# METHOD GET ATTRIBUTES

METHOD GET ATTRIBUTES ( path ; attributes {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ⇒ | Method path(s) |
| attributes | Object, Object array | ⇐ | Attribute(s) for selected method(s) |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET ATTRIBUTES** command returns, in *attributes*, the current value of all attributes for the method(s) specified in the *path* parameter.

This command only works with project methods. If you pass an invalid *path*, an error is generated.

In *path*, you can pass either a text containing a method path, or a text array containing an array of paths. You will need to pass the same kind of parameter (variable or array) in *attributes* in order to get the appropriate attributes.

In *attributes*, you pass an object or an array of objects, depending on the kind of parameter passed in *path*. All the attributes for the method(s) are returned as object properties, with "True"/"False" values for Boolean attributes, and text or additional values if necessary (for example, "scope":"table" for the 4D Mobile property).

If the command is executed from a component, by default it applies to the component methods. If you pass the * parameter, it accesses the methods of the host database.

**Note:** The existing **METHOD Get attribute** command is still supported but since it can only return Boolean values, it cannot be used for extended attributes such as 4D Mobile properties.

## Example

You want to get the attributes of the *sendMail* project method. You can write:

```
C_OBJECT($att)
METHOD GET ATTRIBUTES("sendMail";$att)
```

After execution, $att contains, for example:

```
{    "invisible":false,    "preemptive":"capable",    "publishedWeb":false,    "publishedSoap":false,    "publishedWsdl":false,
"shared":false,    "publishedSql":false,    "executedOnServer":false,    "published4DMobile":{        "scope":"table",        "table":"Table_1"
    } }
```

# METHOD GET CODE

METHOD GET CODE ( path ; code {; option} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ➡ | Text or Text array containing one or more method path(s) |
| code | Text, Text array | ⬅ | Code of designated method(s) |
| option | Longint | ➡ | 0 or omitted = simple export (without tokens), 1 = export with tokens |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET CODE** command returns, in the *code* parameter, the contents of the method(s) designated by the *path* parameter. This command can return the code of all types of methods: database methods, triggers, project methods, form methods and object methods.

You can use two types of syntaxes, based either on text arrays, or text variables:

```
C_TEXT(tVpath) // text variables
C_TEXT(tVcode)
METHOD GET CODE(tVpath;tVcode) // code of a single method
```

```
ARRAY TEXT(arrPaths;0) // text arrays
ARRAY TEXT(arrCodes;0)
METHOD GET CODE(arrPaths;arrCodes) // code of several methods
```

You cannot mix the two syntaxes.

If you pass an invalid pathname, the *code* parameter is left empty and an error is generated.

In the text of the *code* generated by this command:

- Command names are written in English for all versions of 4D, except when you use a French version and check the "Use regional system settings" preference (see **Methods Page**). When you use the *option* parameter, the code can contain language tokens in order to make it independent from the 4D programming language and version (see below).
- To increase code readability, text is indented with tab characters based on programming structures, like in the Method editor.
- A line is added in the header of the code generated containing metadata used when importing code, for example:

  ```
  // %attributes = {"lang":"en","invisible":true,"folder":"Web3"}
  ```

  During an import, this line is not imported, it is only used to set the corresponding attributes (attributes that are not specified are reset to their default value). The "lang" attribute sets the export language and prevents an import into an application in a different language (in this case, an error is generated). The "folder" attribute contains the name of the method's parent folder; it is not shown when the method does not have a parent folder.
  Additional attributes can be defined. For more information, refer to the description of the **METHOD SET ATTRIBUTES** command.

The *option* parameter allows you to select the code export mode with respect to the tokenized language elements of the method(s):

- If you pass 0 or omit the *option* parameter, the method code is exported without tokens, i.e. just like it is displayed in the Method editor.
- If you pass 1 or the Code with tokens constant, the method code is exported with tokens, i.e. tokenized elements are followed by their internal reference in the *code* exported contents. For example, the expression "**String**(a)" is exported "**String**:C10(a)", where "C10" is the internal reference of the **String** command.

Tokenized language elements include:

- 4D commands and constants,
- Table and field names,
- 4D plug-in commands.

Code exported with tokens is independent from any subsequent renaming of language elements. Thanks to tokens, code provided as text will always be interpreted correctly by 4D, whether by means of the **METHOD SET CODE** command or even by copy/paste. For more information about the syntax of 4D tokens, please refer to **Using tokens in formulas**.

If the command is executed from a component, it applies by default to the component methods. If you pass the * parameter, it accesses the methods of the host database.

## Example 1

Refer to the example of the **METHOD SET CODE** command.

## Example 2

This example illustrates the effect of the *option* parameter.

You want to export the following "simple_init" method:

```
Case of
   :(Form event=On Load)
      ALL RECORDS([Customer])
End case
```

If you execute the following code:

```
C_TEXT($code)
C_TEXT($contents)
$code:=METHOD Get path(Path project method;"simple_init")
METHOD GET CODE($code;$contents;0) //no tokens
TEXT TO DOCUMENT("simple_init.txt";$contents)
```

The resulting document will contain:

```
  //%attributes = {"lang":"en"} comment added and reserved by 4D
Case of
    : (Form event=On Load)
        ALL RECORDS([Customer])
End case
```

If you execute the following code:

```
C_TEXT($code)
C_TEXT($contents)
$code:=METHOD Get path(Path project method;"simple_init")
METHOD GET CODE($code;$contents;Code with tokens) //use tokens
TEXT TO DOCUMENT("simple_init.txt";$contents)
```

The resulting document will contain:

```
  //%attributes = {"lang":"en"} comment added and reserved by 4D
Case of
    : (Form event:C388=On Load:K2:1)
        ALL RECORDS:C47([Customer:1])
End case
```

# METHOD GET COMMENTS

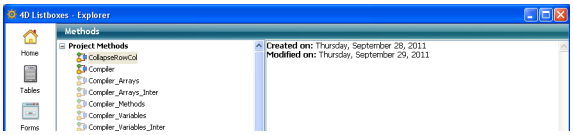
METHOD GET COMMENTS ( path ; comments {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ➡ | Text or Text array containing one or more method path(s) |
| comments | Text, Text array | ⬅ | Comments of designated method(s) |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET COMMENTS** command returns, in the *comments* parameter, the comments of the method(s) designated by the *path* parameter.

The comments retrieved by this command are those specified in the 4D Explorer (not to be confused with lines of comments in the code that are retrieved using **METHOD GET CODE**):



These comments can only be generated for triggers, project methods and form methods. They contain styled text.

**Note:** Forms and form methods share the same comments.

You can use two types of syntaxes, based either on text arrays, or text variables:

```
C_TEXT(tVpath) // text variables
C_TEXT(tVcomments)
METHOD GET COMMENTS(tVpath;tVcomments) // comments of a single method
```

```
ARRAY TEXT(arrPaths;0) // text arrays
ARRAY TEXT(arrComments;0)
METHOD GET COMMENTS(arrPaths;arrComments) // comments of several methods
```

You cannot mix the two syntaxes.

If the command is executed from a component, it applies by default to the component methods. If you pass the * parameter, it accesses the methods of the host database.

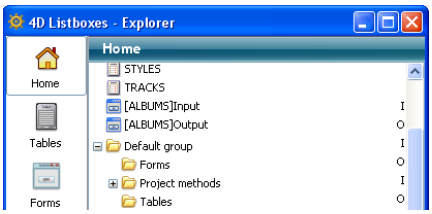
# METHOD GET FOLDERS

METHOD GET FOLDERS ( arrNames {; filter}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrNames | Text array | ⇦ | Array of Home page folder names |
| filter | Text | ⇨ | Name filter |
| * | Operator | ⇨ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET FOLDERS** command returns, in the *arrNames* array, the names of folders created on the Home page of the 4D Explorer:



Since folder names must be unique, the hierarchy is not returned in this array.

You can limit this list of folders by passing a comparison string in the *filter* parameter: in this case, only folders whose names match the filter are returned. You can use the @ character in order to specify "starts with", "ends with" or "contains" type filters. If you pass an empty string, the *filter* parameter is ignored.

If the command is executed from a component, it returns by default the paths of the component methods. If you pass the * parameter, the array contains the paths of the methods of the host database.

# METHOD GET MODIFICATION DATE

METHOD GET MODIFICATION DATE ( path ; modDate ; modTime {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ➡ | Text or Text array containing one or more method path(s) |
| modDate | Date, Date array | ⬅ | Method modification date(s) |
| modTime | Time, Longint array | ⬅ | Method modification time(s) |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET MODIFICATION DATE** command returns, in the *modDate* and *modTime* parameters, the dates and times of the last modification of the method(s) designated by the *path* parameter.

You can use two types of syntaxes, based either on arrays or variables:

```
C_TEXT(tVpath) // variables
C_DATE(vDate)
C_TIME(vTime)
METHOD GET MODIFICATION DATE(tVpath;vDate;vTime) // date and time of a single method
```

```
ARRAY TEXT(arrPaths;0) // arrays
ARRAY DATE(arrDates;0)
ARRAY LONGINT(arrTimes;0)
METHOD GET MODIFICATION DATE(arrPaths;arrDates;arrTimes) // dates and times of several methods
```

You cannot mix the two syntaxes.

If the command is executed from a component, it applies by default to the component methods. If you pass the * parameter, it accesses the methods of the host database.

## Example 1

You want to find out modification dates and times for several methods:

```
ARRAY TEXT(arrPaths;0)
APPEND TO ARRAY(arrPaths;"MyMethod1")
APPEND TO ARRAY(arrPaths;"MyMethod2")
...
ARRAY DATE(arrDates;0)
ARRAY LONGINT(arrTimes;0)
METHOD GET MODIFICATION DATE(arrPaths;arrDates;arrTimes)
```

## Example 2

You want to get modification dates for methods in a module that are prefixed with "Web_". You cannot use the "@" symbol in a path; however, you can write:

```
ARRAY TEXT($_webMethod;0)
METHOD GET NAMES($_webMethod;"Web_@")
ARRAY DATE($_date;0)
ARRAY LONGINT($_time;0)
METHOD GET MODIFICATION DATE($_webMethod;$_date;$_time)
```

# METHOD GET NAMES

METHOD GET NAMES ( arrNames {; filter}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrNames | Text array | ⇦ | Array of project method names |
| filter | Text | ⇨ | Name filter |
| * | Operator | ⇨ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET NAMES** command fills the *arrNames* array with the names of project methods created in the application.

By default, all methods are listed. You can restrict this list by passing a comparison string in the *filter* parameter: in this case, the command only returns methods whose name matches the filter. You must use the @ character in order to set filters of the "starts with", "ends with" or "contains" type. If you pass an empty string, the *filter* parameter is ignored.

If this command is executed from a component, it returns by default the names of the component project methods. If you pass the * parameter, the array contains the host database project methods.

**Note:** Methods placed in the trash are not listed.

## Example

Here are a few typical examples of use:

```
 // List of all project methods of the database
METHOD GET NAMES(t_Names)

 //  List of project methods beginning with a specific string
METHOD GET NAMES(t_Names;"web_@")

 // List of project methods in the host database beginning with a specific string
METHOD GET NAMES(t_Names;"web_@";*)
```

# METHOD Get path

METHOD Get path ( methodType {; aTable}{; objectName{; formObjectName}}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| methodType | Longint | ⇒ | Object type selector |
| aTable | Table | ⇒ | Table reference |
| objectName | Text | ⇒ | Name of form or database method |
| formObjectName | Text | ⇐ | Name of form object |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |
| Function result | Text | ⇒ | Full path of object |

## Description

The **METHOD Get path** command returns the full internal pathname of a method.

In the *methodType* parameter, you pass the type of method whose path you want to get. You can use the following constants, found in the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Path database method | Longint | 2 | Path of database methods specified (English name). List of these methods:<br>*[databaseMethod]/onStartup*<br>*[databaseMethod]/onExit*<br>*[databaseMethod]/onDrop*<br>*[databaseMethod]/onBackupStartup*<br>*[databaseMethod]/onBackupShutdown*<br>*[databaseMethod]/onWebConnection*<br>*[databaseMethod]/onWebAuthentication*<br>*[databaseMethod]/onWebSessionSuspend*<br>*[databaseMethod]/onServerStartup*<br>*[databaseMethod]/onServerShutdown*<br>*[databaseMethod]/onServerOpenConnexion*<br>*[databaseMethod]/onServerCloseConnection*<br>*[databaseMethod]/onSystemEvent*<br>*[databaseMethod]/onSqlAuthentication* |
| Path project form | Longint | 4 | Path of project form methods and all their object methods. Examples:<br>*[projectForm]/myForm/{formMethod}*<br>*[projectForm]/myForm/button1*<br>*[projectForm]/myForm/my%2list*<br>*[projectForm]/myForm/button1* |
| Path project method | Longint | 1 | Name of method.<br>Example: *MyProjectMethod* |
| Path table form | Longint | 16 | Path of table form methods and all their object methods. Example:<br>*[tableForm]/table_1/Form1/{formMethod}*<br>*[tableForm]/table_1/Form1/button1*<br>*[tableForm]/table_1/Form1/my%2list*<br>*[tableForm]/table_2/Form1/my%2list* |
| Path trigger | Longint | 8 | Path of database triggers. Example:<br>*[trigger]/table_1*<br>*[trigger]/table_2* |

Pass values in the *aTable*, *objectName* and *formObjectName* parameters according to the type of object for which you want to get the method pathname:

| **Type of object** | *aTable* | *objectName* | *formObjectName* |
|---|---|---|---|
| Path Project form | | X | X (optional) |
| Path Table form | X | X | X (optional) |
| Path Database method | | X | |
| Path Project method | | X | |
| Path Trigger | X | | |

If the object is not found (method type unknown or not valid, missing table, etc.), an error is generated.

If the command is executed from a component, it returns by default the paths of the component methods. If you pass the * parameter, the array contains the paths of the methods of the host database.

## Example

```
 //Retrieval of the pathname of the "On Startup" database method:
$path:=METHOD Get path(Path database method;"onStartup")

 //Retrieval of the pathname of the trigger for the [Employees] table:
$path:=METHOD Get path(Path trigger;[Employees])

 //Retrieval of the pathname of the "OK" object method of the "input" form for the [Employees] table:
$path:=METHOD Get path(Path table form;[Employees];"input";"OK")
```

# METHOD GET PATHS

METHOD GET PATHS ( {folderName ;} methodType ; arrPaths {; stamp}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| folderName | Text | ⇒ | Name of Home page folder |
| methodType | Longint | ⇒ | Selector of method type to get |
| arrPaths | Text array | ⇐ | Array of method paths and names |
| stamp | Longint variable | ⇒ | Minimum value of stamp |
| | | ⇐ | New current value |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET PATHS** command fills the *arrPaths* array with the internal pathnames and names of methods in the application that are of the type specified by the *methodType* parameter.

If your code is organized in "folders" in the 4D Explorer (Home page), you can pass a folder name in the optional *folderName* parameter. In this case, the *arrPaths* array only contains paths of methods that are found in this location.

**Note:** You cannot use the "@" character in *folderName*.

In the *methodType* parameter, you pass the type of method whose paths you want to get in the *arrPaths* array. You can use the following constants (individually or a combination of them), found in the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Path all objects | Longint | 31 | Paths of all the methods of the database |
| Path database method | Longint | 2 | Path of database methods specified (English name). List of these methods:<br>*[databaseMethod]/onStartup*<br>*[databaseMethod]/onExit*<br>*[databaseMethod]/onDrop*<br>*[databaseMethod]/onBackupStartup*<br>*[databaseMethod]/onBackupShutdown*<br>*[databaseMethod]/onWebConnection*<br>*[databaseMethod]/onWebAuthentication*<br>*[databaseMethod]/onWebSessionSuspend*<br>*[databaseMethod]/onServerStartup*<br>*[databaseMethod]/onServerShutdown*<br>*[databaseMethod]/onServerOpenConnexion*<br>*[databaseMethod]/onServerCloseConnection*<br>*[databaseMethod]/onSystemEvent*<br>*[databaseMethod]/onSqlAuthentication* |
| Path project form | Longint | 4 | Path of project form methods and all their object methods. Examples:<br>*[projectForm]/myForm/{formMethod}*<br>*[projectForm]/myForm/button1*<br>*[projectForm]/myForm/my%2list*<br>*[projectForm]/myForm/button1* |
| Path project method | Longint | 1 | Name of method.<br>Example: *MyProjectMethod* |
| Path table form | Longint | 16 | Path of table form methods and all their object methods. Example:<br>*[tableForm]/table_1/Form1/{formMethod}*<br>*[tableForm]/table_1/Form1/button1*<br>*[tableForm]/table_1/Form1/my%2list*<br>*[tableForm]/table_2/Form1/my%2list* |
| Path trigger | Longint | 8 | Path of database triggers. Example:<br>*[trigger]/table_1*<br>*[trigger]/table_2* |

The *stamp* parameter lets you only get the paths of methods modified after a specific point in time. As part of a version control system, this means that you can update only methods that were modified since the last backup.
Here is how it works: 4D maintains a counter of method modifications. Each time a method is created or saved again, this counter is incremented and its current value is stored in the internal stamp of the method.
If you pass the *stamp* parameter, the command only returns methods whose stamp is greater than or equal to the value passed in this parameter. Moreover, the command returns, in *stamp*, the new current value of the modification counter, i.e. the highest value. If you save this value, you can pass it the next time this command is called so that you only get new or modified methods.

If the command is executed from a component, it returns by default the paths of the component methods. If you pass the * parameter, the array contains the paths of the methods of the host database.

If the command detects a duplicated method name, the error -9802 is generated ("Object path not unique"). In this case, it is advisable to use the MSC in order to verify the database structure.

## Example 1

Retrieval of project methods found in the "web" folder:

```
METHOD GET PATHS("web"; Path Project method;arrPaths)
```

## Example 2

Retrieval of database methods and triggers:

```
METHOD GET PATHS(Path trigger+Path database method;arrPaths)
```

## Example 3

Retrieval of project methods that were modified since the last backup:

```
 // we load the last saved value
$stamp :=Max([Backups]cur_stamp)
METHOD GET PATHS(Path project method;arrPaths;$stamp)
 // we save the new value
CREATE RECORD([Backups])
[Backups]cur_stamp :=$stamp
SAVE RECORD([Backups])
```

## Example 4

Refer to the example of the **METHOD SET CODE** command.

# METHOD GET PATHS FORM

METHOD GET PATHS FORM ( {aTable ;} arrPaths {; filter}{; stamp}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table reference |
| arrPaths | Text array | ⬅ | Array of method paths and names |
| filter | Text | ➡ | Name filter |
| stamp | Longint variable | ➡ | Minimum value of stamp |
| | | ⬅ | New current value |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD GET PATHS FORM** command fills the *arrPaths* array with the internal pathnames and names of the methods for all form objects as well as form methods. Form methods are labeled {formMethod}.

Only objects containing code are listed. For example, buttons that are only associated with a standard action are not returned.

If you pass the *aTable* parameter, the command returns the objects of the table forms associated with this table. If you omit this parameter, the command returns objects of the database project forms.

You can limit this list of forms by passing a comparison string in the *filter* parameter: in this case, only forms whose names match the filter are returned. You can use the @ character in order to specify "starts with", "ends with" or "contains" type filters. If you pass an empty string, the *filter* parameter is ignored.

The *stamp* parameter lets you only get the paths of methods modified after a specific point in time. As part of a version control system, this means that you can update only methods that were modified since the last backup.
Here is how it works: 4D maintains a counter of method modifications. Each time a method is created or saved again, this counter is incremented and its current value is stored in the internal stamp of the method.
If you pass the *stamp* parameter, the command only returns methods whose stamp is greater than or equal to the value passed in this parameter. Moreover, the command returns, in *stamp*, the new current value of the modification counter, i.e. the highest value. If you save this value, you can pass it the next time this command is called so that you only get new or modified methods.

If the command is executed from a component, it returns by default the paths of the component methods. If you pass the * parameter, the array contains the paths of the methods of the host database.

**Note:** The command does not list objects of inherited forms or of subforms.

If the command detects a duplicated method name, the error -9802 is generated ("Object path not unique"). In this case, it is advisable to use the MSC in order to verify the database structure.

## Example 1

List of all objects of the "input" form for the [Employees] table. Note that table form methods (and project form methods) are processed as objects belonging to the form:

```
METHOD GET PATHS FORM([Employees];arrPaths;"input")
 // Contents of arrPaths (for example)
 // [tableForm]/input/{formMethod} -> Form method
 // [tableForm]/input/bOK -> Object method
 // [tableForm]/input/bCancel -> Object method
```

## Example 2

List of objects of the "dial" project form:

```
METHOD GET PATHS FORM(arrPaths;"dial")
```

## Example 3

List of all objects of the "input" form for the [Employees] table from a component:

```
METHOD GET PATHS FORM(([Employees];arrPaths;"input@";*)
```

# METHOD OPEN PATH

METHOD OPEN PATH ( path {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text | ⇒ | Path of method to open |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD OPEN PATH** command opens, in the 4D Method editor, the method whose internal pathname is passed in the *path* parameter.

This command can open all method types (object, form, trigger, project or database); however, the method must already exist. If the *path* parameter does not correspond to an existing method, the error -9801 "Cannot open method" is returned.

You can execute this command from a component, but in this case, you must pass the * parameter because access to the component code is read-only. If you omit the * parameter in this context, the error -9763 is generated

# METHOD RESOLVE PATH

METHOD RESOLVE PATH ( path ; methodType ; ptrTable ; objectName ; formObjectName {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text | ⇒ | Path to resolve |
| methodType | Longint | ⇐ | Object type selector |
| ptrTable | Pointer | ⇐ | Table reference |
| objectName | Text | ⇐ | Name of form or database method |
| formObjectName | Text | ⇐ | Name of form object |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD RESOLVE PATH** command parses the internal path name passed in the *path* parameter and returns its different components in the *methodType*, *ptrTable*, *objectName*, and *formObjectName* parameters.

The *methodType* parameter receives a value indicating the type of the method. You can compare this value with the following constants of the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Path database method | Longint | 2 | Path of database methods specified (English name). List of these methods:<br>*[databaseMethod]/onStartup*<br>*[databaseMethod]/onExit*<br>*[databaseMethod]/onDrop*<br>*[databaseMethod]/onBackupStartup*<br>*[databaseMethod]/onBackupShutdown*<br>*[databaseMethod]/onWebConnection*<br>*[databaseMethod]/onWebAuthentication*<br>*[databaseMethod]/onWebSessionSuspend*<br>*[databaseMethod]/onServerStartup*<br>*[databaseMethod]/onServerShutdown*<br>*[databaseMethod]/onServerOpenConnexion*<br>*[databaseMethod]/onServerCloseConnection*<br>*[databaseMethod]/onSystemEvent*<br>*[databaseMethod]/onSqlAuthentication* |
| Path project form | Longint | 4 | Path of project form methods and all their object methods. Examples:<br>*[projectForm]/myForm/{formMethod}*<br>*[projectForm]/myForm/button1*<br>*[projectForm]/myForm/my%2list*<br>*[projectForm]/myForm/button1* |
| Path project method | Longint | 1 | Name of method.<br>Example: *MyProjectMethod* |
| Path table form | Longint | 16 | Path of table form methods and all their object methods. Example:<br>*[tableForm]/table_1/Form1/{formMethod}*<br>*[tableForm]/table_1/Form1/button1*<br>*[tableForm]/table_1/Form1/my%2list*<br>*[tableForm]/table_2/Form1/my%2list* |
| Path trigger | Longint | 8 | Path of database triggers. Example:<br>*[trigger]/table_1*<br>*[trigger]/table_2* |

The *ptrTable* parameter contains a pointer to a database table when the path references a table form method or a trigger.

The *objectName* parameter contains either:

- A form name when the path references a table form or project form
- A database method name when the path references a database method.

The *formObjectName* parameter contains a form object name when the path references an object method.

If the command is executed from a component, it considers by default that *path* designates a component method. If you pass the * parameter, then it considers that *path* designates a host database method.

## Example 1

Resolution of a database method path:

```
C_LONGINT($methodType)
C_POINTER($tablePtr)
C_TEXT($objectName)
C_TEXT($formObjectName)

METHOD RESOLVE PATH("[databaseMethod]/onStartup";$methodType;$tablePtr;$objectName;$formObjectName)
 // $methodType: 2
 // $tablePtr: Nil pointer
 // $objectName: "onStartup"
 // $formObjectName: ""
```

## Example 2

Resolution of a path for an object of a table form method:

```
C_LONGINT($methodType)
C_POINTER($tablePtr)
C_TEXT($objectName)
C_TEXT($formObjectName)

METHOD RESOLVE PATH("[tableForm]/Table1/output%2A1/myVar%2A1";$methodType;$tablePtr;$objectName;$formObjectName)
 // $methodType: 16
 // $tablePtr: -> [Table1]
 // $objectName: "output*1"
 // $formObjectName: "Btn*1"
```

# METHOD SET ACCESS MODE

METHOD SET ACCESS MODE ( mode )

| Parameter | Type | | Description |
|---|---|---|---|
| mode | Longint | ⇒ | Access mode for locked objects |

## Description

The **METHOD SET ACCESS MODE** command sets the behavior for 4D when you attempt to write access an object already loaded for modification by another user or process. The scope of this command is the current session.

In *mode*, you pass one of the following constants of the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| On object locked abort | Longint | 0 | Loading of object is aborted (default functioning) |
| On object locked confirm | Longint | 2 | 4D displays a dialog box so that you can choose to try again or to abort. In remote mode, this option is not supported (loading is aborted) |
| On object locked retry | Longint | 1 | 4D keeps attempting to load the object until it has been released |

# METHOD SET ATTRIBUTE

METHOD SET ATTRIBUTE ( path ; attribType ; attribValue {; attribType2 ; attribValue2 ; ... ; attribTypeN ; attribValueN}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text | ⇒ | Path of project method |
| attribType | Longint | ⇒ | Type of attribute |
| attribValue | Boolean, Text | ⇒ | True = select attribute, False = deselect attribute or Folder name |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD SET ATTRIBUTE** command sets the value(s) of the *attribType* attribute(s) for the project method designated by the *path* parameter. This command only works with project methods. If you pass an invalid *path*, an error is generated.

In the *attribType* parameter, pass a value indicating the type of attribute to set. You can use the following constants, found in the **Design Object Access** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute executed on server | Longint | 8 | Corresponds to the "Execute on server" option |
| Attribute folder name | Longint | 1024 | Name of folder for the method ("folder" attribute). When you pass this constant, you must pass a folder name in *attribValue*:<br>• if this name corresponds to a valid folder, the method is placed in this parent folder,<br>• if the folder does not exist, the command does not change anything at the parent folder level,<br>• if you pass an empty string, the method is placed at the root level. |
| Attribute invisible | Longint | 1 | Corresponds to the "Invisible" option |
| Attribute published SOAP | Longint | 3 | Corresponds to the "Offered as a Web Service" option |
| Attribute published SQL | Longint | 7 | Corresponds to the "Available through SQL" option |
| Attribute published Web | Longint | 2 | Corresponds to the "Available through 4D HTML tags and URLs (4DACTION...)" option |
| Attribute published WSDL | Longint | 4 | Corresponds to the "Published in WSDL" option |
| Attribute shared | Longint | 5 | Corresponds to the "Shared by components and host database" option |

In the *attribValue* parameter, you can pass either:

- **True** to select the corresponding option or **False** to deselect it, or
- a string (folder name) if you used the Attribute folder name constant in *attribType*.

You can pass multiple *attribType*;*attribValue* pairs in a single call.

You can execute this command from a component, but in this case, you must pass the * parameter because access to the component code is read-only. If you omit the * parameter in this context, the error -9763 is generated.

This command cannot be executed in compiled mode. When it is called in this mode, it will generate the error -9762.

## Example 1

Selection of the "Shared by components and host database" property for the "Choose dialog" project method:

```
METHOD SET ATTRIBUTE("Choose dialog";Attribute shared;True)
```

## Example 2

Setting several attribute/value pairs:

```
METHOD SET ATTRIBUTE(vPath;Attribute invisible;vInvisible;Attribute published Web;v4DAction;Attribute published SOAP;vSoap;Attribute published WSDL;vWSDL;Attribute shared;vExported;Attribute published SQL;vSQL;Attribute executed on server;vRemote;Attribute folder name;vFolder;*)
```

# METHOD SET ATTRIBUTES

METHOD SET ATTRIBUTES ( path ; attributes {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ⇒ | Method path(s) |
| attributes | Object, Object array | ⇒ | Attribute(s) to set for selected method(s) |
| * | Operator | ⇒ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD SET ATTRIBUTES** command allows you to set the *attributes* values for the method(s) specified in the *path* parameter.

In *path*, you can pass either a text containing a method path, or a text array containing an array of paths. You will need to pass the same kind of parameter (string or array) in *attributes* in order to set the appropriate attributes. This command only works with project methods. If you pass an invalid *path*, an error is generated.

In *attributes*, you pass an object or an array of objects (depending on the kind of parameter you passed in *path*) containing all the attributes that you want to set for the method(s).

Method attributes must be set using the **OB SET** or **OB SET ARRAY** commands, with True or False values for Boolean attributes, or specific values for extended attributes (for example, "scope":"table" for the 4D Mobile property). Only attributes that are present in the *attributes* parameter will be updated in the method attributes.

If the command is executed from a component, by default it applies to the component methods. If you pass the * parameter, it accesses the methods of the host database.

**Note:** The existing **METHOD SET ATTRIBUTE** command is still supported but since it can only handle Boolean values, it cannot be used for extended attributes such as 4D Mobile properties.

The supported attributes are:

```
{    "invisible" : false, // true if visible    "preemptive" : "capable" // or "incapable" or "indifferent"    "publishedWeb" : false,  // true if available through 4D tags and URLs    "publishedSoap": false,  // true if offered as Web Service    "publishedWsdl": false,  // true if published in WSDL    "shared" : false,  // true if shared by components and host database    "publishedSql" : false,  // true if available through SQL "executedOnServer" : false, // true if executed on server    "published4DMobile" : {        "scope": "table",  // "none" or "table" or "currentRecord" or "currentSelection"        "table": "aTableName"  // present if scope is different from "none"    } }
```

**Note:** Regarding "published4DMobile" attributes, if the "table" value does not exist or if the "scope" is invalid, these attributes are ignored.

## Example 1

You want to set a single attribute:

```
C_OBJECT($attributes)
OB SET($attributes;"executedOnServer";True)
METHOD SET ATTRIBUTES("aMethod";$attributes) //Only the "executedOnServer" attribute is modified
```

## Example 2

You want a method to be unavailable through 4D Mobile (the "none" value must be passed for the "scope" attribute):

```
C_OBJECT($attributes)
C_OBJECT($fourDMobileAttribute)
OB SET($fourDMobileAttribute;"scope";"none")
OB SET($attributes;"published4DMobile";$fourDMobileAttribute)
METHOD SET ATTRIBUTES("aMethod";$attributes)
```

# METHOD SET CODE

METHOD SET CODE ( path ; code {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ➡ | Text or Text array containing one or more method path(s) |
| code | Text, Text array | ➡ | Code of designated method(s) |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD SET CODE** command modifies the code of the method(s) designated by the *path* parameter with the contents passed in the *code* parameter. This command can access the code of all types of methods: database methods, triggers, project methods, form methods and object methods.

In the case of a project method: if this method already exists in the database, its contents are replaced; if it does not exist, it is created with its contents.

You can use two types of syntaxes, based either on text arrays, or text variables:

```
C_TEXT(tVpath) // text variables
C_TEXT(tVcode)
METHOD SET CODE(tVpath;tVcode) // code of a single method
```

```
ARRAY TEXT(arrPaths;0) // text arrays
ARRAY TEXT(arrCodes;0)
METHOD SET CODE(arrPaths;arrCodes) // code of several methods
```

You cannot mix the two syntaxes.

If you pass an invalid pathname, the command does nothing. .

When **METHOD SET CODE** is called, the method attributes are reset by default. However, if the first line of the method *code* contains valid metadata (expressed in JSON), they are used to specify the method attributes and the first line is not inserted. Example of metadata:

```
// %attributes = {"invisible":true,"lang":"fr","folder":"Security"}
```

**Note:** These metadata are generated automatically by the **METHOD GET CODE** command. For more information about supported attributes, refer to the description of the **METHOD SET ATTRIBUTES** command.

Concerning the "folder" property of the metadata:

- When this property is present and corresponds to a valid folder, the method is placed in its parent folder,
- If this property is not present or if the folder does not exist, the command makes no changes at the parent folder level,
- When this property contains an empty string, the method is placed at the root level.

You can execute this command from a component, but in this case, you must pass the * parameter because access to the component code is read-only. If you omit the * parameter in this context, the error -9763 is generated

## Example

This example exports and imports all the project methods of an application:

```
$root_t:=Get 4D folder(Database folder)+"methods"+Folder separator
ARRAY TEXT($fileNames_at;0)
CONFIRM("Import or export methods?";"Import";"Export")

If(OK=1)
   DOCUMENT LIST($root_t;$fileNames_at)
```

```
      For($loop_l;1;Size of array($fileNames_at))
         $filename_t:=$fileNames_at{$loop_l}
         DOCUMENT TO BLOB($root_t+$filename_t;$blob_x)
         METHOD SET CODE($filename_t;BLOB to text($blob_x;UTF8 text without length))
      End for
   Else
      If(Test path name($root_t)#Is a folder)
         CREATE FOLDER($root_t;*)
      End if
      METHOD GET PATHS(Path project method;$fileNames_at)
      METHOD GET CODE($fileNames_at;$code_at)
      For($loop_l;1;Size of array($fileNames_at))
         $filename_t:=$fileNames_at{$loop_l}
         SET BLOB SIZE($blob_x;0)
         TEXT TO BLOB($code_at{$loop_l};$blob_x;UTF8 text without length)
         BLOB TO DOCUMENT($root_t+$filename_t;$blob_x)
      End for
   End if
   SHOW ON DISK($root_t)
```

# METHOD SET COMMENTS

METHOD SET COMMENTS ( path ; comments {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | Text, Text array | ➡ | Text or Text array containing one or more method path(s) |
| comments | Text, Text array | ➡ | Comments of designated method(s) |
| * | Operator | ➡ | If passed = command applies to host database when executed from a component (parameter ignored outside of this context) |

## Description

The **METHOD SET COMMENTS** command replaces the comments of the method(s) designated by the *path* parameter by those specified in the *comments* parameter.

The comments modified by this command are those specified in the 4D Explorer (not to be confused with lines of comments in the code). These comments can only be generated for triggers, project methods and form methods. They contain styled text

**Note:** Forms and form methods share the same comments..

You can use two types of syntaxes, based either on text arrays, or text variables:

```
C_TEXT(tVpath) // text variables
C_TEXT(tVcomments)
METHOD SET COMMENTS(tVpath;tVcomments) // comments for a single method
```

```
ARRAY TEXT(arrPaths;0) // text arrays
ARRAY TEXT(arrComments;0)
METHOD SET COMMENTS(arrPaths;arrComments) // comments for several methods
```

You cannot mix the two syntaxes.

If you pass an invalid pathname, an error is generated.

You can execute this command from a component, but in this case, you must pass the * parameter because access to the component code is read-only. If you omit the * parameter in this context, the error -9763 is generated

## Example

Add a modification date to an existing trigger comment:

```
METHOD GET COMMENTS("[trigger]/Table1";$comments)
$comments:="Modif:"+String(Current date)+"¥r"+$comments
METHOD SET COMMENTS("[trigger]/Table1";$comments)
```

# Drag and Drop

- Drag and Drop
- On Drop Database Method
- DRAG AND DROP PROPERTIES
- Drop position
- SET DRAG ICON

# Drag and Drop

4D allows built-in drag and drop capability between objects in your forms and applications. You can drag and drop one object to another, in the same window or in another window. In other words, drag and drop can be performed within a process or from one process to another.

You can also drag and drop objects between 4D forms and other applications, and vice versa. For example, it is possible to drag and drop a GIF picture file onto a 4D picture field. It is also possible to select text in a word processing application and drop it onto a 4D text variable.

Finally, it is possible to drop objects directly onto the application without necessarily having a form in the foreground. The **On Drop Database Method** can be used to manage the drag and drop action in this case. This means, for example, that you can open a 4D Write document by dropping it onto the 4D application icon.

**Note**: As an introduction, we assume that a drag and drop action “transports” some data from one point to another. Later, we will see that drag and drop can also be a metaphor for any type of operation.

## Draggable and Droppable Object Properties

To drag and drop an object to another object, you must select the **Draggable property** for that object in the Property List window. In a drag-and-drop operation, the object that you drag is the **source object**.

To make an object the destination of a drag and drop operation, you must select the **Droppable property** for that object in the Property List window. In a drag-and-drop operation, the object that receives data is the **destination object**.

**Automatic Drag** and **Automatic Drop**: These additional properties are available for text fields and variables as well as for combo boxes and list boxes. The Automatic Drop option is also available for picture fields and variables. They can be used to enable an automatic drag and drop mode based on copying the contents (the drag and drop action is no longer managed by 4D form events). Please refer to the "Automatic Drag and Drop" paragraph at the end of this section.

By default, newly created objects can be neither dragged nor dropped. It is up to you to set these properties.

All objects in an input or dialog form can be made to be dragged and dropped. Individual elements of an array (i.e., scrollable area), items of a hierarchical list or rows in a list box can be dragged and dropped. Conversely, you can drag and drop an object onto an individual element of an array or an item of a hierarchical list or a list box row. However, you cannot drag and drop objects from the detail area of an output form.

You can also manage dragging and dropping onto the application, outside of any form, using the **On Drop Database Method**.

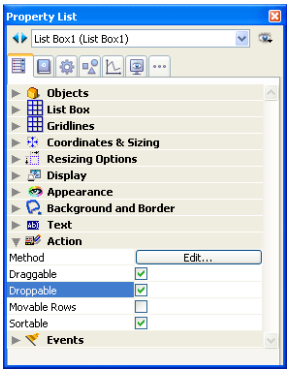
You can easily create a drag-and-drop user interface, because 4D allows you to use any type of active object (field or variable) as source or destination objects. For example, you can drag and drop a button.

**Notes**:

- To drag a text or a button labeled "draggable," you must first press the **Alt** (Windows) or **Option** (Mac OS) keys.
- By default, in the case of picture fields and variables, the picture and its reference are both dragged. If you only want to drag the reference of the variable or field, first hold down the **Alt** (Windows) or **Option** (Mac OS) key.
- When the “Draggable” and “Movable Rows” properties are both set for a List box object, the “Movable Rows” property takes priority when a row is moved. Dragging is not possible in this case.

An object that is capable of being both dragged and dropped can also be dropped onto itself, unless you reject the operation. For details, see the discussion below.

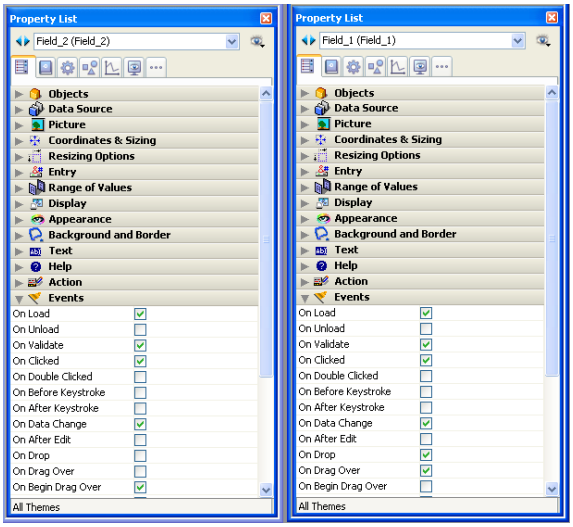
The following figure shows the Property List window with the Droppable and Draggable properties set for the selected object:



## Drag-and-Drop Programmatical Handling

Management of drag and drop by programming is based on three form events: On Begin Drag Over, On Drag Over and On Drop.
Note that the On Begin Drag Over event **is generated in the context of the source object** of the drag while On Drag Over and On Drop **are only sent to the destination object**.

In order for the application to process these events, they must be selected in an appropriate manner in the Property List:
**Property List**:



### On Begin Drag Over

The On Begin Drag Over form event can be selected for any form objects that can be dragged. It is generated in every case where the object has the **Draggable** property.
Unlike the On Drag Over form event, On Begin Drag Over is called within the context of the source object of the drag action. It can be called from the method of the source object or the form method of the source object.
This event is useful for advanced management of the drag action. It can be used to:

- Get the data and signatures found in the pasteboard (via the **GET PASTEBOARD DATA** command).
- Add data and signatures to the pasteboard (via the **APPEND DATA TO PASTEBOARD** command).
- Use a custom icon during the drag action (via the **SET DRAG ICON** command).
- Accept or refuse dragging via $0 in the method of the dragged object. To indicate that drag actions are accepted, the method of the source object must return *0* (zero); you must therefore execute *$0:=0*. To indicate that drag actions are refused, the method of the source object must return *-1* (minus one); you must therefore execute *$0:=-1*. If no result is returned, 4D considers that drag actions are accepted.

4D data are put in the pasteboard before calling the event. For example, in the case of dragging without the **Automatic Drag** action, the dragged text is already in the pasteboard when the event is called.

### On Drag Over

The On Drag Over event is repeatedly sent to the destination object when the mouse pointer is moved over the object. In response to this event, you usually:

- Call the **DRAG AND DROP PROPERTIES** command, which informs you about the source object.
- Depending on the nature and type of both the destination object (whose object method is currently being executed) and the source object, you **accept** or **reject** the drag and drop.

To accept the drag, the destination object method must return *0* (zero), so you write *$0:=0*. To reject the drag, the object method must return *-1* (minus one), so you write *$0:=-1*. During an On Drag Over event, 4D treats the object method as a function. If no result is returned, 4D assumes that the drag is accepted.

If you accept the drag, the destination object is highlighted. If you reject the drag, the destination is not highlighted. Accepting the drag does not mean that the dragged data is going to be inserted into the destination object. It only means that if the mouse button was released at this point, the destination object would accept the dragged data.

If you do not process the On Drag Over event for a droppable object, that object will be highlighted for all drag over operations, no matter what the nature and type of the dragged data.

The On Drag Over event is the means by which you control the first phase of a drag-and-drop operation. Not only can you test whether the dragged data is of a type compatible with the destination object, and then accept or reject the drag; you can simultaneously notify the user of this fact, because 4D highlights (or not) the destination object, based on your decision.

The code handling an On Drag Over event should be short and execute quickly, because that event is sent repeatedly to the current destination object, due to the movements of the mouse.

**WARNING**: Beginning with version 11 of 4D, if the drag and drop is an **interprocess drag and drop**, which means the source object is located in a process (window) other than that of the destination object, the object method of the destination object for an On Drag Over event is executed **within the context of the destination process**. To find out the value of the elements being dragged, you must use the interprocess communication commands. It is usually recommended in this case to use the On Begin Drag Over event and the commands of the **Pasteboard** theme.

### On Drop

The On Drop event is sent once to the destination object when the mouse pointer is released over the object. This event is the second phase of the drag-and-drop operation, in which you perform an operation in response to the user action.

This event is not sent to the object if the drag was not accepted during the On Drag Over events. If you process the On Drag Over event for an object and reject a drag, the On Drop event does not occur. Thus, if during the On Drag Over event you have tested the data type compatibility between the source and destination objects and have accepted a possible drop, you do not need to re-test the data during the On Drop. You already know that the data is suitable for the destination object.

An interesting aspect of the 4D drag-and-drop implementation is that 4D lets you do whatever you want. Examples:

- If a hierarchical list item is dropped over a text field, you can insert the text of the list item at the beginning, at the end, or in the middle of the text field.
- Your form contains a two-state picture button, which could represent an empty or full trash can. Dropping an object onto that button could mean (from the user interface standpoint) “delete the object that has been dragged and dropped into the trash can.” Here, the drag and drop does not transport data from one point to another; instead, it performs an action.
- Dragging an array element from a floating window to an object in a form could mean “in this window, show the Customer record whose name you just dragged and dropped from the floating window listing the Customers stored in the database.”
- And so on.

So, the 4D drag-and-drop interface is a framework which enables you to implement any user interface metaphor you may devise.

## Drag-and-drop commands

The **DRAG AND DROP PROPERTIES** command returns:

- A pointer to the dragged object (field or variable)
- The element or item number, if the dragged object is an array element or a list item
- The process number of the source process.

The **Drop position** command returns the element number of the item position of the target element or list item, if the destination object is an array (i.e., scrollable area), a hierarchical list, a text or a combo box, as well as the column number if the object is a list box.

Commands like **RESOLVE POINTER** and **Type** are useful for testing the nature and type of the source object.

When the drag-and-drop operation is intended to copy the dragged data, the functionality of these commands depend on how many processes are involved:

- If the drag and drop is limited to one process, use these commands to perform the appropriate actions (i.e., simply assigning the source object to the destination object).
- If the drag and drop is an interprocess drag and drop, you need to be careful while getting access to the dragged data; you must access the data instance from the source process. If the dragged data comes from a variable, use **GET**

**PROCESS VARIABLE** to get the right value. If the dragged data comes from a field, remember that the current record for a table is probably different for the two processes, so you need to access the right record. It is usually recommended in this case to use the commands of the **Pasteboard** theme and the On Begin Drag Over event.

If the drag and drop is not intended to move data, but is instead a user interface metaphor for a particular operation, you can perform whatever you want.

## Commands of the Pasteboard Theme

If the drag and drop operation involves the moving of heterogenous data or documents between two 4D applications or a 4D application and a third-party application, the commands of the "Pasteboard" theme will provide you with the tools needed. In fact, these commands can be used to manage both the copy/paste and the drag and drop of data. 4D uses two pasteboards: one for copied (or cut) data, which is the actual clipboard, and the other for data being dragged and dropped. These two pastebaoards are managed using the same commands. You access one or the other depending on the context.

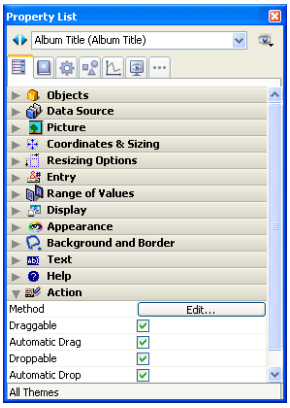
For more information about using the commands of the "Pasteboard" theme for drag and drop operations, please refer to the **Managing Pasteboards** section.

## Automatic Drag and Drop

Text areas (fields, variables, combo boxes and List boxes) as well as picture objects allow the automatic drag and drop, which is the movement or copy of a text or picture selection from one area to another by a single click. It can be used in the same 4D area, between two 4D areas, or between 4D and another application, for example WordPad.

**Note**: In the case of automatic drag and drop between two 4D areas, the data are moved, in other words, they are removed from the source area. If you want to copy the data, hold down the **Ctrl** (Windows) or **Option** (OS X) key during the action (under OS X, you need to hit the **Option** key *after* you start to drag the item(s)).

Automatic drag and drop can be configured separately for each form object via two options of the Property List: **Automatic Drag** and **Automatic Drop**:



- **Automatic Drag** (Text type objects only): When this option is checked, the automatic drag mode is activated for the object. In this mode, the **On Begin Drag** form event is NOT generated.
  If you want to "force" the use of the standard drag while automatic drag is enabled, hold down the **Alt** (Windows) or **Option** (Mac OS) key during the action (under OS X, you need to hit the **Option** key *before* you start to drag the item(s)). This option is not available for pictures.

- **Automatic Drop**: This option is used to activate the automatic drop mode. In this mode, 4D automatically manages — if possible — the insertion of dragged data of the text or picture type that is dropped onto the object (the data are pasted into the object). The On Drag Over and On Drop form events are not generated in this case. On the other hand, the On After Edit (during a drop) and On Data Change (when the object loses the focus) events are generated.
  In the case of data other than text or pictures (another 4D object, file, etc. ) or complex data being dropped, the application refers to the value of the Droppable option: if it is checked, the On Drag Over and On Drop form events are generated; otherwise, the drop is refused. This also depends on the value of the "Prevent drop of data not coming from 4D" option (see below).

## Prevent drop of data not coming from 4D (compatibility)

Beginning with version 11, 4D allows drag and drop of selections, objects and/or files external to 4D, like picture files for example. This possibility must be supported by the database code.
In databases converted from previous versions of 4D, this possibility may lead to malfunctioning if the existing code is not adapted accordingly. For this reason, an option in the Preferences can be used to disable this function: **Prevent drop of**

**data not coming from 4D**. This option is found on the Application/Compatibility page. It is checked by default in converted databases.

When this option is check, the drop of external objects into 4D forms is refused. Note however that the insertion of external objects remains possible in objects having the **Automatic Drop** option, when the application can interpret the dropped data (text or picture).

# On Drop Database Method

The **On Drop Database Method** is available in local or remote 4D applications.

This database method is automatically executed in the case of objects being dropped in the 4D application outside of any form or windows, i.e.:

- In an empty area of the MDI window (Windows),
- On the 4D icon in the Dock (Mac OS) or on the system desktop.

Under Mac OS, you need to hold down the **Option**+**Command** keys during the drop in order for the database method to be called.

When a drop occurs on the 4D application icon on the desktop, the **On Drop Database Method** is only called when the application is already launched, except in the case of applications merged with 4D Desktop. In this case, the database method is called even when the application is not launched. This means that it is possible to define custom document signatures.

## Example

This example can be used to open a 4D Write document that is dropped outside of any form:

```
  `On Drop database method
droppedFile:=Get file from pasteboard(1)
If(Position(".4W7";droppedFile)=Length(droppedFile)-3)
   externalArea:=Open external window(100;100;500;500;0;droppedFile;"_4D Write")
   WR OPEN DOCUMENT(externalArea;droppedFile)
End if
```

# DRAG AND DROP PROPERTIES

DRAG AND DROP PROPERTIES ( srcObject ; srcElement ; srcProcess )

| Parameter | Type | | Description |
|---|---|---|---|
| srcObject | Pointer | ⇐ | Pointer to drag-and-drop source object |
| srcElement | Longint | ⇐ | Dragged array element number, or Dragged list box row number, or Dragged hierarchical list item, or -1 if source object is neither an array nor a list box nor a hierarchical list |
| srcProcess | Longint | ⇐ | Source process number |

## Description

**Compatibility note:** Since version 11 of 4D, it is recommended to manage drag and drop operations, especially interprocess ones, using the On Begin Drag Over event and the commands of the **Pasteboard** theme.

The **DRAG AND DROP PROPERTIES** command enables you to obtain information about the source object when an On Drag Over or On Drop event occurs for a “complex” object (array, list box or hierarchical list).

Typically, you use **DRAG AND DROP PROPERTIES** from within the object method of the object (or from one of the subroutines it calls) for which the On Drag Over or On Drop event occurs (the destination object).

**Important:** A form object accepts dropped data if its **Droppable** property has been selected. Also, its object method must be activated for On Drag Over and/or On Drop, in order to process these events.

After the call:

- The *srcObject* parameter is a pointer to the source object (the object that has been dragged and dropped). Note that this object can be the destination object (the object for which the On Drag Over or On Drop event occurs) or a different object. Dragging and dropping data from and to the same object is useful for arrays and hierarchical lists—it is a simple way of allowing the user to sort an array or a list manually.
- If the dragged and dropped data is an array element (the source object being an array), the *srcElement* parameter returns the number of this element. If the dragged and dropped data is a list box row, the *srcElement* parameter returns the number of this row. If the drag and dropped data is a list item (the source object being a hierarchical list), the *srcElement* parameter returns the position of this item. Otherwise, if the source object does not belong to any of these categories, *srcElement* is equal to -1.
- Drag and drop operations can occur between processes. The *srcProcess* parameter is equal to the number process to which the source object belongs. It is important to test the value of this parameter. You can respond to a drag and drop within the same process by simply copying the source data to the destination object. On the other hand, when treating an interprocess drag and drop, you will use the **GET PROCESS VARIABLE** command to get the source data from the source process object instance. You will usually implement drag and drop in the user interface from source variables (i.e., arrays and lists) toward data entry areas (fields or variables).

If you call **DRAG AND DROP PROPERTIES** when there is no drag and drop event, *srcObject* returns a NIL pointer, *srcElement* returns -1 and *srcProcess* returns 0.

**Tip:** 4D automatically handles the graphical aspect of a drag and drop. You must then respond to the event in the appropriate way. In the following examples, the response is to copy the data that has been dragged. Alternatively, you can implement sophisticated user interfaces where, for example, dragging and dropping an array element from a floating window will fill in the destination window (the window where the destination object is located) with structured data (i.e., several fields coming from a record uniquely identified by the source array element).

You use **DRAG AND DROP PROPERTIES** during an On Drag Over event in order to decide whether the destination object accepts the drag and drop operation, depending on the type and/or the nature of the source object (or any other reason). If you accept the drag and drop, the object method must return *$0:=0*. If you do not accept the drag and drop, the object method must return *$0:=-1*. Accepting or refusing the drag and drop is reflected on the screen—the object is or is not highlighted as the potential destination of the drag-and-drop operation.

## Example 1

In several of your database forms, there are scrollable areas in which you want to manually reorder the elements by simple drag and drop from one part of the scrollable area into another within it. Rather than writing specific code for each case, you may implement a generic project method that will handle any one of these scrollable areas. You could write something like:

```
   ` Handle self array drag and drop project method
   ` Handle self array drag and drop ( Pointer ) -> Boolean
   ` Handle self array drag and drop ( -> Array ) -> Is a self array drag and drop

Case of
   :(Form event=On Drag Over)
      DRAG AND DROP PROPERTIES($vpSrcObj;$vlSrcElem;$vlPID)
      If($vpSrcObj=$1)
   ` Accept the drag and drop if it is from the array to itself
         $0:=0
      Else
         $0:=-1
      End if
   :(Form event=On Drop)
   ` Get the information about the drag and drop source object
      DRAG AND DROP PROPERTIES($vpSrcObj;$vlSrcElem;$vlPID)
   ` Get the destination element number
      $vlDstElem:=Drop position
   ` If the element was not dropped over itself
      If($vlDstElem #$vlSrcElem)
   ` Save dragged element in element 0 of the array
         $1->{0}:=$1->{$vlSrcElem}
   ` Delete the dragged element
         DELETE FROM ARRAY($1->;$vlSrcElem)
   ` If the destination element was beyond the dragged element
         If($vlDstElem>$vlSrcElem)
   ` Decrement the destination element number
            $vlDstElem:=$vlDstElem-1
         End if
   ` If the drag and drop occurred beyond the last element
         If($vlDstElem=-1)
   ` Set the destination element number to a new element at the end of the array
            $vlDstElem:=Size of array($1->)+1
         End if
   ` Insert this new element
         INSERT IN ARRAY($1->;$vlDstElem)
   ` Set its value which was previously saved in the element zero of the array
         $1->{$vlDstElem}:=$1->{0}
   ` The element becomes the new selected element of the array
         $1->:=$vlDstElem
      End if
End case
```

Once you have implemented this project method, you can use it in the following way:

```
   ` anArray Scrollable Area Object Method

Case of
   ` ...
   :(Form event=On Drag Over)
      $0:=Handle self array drag and drop(Self)
   :(Form event=On Drop)
      Handle self array drag and drop(Self)
   ` ...
End case
```

## Example 2

In several of your database forms, you have text enterable areas in which you want to drag and drop data from various sources. Rather than writing specific code for each case, you may implement a generic project method that will handle any one of these text enterable areas. You could write something like:

```
   ` Handle dropping to text area project method
   ` Handle dropping to text area ( Pointer )
   ` Handle dropping to text area ( -> Text or String variable )
```

```
Case of
  ` Use this event for accepting or rejecting the drag and drop
    :(Form event=On Drag Over)
  ` Initialize $0 for rejecting
      $0:=-1
  ` Get the information about the drag and drop source object
      DRAG AND DROP PROPERTIES($vpSrcObj;$vlSrcElem;$vlPID)
  ` In this example, we do not allow drag and drop from an object to itself
      If($vpSrcObj #$1)
  ` Get the type of the data which is being dragged
         $vlSrcType:=Type($vpSrcObj->)
         Case of
            :($vlSrcType=Is text)
  ` OK for text variables
               $0:=0
            :($vlSrcType=Is string var)
  ` String Variable is OK
               $0:=0
            :(($vlSrcType=String array)|($vlSrcType=Text array))
  ` String and Text Arrays are OK
               $0:=0
            :(($vlSrcType=Is longint)|($vlSrcType=Is real)
               If(Is a list($vpSrcObj->))
  ` Hierarchical list is OK
                  $0:=0
               End if
         End case
      End if

  ` Use this event for performing the actual drag and drop action
    :(Form event=On Drop)
      $vtDraggedData:=""
  ` Get the information about the drag and drop source object
      DRAG AND DROP PROPERTIES($vpSrcObj;$vlSrcElem;$vlPID)
  ` Get the type of the variable which has been dragged
      $vlSrcType:=Type($vpSrcObj->)
      Case of
  ` If it is an array
         :(($vlSrcType=String array)|($vlSrcType=Text array))
            If($vlPID #Current process)
  ` Read the element from the source process instance of the variable
               GET PROCESS VARIABLE($vlPID;$vpSrcObj->{$vlSrcElem};$vtDraggedData)
            Else
  ` Copy the array element
               $vtDraggedData:=$vpSrcObj->{$vlSrcElem}
            End if
  ` If it is a list
         :(($vlSrcType=Is real)|($vlSrcType=Is longint))
  ` If it is a list from another process
            If($vlPID #Current process)
  `Get the List Reference from the other process
               GET PROCESS VARIABLE($vlPID;$vpSrcObj->;$vlList)
            Else
               $vlList:=$vpSrcObj->
            End if
  ` If the list exists
            If(Is a list($vpSrcObj->))
  `Get the text of the item whose position was obtained
               GET LIST ITEM($vlList;$vlSrcElem;$vlItemRef;$vsItemText)
               $vtDraggedData:=$vsItemText
            End if
         Else
  ` It is a string or a text variable
            If($vlPID #Current process)
               GET PROCESS VARIABLE($vlPID;$vpSrcObj->;$vtDraggedData)
            Else
               $vtDraggedData:=$vpSrcObj->
            End if
      End case
  ` If there is actually something to drop (the source object may be empty)
```

```
      If($vtDraggedData #"")
         $1->:=$1->+$vtDraggedData
      End if
   End case
```

Once you have implemented this project method, you can use it in the following way:

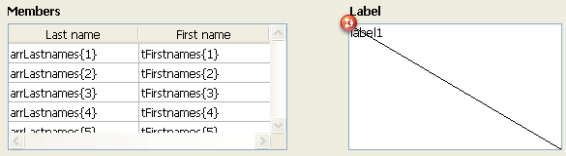
```
   ` [anyTable]aTextField Object Method

   Case of
      ` ...
      :(Form event=On Drag Over)
         $0:=Handle dropping to text area(Self)

      :(Form event=On Drop)
         Handle dropping to text area(Self)
      ` ...
   End case
```

## Example 3

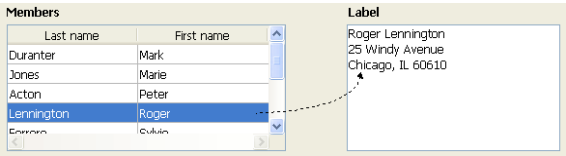
We want to fill a text area (for example, a label) with data dragged from a list box.



Here is the label1 object method:

```
   Case of
      :(Form event=On Drag Over)
         DRAG AND DROP PROPERTIES($source;$arrayrow;$processnum)
         If($source=Get pointer("list box1"))
            $0:=0 `The drop is accepted
         Else
            $0:=-1 `The drag is refused
         End if
      :(Form event=On Drop)
         DRAG AND DROP PROPERTIES($source;$arrayrow;$processnum)
         QUERY([Members];[Members]LastName=arrNames{$arrayrow})
         If(Records in selection([Members])#0)
            label1:=[Members]FirstName+" "+[Members]LastName+Char(Carriage return)+[Members]Address
            +Char(Carriage return)+[Members]City+","+" "+[Members]State
            +" "+[Members]ZipCode
         End if
   End case
```

It then becomes possible to carry out the following action:



# Drop position

Drop position {( columnNumber | pictPosY )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| columnNumber \| pictPosY | Longint | ⇦ | List box column number (-1 if the drop occurs beyond the last column) or<br>Position of Y coordinate in picture |
| Function result | Longint | ⇨ | • Number (array/list box) or<br>• Position (hierarchical list) or<br>• Position in string (text/combo box) of destination item or<br>• -1 if drop occurred beyond the last array element or list item<br>• Position of X coordinate in picture |

## Description

The **Drop position** command can be used to find out the location, in a “complex” destination object, where an object has been (dragged and) dropped.

Typically, you will use **Drop position** when handling a drag and drop event that occurred over an array, a list box, a hierarchical list or a text or picture field.

- If the destination object is an array, the command returns an element number.
- If the destination object is a list box, the command returns a row number. In this case, the command also returns the column number where the drop took place in the optional *columnNumber* parameter.
- If the destination object is a hierarchical list, the command returns an item position.
- If the destination object is a text type variable or field, or a combo box, the command returns a character position within the string.
  In all the above cases, the command may return -1 if the source object has been dropped beyond the last element or the last item of the destination object.
- If the destination object is a picture type variable or field, the command returns the horizontal location of the click and, in the optional *pictPosY* parameter, the vertical location of the click. The values returned are expressed in pixels and in relation to the local coordinate system.

If you call **Drop position** when handling an event that is not a drag-and-drop event and that occurred over an array a list box, a combo box, a hierarchical list, a text or a picture, the command returns -1.

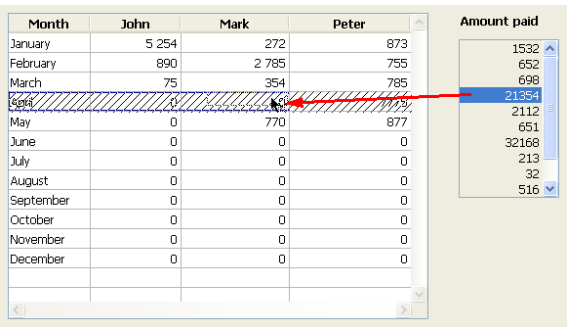
**Important:** A form object accepts dropped data if its **Droppable** property has been selected. Also, its object method must be activated for On Drag Over and/or On Drop, in order to process these events.

## Example 1

See the examples for the **DRAG AND DROP PROPERTIES** command.

## Example 2

In the following example, a list of amounts paid must be broken down per month and per person. This is carried out by drag and drop from a scrollable area:



The list box object method contains the following code:

```
Case of
   :(Form event=On Drag Over)
      DRAG AND DROP PROPERTIES($source;$arrayrow;$processnum)
      If($source=Get pointer("SA1")) `If the drop does come from the scrollable area
         $0:=0
      Else
         $0:=-1 `The drop is refused
      End if
   :(Form event=On Drop)
      DRAG AND DROP PROPERTIES($source;$arrayrow;$processnum)
      $rownum:=Drop position($colnum)
      If($colnum=1)
         BEEP
      Else
         Case of `Adding of dropped values
            :($colnum=2)
               John{$rownum}:=John{$rownum}+SA1{$arrayrow}
            :($colnum=3)
               Mark{$rownum}:=Mark{$rownum}+SA1{$arrayrow}
            :($colnum=4)
               Peter{$rownum}:=Peter{$rownum}+SA1{$arrayrow}
         End case
         DELETE FROM ARRAY(SA1;$arrayrow) `Updating of area
      End if
End case
```

# SET DRAG ICON

SET DRAG ICON ( icon {; horOffset {; vertOffset}} )

| Parameter | Type | | Description |
|---|---|---|---|
| icon | Picture | ⇒ | Icon to use during drag |
| horOffset | Longint | ⇒ | Horizontal offset from left edge of picture with respect to cursor position (>0 = to the left, <0 = to the right) |
| vertOffset | Longint | ⇒ | Vertical offset from top edge of picture with respect to cursor position (>0 = upwards, <0 = downwards) |

## Description

The **SET DRAG ICON** command associates the icon picture with the cursor during drag and drop operations that are managed by programming.

This command can only be called in the context of the On Begin Drag Over form event (see the **Form event** command).

In the *icon* parameter, pass the picture to use. Its maximum size is 256x256 pixels. If one of its dimensions exceeds 256 pixels, it is automatically resized.

In *horOffset* and *vertOffset*, you can pass offset values in pixels:

- for *horOffset*, you pass the horizontal offset from the left edge of the icon with respect to the cursor position. Pass a positive value to apply this offset towards the left or a negative value to apply it towards the right.
- for *vertOffset*, you pass the vertical offset from the top edge of the icon with respect to the cursor position. Pass a positive value to apply this offset upwards or a negative value to apply it downwards.

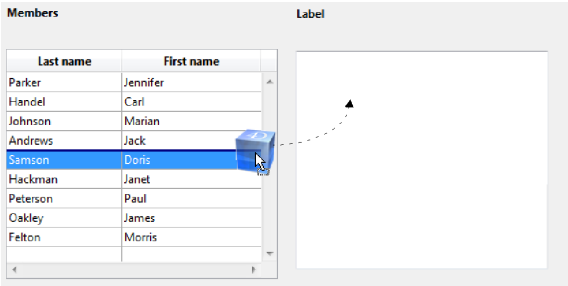
If you omit this parameter, the cursor is placed at the center of the icon.

## Example

In a form, a user can generate a label by dragging and dropping a row. In the object method of the list box, you can write:

```
If(Form event=On Begin Drag Over)
   READ PICTURE FILE(Get 4D folder(Current resources folder)+"splash.png";vpict)
   CREATE THUMBNAIL(vpict;vpict;48;48)
   SET DRAG ICON(vpict)
End if
```

When you drag a row, the picture appears as shown here:



Note that you can modify the position of the cursor with respect to the picture:

```
SET DRAG ICON(vpict;0;0)
```

# Entry Control

- EDIT ITEM
- FILTER KEYSTROKE
- Get edited text
- GET HIGHLIGHT
- GOTO OBJECT
- HIGHLIGHT TEXT
- Keystroke

# EDIT ITEM

EDIT ITEM ( {* ;} object {; item} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If set, object is an object name (string) If omitted, object is a table or variable |
| object | Form object | ⇒ | Object name (if * set) or Table or variable (if * omitted) |
| item | Longint | ⇒ | Item number |

## Description

The **EDIT ITEM** command allows you to edit the current item or the item number *item* in the array or the list set in the *object* parameter.
This means that the selected item can be modified; entering a character entirely replaces the item content.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (in this case, pass a string in *object*). If you do not pass the parameter, you indicate that the *object* parameter is a table or a variable. In this case, you do not pass a string but a table or a variable reference.

This command applies to the following enterable objects:

- Hierarchical lists
- List boxes
- Subforms (in this case, only an object name — the subform — can be passed in *object*),
- List forms displayed using the **DISPLAY SELECTION** or **MODIFY SELECTION** commands.

If the command is used with an enterable object that is not a list, it then acts the same as the **GOTO OBJECT** command. The command does nothing if the list or the array is empty or invisible. Also, if the list or the array is not enterable, the command only selects the specified item without changing to editing mode. Regarding list boxes, if the column does not allow text entry (entry by check boxes or drop-down lists only), the specified element gets the focus.

The optional *item* parameter allows you to set the position of the item (hierarchical list) or the row number (list box, list forms and subform in “multiple selection” mode) to change to editing mode. If you do not pass this parameter, the command is applied to the current item for *object*. If there is no current item, the first item of *object* changes to editing mode.

**Notes:**

- In subforms and list forms, the command changes the first field of a specified row to edit mode, in the order of entry.
- In listboxes displayed in hierarchical mode, if the targeted item belongs to a hierarchical level that is collapsed, this level (as well as any parent levels) will be expanded automatically so that the item is visible.

## Example 1

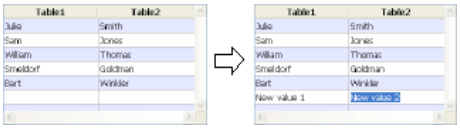
This command can be particularly useful when creating a new item in a hierarchical list. When the command is called, the last item added or inserted in the list automatically becomes editable without the user having to do anything.
The following code may be the method of a button that allows you to insert a new item in an existing list. The default text “New_item” is automatically ready to be changed:

```
vlUniqueRef:=vlUniqueRef+1
INSERT IN LIST(hList;*;"New_item";vlUniqueRef)
EDIT ITEM(*;"MyList")
```

## Example 2

Given two columns in a list box whose variable names are “Array1” and “Array2” respectively. The following example inserts a new item in the two arrays and passes the new item of Array2 into editing mode:

```
$vlRowNum:=Size of array(Array1)+1
LISTBOX INSERT ROWS(*;"MyListBox";$vlRowNum)
Array1{$vlRowNum}:="New value 1"
Array2{$vlRowNum}:="New value 2"
EDIT ITEM(Array2;$vlRowNum)
```



# FILTER KEYSTROKE

FILTER KEYSTROKE ( filteredChar )

| Parameter | Type | | Description |
|---|---|---|---|
| filteredChar | String | ⇒ | Filtered keystroke character or Empty string to cancel the keystroke |

## Description

**FILTER KEYSTROKE** enables you to replace the character entered by the user into a field or an enterable area with the first character of the string *filteredChar* you pass.

If you pass an empty string, the keystroke is cancelled and ignored.

Usually, you will call **FILTER KEYSTROKE** within a form or object method while handling an On Before Keystroke form event. To detect keystroke events, use the command **Form event**. To obtain the actual keystroke, use the commands **Keystroke** or **Get edited text**.

**IMPORTANT NOTE:** The command **FILTER KEYSTROKE** allows you to cancel or replace the character entered by the user with another character. On the other hand, if you want to insert more than one character for a specific keystroke, remember that the text you see on the screen is NOT YET the value of the data source field or variable for the area being edited. The data source field or variable is assigned the entered value after the data entry for the area is validated. It is therefore up to you to "shadow" the data entry into a variable and then to work with this shadow value and reassign the enterable area (see the example in this section). You can also use the **Get edited text** command.

You will use the command **FILTER KEYSTROKE** for:

- Filtering characters in a customized way
- Filtering data entry in a way that you cannot produce using data entry filters
- Implement dynamic lookup or autocomplete areas

**WARNING:** If you call the command **Keystroke** after calling **FILTER KEYSTROKE**, the character you pass to this command is returned instead of the character actually entered.

## Example 1

Using the following code:

```
 //myObject enterable area object method
Case of
   :(Form event=On Load)
      myObject:=""
   :(Form event=On Before Keystroke)
      If(Position(Keystroke;"0123456789")>0)
         FILTER KEYSTROKE("*")
      End if
End case
```

All the digits entered in the area *myObject* are transformed into star characters.

## Example 2

This code implements the behavior of a Password enterable area in which all the entered characters are replaced (on the screen) by random characters:

```
 //vsPassword enterable area object method
Case of
   :(Form event=On Load)
      vsPassword:=""
      vsActualPassword:=""
   :(Form event=On Before Keystroke)
      Handle keystroke(->vsPassword;->vsActualPassword)
      If(Position(Keystroke;Char(Backspace)+Char(Left arrow key)+Char(Right arrow key)+Char(Up arrow key)+Char(Down arrow
```

```
key))=0)
         FILTER KEYSTROKE(Char(65+(Random%26)))
      End if
End case
```

After the data entry is validated, you retrieve the actual password entered by the user in the variable *vsActualPassword*.
Note: The method **Handle keystroke** is listed in the Example section for the command **Keystroke.**

## Example 3

In your application, you have some text areas into which you can enter a few sentences. Your application also includes a dictionary table of terms commonly used throughout your database. While editing your text areas, you would like to be able to quickly retrieve and insert dictionary entries based on the selected characters in a text area. You have two ways to do this:
- Provide some buttons with associated keys, or
- Intercept special keystrokes during the editing of the text area

This example implements the second solution, based on the Help key.

As explained above, during the editing of the text area, the data source for this area will be assigned the entered value after you validate the data entry. In order to retrieve and insert dictionary entries into the text area while this area is being edited, you therefore need to shadow the data entry. You pass pointers to the enterable area and the shadow variable as the first two parameters, and you pass a string of the “forbidden” characters as the third parameter. No matter how the keystroke will be treated, the method returns the original keystroke. The “forbidden” characters are those that you do not want to be inserted into the enterable area and you want to treat as special characters.

```
  ` Shadow keystroke project method
  ` Shadow keystroke ( Pointer ; Pointer ; String ) -> String
  ` Shadow keystroke ( -> srcArea ; -> curValue ; Filter ) -> Old keystroke
C_STRING(1;$0)
C_POINTER($1;$2)
C_TEXT($vtNewValue)
C_STRING(255;$3)
  ` Return the original keystroke
$0:=Keystroke
  ` Get the text selection range within the enterable area
GET HIGHLIGHT($1->;$vlStart;$vlEnd)
  ` Start working with the current value
$vtNewValue:=$2->
  ` Depending on the key pressed or the character entered,
  ` Perform the appropriate actions
Case of
  ` The Backspace (Delete) key has been pressed
   :(Character code($0)=Backspace)
  ` Delete the selected characters or the character at the left of the text cursor
      $vtNewValue:=Delete text($vtNewValue;$vlStart;$vlEnd)
  ` An Arrow key has been pressed
  ` Do nothing, but accept the keystroke
   :(Character code($0)=Left arrow key)
   :(Character code($0)=Right arrow key)
   :(Character code($0)=Up arrow key)
   :(Character code($0)=Down arrow key)

  ` An acceptable character has been entered
   :(Position($0;$3)=0)
      $vtNewValue:=Insert text($vtNewValue;$vlStart;$vlEnd;$0)
   Else
  ` The character is not accepted
      FILTER KEYSTROKE("")
End case
  ` Return the value for the next keystroke handling
$2->:=$vtNewValue
```

This method uses the two following submethods:

```
  ` Delete text project method
  ` Delete text ( String ; Long ; Long ) -> String
  ` Delete text ( -> Text ; SelStart ; SelEnd ) -> New text
```

```
C_TEXT($0;$1)
C_LONGINT($2;$3)
$0:=Substring($1;1;$2-1-Num($2=$3))+Substring($1;$3)

 ` Insert text project method
 ` Insert text ( String ; Long ; Long ; String ) -> String
 ` Insert text ( -> srcText ; SelStart ; SelEnd ; Text to insert ) -> New text
C_TEXT($0;$1;$4)
C_LONGINT($2;$3)
$0:=$1
If($2#$3)
   $0:=Substring($0;1;$2-1)+$4+Substring($0;$3)
Else
   Case of
      :($2<=1)
         $0:=$4+$0
      :($2>Length($0))
         $0:=$0+$4
      Else
         $0:=Substring($0;1;$2-1)+$4+Substring($0;$2)
   End case
End if
```

After you have added these project methods to your project, you can use them in this way:

```
 ` vsDescription enterable area object method
Case of
   :(Form event=On Load)
      vsDescription:=""
      vsShadowDescription:=""
 ` Establish the list of the "forbidden" characters to be treated as special keys
 ` ( here, in this example, only the Help Key is filtered)
      vsSpecialKeys:=Char(HelpKey)
   :(Form event=On Before Keystroke)
      $vsKey:=Shadow keystroke(->vsDescription;->vsShadowDescription;vsSpecialKeys)
      Case of
         :(Character code($vsKey)=Help key)
 ` Do something when the Help key is pressed
 ` Here, in this example, a Dictionary entry must be searched and inserted
            LOOKUP DICTIONARY(->vsDescription;->vsShadowDescription)
      End case
End case
```

The **LOOKUP DICTIONARY** project method is listed below. Its purpose is to use the shadow variable for reassigning the enterable area being edited:

```
 ` LOOKUP DICTIONARY project method
 ` LOOKUP DICTIONARY ( Pointer ; Pointer )
 ` LOOKUP DICTIONARY ( -> Enterable Area ; ->ShadowVariable )

C_POINTER($1;$2)
C_LONGINT($vlStart;$vlEnd)

 ` Get the text selection range within the enterable area
GET HIGHLIGHT($1->;$vlStart;$vlEnd)
 ` Get the selected text or the word on the left of the text cursor
$vtHighlightedText:=Get highlighted text($2->;$vlStart;$vlEnd)
 ` Is there something to look for?
If($vtHighlightedText#"")
 ` If the text selection was the text cursor,
 ` the selection now starts at the word preceeding the text cursor
   If($vlStart=$vlEnd)
      $vlStart:=$vlStart-Length($vtHighlightedText)
   End if
 ` Look for the first avaliable dictionary entry
   QUERY([Dictionary];[Dictionary]Entry=$vtHighlightedText+"@")
 ` Is there one?
   If(Records in selection([Dictionary])>0)
 ` If so, insert it in the shadow text
```

```
      $2->:=Insert text($2->;$vlStart;$vlEnd;[Dictionary]Entry)
   ` Copy the shadow text to the enterable being edited
      $1->:=$2->
   ` Set the selection just after the insert dictionary entry
      $vlEnd:=$vlStart+Length([Dictionary]Entry)
      HIGHLIGHT TEXT(vsComments;$vlEnd;$vlEnd)
   Else
   ` There is no corresponding entry in the Dictionary
      BEEP
   End if
Else
   ` There is no highlighted text
   BEEP
End if
```

The **Get highlighted text** method is listed here:

```
   ` Get highlighted text project method
   ` Get highlighted text ( String ; Long ; Long ) -> String
   ` Get highlighted text ( Text ; SelStart ; SelEnd ) -> highlighted text
C_TEXT($0;$1)
C_LONGINT($2;$3)
If($2<$3)
   $0:=Substring($1;$2;$3-$2)
Else
   $0:=""
   $2:=$2-1
   Repeat
      If($2>0)
         If(Position($1≤$2≥;" ,.!?:;()-_--")=0)
            $0:=$1≤$2≥+$0
            $2:=$2-1
         Else
            $2:=0
         End if
      End if
   Until($2=0)
End if
```

# Get edited text

Get edited text -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Text | Text being entered |

## Description

The **Get edited text** command is mainly to be used with the form event On After Keystroke to retrieve the text as it is being entered. It can also be used with the On Before Keystroke form event. For more information about those form events, please refer to the description of the command **Form event**.

The combination of this command with On Before Keystroke and On After Keystroke form events works as follows:

- As soon as a character is typed on the keyboard, the On Before Keystroke event is generated. In this case, the **Get edited text** function returns the contents of the area before the last keystroke occurred. For example, if the area contains "PA" and the user types an "R", **Get edited text** returns "PA" in the On Before Keystroke event. If the area is empty initially, **Get edited text** returns an empty string.
- Next, the On After Keystroke form event is generated. In this case, **Get edited text** returns the contents of the area including the last character entered on the keyboard. For example, when the area contains "PA" and the user types an "R", **Get edited text** returns "PAR" in the On After Keystroke event.

These two events are only generated in the object methods concerned.

When used in a context other than text entry in a form object, this function returns an empty string.

## Example 1

The following method automatically puts the characters being entered in capitals:

```
If(Form event=On After Keystroke)
   [Trips]Agencies:=Uppercase(Get edited text)
End if
```

## Example 2

Here is an example of how to process on the fly characters entered in a text field. The idea consists of placing in another text field (called "Words") all the words of the sentence being entered. To do so, write the following code in the object method of the field:

```
If(Form event=On After Keystroke)
   $RealTimeEntry:=Get edited text
   PLATFORM PROPERTIES($platform)
   If($platform#3) ` Mac OS
      Repeat
         $DecomposedSentence:=Replace string($RealTimeEntry;Char(32);Char(13))
      Until(Position(" ";$DecomposedSentence)=0)
   Else ` Windows
      Repeat
         $DecomposedSentence:=Replace string($RealTimeEntry;Char(32);Char(13)+Char(10))
      Until(Position(" ";$DecomposedSentence)=0)
   End if
   [Example]Words:=$DecomposedSentence
End if
```

**Note:** This example is not comprehensive because we have assumed that words are separated uniquely by spaces (Char (32)). For a complete solution you will need to add other filters to extract all the words (delimited by commas, semi-colons, apostrophes, etc.).

# GET HIGHLIGHT

GET HIGHLIGHT ( {* ;} object ; startSel ; endSel )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Field, Variable, Form object | ➡ | Object name (if * is specified) or Field or variable (if * is omitted) |
| startSel | Longint | ⬅ | Current text selection starting position |
| endSel | Longint | ⬅ | Current text selection ending position |

## Description

The **GET HIGHLIGHT** command is used to determine what text is currently highlighted in *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass the * parameter, you indicate that the *object* parameter is a field or variable. In this case, you pass the field or variable reference (form fields or variables only) instead of a string.

**Note:** This command cannot be used with fields in the List form of a subform.

Text can be highlighted by the user or by the **HIGHLIGHT TEXT** command.

The parameter *startSel* returns the position of the first highlighted character.

The parameter *endSel* returns the position of the last highlighted character plus one.

If *startSel* and *endSel* are returned equal, the insertion point is positioned before the character specified by *startSel*. The user has not selected any text, and no characters are highlighted.

If the object designated by the *object* parameter is not found in the form, the command returns -1 in *startSel* and -2 in *endSel*.

## Example 1

The following example gets the highlighted selection from the field called *[Products]Comments*:

```
GET HIGHLIGHT([Products]Comments;vFirst;vLast)
If(vFirst<vLast)
   ALERT("The selected text is: "+Substring([Products]Comments;vFirst;vLast-vFirst))
End if
```

## Example 2

See example for the **FILTER KEYSTROKE** command.

## Example 3

Modification of highlighted text style:

```
GET HIGHLIGHT(*;"myText";$startsel,$endsel)
ST SET ATTRIBUTES(*;"myText";$startsel,$endsel;Attribute underline style;1;Attribute bold style;1)
```

# GOTO OBJECT

GOTO OBJECT ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified = object is an object name (string) If omitted = object is a field or a variable |
| object | Field, Variable | ⇒ | Object name (if * specified) or Field or Variable (if * omitted) to go to |

## Description

The **GOTO OBJECT** command is used to select the data entry object *object* as the active area of the form. It is equivalent to the user's clicking on or tabbing into the field or variable.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the section **Object Properties**.

To remove any focus in the current form, call the command while passing an empty object name in *object* (see example 2).

The **GOTO OBJECT** command can be used in the context of a subform. When it is called from a subform, it first looks for the object in the subform, then, if the search does not find anything there, it extends the search to objects of the parent form.

## Example 1

The **GOTO OBJECT** command can be used in both ways:

```
GOTO OBJECT([People]Name) ` Field Reference
GOTO OBJECT(*;"AgeArea") ` Object Name
```

## Example 2

You don't want any object of the form to have the focus:

```
GOTO OBJECT(*;"")
```

## Example 3

See the example for the **REJECT** command.

# HIGHLIGHT TEXT

HIGHLIGHT TEXT ( {* ;} object ; startSel ; endSel )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Field, Variable, Form object | ⇒ | Object name (if * is specified) or Enterable field or variable (if * is omitted) |
| startSel | Longint | ⇒ | New text selection starting position |
| endSel | Longint | ⇒ | New text selection ending position |

## Description

The **HIGHLIGHT TEXT** command highlights a section of the text in *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass the * parameter, you indicate that the *object* parameter is a field or variable. In this case, you pass the field or variable reference (form fields or variables only) instead of a string.

If *object* is not the object currently being edited, it gets the focus.

**Note:** This command cannot be used with fields in a subform.

*startSel* is the first character position to be highlighted, and *lastSel* is the last character plus one to be highlighted. If *startSel* and *lastSel* are equal, the insertion point is positioned before the character specified by *startSel*, and no characters are highlighted.

If *lastSel* is greater than the number of characters in *object*, then all characters between *startSel* and the end of the text are highlighted.

## Example 1

The following example selects all the characters of the enterable field *[Products]Comments*:

```
HIGHLIGHT TEXT([Products]Comments;1;Length([Products]Comments)+1)
```

## Example 2

The following example moves the insertion point to the beginning of the enterable field *[Products]Comments*:

```
HIGHLIGHT TEXT([Products]Comments;1;1)
```

## Example 3

The following example moves the insertion point to the end of the enterable field *[Products]Comments*:

```
$vLen:=Length([Products]Comments)+1
HIGHLIGHT TEXT([Products]Comments;$vLen;$vLen)
```

## Example 4

See example for the **FILTER KEYSTROKE** command.

# Keystroke

Keystroke -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | String | Character entered by user |

## Description

**Keystroke** returns the character entered by the user into a field or an enterable area.

Usually, you will call **Keystroke** within a form or object method while handling an On Before Keystroke or On After Keystroke form event. To detect keystroke events, use the command **Form event**.

To replace the character actually entered by the user with another character, use the command **FILTER KEYSTROKE**.

**Note:** The **Keystroke** function does not work in subforms.

**IMPORTANT NOTE:** If you want to perform some "on the fly" operations depending on the current value of the enterable area being edited, as well as the new character to be entered, remember that the text you see on screen is NOT YET the value of the data source field or variable for the area being edited. The data source field or variable is assigned the entered value after the data entry for the area is validated (e.g., tabulation to another area, click on a button, and so on). It is therefore up to you to "shadow" the data entry into a variable and then to work with this shadow value. You must do so if you need to know the current text value for executing any particular actions. You can also use the function **Get edited text**.

You will use the command **Keystroke** for:

- Filtering characters in a customized way
- Filtering data entry in a way that you cannot produce using data entry filters
- Implement dynamic lookup or autocomplete areas

## Example 1

See examples for the **FILTER KEYSTROKE** command.

## Example 2

When you process an On Before Keystroke event, you are dealing with the editing of the current text area (the one where the cursor is), not with the "future value" of the data source (field or variable) for this area. The ***Handle keystroke*** project method allows to shadow any text area data entry into a second variable, which you can use to perform the actions while entering characters into the area. You pass a pointer to the area's data source as the first parameter and a pointer to the shadow variable as second parameter. The method returns the new value of the text area in the shadow variable, and returns **True** if the value is different from it what was before the last entered character was inserted.

```
  ` Handle keystroke project method
  ` Handle keystroke ( Pointer ; Pointer ) -> Boolean
  ` Handle keystroke ( -> srcArea ; -> curValue ) -> Is new value

C_POINTER($1;$2)
C_TEXT($vtNewValue)

  ` Get the text selection range within the enterable area
GET HIGHLIGHT($1->;$vlStart;$vlEnd)
  ` Start working with the current value
$vtNewValue:=$2->
  ` Depending on the key pressed or the character entered,
  ` Perform the appropriate actions
Case of

  ` The Backspace (Delete) key has been pressed
   :(Character code(Keystroke)=Backspace)
  ` Delete the selected characters or the character at the left of the text cursor
      $vtNewValue:=Substring($vtNewValue;1;$vlStart-1-Num($vlStart=$vlEnd))
      +Substring($vtNewValue;$vlEnd)
```

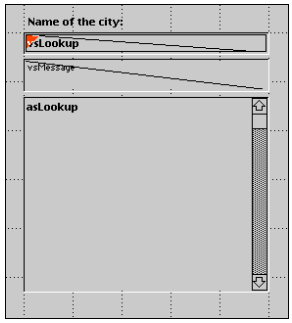
```
   ` An acceptable character has been entered
    :(Position(Keystroke;"abcdefghjiklmnopqrstuvwxyz -0123456789")>0)
       If($vlStart#$vlEnd)
   ` One or several characters are selected, the keystroke is going to override them
          $vtNewValue:=Substring($vtNewValue;1;$vlStart-1)
          +Keystroke+Substring($vtNewValue;$vlEnd)
       Else
   ` The text selection is the text cursor
          Case of
   ` The text cursor is currently at the begining of the text
             :($vlStart<=1)
   ` Insert the character at the begining of the text
                $vtNewValue:=Keystroke+$vtNewValue
   ` The text cursor is currently at the end of the text
             :($vlStart>=Length($vtNewValue))
   ` Append the character at the end of the text
                $vtNewValue:=$vtNewValue+Keystroke
             Else
   ` The text cursor is somewhere in the text, insert the new character
                $vtNewValue:=Substring($vtNewValue;1;$vlStart-1)+Keystroke
                +Substring($vtNewValue;$vlStart)
          End case
       End if

   ` An Arrow key has been pressed
   ` Do nothing, but accept the keystroke
    :(Character code(Keystroke)=Left arrow key)
    :(Character code(Keystroke)=Right arrow key)
    :(Character code(Keystroke)=Up arrow key)
    :(Character code(Keystroke)=Down arrow key)
   `
    Else
   ` Do not accept characters other than letters, digits, space and dash
       FILTER KEYSTROKE("")
End case
   ` Is the value now different?
$0:=($vtNewValue#$2->)
   ` Return the value for the next keystroke handling
$2->:=$vtNewValue
```

After this project method is added to your application, you can use it as follows:

```
   ` myObject enterable area object method
Case of
   :(Form event=On Load)
      MyObject:=""
      MyShadowObject:=""
   :(Form event=On Before Keystroke)
      If(Handle keystroke(->MyObject;->MyShadowObject))
   ` Perform appropriate actions using the value stored in MyShadowObject
      End if
End case
```

Let's examine the following part of a form:

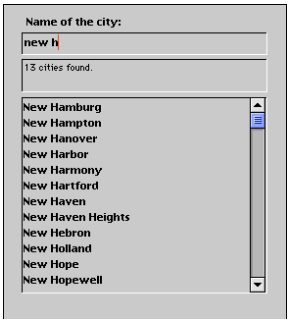


It is composed of the following objects: an enterable area *vsLookup*, a non-enterable area *vsMessage*, and a scrollable area *asLookup*. While entering characters in *vsLookup*, the method for that object performs a query on a [US Zip Codes] table, allowing the user to find US cities by typing only the first characters of the city names.

The *vsLookup* object method is listed here:

```
   ` vsLookup enterable area object method
Case of
   :(Form event=On Load)
      vsLookup:=""
      vsResult:=""
      vsMessage:="Enter the first characters of the city you are looking for."
      CLEAR VARIABLE(asLookup)
   :(Form event=On Before Keystroke)
      If(Handle keystroke(->vsLookup;->vsResult))
         If(vsResult#"")
            QUERY([US Zip Codes];[US Zip Codes]City=vsResult+"@")
            MESSAGES OFF
            DISTINCT VALUES([US Zip Codes]City;asLookup)
            MESSAGES ON
            $vlResult:=Size of array(asLookup)
            Case of
               :($vlResult=0)
                  vsMessage:="No city found."
               :($vlResult=1)
                  vsMessage:="One city found."
               Else
                  vsMessage:=String($vlResult)+" cities found."
            End case
         Else
            DELETE FROM ARRAY(asLookup;1;Size of array(asLookup))
            vsMessage:="Enter the first characters of the city you are looking for."
         End if
      End if
End case
```

Here is the form being executed:



Using the interprocess communication capabilities of 4D, you can similarily build user interfaces in which Lookup features are provided in floating windows that communicate with processes in which records are listed or edited.

# Form Events

- Activated
- After
- Before
- CALL SUBFORM CONTAINER
- Clickcount
- Contextual click
- Deactivated
- Form event Updated 16.0
- In break
- In footer
- In header
- Is waiting mouse up New 16.0
- Outside call
- Right click
- SET TIMER
- *_o_During*

# Activated

Activated -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Returns TRUE if the execution cycle is an activation |

## Description

The **Activated** command (obsolete) returns **True** in a form method when the window containing the form becomes the frontmost window of the frontmost process.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Activate event.

**WARNING:** Do not place a command such as **TRACE** or **ALERT**in the **Activated** phase of the form, as this will cause an endless loop.

**Note:** In order for the **Activated** execution cycle to be generated, make sure that the On Activate event property of the form has been selected in the Design environment.

# After

After -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | Returns True if the execution cycle is an after |

## Description

**After** returns True for the After execution cycle.

In order for the **After** execution cycle to be generated, make sure that the On Validate event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Validate event.

# Before

Before -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Returns True if the execution cycle is a before |

## Description

**Before** returns True for the Before execution cycle.

In order for the **Before** execution cycle to be generated, make sure that the On Load event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Load event.

# CALL SUBFORM CONTAINER

CALL SUBFORM CONTAINER ( event )

| Parameter | Type | | Description |
|---|---|---|---|
| event | Longint | ⇨ | Event to be sent |

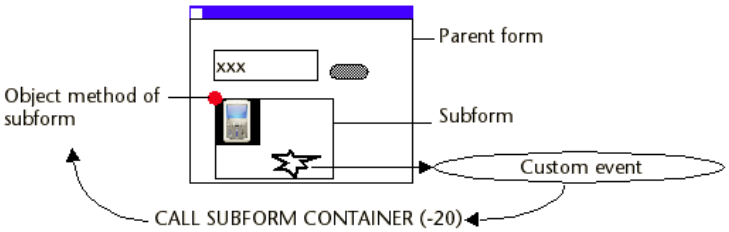
## Description

The **CALL SUBFORM CONTAINER** command lets a subform instance send the *event* to the subform object that contains it. The subform object can then process the *event* in the context of the parent form.

This command must be placed in the form method of the subform or in the object method of one of the subform objects. The event will only be received in the object method of the subform container.

In *event*, you can pass any predefined form event of 4D (you can use the constants of the "**Form Events**" theme) or any value corresponding to a custom event. In the first case, the event must be checked for the subform. In the case of a custom event, it is recommended to pass a negative value in *event* in order to avoid the risk of interfering with existing or future 4D event numbers.

*Example of execution of the* **CALL SUBFORM CONTAINER** *command:*



# Clickcount

Clickcount -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Longint | Number of consecutive clicks |

## Description

The **Clickcount** command returns, in the context of a mouse click event, the number of times the user has clicked in rapid succession with the same mouse button. Typically, this command returns 2 for a double-click.

This command allows you to detect double-clicks in listbox headers or footers, and also to handle sequences of triple-clicks or more.

Every mouse button click generates a separate click event. For example, if a user double-clicks, an event is sent for the first click in which **Clickcount** returns 1; then another event is sent for the second click in which **Clickcount** returns 2.

This command must only be used in the context of On Clicked, On Header Click or On Footer Click form events. It is therefore necessary to check in Design mode that the appropriate event has been properly selected in the Form properties and/or for the specific object.

When both On Clicked and On Double Clicked form events are enabled, the following sequence will be returned by **Clickcount**:

- 1 in On Clicked event
- 2 in On Double Clicked event
- 2+n in On Clicked event

## Example 1

The following code structure can be placed in a listbox header to handle single- and double-clicks:

```
Case of
   :(Form event=On Header Click)
      Case of
         :(Clickcount=1)
            ... //single-click action
         :(Clickcount=2)
            ... //double-click action
      End case
End case
```

## Example 2

Labels are not enterable but they become so after a triple-click. If you want to allow users to edit labels, you can write the following in the object method:

```
If(Form event=On Clicked)
   Case of
      :(Clickcount=3)
         OBJECT SET ENTERABLE(*;"Label";True)
         EDIT ITEM(*;"Label")
   End case
End if
```

# Contextual click

Contextual click -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | True if a contextual click was detected, otherwise False |

## Description

The **Contextual click** command returns True if a contextual click has been made:

- Under Windows and Mac OS, contextual clicks are made using the right button of the mouse.
- Under Mac OS, contextual clicks can also be made using a **Control+click** combination.

This command should be used only in the context of the On Clicked form event. It is therefore necessary to verify in Design mode that the event has been properly selected in the Form properties and/or in the specific object.

## Example

This method, combined with a scrollable area, enables you to change the value of an array element using a context menu:

```
If(Contextual click)
   If(Pop up menu("True:False")=1)
      myArray{myArray}:="True"
   Else
      myArray{myArray}:="False"
   End if
End if
```

# Deactivated

Deactivated -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Returns TRUE if the execution cycle is a deactivation |

## Description

The **Deactivated** command returns True in a form or object method when the frontmost window of the frontmost process, containing the form, moves to the back.

In order for the **Deactivated** execution cycle to be generated, make sure that the On Deactivate event property of the form and/or the objects has been selected in Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Deactivate event.

# Form event

Form event -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Form event number |

## Description

**Form event** returns a numeric value identifying the type of form event that has just occurred. Usually, you will use **Form event** from within a form or object method.

4D provides predefined constants (found in the **Form Events** theme) in order to compare the values returned by the **Form event** command.

Certain events are generic (generated for any type of object) and others are specific to a particular type of object.

| Constant | Type | Value | Comment |
|---|---|---|---|
| On Load | Longint | 1 | The form is about to be displayed or printed |
| On Mouse Up | Longint | 2 | (*Pictures only*) The user has just released the left mouse button in a Picture object |
| On Validate | Longint | 3 | The record data entry has been validated |
| On Clicked | Longint | 4 | A click occurred on an object |
| On Header | Longint | 5 | The form's header area is about to be printed or displayed |
| On Printing Break | Longint | 6 | One of the form's break areas is about to be printed |
| On Printing Footer | Longint | 7 | The form's footer area is about to be printed |
| On Display Detail | Longint | 8 | A record is about to be displayed in a list or a row is about to be displayed in a list box. |
| On Outside Call | Longint | 10 | The form received a **CALL PROCESS** call |
| On Activate | Longint | 11 | The form's window becomes the frontmost window |
| On Deactivate | Longint | 12 | The form's window ceases to be the frontmost window |
| On Double Clicked | Longint | 13 | A double click occurred on an object |
| On Losing Focus | Longint | 14 | A form object is losing the focus |
| On Getting Focus | Longint | 15 | A form object is getting the focus |
| On Drop | Longint | 16 | Data has been dropped onto an object |
| On Before Keystroke | Longint | 17 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text without this character. |
| On Menu Selected | Longint | 18 | A menu item has been chosen |
| On Plug in Area | Longint | 19 | An external object requested its object method to be executed |
| On Data Change | Longint | 20 | Object data has been modified |
| On Drag Over | Longint | 21 | Data could be dropped onto an object |
| On Close Box | Longint | 22 | The window's close box has been clicked |
| On Printing Detail | Longint | 23 | The form's detail area is about to be printed |
| On Unload | Longint | 24 | The form is about to be exited and released |
| On Open Detail | Longint | 25 | The detail form associated with the output form or with the listbox is about to be opened |
| On Close Detail | Longint | 26 | You left the detail form and are going back to the output form |
| On Timer | Longint | 27 | The number of ticks defined by the **SET TIMER** command has passed |
| On After Keystroke | Longint | 28 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text including this character. |
| On Resize | Longint | 29 | The form window is resized |
| On After Sort | Longint | 30 | (*List box only*) A standard sort has just been carried out in a list box column |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| On Selection Change | Longint | 31 | • *List box*: The current selection of rows or columns is modified<br>• *Records in list*: The current record or the current selection of rows is modified in a list form or subform<br>• *Hierarchical list*: The selection in the list is modified following a click or a keystroke<br>• *Enterable field or variable*: The text selection or the position of the cursor in the area is modified following a click or a keystroke |
| On Column Moved | Longint | 32 | (*List box only*) A list box column is moved by the user via drag and drop |
| On Column Resize | Longint | 33 | (*List box only*) The width of a list box column is modified by a user with the mouse |
| On Row Moved | Longint | 34 | (*List box only*) A list box row is moved by the user via drag and drop |
| On Mouse Enter | Longint | 35 | The mouse cursor enters the graphic area of an object |
| On Mouse Leave | Longint | 36 | The mouse cursor leaves the graphic area of an object |
| On Mouse Move | Longint | 37 | The mouse cursor moves at least one pixel OR a modifier key (Shift, Alt, Shift Lock) was pressed. If the event is checked for an object only, it is generated only when the cursor is within the graphic area of the object |
| On Alternative Click | Longint | 38 | • *3D buttons*: The “arrow” area of a 3D button is clicked<br>• *List boxes*: In a column of an object array, an ellipsis button ("alternateButton" attribute) is clicked<br>**Note**: Ellipsis buttons are only available for versions v15 or higher. |
| On Long Click | Longint | 39 | (*3D buttons only*) A 3D button is clicked and the mouse button remains pushed for a certain lapse of time |
| On Load Record | Longint | 40 | During entry in list, a record is loaded during modification (the user clicks on a record line and a field changes to editing mode) |
| On Before Data Entry | Longint | 41 | (*List box only*) A list box cell is about to change to editing mode |
| On Header Click | Longint | 42 | (*List box only*) A click occurs in a column header of the list box |
| On Expand | Longint | 43 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been expanded using a click or a keystroke |
| On Collapse | Longint | 44 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been collapsed using a click or a keystroke |
| On After Edit | Longint | 45 | The contents of the enterable object that has the focus has just been modified |
| On Begin Drag Over | Longint | 46 | An object is being dragged |
| On Begin URL Loading | Longint | 47 | (*Web areas only*) A new URL is loaded in the Web area |
| On URL Resource Loading | Longint | 48 | (*Web areas only*) A new resource is loaded in the Web area |
| On End URL Loading | Longint | 49 | (*Web areas only*) All the resources of the URL have been loaded |
| On URL Loading Error | Longint | 50 | (*Web areas only*) An error occurred when the URL was loading |
| On URL Filtering | Longint | 51 | (*Web areas only*) A URL was blocked by the Web area |

| Constant | Type | Value | Comment |
|---|---|---|---|
| On Open External Link | Longint | 52 | (*Web areas only*) An external URL has been opened in the browser |
| On Window Opening Denied | Longint | 53 | (*Web areas only*) A pop-up window has been blocked |
| On bound variable change | Longint | 54 | The variable bound to a subform is modified. |
| _o_On Mac toolbar button | Longint | 55 | *** Obsolete constant *** |
| On Page Change | Longint | 56 | The current page of the form is changed |
| On Footer Click | Longint | 57 | (*List boxes only*) A click occurs in the footer of a list box or a list box column |
| On Delete Action | Longint | 58 | (*Hierarchical lists and List boxes*) The user attempts to delete an item |
| On Scroll | Longint | 59 | The user scrolls the contents of a picture field or variable using the mouse or keyboard. |

**Note:** The events specific to output forms cannot be used with **project forms**. This includes: On Display Detail, On Open Detail, On Close Detail, On Load Record, On Header, On Printing Detail, On Printing Break, On Printing Footer.

## Events and Methods

When a form event occurs, 4D performs the following actions:

- First, it browses the objects of the form and calls the object method for any object (involved in the event) whose corresponding object event property has been selected.
- Second, it calls the form method if the corresponding form event property has been selected.

Do not assume that the object methods, if any, will be called in a particular order. The rule of thumb is that the object methods are always called before the form method. If an object is a subform, the object methods of the subform's list form are called, then the form method of the list form is called. 4D then continues to call the object methods of the parent form. In other words, when an object is a subform, 4D uses the same rule of thumb for the object and form methods within the subform object.

Except for the On Load and On Unload events, if the form event property is not selected for a given event, this does not prevent calls to object methods for the objects whose same event property is selected. In other words, enabling or disabling an event at the form level has no effect on the object event properties.

The number of objects involved in an event depends on the nature of the event:

- On Load event - All the objects of the form (from any page) whose On Load object event property is selected will have their object method called. Then, if the On Load form event property is selected, the form will have its form method called.
- On Activate or On Resize event - No object method will be called, because this event applies to the form as a whole and not to a particular object. Consequently, if the On Activate form event property is selected, only the form will have its form method called.
- On Timer event - This event is generated only if the form method contains a previous call to the **SET TIMER** command. If the On Timer form event property is selected, only the form method will receive the event, no object method will be called.
- On Drag Over event - Only the droppable object involved in the event will have its object method called if the "Droppable" event property is selected for it. The form method will not be called.
- Conversely, for the On Begin Drag Over event, the object method or form method of the object being dragged will be called (if the "Draggable" event property is selected for the it).

**WARNING:** Unlike all other events, during a On Begin Drag Over event, the method called is executed in the context of the process of the drag and drop source object, not in that of the drag and drop destination object. For more information, see the **Drag and Drop** section.

- If the On Mouse Enter, On Mouse Move and On Mouse Leave events have been checked for the form, they are generated for each form object. If they are checked for an object, they are generated only for that object. When there are superimposed objects, the event is generated by the first object capable of managing it that is found going in order from top level to bottom. Objects that are made invisible using the **OBJECT SET VISIBLE** command do not generate these events. During object entry, other objects may receive these type of events depending on the position of the mouse.
  Note that the On Mouse Move event is generated not only when the mouse cursor is moved but also when the user presses a modifier key such as **Shift**, **Shift Lock**, **Ctrl** or **Option** (this makes it possible to manage copy- or move-type drag-and-drop operations).

- Records in list: The sequence of calls to methods and form events in the list forms displayed via **DISPLAY SELECTION** and **MODIFY SELECTION** and the subforms is as follows:
  For each object in the header area:
    - Object method with On Header event
    - Form method with On Header event

  For each record:
    - For each object in the detail area:
      - Object method with On Display Detail event
    - Form method with On Display Detail event

- Calling a 4D command that displays a dialog box from the On Display Detail and On Header events is not allowed and will cause a syntax error to occur. More particularly, the commands concerned are: **ALERT**, **DIALOG**, **CONFIRM**, **Request**, **ADD RECORD**, **MODIFY RECORD**, **DISPLAY SELECTION** and **MODIFY SELECTION**.
- On Page Change: This event is only available at the form level (it is called in the form method). It is generated each time the current page of the form changes (following a call to the **FORM GOTO PAGE** command or a standard navigation action). Note that it is generated after the page is fully loaded, i.e. once all the objects it contains are initialized (including Web areas). This event is useful for executing code that requires all objects to be initialized beforehand. You can also use it to optimize the application by executing code (for example, a search) only after a specific page of the form is displayed and not just as soon as page 1 is loaded. If the user does not go to this page, the code is not executed .

The following table summarizes how object and form methods are called for each event type:

| Event | Object Methods | Form Method | Which Objects |
|---|---|---|---|
| On Load | Yes | Yes | All objects |
| On Unload | Yes | Yes | All objects |
| On Validate | Yes | Yes | All objects |
| On Clicked | Yes (if clickable or enterable) (*) | Yes | Involved object only |
| On Double Clicked | Yes (if clickable or enterable) (*) | Yes | Involved object only |
| On Before Keystroke | Yes (if enterable) (*) | Yes | Involved object only |
| On After Keystroke | Yes (if enterable) (*) | Yes | Involved object only |
| On After Edit | Yes (if enterable) (*) | Yes | Involved object only |
| On Getting Focus | Yes (if tabbable) (*) | Yes | Involved object only |
| On Losing Focus | Yes (if tabbable) (*) | Yes | Involved object only |
| On Activate | Never | Yes | None |
| On Deactivate | Never | Yes | None |
| On Outside Call | Never | Yes | None |
| On Page Change | Never | Yes | None |
| On Begin Drag Over | Yes (if draggable) (**) | Yes | Involved object only |
| On Drop | Yes (if droppable) (**) | Yes | Involved object only |
| On Drag Over | Yes (if droppable) (**) | Never | Involved object only |
| On Mouse Enter | Yes | Yes | All objects |
| On Mouse Move | Yes | Yes | All objects |
| On Mouse Leave | Yes | Yes | All objects |
| On Mouse Up | Yes | Never | Involved object only |
| On Menu Selected | Never | Yes | None |
| On Bound variable change | Never | Yes | None |
| On Data Change | Yes (if modifiable) (*) | Yes | Involved object only |
| On Plug in Area | Yes | Yes | Involved object only |
| On Header | Yes | Yes | All objects |
| On Printing Detail | Yes | Yes | All objects |
| On Printing Break | Yes | Yes | All objects |
| On Printing Footer | Yes | Yes | All objects |
| On Close Box | Never | Yes | None |
| On Display Detail | Yes | Yes | All objects |
| On Open Detail | No, except for List boxes | Yes | None except List boxes |
| On Close Detail | No, except for List boxes | Yes | None except List boxes |
| On Resize | Never | Yes | None |
| On Selection Change | Yes (***) | Yes | Involved object only |
| On Load Record | Never | Yes | None |
| On Timer | Never | Yes | None |
| On Scroll | Yes | Never | Involved object only |
| On Before Data Entry | Yes (List box) | Never | Involved object only |
| On Column Moved | Yes (List box) | Never | Involved object only |
| On Row Moved | Yes (List box) | Never | Involved object only |
| On Column Resize | Yes (List box) | Never | Involved object only |
| On Header Click | Yes (List box) | Never | Involved object only |
| On Footer Click | Yes (List box) | Never | Involved object only |
| On After Sort | Yes (List box) | Never | Involved object only |
| On Long Click | Yes (3D button) | Yes | Involved object only |
| On Alternative Click | Yes (3D button and List box) | Never | Involved object only |
| On Expand | Yes (Hier. list and list box) | Never | Involved object only |
| On Collapse | Yes (Hier. list and list box) | Never | Involved object only |
| On Delete Action | Yes (Hier. list and list box) | Never | Involved object only |
| On URL Resource Loading | Yes (Web Area) | Never | Involved object only |

| | | | |
|---|---|---|---|
| On Begin URL Loading | Yes (Web Area) | Never | Involved object only |
| On URL Loading Error | Yes (Web Area) | Never | Involved object only |
| On URL Filtering | Yes (Web Area) | Never | Involved object only |
| On End URL Loading | Yes (Web Area) | Never | Involved object only |
| On Open External Link | Yes (Web Area) | Never | Involved object only |
| On Window Opening Denied | Yes (Web Area) | Never | Involved object only |

(*) For more infomation, see the "Events, Objects and Properties" section below.
(**) Refer to the "**Drag and Drop**" chapter for more information.
(***) Only list box, hierarchical list and subform type objects support this event.

**IMPORTANT:** Always keep in mind that, for any event, the method of a form or an object is called if the corresponding event property is selected for the form or objects. The benefit of disabling events in the Design environment (using the Property List of the Form editor) is that you can greatly reduce the number of calls to methods and therefore significantly optimize the execution speed of your forms.

**WARNING:** The On Load and On Unload events are generated for objects if they are enabled for both the objects and the form to which the objects belong. If the events are enabled for objects only, they will not occur; these two events must also be enabled at the form level.

## Events, Objects and Properties

An object method is called if the event can actually occur for the object, depending on its nature and properties. The following section details the events you will generally use to handle the various types of objects.
Keep in mind that the Property List of the Form editor only displays the events compatible with the selected object or the form.

### Clickable Objects

Clickable objects are mainly handled using the mouse. They include:

- Boolean enterable fields or variables
- Buttons, default buttons, radio buttons, check boxes, button grids
- 3D Buttons, 3D radio buttons, 3D check boxes
- Pop-up menus, hierarchical pop-up menus, picture menus
- Drop-down lists, menus/drop-down lists
- Scrollable areas, hierarchical lists, list boxes and list box columns
- Invisible buttons, highlight buttons, radio pictures
- Thermometers, rulers, dials (also known as slider objects)
- Tab controls
- Splitters.

After the On Clicked or On Double Clicked object event property is selected for one of these objects, you can detect and handle the clicks within or on the object, using the **Form event** command that returns On Clicked or On Double Clicked, depending on the case.

**Note:** Starting with 4D v14, enterable fields and variables containing text (of the text, date, time, or number type) also generate the On Clicked and On Double Clicked events.

If both events are selected for an object, the On Clicked and then the On Double Clicked events will be generated when the user double-clicks the object.

For all these objects, the On Clicked event occurs once the mouse button is released. However, there are several exceptions:

- Invisible buttons - The On Clicked event occurs as soon as the click is made and does not wait for the mouse button to be released.
- Slider objects (thermometers, rulers, and dials) - If the display format indicates that the object method must be called while you are sliding the control, the On Clicked event occurs as soon as the click is made.

In the context of an On Clicked event, you can test the number of clicks made by the user by means of the **Clickcount** command.

**Note:** Some of these objects can be activated with the keyboard. For example, once a check box gets the focus, it can be entered using the space bar. In such a case, an On Clicked event is still generated.

**WARNING:** Combo boxes are not considered to be clickable objects. A combo box must be treated as an enterable text area whose associated drop-down list provides default values. Consequently, you handle data entry within a combo box through

the On Before Keystroke, On After Keystroke and On Data Change events.

**Note**: Starting with 4D v13, pop-up menu/drop-down list and hierarchical pop-up menus can generate the On Data Change event. This allows you to detect the activation of the object when a value different from the current value is selected.

### Keyboard Enterable Objects

Keyboard enterable objects are objects into which you enter data using the keyboard and for which you may filter the data entry at the lowest level by detecting On After Edit, On Before Keystroke, On After Keystroke and On Selection Change events. You can take advantage of these events using the **Get edited text** command.
Keyboard enterable objects and data types include:

- All enterable field objects of the alpha, text, date, time, number or (On After Edit only) picture type
- All enterable variables of the alpha, text, date, time, number or (On After Edit only) picture type
- Combo boxes (except On Selection Change)
- List boxes.

**Note:** Starting with 4D v14, enterable fields and variables containing text (of the text, date, time, or number type) also generate the On Clicked and On Double Clicked events.

**Note:** Even though they are "enterable" objects, hierarchical lists do not manage the On After Edit, On Before Keystroke and On After Keystroke form events (see also the "Hierarchical lists" paragraph below).

- On Before Keystroke and On After Keystroke
  **Note:** The On After Keystroke event can generally be replaced by the On After Edit event (see below).
  After the On Before Keystroke and On After Keystroke event properties are selected for an object, you can detect and handle the keystrokes within the object, using the Form event command that will return On Before Keystroke and then On After Keystroke (for more information, please refer to the description of the **Get edited text** command). These events are also activated by language commands that simulate a user action like **POST KEY**.
  Keep in mind that user modifications that are not carried out using the keyboard (paste, drag-drop, etc.) are not taken into account. To process these events, you must use On After Edit.
  **Note:** The On Before Keystroke and On After Keystroke events are not generated when using an input method. An input method (or IME, Input Method Editor) is a program or a system component that can be used to enter complex characters or symbols (for example, Japanese or Chinese) using a Western keyboard.

- On After Edit
  When it is used, this event is generated after each change made to the contents of an enterable object, regardless of the action that caused the change, i.e.:
  - Standard editing actions which modify content like paste, cut, delete or cancel;
  - Dropping a value (action similar to paste);
  - Any keyboard entry made by the user; in this case, the On After Edit event is generated after the On Before Keystroke and On After Keystroke events, if they are used.
  - Any modification made using a language command that simulates a user action (i.e., **POST KEY**).

  Be aware that the following actions do NOT trigger this event:
  - Editing actions that do not modify the contents of the area like copy or select all; or dragging a value (action similar to copy); however, these actions do modify the location of the cursor and thus trigger the On Selection Change event.
  - Any modifications made to the contents by programming, except for the commands simulating a user action.
  This event can be used to control user actions in order, for example, to prevent the pasting in of text that is too long, to block certain characters or to prevent a password field from being cut.

- On Selection Change
  When it is applied to a text field or variable (enterable or not), this event is triggered each time the position of the cursor changes. This happens, for instance, as soon as the user selects text using the mouse or keyboard arrow keys, or when the user enters text. This lets you call, for example, commands such as **GET HIGHLIGHT**.

### Modifiable Objects

Modifiable objects have a data source whose value can be changed using the mouse or the keyboard; they are not truly considered as user interface controls handled through the On Clicked event. They include:

- All enterable field objects (except BLOBs)
- All enterable variables (except BLOBs, pointers, and arrays)
- Combo boxes
- External objects (for which full data entry is accepted by the plug-in)
- Hierarchical lists
- List boxes and list box columns.

These objects receive On Data Change events. After the On Data Change object event property is selected for one of these objects, you can detect and handle the change of the data source value, using the **Form event** command that will return On Data Change. The event is generated as soon as the variable associated with the object is updated internally by 4D (i.e., in general, when the entry area of the object loses the focus).

### Tabbable Objects

Tabbable objects get the focus when you use the Tab key to reach them and/or click on them. The object having the focus receives the characters (typed on the keyboard) that are not modifiers to a menu item or to an object such as a button.

All objects are tabbable, EXCEPT the following:

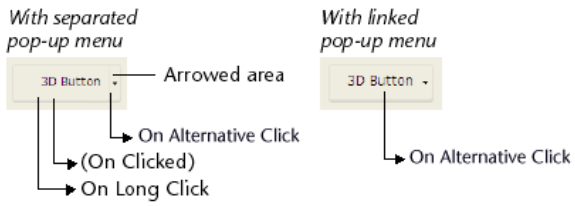
- Non-enterable fields or variables
- Button grids
- 3D buttons, 3D radio buttons, 3D check boxes
- Pop-up menus, hierarchical pop-up menus
- Menus/drop-down lists
- Picture menus
- Scrollable areas
- Invisible buttons, highlight buttons, radio picture buttons
- Graphs
- External objects (for which full data entry is accepted by the 4D plug-in)
- Tab controls
- Splitters.

After the On Getting Focus and/or On losing Focus object event properties are selected for a tabbable object, you can detect and handle the change of focus, using the **Form event** command that will return On Getting Focus or On losing Focus, depending on the case.

### 3D buttons

3D buttons let you set up advanced graphic interfaces (for a description of 3D buttons, refer to the Design Reference manual). In addition to generic events, two specific events can be used to manage these buttons:

- On Long Click: This event is generated when a 3D button receives a click and the mouse button is held for a certain length of time. In theory, the length of time for which this event is generated is equal to the maximum length of time separating a double-click, as defined in the system preferences.
  This event can be generated for all styles of 3D buttons, 3D radio buttons and 3D check boxes, with the exception of “previous generation” 3D buttons (i.e. background offset style) and arrow areas of 3D buttons with a pop-up menu (see below).
  This event is generally used to display pop-up menus in case of long button clicks. The On Clicked event, if enabled, is generated if the user releases the mouse button before the “long click” time limit.
- On Alternative Click: Some 3D button styles can be linked to a pop-up menu and display an arrow. Clicking on this arrow causes a selection pop-up to appear that provides a set of alternative actions in relation to the primary button action.
  4D allows you to manage this type of button using the On Alternative Click event. This event is generated when the user clicks on the “arrow” (as soon as the mouse button is held down):
  - If the pop-up menu is “separated,” the event is only generated when a click occurs on the portion of the button with the arrow.
  - If the pop-up menu is “linked,” the event is generated when a click occurs on any part of the button. Please note that the On Long Click event cannot be generated with this type of button.



The following 3D button, 3D radio button and 3D check box styles accept the “With pop-up menu” property: None, Toolbar button, Bevel, Rounded bevel and Office XP.

### List boxes

Several form events can be used to manage various specific features of list boxes:

- On Before Data Entry: This event is generated just before a cell in the list box is edited (before the entry cursor is displayed). This event allows the developer, for example, to display a different text depending on whether the user is in the display or edit mode.
- On Selection Change: This event is generated each time the current selection of rows or columns of the list box is modified. This event is also generated for lists of records and hierarchical lists.
- On Column Moved: This event is generated when a column of the list box is moved by the user using drag and drop. It is not generated if the column is dragged and then dropped in its initial location. The **LISTBOX MOVED COLUMN NUMBER** command returns the new position of the column.
- On Row Moved: This event is generated when a row of the list box is moved by the user using drag and drop. It is not generated if the row is dragged and then dropped in its initial location.
- On Column Resize: This event is generated when the width of a column in the list box is modified by a user. Starting with 4D v16, the event is triggered "live," i.e., sent continuously during the event, for as long as the list box or column concerned is being resized. This resizing is performed manually by a user, or may occur as a result of the list box and its column(s) being resized along with the form window itself (whether the form is resized manually or using the **RESIZE FORM WINDOW** command).
  **Note:** The On Column Resize event is not triggered when a "fake" column is resized (for more information on fake columns, please refer to **Resizing Options theme**).
- On Expand and On Collapse: These events are generated when a row of the hierarchical list box is expanded or collapsed.
- On Header Click: This event is generated when a click occurs on the header of a column in the list box. In this case, the **Self** command lets you find out the header of the column that was clicked. The On Clicked event is generated when a right click (Windows) or Ctrl+click (Mac OS) occurs on a column or column header. You can test the number of clicks made by the user by means of the **Clickcount** command.
  If the **Sortable** property was checked in the list box, you can decide whether or not to authorize a standard sort of the column by passing the value 0 or -1 in the $0 variable:
  - If $0 equals 0, a standard sort is performed.
  - If $0 equals -1, a standard sort is not performed and the header does not display the sort arrow. The developer can still generate a column sort based on customized sort criteria using the 4D array management commands.
  If the **Sortable** property is not selected for the list box, the $0 variable is not used.
- On Footer Click: This event is available for a list box or list box column object. It is generated when a click occurs in the footer of a list box or a list box column. In this case, the **OBJECT Get pointer** command returns a pointer to the variable of the footer that is clicked. The event is generated for both left and right clicks.
  You can test the number of clicks made by the user by means of the **Clickcount** command.
- On After Sort: This event is generated just after a standard sort is performed (i.e. it is not generated if $0 returns -1 in the On Header Click event). This mechanism is useful for storing the directions of the last sort performed by the user. In this event, the **Self** command returns a pointer to the variable of the sorted column header.
- On Delete Action: This event is generated each time a user attempts to delete the selected item(s) by pressing a deletion key (**Delete** or **Backspace**) or selecting a menu item whose associated standard action is 'Clear' (such as the **Clear** command in the **Edit** menu). This event is only available at the level of the list box object. Note that generating the event is the only action carried out by 4D: the program does not delete any items. It is up to the developer to handle the deletion and any prior warning messages that are displayed.
- On Scroll (new in v15): This event is generated as soon as a user scrolls the rows or columns of the list box. The event is only generated when the scroll is the result of a user action: using the scroll bars and/or cursors, using the mouse wheel or the keyboard. It is not generated when scrolling is due to the execution of the **OBJECT SET SCROLL POSITION** command.
  This event is triggered after any other user event related to the scrolling action (On Clicked, On After Keystroke, etc.). The event is only generated in the object method (not in the form method). Refer to example 15.
- On Alternative Click (new in v15): This event is generated in columns of object array type list boxes, when the user clicks on a widget ellipsis button ("alternateButton" attribute). For more information, refer to the **Using object arrays in columns (4D View Pro)** section.

Two generic events can also be used in the context of "selection" type list boxes:

- On Open Detail: This event is generated when a record is about to be displayed in the detail form associated with a "selection" type list box (and before this form is opened).
- On Close Detail: This event is generated when a record displayed in the detail form associated with a "selection" type list box is about to be closed (regardless of whether or not the record was modified).

### Hierarchical lists

In addition to generic events, several specific events can be used to handle user actions performed on hierarchical lists:

- On Selection Change: This event is generated every time the selection in the hierarchical list is modified after a mouse click or keystroke.
  This event is also generated in list box objects and record lists.
- On Expand: This event is generated every time an element of the hierarchical list is expanded with a mouse click or keystroke.
- On Collapse: This event is generated every time an element of the hierarchical list is collapsed with a mouse click or keystroke.
- On Delete Action: This event is generated each time a user attempts to delete the selected item(s) by pressing a deletion key (**Delete** or **Backspace**) or selecting the **Delete** command from the **Edit** menu. Note that generating the event is the only action carried out by 4D: the program does not delete any items. It is up to the developer to handle the deletion and any prior warning messages that are displayed (see the example).

These events are not mutually exclusive. They can be generated one after another for a hierarchical list:
- Following a keystroke (in order):

| Event | Context |
|---|---|
| On Data Change | Element was edited |
| On Expand/On Collapse | Opening/Closing of a sublist using the -> or <- arrow keys |
| On Selection Change | Selection of a new element |
| On Clicked | Activation of the list using keyboard |

- Following a mouse click (in order):

| Event | Context |
|---|---|
| On Data Change | Element was edited |
| On Expand/On Collapse | Opening/Closing of a sublist using the expand/collapse icons or Double-click on non-editable sublist |
| On Selection Change | Selection of a new element |
| On Clicked / On Double Clicked | Activation of the list using click or double-click |

### Picture fields and variables

- The On Scroll form event is generated as soon as a user scrolls a picture within the area (field or variable) that contains it. You can scroll the contents of a picture area when the size of the area is smaller than its contents and the display format is "**Truncated (non Centered)**". For more information about this, refer to **Picture formats**.
  The event is generated when the scroll is the result of a user action: using the scroll bars and/or cursors, using the mouse wheel or the keyboard (for more information about scrolling using the keyboard, refer to **Scroll bars**). It is not generated when the object is scrolled due to the execution of the **OBJECT SET SCROLL POSITION** command. This event is triggered after any other user event related to the scrolling action (On Clicked, On After Keystroke, etc.). It is generated in the object method (not in the form method). Refer to example 14.

- (New in v16) The On Mouse Up event is generated when the user has just released the left mouse button while dragging in a picture area (field or variable). This event is useful, for example, when you want the user to be able to move, resize or draw objects in a SVG area.
  When the On Mouse Up event is generated, you can get the local coordinates where the mouse button was released. These coordinates are returned in the **MouseX** and **MouseY** **System Variables**. The coordinates are expressed in pixels with respect to the top left corner of the picture (0,0).
  When using this event, you must also use the **Is waiting mouse up** command to handle cases where the "state manager" of the form is desynchronized, i.e. when the On Mouse Up event is not received after a click. This is the case for example when an alert dialog box is displayed above the form while the mouse button has not been released. For more information and an example of use of the On Mouse Up event, please refer to the description of the **Is waiting mouse up** command.

  **Note:** If the "Draggable" option is checked for the picture object, the On Mouse Up event is never generated.

### Subforms

A subform container object (object included in the parent form, which contains one subform instance) supports the following events:

- On Load and On Unload: respectively opening and closing of the subform (these events must also have been activated at the parent form level in order to be taken into account). Note that these events are generated before those of the parent form. Also note that, in accordance with the operating principles of form events, if the subform is placed on a

page other than page 0 or 1, these events will only be generated when that page is displayed/closed (and not when the form is displayed/closed.
- On Validate: validation of data entry in the subform.
- On Data Change: the value of the variable of the subform object has been modified.
- On Getting Focus and On Losing Focus: subform container just got or lost the focus. These events are generated in the method of the subform object when they are checked. They are sent to the form method of the subform, which means, for example, that you can manage the display of navigation buttons in the subform according to the focus.
  Note that subform objects can themselves have the focus.
- On Bound Variable Change: This specific event is generated in the context of the form method of the subform as soon as a value is assigned to the variable bound with the subform in the parent form (even if the same value is reassigned) and if the subform belongs to the current form page or to page 0. For more information about managing subforms, please refer to the *Design Reference* manual.

**Note:** It is possible to specify any custom event type that could be generated in a subform via the **CALL SUBFORM CONTAINER** command. This command lets you call the container object method and to pass an event code to it.

**Note:** The On Clicked and On Double Clicked events generated in the subform are received first by the form method of the subform and then by the form method of the host form.

### Web Areas

Seven form events are available specifically for Web areas:

- On Begin URL Loading: This event is generated at the start of loading a new URL in the Web area. The "URL" variable associated with the Web area can be used to find out the URL being loaded.
  **Note:** The URL being loaded is different from the current URL (refer to the description of the **WA Get current URL** command).
- On URL Resource Loading: This event is generated each time a new resource (picture, frame, etc.) is loaded on the current Web page.
  The "Progression" variable associated with the area lets you find out the current state of the loading.
- On End URL Loading: This event is generated when all the resources of the current URL have been loaded.
  You can call the **WA Get current URL** command in order to find out the URL that was loaded.
- On URL Loading Error: This event is generated when an error is detected during the loading of a URL.
  You can call the **WA GET LAST URL ERROR** command in order to get information about the error.
- On URL Filtering: This event is generated when the loading of a URL is blocked by the Web area because of a filter set up using the **WA SET URL FILTERS** command.
  You can find out the blocked URL using the **WA Get last filtered URL** command.
- On Open External Link: This event is generated when the loading of a URL was blocked by the Web area and the URL was opened with the current system browser, because of a filter set up via the **WA SET EXTERNAL LINKS FILTERS** command.
  You can find out the blocked URL using the **WA Get last filtered URL** command.
- On Window Opening Denied: This event is generated when the opening of a pop-up window is blocked by the Web area. 4D Web areas do not allow the opening of pop-up windows.
  You can find out the blocked URL using the **WA Get last filtered URL** command.

## Example 1

This example shows the On Validate event being used to automatically assign (to a field) the date that the record is modified:

```
 //Method of a form
Case of
 // ...
   :(Form event=On Validate)
      [aTable]Last Modified On:=Current date
End case
```

## Example 2

In this example, the complete handling of a drop-down list (initialization, user clicks, and object release) is encapsulated in the method of the object:

```
 //asBurgerSize Drop-down list Object Method
Case of
   :(Form event=On Load)
      ARRAY TEXT(asBurgerSize;3)
      asBurgerSize{1}:="Small"
      asBurgerSize{1}:="Medium"
      asBurgerSize{1}:="Large"
   :(Form event=On Clicked)
      If(asBurgerSize#0)
         ALERT("You chose a "+asBurgerSize{asBurgerSize}+" burger.")
      End if
   :(Form event=On Unload)
      CLEAR VARIABLE(asBurgerSize)
End case
```

## Example 3

This example shows how, in an object method, to accept and later handle a drag and drop operation for a field object that only accepts picture values.

```
 //[aTable]aPicture enterable picture field object method
Case of
   :(Form event=On Drag Over)
 //A drag-and-drop operation has started and the mouse is currently over the field
 //Get the information about the source object
      DRAG AND DROP PROPERTIES($vpSrcObject;$vlSrcElement;$lSrcProcess)
 //Note that we do not need to test the source process ID number
 //for the object method executed since it is in the same process
      $vlDataType:=Type($vpSrcObject->)
 //Is the source data a picture (field, variable or array)?
      If(($vlDataType=Is picture)|($vlDataType=Picture array))
 //If so, accept the drag.
         $0:=0
      Else
 //If so, refuse the drag
         $0:=-1
      End if
   :(Form event=On Drop)
 //The source data has been dropped on the object, we therefore need to copy it
 //into the object
 //Get the information about the source object
      DRAG AND DROP PROPERTIES($vpSrcObject;$vlSrcElement;$lSrcProcess)
      $vlDataType:=Type($vpSrcObject->)
      Case of
 //The source object is Picture field or variable
         :($vlDataType=Is picture)
 //Is the source object from the same process (thus from the same window and form)?
            If($lSrcProcess=Current process)
 //If so, just copy the source value
               [aTable]aPicture:=$vpSrcObject->
            Else
 //If not, is the source object a variable?
               If(Is a variable($vpSrcObject))
 //If so, get the value from the source process
                  GET PROCESS VARIABLE($lSrcProcess;$vpSrcObject->;$vgDraggedPict)
                  [aTable]aPicture:=$vgDraggedPict
               Else
 //If not, use CALL PROCESS to get the field value from the source process
               End if
            End if
 //The source object is an array of pictures
         :($vlDataType=Picture array)
 //Is the source object from the same process (thus from the same window and form)?
            If($lSrcProcess=Current process)
 //If so, just copy the source value
               [aTable]aPicture:=$vpSrcObject->{$vlSrcElement}
            Else
```

```
   //If not, get the value from the source process
               GET PROCESS VARIABLE($lSrcProcess;$vpSrcObject->{$vlSrcElement};$vgDraggedPict)
               [aTable]aPicture:=$vgDraggedPict
            End if
      End case
End case
```

**Note:** For other examples showing how to handle On Drag Over and On Drop events, see the examples of the **DRAG AND DROP PROPERTIES** command.

## Example 4

This example is a template for a form method. It shows each of the possible events that can occur when a summary report uses a form as an output form:

```
   //Method of a form being used as output form for a summary report
$vpFormTable:=Current form table
Case of
   //...
   :(Form event=On Header)
   //A header area is about to be printed
      Case of
         :(Before selection($vpFormTable->))
   //Code for the first break header goes here
         :(Level=1)
   //Code for a break header level 1 goes here
         :(Level=2)
   //Code for a break header level 2 goes here
   //...
      End case
   :(Form event=On Printing Detail)
   //A record is about to be printed
   //Code for each record goes here
   :(Form event=On Printing Break)
   //A break area is about to be printed
      Case of
         :(Level=0)
   //Code for a break level 0 goes here
         :(Level=1)
   //Code for a break level 1 goes here
   //...
      End case
   :(Form event=On Printing Footer)
      If(End selection($vpFormTable->))
   //Code for the last footer goes here
      Else
   //Code for a footer goes here
      End if
End case
```

## Example 5

This example shows the template of a form method that handles the events that can occur for a form displayed using the **DISPLAY SELECTION** or **MODIFY SELECTION** commands. For didactic purposes, it displays the nature of the event in the title bar of the form window.

```
   //A form method
Case of
   :(Form event=On Load)
      $vsTheEvent:="The form is about to be displayed"
   :(Form event=On Unload)
      $vsTheEvent:="The output form has been exited and is about to disappear from the screen"
   :(Form event=On Display Detail)
      $vsTheEvent:="Displaying record #"+String(Selected record number([TheTable]))
   :(Form event=On Menu Selected)
      $vsTheEvent:="A menu item has been selected"
```

```
    :(Form event=On Header")
       $vsTheEvent:="The header area is about to be drawn"
    :(Form event=On Clicked")
       $vsTheEvent:="A record has been clicked"
    :(Form event=On Double Clicked")
       $vsTheEvent:="A record has been double clicked"
    :(Form event=On Open Detail)
       $vsTheEvent:="The record #"+String(Selected record number([TheTable]))+" is double-clicked"
    :(Form event=On Close Detail)
       $vsTheEvent:="Going back to the output form"
    :(Form event=On Activate)
       $vsTheEvent:="The form's window has just become the frontmost window"
    :(Form event=On Deactivate)
       $vsTheEvent:="The form's window is no longer the frontmost window"
    :(Form event=On Menu Selected)
       $vsTheEvent:="A menu item has been chosen"
    :(Form event=On Outside Call)
       $vsTheEvent:="A call from another has been received"
    Else
       $vsTheEvent:="What's going on? Event #"+String(Form event)
End case
SET WINDOW TITLE($vsTheEvent)
```

## Example 6

For examples on how to handle On Before Keystroke and On After Keystroke events, see examples for the **Get edited text**, **Keystroke** and **FILTER KEYSTROKE** commands.

## Example 7

This example shows how to treat clicks and double clicks in the same way in a scrollable area:

```
 //asChoices scrollable area object method
Case of
   :(Form event=On Load)
      ARRAY TEXT(asChoices;...)
 //...
      asChoices:=0
   :((Form event=On Clicked)|(Form event=On Double Clicked))
      If(asChoices#0)
 //An item has been clicked, do something here
 //...
      End if
 //...
End case
```

## Example 8

This example shows how to treat clicks and double clicks using a different response. Note the use of the element zero for keeping track of the selected element:

```
 //asChoices scrollable area object method
Case of
   :(Form event=On Load)
      ARRAY TEXT(asChoices;...)
 // ...
      asChoices:=0
      asChoices{0}:="0"
   :(Form event=On Clicked)
      If(asChoices#0)
         If(asChoices#Num(asChoices))
 //A new item has been clicked, do something here
 //...
```

```
   //Save the new selected element for the next time
            asChoices{0}:=String(asChoices)
         End if
      Else
         asChoices:=Num(asChoices{0})
      End if
   :(Form event=On Double Clicked)
      If(asChoices#0)
   //An item has been double clicked, do something different here
      End if
   // ...
End case
```

## Example 9

This example shows how to maintain a status text information area from within a form method, using the On Getting Focus and On Losing Focus events:

```
   //[Contacts];"Data Entry" form method
Case of
   :(Form event=On Load)
      C_TEXT(vtStatusArea)
      vtStatusArea:=""
   :(Form event=On Getting Focus)
      RESOLVE POINTER(Focus object;$vsVarName;$vlTableNum;$vlFieldNum)
      If(($vlTableNum#0) & ($vlFieldNum#0))
         Case of
            :($vlFieldNum=1) //Last name field
               vtStatusArea:="Enter the Last name of the Contact; it will be capitalized automatically"
   //...
            :($vlFieldNum=10) //Zip Code field
               vtStatusArea:="Enter a 5-digit zip code; it will be checked and validated automatically"
   //...
         End case
      End if
   :(Form event=On Losing Focus)
      vtStatusArea:=""
   //...
End case
```

## Example 10

This example shows how to respond to a close window event with a form used for record data entry:

```
   //Method for an input form
$vpFormTable:=Current form table
Case of
   //...
   :(Form event=On Close Box)
      If(Modified record($vpFormTable->))
         CONFIRM("This record has been modified. Save Changes?")
         If(OK=1)
            ACCEPT
         Else
            CANCEL
         End if
      Else
         CANCEL
      End if
   //...
End case
```

## Example 11

This example shows how to capitalize a text or alphanumeric field each time its data source value is modified:

```
 //[Contacts]First Name Object method
Case of
 //...
   :(Form event=On Data Change)
      [Contacts]First Name:=Uppercase(Substring([Contacts]First Name;1;1))+Lowercase(Substring([Contacts]First Name;2))
 //...
End case
```

## Example 12

This example shows how to capitalize a text or alphanumeric field each time its data source value is modified:

```
 //[Contacts]First Name Object method
Case of
 //...
   :(Form event=On Data Change)
      [Contacts]First Name:=Uppercase(Substring([Contacts]First Name;1;1))+Lowercase(Substring([Contacts]First Name;2))
 //...
End case
```

## Example 13

The following example illustrates how to manage a deletion action in a hierarchical list:

```
... //method of hierarchical list
:($Event=On Delete Action)
ARRAY LONGINT($itemsArray;0)
$Ref:=Selected list items(<>HL;$itemsArray;*)
$n:=Size of array($itemsArray)

Case of
   :($n=0)
      ALERT("No item selected")
      OK:=0
   :($n=1)
      CONFIRM("Do you want to delete this item?")
   :($n>1)
      CONFIRM("Do you want to delete these items?")
End case

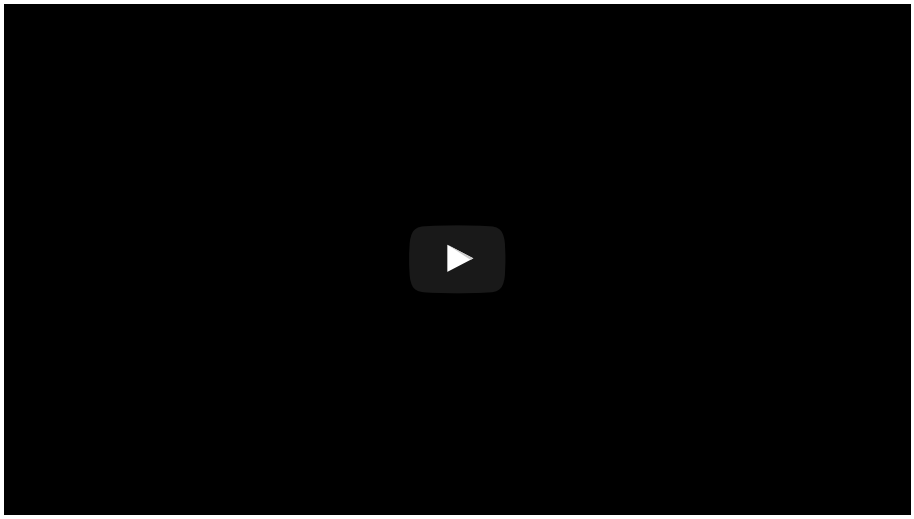
If(OK=1)
   For($i;1;$n)
      DELETE FROM LIST(<>HL;$itemsArray{$i};*)
   End for
End if
```

## Example 14

In this example, the On Scroll form event allows us to synchronize the display of two pictures in a form. The following code is added in the "satellite" object method (picture field or variable):

```
Case of
   :(Form event=On Scroll)
 // we take the position of the left picture
      OBJECT GET SCROLL POSITION(*;"satellite";vPos;hPos)
 // and we apply it to the right picture
      OBJECT SET SCROLL POSITION(*;"plan";vPos;hPos;*)
End case
```

Result:



## Example 15

You want to draw a red rectangle around the selected cell of a list box, and you want the rectangle to move along with the list box if it is scrolled vertically by the user. In the list box object method, you can write:

```
Case of

   :(Form event=On Clicked)
      LISTBOX GET CELL POSITION(*;"LB1";$col;$raw)
      LISTBOX GET CELL COORDINATES(*;"LB1";$col;$raw;$x1;$y1;$x2;$y2)
      OBJECT SET VISIBLE(*;"RedRect";True) //initialize a red rectangle
      OBJECT SET COORDINATES(*;"RedRect";$x1;$y1;$x2;$y2)

   :(Form event=On Scroll)
      LISTBOX GET CELL POSITION(*;"LB1";$col;$raw)
      LISTBOX GET CELL COORDINATES(*;"LB1";$col;$raw;$x1;$y1;$x2;$y2)
      OBJECT GET COORDINATES(*;"LB1";$xlb1;$ylb1;$xlb2;$ylb2)
      $toAdd:=LISTBOX Get headers height(*;"LB1") //height of the header so as not to overlap it
      If($ylb1+$toAdd<$y1) & ($ylb2>$y2) //if we are inside the list box
 //to keep it simple, we only handle headers
 //but we should handle horizontal clipping
 //as well as scroll bars
         OBJECT SET VISIBLE(*;"RedRect";True)
         OBJECT SET COORDINATES(*;"RedRect";$x1;$y1;$x2;$y2)
      Else
         OBJECT SET VISIBLE(*;"RedRect";False)
      End if

End case
```

As a result, the red rectangle follows the scrolling of the list box:

| John | Mark | Amy | Jenny |

# In break

In break -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | Returns True if the execution cycle is in break |

## Description

**In break** returns True for the In break execution cycle.

In order for the **In break** execution cycle to be generated, make sure that the On Printing Break event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Printing Break event.

# In footer

In footer -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean |  | Returns True if the execution cycle is in footer |

## Description

**In footer** returns True for the In footer execution cycle.

In order for the **In footer** execution cycle to be generated, make sure that the On Printing Footer event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Printing Footer event.

# In header

In header -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Returns True if the execution cycle is in header |

## Description

**In header** returns True for the In header execution cycle.

In order for the **In header** execution cycle to be generated, make sure that the On Header event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Header event.

# Is waiting mouse up

Is waiting mouse up -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True if the object is waiting for a mouse up event, False otherwise |

## Description

The **Is waiting mouse up** command returns **True** if the current object has been clicked and the mouse button has not been released, while the parent window has the focus. Otherwise, it returns **False**, in particular if the parent window has lost the focus before the mouse button was released.

The command must be called in the context of the current object. It is designed to be used in conjunction with the On Mouse Up form event which is available for picture fields and variables. It allows your code to handle the cases where the user clicked and started to move something within a form object picture, and this action is interrupted by an external event, such as an alert dialog box. In this case, the internal state of the object can be suspended indefinitely because it is waiting for a mouse up event which will never occur. To prevent this issue, you must protect your mouse moving code within a **Is waiting mouse up** command which makes you sure that it is executed in a valid context.

## Example

The following code can be used to manage a mouse tracking feature in a picture object:

```
 //Object method of the picture object
C_LONGINT(vLtracking) //flag for tracking mode
Case of
   :(Form event=On Clicked)
      If(Is waiting mouse up) //the mouse button is still not released
         vLtracking:=1 //we are in tracking mode
 //... Write here initialization code for the tracking feature
      End if
   :(Form event=On Mouse Move)
      If(vLtracking=1) //we are in tracking mode
         If(Not(Is waiting mouse up)) //we'll never have the mouse up
            vLtracking:=0 //stop the tracking mode
 //... Write here the code for handling or canceling user tracking action
         Else //the object is still waiting for a mouse up
 //... Write here the code for the tracking
         End if
      End if
   :(Form event=On Mouse Up) //the mouse button was released
 //... Write here the code to complete the tracking action
      vLtracking:=0 //end of the tracking mode
End case
```

# Outside call

Outside call -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True if the execution cycle is an outside call |

## Description

**Outside call** returns True for the After execution cycle.

In order for the **Outside call** execution cycle to be generated, make sure that the On Outside Call event property for the form and/or the objects has been selected in the Design environment.

**Note:** This command is equivalent to using **Form event** and testing whether it returns the On Outside Call event.

# Right click

Right click -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True if a right click was detected, otherwise False |

## Description

The **Right click** command returns True if the right button of the mouse has been clicked.

This command should be used only in the context of the On Clicked form event. It is therefore necessary to verify in Design mode that the event has been properly selected in the Form properties and/or in the specific object.

# SET TIMER

SET TIMER ( tickCount )

| Parameter | Type | | Description |
|---|---|---|---|
| tickCount | Longint | ⇒ | Tickcount or -1=Trigger as soon as possible |

## Description

The **SET TIMER** command activates the On Timer form event and sets, for the current form and process, the number of ticks elapsed between each On Timer form event.

**Note:** For more information about this new form event, please refer to the description of the command **Form event**.

If this command is called in a context in which it is not displaying a form, it will have no effect.

**Note:** When the **SET TIMER** command is executed in the context of a subform (form method of the subform), the On Timer event is generated in the subform and not at the parent form level.

If you pass -1 in the *tickCount* parameter, the command will activate the On Timer form event "as soon as possible", in other words, as soon as the 4D application hands over control to the event manager. More particularly, this means that you can make sure that a form is completely displayed before beginning processing (application fluidity).

To procedurally disable the triggering of the On Timer form event, call **SET TIMER** again and pass 0 in *tickCount*.

## Example

Let's imagine that you want, when a form is displayed on screen, the computer to beep every three seconds. To do so, write the following form method:

```
If(Form event=On Load)
   SET TIMER(60*3)
End if

If(Form event=On Timer)
   BEEP
End if
```

# _o_During

_o_During -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | Returns True if the execution cycle is during |

## Compatibility note

Use of this old generic execution cycle function is not recommended. It is recommended to use **Form event** and test the specific events returned, like On Clicked.

# Forms

# CALL FORM

CALL FORM ( window ; method {; param}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number |
| method | Text | ⇒ | Name of project method to call |
| param | Expression | ⇒ | Parameter(s) passed to method |

## Description

The **CALL FORM** command executes the project method whose name you passed in *method* with the optional *param*(s) in the context of a form displayed in a *window*, regardless of the process owning the window.

Just like in the worker-based interprocess communication feature (see **About workers**), a message box is associated with the window and can be used when the window displays a form (after the On Load form event). **CALL FORM** encapsulates the method name and its arguments in a message that is posted in the window's message box. The form then executes the message in its own process. The calling process can be cooperative or preemptive, thus this feature allows a preemptive process to exchange information with forms.

In *window*, you pass the window reference number of the window displaying the called form.

In *method*, you pass the name of the project method to be executed in the context of the *window* parent process.

You can also pass parameters to the method using one or more *param* parameters. You pass parameters the same way you would pass them to a subroutine (see the **Passing Parameters to Methods** section). Upon starting execution in the context of the form, the method receives the parameter values in *$1*, *$2*, and so on. Remember that arrays cannot be passed as parameters to a method. Furthermore, in the context of the **CALL FORM** command, the following additional considerations need to be taken into account:

- Pointers to tables or fields are allowed.
- Pointers to variables, particularly local and process variables, are not recommended since these variables may be undefined at the moment they are being accessed by the process method.
- If you pass an Object type parameter, 4D creates a copy of the object in the destination process if the form is in a process different from the one calling the **CALL FORM** command.

## Example 1

You want to open two different dialog windows from the same form, but with different background colors and different messages. You also want to send messages afterwards and display them in each dialog window.

In the main form, a button opens the two dialogs:

```
 //Object method to create forms
 //First window
formRef1:=Open form window("FormMessage";Palette form window;On the left)
SET WINDOW TITLE("MyForm1";formRef1)
DIALOG("FormMessage";*)
SHOW WINDOW(formRef1)

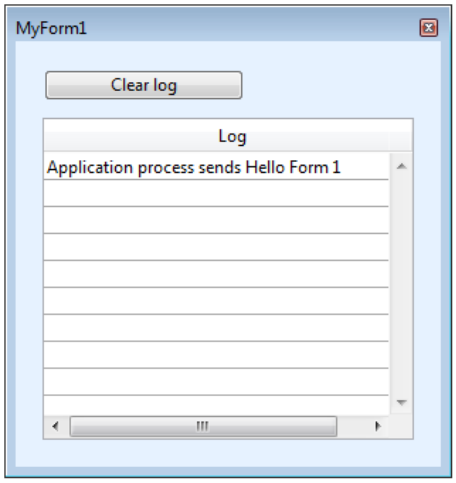
 //Second window
formRef2:=Open form window("FormMessage";Palette form window;On the left+500)
SET WINDOW TITLE("MyForm2";formRef2)
DIALOG("FormMessage";*)
SHOW WINDOW(formRef2)

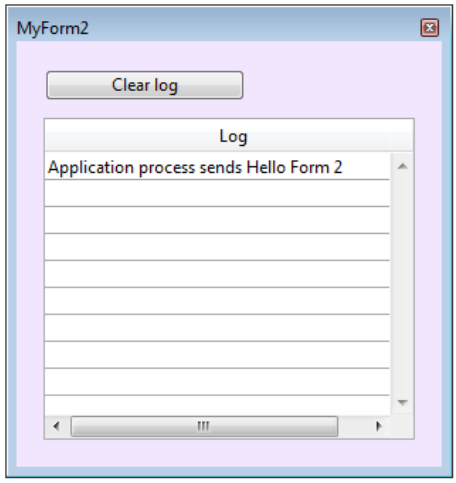
 //Send colors
CALL FORM(formRef1;"doSetColor";0x00E6F2FF)
CALL FORM(formRef2;"doSetColor";0x00F2E6FF)
 //Create messages
CALL FORM(formRef1;"doAddMessage";Current process name;"Hello Form 1")
CALL FORM(formRef2;"doAddMessage";Current process name;"Hello Form 2")
```

The *doAddMessage* method only adds a row in the list box in the "FormMessage" form:

```
C_TEXT($1) //Caller name
C_TEXT($2) //Message to display
 //Receive message from $2 and log the message in the list box
$p:=OBJECT Get pointer(Object named;"Column1")
INSERT IN ARRAY($p->;1)
$p->{1}:=$1+" sends "+$2
```

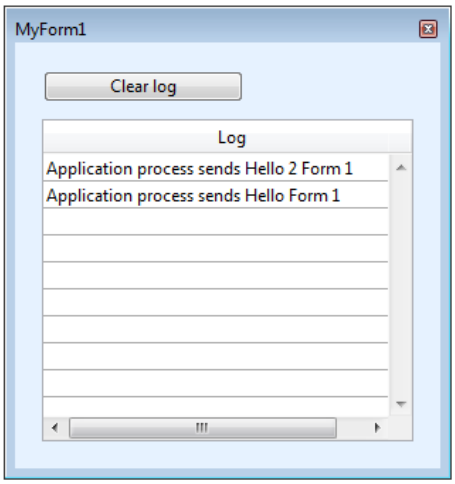
At runtime, you get the following result:

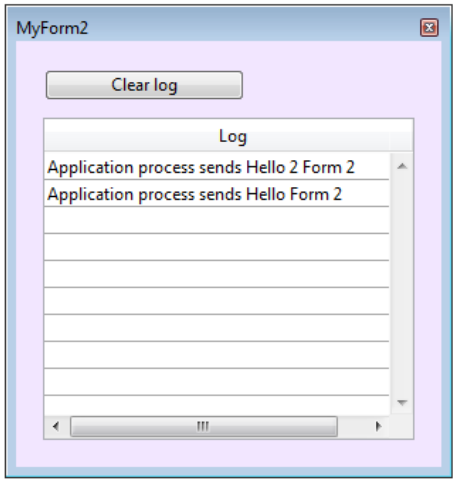




You can then add other messages by executing the **CALL FORM** command again:

```
CALL FORM(formRef1;"doAddMessage";Current process name;"Hello 2 Form 1")
CALL FORM(formRef2;"doAddMessage";Current process name;"Hello 2 Form 2")
```





## Example 2

You can use the **CALL FORM** command to pass custom settings to a form, for example configuration values, without having to use process variables:

```
$win:=Open form window("form")
CALL FORM($win;"configure";param1;param2)
DIALOG("form")
```

# Current form name

Current form name -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Text | ➲ | Name of current project form or current table form in the process |

## Description

The **Current form name** command returns the name of the current form defined for the process. The current form can be a project form or a table form.

By default, if you have not called the **FORM LOAD** command in the current process, the current form is the one being displayed or printed. If you have called the **FORM LOAD** command in the process, the current form is the one set by this command and it remains so until you call **FORM UNLOAD** (or **CLOSE PRINTING JOB**).

If there is no current form defined for the process, the command returns an empty string.

## Example 1

In an input form, place the following code in a button:

```
C_TEXT($FormName)
$win:=Open form window([Members];"Input";Plain form window)
DIALOG([Members];"Input")
$FormName:=Current form name
 // $FormName = "Input"
FORM LOAD([Members];"Drag")
$FormName:=Current form name
 // $FormName = "Drag"
 //...
```

## Example 2

You want to get the current form if it is a project form:

```
$PointerTable:=Current form table
If(Nil($PointerTable)) // this is a project form
   $FormName:=Current form name
   ... // processing
End if
```

# FORM FIRST PAGE

FORM FIRST PAGE
Does not require any parameters

## Description

**FORM FIRST PAGE** changes the currently displayed form page to the first form page. If no form is being displayed or loaded by the **FORM LOAD** command, or if the first form page is already displayed, **FORM FIRST PAGE** does nothing.

## Example

The following example is a one-line method called from a menu command. It displays the first form page:

```
FORM FIRST PAGE
```

# FORM Get current page

FORM Get current page {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Returns number of current subform page |
| Function result | Longint | ⇐ | Number of currently displayed form page |

## Description

The **FORM Get current page** command returns the number of the currently displayed form page or of the current form loaded by the **FORM LOAD** command.

The * parameter is useful when the command is called in the context of a page type subform containing several pages. In this case, when you pass this parameter, the command changes the page of the current subform (the one that called the command). By default, when the * parameter is omitted, the command is always applied to the parent form.

## Example

In a form, when you select a menu item from the menu bar or when the form receives a call from another process, you can perform different actions depending on the form page currently displayed. In this example, you write:

```
  ` [myTable];"myForm" Form Method
Case of
   :(Form event=On Load)
  ` ...
   :(Form event=On Unload)
  ` ...
   :(Form event=On Menu Selected)
      $vlMenuNumber:=Menu selected>>16
      $vlItemNumber:=Menu selected & 0xFFFF
      Case of
         :($vlMenuNumber=...)
            Case of
               :($vlItemNumber=...)
               :(FORM Get current page=1)
  ` Do appropriate action for page 1
               :(FORM Get current page=2)
  ` Do appropriate action for page 2
  ` ...
               :($vlItemNumber=...)
  ` ...
            End case
         :($vlMenuNumber=...)
  ` ...
      End case
   :(Form event=On Outside Call)
      Case of
         :(FORM Get current page=1)
  ` Do appropriate reply for page 1
         :(FORM Get current page=2)
  ` Do appropriate reply for page 2
      End case
  ` ...
End case
```

# FORM GET HORIZONTAL RESIZING

FORM GET HORIZONTAL RESIZING ( resize {; minWidth {; maxWidth}} )

| Parameter | Type | | Description |
|---|---|---|---|
| resize | Boolean | ⇦ | True: Form can be resized horizontally False: Form cannot be resized horizontally |
| minWidth | Longint | ⇦ | Smallest form width allowed (pixels) |
| maxWidth | Longint | ⇦ | Largest form width allowed (pixels) |

## Description

The **FORM GET HORIZONTAL RESIZING** command returns the horizontal resizing properties of the current form in the *resize*, *minWidth* and *maxWidth* variables. These properties may have been set for the form in the Form editor in Design mode or for the current process via the **FORM SET HORIZONTAL RESIZING** command.

# FORM GET OBJECTS

FORM GET OBJECTS ( objectsArray {; variablesArray {; pagesArray}} {; formPageOption | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| objectsArray | String array | ⇦ | Name of form objects |
| variablesArray | Pointer array | ⇦ | Pointers to variables or fields associated with objects |
| pagesArray | Integer array | ⇦ | Page number of each object |
| formPageOption \| * | Longint, Operator | ⇨ | 1=Form current page, 2=Form all pages, 4=Form inherited<br>If * passed (obsolete) = current page with inherited objects |

## Description

The **FORM GET OBJECTS** command returns the list of all objects present in the current form in the form of (an) array(s). This list can be restricted to the current form page and can exclude objects of inherited forms. The command can be used with both input and output forms.

If an array passed as a parameter is not previously declared, the command creates it and automatically sets its size. However, in the interest of compiling the application, we recommend that you explicitly declare each array.

Pass the name of the string array that will contain object names (each object name is unique within a form) in *objectsArray*. The order in which objects appear in the array is not significant.

The other arrays optionally filled by the command are synchronized with the first array.

Pass the name of the pointer array that already contains pointers to variables or fields associated with objects in the optional *variablesArray* parameter. If an object does not have an associated variable, the pointer **Nil** is returned. If there is a “subform” type object, a pointer to the table of the subform is returned.

The third array (optional), *pagesArray*, is filled with the form page numbers. Each line of this array contains the page number of the corresponding object.

The optional * parameter allows you to reduce the list of objects returned to the current page of the form. When this parameter is passed, only objects of the current page, page 0 and inherited pages are returned by the command. In other words, all the objects present in the current page of the form (visible or not) are processed by the command.

The optional *formPageOption* parameter allows you to specify the form part(s) from where you want to get objects. By default, if the *formPageOption* parameter is omitted (as well as the * parameter), objects from all pages, including inherited objects, are returned. To reduce the scope of the command, you can pass a value in *formPageOption*. You can pass one (or a combination) of the following constants, found in the "**Form Objects (Access)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Form all pages | Longint | 2 | Returns all objects of all the pages, excluding inherited objects |
| Form current page | Longint | 1 | Returns all objects of the current page, including page 0 but excluding inherited objects |
| Form inherited | Longint | 4 | Returns inherited objects only |

**Compatibility note:** Passing the * parameter is equivalent to passing Form current page+Form inherited. The syntax using the * parameter is now deprecated and should no longer be used.

## Example 1

You want to get information on all pages including objects from the inherited form (if any):

```
 //open form
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray)
```

Or:

```
 //loaded form
FORM LOAD([Table1];"MyForm")
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray;Form all pages+Form inherited)
```

## Example 2

You want to get information on the current page only, with page 0 of the loaded form and inherited form objects (if any):

```
FORM LOAD("MyForm")
FORM GOTO PAGE(2)
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray;Form current page+Form inherited)
```

## Example 3

You want to get information on all objects in the inherited form (if any). If there is no inherited form, arrays will be returned empty.

```
FORM LOAD("MyForm")
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray;Form inherited)
```

## Example 4

You want to get information on page 4 objects, including page 0 objects, but without inherited form objects (if any):

```
FORM LOAD([Table1];"MyForm")
FORM GOTO PAGE(4)
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray;Form current page)
```

## Example 5

You want to get information on objects on all pages, but without inherited form objects (if any):

```
FORM LOAD([Table1];"MyForm")
FORM GET OBJECTS(objectsArray;variablesArray;pagesArray;Form all pages)
```

# FORM GET PARAMETER

FORM GET PARAMETER ( {aTable ;} form ; selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Form table or Default table if this parameter is omitted |
| form | String | ⇒ | Form name |
| selector | Longint | ⇒ | Code of the parameter |
| value | Longint | ⇐ | Current value of the parameter |

## Description

The **FORM GET PARAMETER** command can be used to get the current *value* of a parameter of the form indicated by *aTable* and *form*.

*selector* indicates the parameter of the form whose value you want to find out. You can use the following constant, found in the "**Form Parameters**" theme:

| Constant | Type | Value |
|---|---|---|
| NonInverted objects | Longint | 0 |

When you use the NonInverted Objects constant as *selector*, the command returns, in *value*, the actual display mode of the form in Application mode under Windows. This parameter is used when applications are displayed using "right-to-left" languages. For more information about the support of right-to-left languages, please refer to the *Design Reference* manual of 4D.

- If *value* returns 0, the form objects are inverted,
- If *value* returns 1, the form objects are not inverted.

If the command is not called within the context of the Application mode under Windows, it always returns 1.

Keep in mind that the actual inversion of form objects will depend on a combination of several parameters: the values of the "Inversion of objects in Application mode" preference, the value of the "Do not invert objects" form option and the system on which the database is running. The following table specifies the value returned by the **FORM GET PARAMETER** command depending on the various combinations of these parameters:

| Preferences: "Inversion of objects in Application mode" (1) | Form property: "Do not invert objects" | Right-to-left Display under Windows | Value returned by FORM GET PARAMETER |
|---|---|---|---|
| No | X | X | 1 |
| | | X | 1 |
| | X | | 1 |
| | | | 1 |
| Automatic | X | X | 1 |
| | | X | 0 |
| | X | | 1 |
| | | | 1 |
| Yes | X | X | 1 |
| | | X | 0 |
| | X | | 1 |
| | | | 0 |

(1) This preference can also be set or read using the **SET DATABASE PARAMETER** and **Get database parameter** commands.

# FORM GET PROPERTIES

FORM GET PROPERTIES ( {aTable ;} formName ; width ; height {; numPages {; fixedWidth {; fixedHeight {; title}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table of the form or Default table, if omitted |
| formName | String | ⇒ | Name of the form |
| width | Longint | ⇐ | Width of the form (in pixels) |
| height | Longint | ⇐ | Height of the form (in pixels) |
| numPages | Longint | ⇐ | Number of pages in the form |
| fixedWidth | Boolean | ⇐ | True = Fixed width, False = Variable width |
| fixedHeight | Boolean | ⇐ | True = Fixed height, False = Variable height |
| title | Text | ⇐ | Title of the form's window |

## Description

The **FORM GET PROPERTIES** command returns the properties of the form *formName*.

The *width* and *height* parameters return the form's width and height in pixels. These values are determined from the form's Default window size properties:

- If the form's size is **automatic**, its width and height are calculated so that all the form's objects are visible, by taking into consideration the horizontal and vertical margins that were defined.
- If the form's size is **set**, its width and height are those manually entered in the corresponding areas.
- If the form's size is **based on an object**, its width and height are calculated in relation to this object's position.

The *numPages* parameter returns the number of pages in the form, excluding page 0 (zero).

The *fixedWidth* and *fixedHeight* parameters indicate if the length and width of the form are resizable (the parameter returns **False**) or set (the parameter returns **True**).

The *title* parameter returns the title of the form's window as it was defined in the Property List of the Form editor. If no name was defined, the *title* parameter returns an empty string.

# FORM GET VERTICAL RESIZING

FORM GET VERTICAL RESIZING ( resize {; minHeight {; maxHeight}} )

| Parameter | Type | | Description |
|---|---|---|---|
| resize | Boolean | ⇦ | True: Form can be resized vertically False: Form cannot be resized vertically |
| minHeight | Longint | ⇦ | Smallest form height allowed (pixels) |
| maxHeight | Longint | ⇦ | Largest form height allowed (pixels) |

## Description

The **FORM GET VERTICAL RESIZING** command returns the vertical resizing properties of the current form in the *resize*, *minHeight* and *maxHeight* variables. These properties may have been set for the form in the Form editor in Design mode or for the current process via the **FORM SET VERTICAL RESIZING** command.

# FORM GOTO PAGE

FORM GOTO PAGE ( pageNumber {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| pageNumber | Longint | ⇒ | Form page to display |
| * | Operator | ⇒ | Change page of current subform |

## Description

**FORM GOTO PAGE** changes the currently displayed form page to the form page specified by *pageNumber*.

If no form is displayed or loaded by the **FORM LOAD** command, or if *pageNumber* corresponds to the current page of the form, **FORM GOTO PAGE** does nothing. If *pageNumber* is greater than the number of pages, the last page is displayed. If *pageNumber* is less than one, the first page is displayed.

The * parameter is useful when the command is called in the context of a page type subform containing several pages. In this case, when you pass this parameter, the command changes the page of the current subform (the one that called the command). By default, when the * parameter is omitted, the command is always applied to the parent form.

### About form page management commands

Automatic action buttons perform the same tasks as the **FORM FIRST PAGE**, **FORM LAST PAGE**, **FORM NEXT PAGE**, **FORM PREVIOUS PAGE** and **FORM GOTO PAGE** commands that you can apply to objects such as tab controls, drop-down list boxes, and so on. Whenever appropriate, use automatic action buttons instead of commands.

Page commands can be used with input forms or with forms displayed in dialogs. Output forms use only the first page. A form always has at least one page—the first page. Remember that regardless of the number of pages a form has, only one form method exists for each form.

- Use the **FORM Get current page** command to find out which page is being displayed.
- Use the On Page Change **Form event** that is generated each time the current page of the form changes.

**Note:** When **designing** a form, you can work with pages 1 through X, as well as with page 0, in which you put objects that will appear in all of the pages. When **using** a form, and therefore when calling page commands, you work with pages 1 through X; page 0 is automatically combined with the page being displayed.

## Example

The following example is an object method for a button. It displays a specific page, page 3:

```
FORM GOTO PAGE(3)
```

# FORM LAST PAGE

FORM LAST PAGE
Does not require any parameters

## Description

**FORM LAST PAGE** changes the currently displayed form page to the last form page. If a form is not being displayed or loaded by the **FORM LOAD** command, or if the last form page is already displayed, **FORM LAST PAGE** does nothing.

## Example

The following example is a one-line method called from a menu command. It displays the last form page:

```
FORM LAST PAGE
```

# FORM LOAD

FORM LOAD ( {aTable ;} form {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table form to load (if omitted, load a project form) |
| form | String | ⇒ | Name of form (project or table) to open |
| * | Operator | ⇒ | If passed = command applies to host database when it is executed from a component (parameter ignored outside of this context) |

## Description

The **FORM LOAD** command is used to load the *form* (project or table) in memory in the current process in order to print its data or parse its contents. There can only be one current form per process.

### Printing data

In order to be able to execute this command, a print job must be opened beforehand using the **OPEN PRINTING JOB** command. The **OPEN PRINTING JOB** command makes an implicit call to the **FORM UNLOAD** command, so in this context it is necessary to execute **FORM LOAD**. Once loaded, this *form* becomes the current printing form. All the object management commands, and in particular the **Print object** command, work with this form.

If a printing form has already been loaded beforehand (via a previous call to the **FORM LOAD** command), it is closed and replaced by *form*. You can open and close several project forms in the same print session. Changing the printing form via the **FORM LOAD** command does not generate page breaks. It is up to the developer to manage page breaks.

Only the On Load form event is executed during the opening of the project form, as well as any object methods of the form. Other form events are ignored. The On Unload form event is executed at the end of printing.

To preserve the graphic consistency of forms, it is recommended to apply the "Printing" appearance property regardless of the platform.

The current printing form is automatically closed when the **CLOSE PRINTING JOB** command is called.

**Compatibility note:** In versions of 4D prior to v14, the **FORM LOAD** command (named OPEN PRINTING FORM) accepted an empty string in the *form* parameter to close the current project form. This syntax is no longer supported and returns an error. You must use the **FORM UNLOAD** command or the **CLOSE PRINTING JOB** command in order to close the form.

### Parsing form contents

This consists in loading an off-screen form for parsing purposes. To do this, just call **FORM LOAD** outside the context of a print job. In this case, form events are not executed.

**FORM LOAD** can be used with the **FORM GET OBJECTS** and **OBJECT Get type** commands in order to perform any type of processing on the form contents. You must then call the **FORM UNLOAD** command in order to release the form from memory.

Note that in all cases, the form on screen remains loaded (it is not affected by the **FORM LOAD** command) so it is not necessary to reload it after calling **FORM UNLOAD**.

When the command is executed from a component, it loads the component forms by default. If you pass the * parameter, the method loads the host database forms.

**Reminder:** In the off-screen context, do not forget to call **FORM UNLOAD** to avoid any risk of memory overflow.

## Example 1

Calling a project form in a print job:

```
OPEN PRINTING JOB
FORM LOAD("print_form")
 // execution of events and object methods
```

## Example 2

Calling a table form in a print job:

```
OPEN PRINTING JOB
FORM LOAD([People];"print_form")
 // execution of events and object methods
```

## Example 3

Parsing of form contents to carry out processing on text input areas:

```
FORM LOAD([People];"my_form")
 // selection of form without execution of events or methods
FORM GET OBJECTS(arrObjNames;arrObjPtrs;arrPages;*)
For($i;1;Size of array(arrObjNames))
   If(OBJECT Get type(*;arrObjNames{$i})=Object type text input)
 //… processing
   End if
End for
FORM UNLOAD //do not forget to unload the form
```

# FORM NEXT PAGE

FORM NEXT PAGE
Does not require any parameters

## Description

**FORM NEXT PAGE** changes the currently displayed form page to the next form page. If no form is being displayed or loaded by the **FORM LOAD** command, or if the last form page is already displayed, **FORM NEXT PAGE** does nothing.

## Example

The following example is a one-line method called from a menu command. It displays the form page that follows the one currently displayed:

```
FORM NEXT PAGE
```

# FORM PREVIOUS PAGE

FORM PREVIOUS PAGE
Does not require any parameters

## Description

**FORM PREVIOUS PAGE** changes the currently displayed form page to the previous form page. If no form is being displayed or loaded by the **FORM LOAD** command, or if the first form page is already displayed, **FORM PREVIOUS PAGE** does nothing.

## Example

The following example is a one-line method called from a menu command. It displays the form page that precedes the one currently displayed:

```
FORM PREVIOUS PAGE
```

# FORM SCREENSHOT

FORM SCREENSHOT ( {{aTable ;} formName ;} formPict {; pageNum} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Form table |
| formName | Text | ⇒ | Name of form |
| formPict | Picture | ⇐ | Picture of form being executed if first parameter(s) omitted, or<br>Picture of form in Form editor if a form name is passed |
| pageNum | Longint | ⇒ | Form page number |

## Description

The **FORM SCREENSHOT** command returns a form as a picture. This command accepts two different syntaxes: depending on the syntax used, you get either a picture of an executed form, or a picture of the form in the Form editor.

- **FORM SCREENSHOT** ( *formPict* )
  This syntax gets the exact screenshot of the current page of the form being executed or loaded by means of the **FORM LOAD** command: the picture returned in the *formPict* parameter contains all the form's visible objects with the current field and variable values of the form, subform, and so on. The form is returned in full, without taking the size of the window that contains it into account.
  Note that this syntax only works with input forms.

- **FORM SCREENSHOT** ( {*aTable* ;} *formName* ; *formPict* {; *pageNum*} )
  This syntax gets a screenshot of a form "template" as it is displayed in the Form editor. All visible objects are drawn like they are in the editor; the command takes inherited forms and objects placed on page 0 into account.
  If you want a screenshot for a table form, pass the form table in the *aTable* parameter and then pass its name as a string in *formName*. For a project form, pass the form name directly in *formName*.
  By default, the command returns a screenshot of page 1 of the form. If you only want a picture of page 0, or any other page of the form, pass the desired page number in the *pageNum* parameter.

**Note:** Since the first two parameters of this command are optional, you cannot pass a function returning a pointer, such as **Current form table**-> or **Table**->, directly as an argument. Although this syntax would work in interpreted mode, it would be rejected during compilation, so instead you need to use an intermediate pointer variable in this case. For more information, refer to "**Direct use of commands returning pointers**".

# FORM SET HORIZONTAL RESIZING

FORM SET HORIZONTAL RESIZING ( resize {; minWidth {; maxWidth}} )

| Parameter | Type | | Description |
|---|---|---|---|
| resize | Boolean | ⇒ | True: The form can be resized horizontally False: The form cannot be resized horizontally |
| minWidth | Longint | ⇒ | Smallest form width allowed (pixels) |
| maxWidth | Longint | ⇒ | Largest form width allowed (pixels) |

## Description

The **FORM SET HORIZONTAL RESIZING** command allows you to change the horizontal resizing properties of the current form through programming. By default, these properties are set in the Design environment Form editor. New properties are set for the current process; they are not stored with the form.

The *resize* parameter lets you set whether the form can be resized horizontally; in other words, if the width can be changed (manually by the user or through programming).

If you pass **True**, the form width can be modified by the user; 4D uses values passed in *minWidth* and *maxWidth* as markers.

If you pass **False**, the current form width cannot be changed; in this case, there is no need to pass values in the *minWidth* and *maxWidth* parameters.

If you passed **True** in the first parameter, you can pass new minimum and maximum widths (in pixels) in the optional *minWidth* and *maxWidth* parameters. If you leave these parameters out, the values set in the Design environment (if any) are used.

## Example

Refer to the example of the **FORM SET SIZE** command.

# FORM SET INPUT

FORM SET INPUT ( {aTable ;} form {; userForm}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to set the input form, or Default table, if omitted |
| form | String | ⇒ | Name of the form to set as input form |
| userForm | String | ⇒ | Name of user form to use |
| * | | ⇒ | Automatic window size |

## Description

The **FORM SET INPUT** command sets the current input form for *aTable* to *form* or *userForm*. The form must belong to *aTable*.

The scope of this command is the current process. Each table has its own input form in each process.

**Note:** For structural reasons, this command is not compatible with project forms. If you pass a project form in *form*, the command does nothing.

**FORM SET INPUT** does not display the form; it just designates which form is used for data entry, import, or operation by another command. For information about creating forms, see the 4D *Design Reference* manual.

The default input form is defined in the Explorer window for each table. This default input form is used if the **FORM SET INPUT** command is not used to specify an input form, or if you specify a form that does not exist.

The optional *userForm* parameter lets you specify a user form (coming from *form*) as the default input form. If you pass a valid user form name, this form will be used by default instead of the input form in the current process. This allows you to have several different custom user forms simultaneously (generated using the **CREATE USER FORM** command) and to use the one that suits according to the context.
For more information about user forms, refer to the **Overview of user forms** section.

Input forms are displayed by a number of commands, which are generally used to allow the user to enter new data or modify old data. The following commands display an input form for data entry or query purposes:

- **ADD RECORD**
- **DISPLAY RECORD**
- **MODIFY RECORD**
- **QUERY BY EXAMPLE**

The **DISPLAY SELECTION** and **MODIFY SELECTION** commands display a list of records using the output form. The user can double-click on a record in the list, which displays the input form.

The import commands **IMPORT TEXT**, **IMPORT SYLK** and **IMPORT DIF** use the current input form for importing records.

The optional * parameter is used in conjunction with the form properties you set in the Design environment Form Properties window and the command **Open window**. Specifying the * parameter tells 4D to use the form properties to automatically resize the window for the next use of the form (as an input form or as a dialog box). See **Open window** for more information.

**Note:** Whether or not you pass the optional * parameter, **FORM SET INPUT** changes the input form for the table.

## Example 1

The following example shows a typical use of **FORM SET INPUT**:

```
FORM SET INPUT([Companies];"New Comp") ` Form for adding new companies
ADD RECORD([Companies]) ` Add a new company
```

## Example 2

In an invoicing database managing several companies, the creation of an invoice must be carried out using the corresponding user form:

```
Case of
   :(company="4D SAS")
      FORM SET INPUT([Invoices];"Input";"4D_SAS")
   :(company="4D Inc")
      FORM SET INPUT([Invoices];"Input";"4D_Inc")
   :(company="Acme")
      FORM SET INPUT([Invoices];"Input";"ACME")
End case
ADD RECORD([Factures])
```

# FORM SET OUTPUT

FORM SET OUTPUT ( {aTable ;} form {; userForm} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to set the output form, or Default table, if omitted |
| form | String | ⇒ | Form name |
| userForm | String | ⇒ | Name of user form to use |

## Description

The **FORM SET OUTPUT** command sets the current output form for *table* to *form* or *userForm*. The form must belong to *aTable*.

The scope of this command is the current process. Each table has its own output form in each process.

**Note:** For structural reasons, this command is not compatible with project forms. If you pass a project form in *form*, the command does nothing.

**FORM SET OUTPUT** does not display the form; it just designates which form is printed, displayed, or used by another command. For information about creating forms, see the 4D *Design Reference* manual.

The default output form is defined in the Explorer window for each table. This default output form is used if the **FORM SET OUTPUT** command is not used to specify an output form, or if you specify a form that does not exist.

The optional *userForm* parameter lets you specify a user form (coming from *form*) as the default output form. If you pass a valid user form name, this form will be used by default instead of the output form in the current process. This allows you to have several different custom user forms simultaneously (generated using the **CREATE USER FORM** command) and to use the one that suits according to the context.

For more information about user forms, refer to the **Overview of user forms** section.

Output forms are used by three groups of commands. One group displays a list of records on screen, another group generates reports, and the third group exports data. The **DISPLAY SELECTION** and **MODIFY SELECTION** commands display a list of records using an output form. You use the output form when creating reports with the **PRINT LABEL** and **PRINT SELECTION** commands. Each of the export commands (**EXPORT DIF**, **EXPORT SYLK** and **EXPORT TEXT**) also uses the output form.

## Example

The following example shows a typical use of **FORM SET OUTPUT**. Note that although the **FORM SET OUTPUT** command appears immediately before the output form is used, this is not required. In fact, the command may be executed in a completely different method, as long as it is executed prior to this method:

```
FORM SET INPUT([Parts];"Parts In") ` Select the input form
FORM SET OUTPUT([Parts];"Parts List") ` Select the output form
MODIFY SELECTION([Parts]) ` This command uses both forms
```

# FORM SET SIZE

FORM SET SIZE ( {object ;} horizontal ; vertical {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| object | String | ⇒ | Object name indicating form limits |
| horizontal | Longint | ⇒ | If * passed: horizontal margin (pixels)<br>If * omitted: width (pixels) |
| vertical | Longint | ⇒ | If * passed: vertical margin (pixels)<br>If * omitted: height (pixels) |
| * | Operator | ⇒ | • If passed, use horizontal and vertical as form margins<br>• If omitted, use horizontal and vertical as width and height of the form<br>This parameter cannot be passed if the object parameter is passed. |

## Description

The **FORM SET SIZE** command allows you to change the size of the current form by programming. The new size is defined for the current process; it is not saved with the form.

As in the Design environment, you can use this command to set the form size in three ways:

- Automatically — 4D determines the size of the form based on the notion that all objects must be visible — and possibly adding a horizontal and vertical margin,
- On the place where a form object is found, where a horizontal and vertical margin may be added,
- By entering “fixed” sizes (width and height).
  For more information on resizing forms, refer to the 4D *Design Reference* manual.

**Automatic size**

If you want the size of the form to be set automatically, you must use the following syntax:

```
FORM SET SIZE(horizontal;vertical;*)
```

In this case, you must pass the margins (in pixels) that you want to add to the right and bottom of the form in *horizontal* and *vertical*.

**Object-based size**

If you want the form size to be based on an object, you must use the following syntax:

```
FORM SET SIZE(object;horizontal;vertical)
```

In this case, you must pass the margins (in pixels) that you want to add to the right and bottom of the object in *horizontal* and *vertical*. You cannot pass the * parameter.

**Fixed size**

In you want to have a fixed form size, you must use the following syntax:

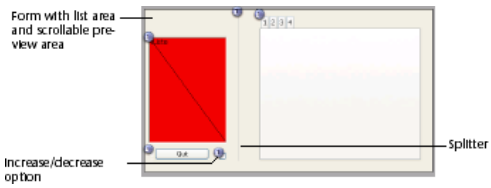
```
FORM SET SIZE(horizontal;vertical)
```

In this case, you must pass the width and height (in pixels) of the form in *horizontal* and *vertical*.

The **FORM SET SIZE** command changes the size of the form, but also takes into account the resizing properties. For example, if the minimum width of a form is 500 pixels and if the command sets a width of 400 pixels, the new form width will be 500 pixels.
Also note that this command does not change the size of the form window (you can resize a form without changing the size of the window and vice versa). To change the size of the form window, refer to the **RESIZE FORM WINDOW** command.

## Example

The following example shows how an Explorer type window is set up. The following form is created in the Design environment :

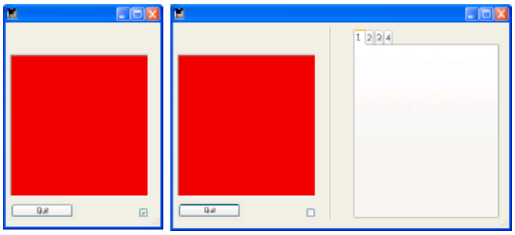


The size of the form is “automatic”.

The window is displayed using the following code:

```
$ref:=Open form window([Table 1];"Form1";Plain form window;Horizontally centered;Vertically centered;*)
DIALOG([Table 1];"Form1")
CLOSE WINDOW
```

The right part of the window can be displayed or hidden by clicking on the increase/decrease option:



The object method associated with this button is as follows:

```
Case of
   :(Form event=On Load)
      C_BOOLEAN(b1;<>collapsed)
      C_LONGINT(margin)
      margin:=15
      b1:=<>collapsed
      If(<>collapsed)
         FORM SET HORIZONTAL RESIZING(False)
         FORM SET SIZE("b1";margin;margin)
      Else
         FORM SET HORIZONTAL RESIZING(True)
         FORM SET SIZE("tab";margin;margin)
      End if

   :(Form event=On click)
      <>collapsed:=b1
      If(b1)
 `collapsed
         OBJECT GET COORDINATES(*;"b1";$l;$t;$r;$b)
         GET WINDOW RECT($lf;$tf;$rf;$bf;Current form window)
         SET WINDOW RECT($lf;$tf;$lf+$r+margin;$tf+$b+margin;Current form window)
         SET FORM HORIZONTAL RESIZING(False)
         SET FORM SIZE("b1";margin;margin)

      Else
 `expanded
         OBJECT GET COORDINATES(*;"tab";$l;$t;$r;$b)
         GET WINDOW RECT($lf;$tf;$rf;$bf;Current form window)
         SET WINDOW RECT($lf;$tf;$lf+$r+margin;$tf+$b+margin;Current form window)
         FORM SET HORIZONTAL RESIZING(True)
         FORM SET SIZE("tab";margin;margin)
      End if

End case
```

# FORM SET VERTICAL RESIZING

FORM SET VERTICAL RESIZING ( resize {; minHeight {; maxHeight}} )

| Parameter | Type | | Description |
|---|---|---|---|
| resize | Boolean | ⇒ | True: The form can be resized vertically<br>False: The form cannot be resized vertically |
| minHeight | Longint | ⇒ | Smallest form height allowed (pixels) |
| maxHeight | Longint | ⇒ | Largest form height allowed (pixels) |

## Description

The **FORM SET VERTICAL RESIZING** command allows you to change the vertical resizing properties of the current form through programming. By default, these properties are set in the Design environment Form editor. New properties are set for the current process; they are not stored with the form.

The *resize* parameter lets you set whether the form can be resized vertically; in other words, if the height can be changed (manually by the user or through programming).

If you pass **True**, the form height can be modified by the user; 4D uses values passed in *minHeight* and *maxHeight* as markers.

If you pass **False**, the current form height cannot be changed; in this case, there is no need to pass values in the *minHeight* and *maxHeight* parameters.

If you passed **True** in the first parameter, you can pass new minimum and maximum heights (in pixels) in the optional *minHeight* and *maxHeight* parameters. If you leave these parameters out, the values set in the Design environment (if any) are used.

## Example

Refer to the example of the **FORM SET SIZE** command.

# FORM UNLOAD

FORM UNLOAD
Does not require any parameters

## Description

The **FORM UNLOAD** command releases from memory the current form designated using the **FORM LOAD** command.

Calling this command is necessary when you use the **FORM LOAD** command outside of the printing context (in the case of printing, the current form is automatically closed again when the **CLOSE PRINTING JOB** command is called).

# Formulas

- Using tokens in formulas
- EDIT FORMULA
- EXECUTE FORMULA
- GET ALLOWED METHODS
- SET ALLOWED METHODS

# Using tokens in formulas

## Overview

4D's language includes a unique *tokenization* system for all object names of the language that are used in the code (constants, commands, tables, fields and keywords). *Tokenizing* these names means that as you type in the code editor they are stored internally as absolute references (numbers) and then restored as text during execution or display depending on the context. This allows you to guarantee that the code will always be interpreted correctly, even if you rename your tables or fields, or when 4D language commands are renamed over the course of different application versions.

**Note:** This also ensures automatic translation of the code when you have enabled the "Use regional system settings" option on the **Methods Page** of the Preferences and open your databases with 4D versions in different languages.

*Tokenisation* is completely transparent for 4D developers when working in the code editor. However, this mechanism is not automatically implemented in 4D formulas since they consist of text that is interpreted at runtime, and not as it is typed. In fact, this is the case as soon as 4D code is expressed as raw text, more specifically when code is exported and then imported using the **METHOD GET CODE** and **METHOD SET CODE** commands, copied/pasted or interpreted from **4D Transformation Tags**.
To continue to benefit from *tokenization* mechanisms in these contexts, you just need to use an explicit syntax (described below) which consists in preceding object names in the language by their *token*.

## Token syntax

By default, the *token* mechanism is not implemented automatically in 4D formulas (as well as contexts where 4D code is expressed as raw text, see above). As a result, for named elements contains in expressions, 4D offers a special syntax you can use to reference the *tokens* directly: you just need to add a specific suffix after the element name to indicate its type (command, field, etc.), followed by its reference. The **token syntax** is detailed in this table:

| Element | Example (standard syntax) | Suffix | Example (token syntax) | Comments |
|---|---|---|---|---|
| 4D Command | String(a) | :Cxx | String:C10(a) | xx is the command number |
| Table | [Employees] | :xx | [Employees:1] | xx is the table number |
| Field | [Employees]Name | :xx | [Employees:1]Name:2 | xx is the field number |
| 4D Plugin | PV PRINT(area) | :Pxx:yy | PV PRINT:P13000:229(area) | xx is the plug-in ID and yy is the index of the command |

**Note:** Uppercase letters (C, P) must be used in the suffixes; otherwise, they will not be interpreted correctly.

When you use this syntax, you guarantee that your formulas will be interpreted correctly even in the case of renaming or when the database is executed in a different language.

**Note :** Constants are also tokenized in the language however in formulas you can just pass their value in order make them independent of the context.

This syntax is accepted in all 4D formulas (or 4D expressions) regardless of the calling context:

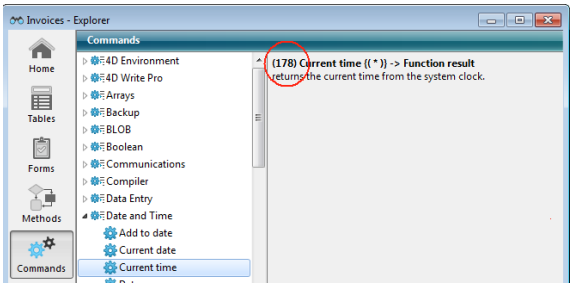
- 4D formulas executed using the **Formula editor** or using commands such as **EXECUTE FORMULA**, **APPLY TO SELECTION**, **QUERY BY FORMULA**, **LISTBOX INSERT COLUMN FORMULA**, etc.
- expressions inserted in rich text areas (see **ST INSERT EXPRESSION** and **Supported tags**),
- expressions calculated in transformation tags (see **4D Transformation Tags**),
- expressions inserted in plug-in areas,
- expressions inserted in 4D Write Pro areas (starting with 4D v15).

## Where to find the element numbers?

The token syntax requires the addition of the reference numbers of various elements. The location of these references depends on the type of element.

### 4D commands

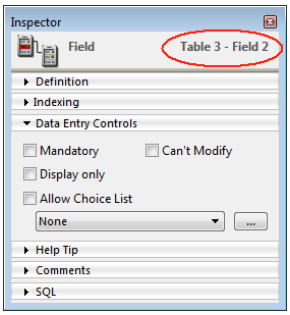
Command numbers can be found in this *Language Reference* manual ("Properties" area) as well as on the **Commands** page of the Explorer:



## Tables and fields

Table and field numbers can be obtained using the **Table** and **Field** commands.

They are also displayed in the **Inspector palette** of the Structure editor:



## 4D plug-in commands

To know what the tokens are for 4D plug-in commands, the trick is to enter the desired code in the Method editor and then restart 4D after disabling the plug-in (for example, by moving its folder). This means that only tokens will be displayed in the Method editor, and you can then copy the ones you need.

Code with plug-in installed:

```
12    PV SET ROWS HEIGHT (Area;1;10;PV Get row height (Area;10)+$Height)
```

The same code after plug-in has been disabled:

```
12    ô13000;75ô (Area;1;10;ô13000;76ô (Area;10)+$Height)
```

# EDIT FORMULA

EDIT FORMULA ( aTable ; formula )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to display by default in the Formula editor |
| formula | String variable | ⇒ | Variable containing the formula to display in the Formula editor or "" to display editor only |
| | | ⇐ | Formula validated by the user |

## Description

The **EDIT FORMULA** command displays the Formula editor in order to let the user write or modify a formula. The editor contains the following on opening:

- in the left list, the fields of the table passed in the *table* parameter,
- in the formula area, the formula contained in the *formula* variable. If you passed an empty string in *formula*, the Formula editor is displayed without a formula.

The user can modify the *formula* displayed and save it. It is also possible to write or load a new formula. Regardless, if the user validates the dialog box, the system variable OK is set to 1 and the *formula* variable contains the formula defined by the user. If the user cancels the formula, the system variable OK is set to 0 and the *formula* variable is left untouched.

**Notes:**

- By default, access to methods and commands is restricted for all users (except for the Designer and Administrator, in databases created with 4D 2004.4 and higher). When this mechanism is enabled, you must explicitly designate the elements that can be accessed by the users using the **SET ALLOWED METHODS** command. If *formula* calls methods that were not first “authorized” in the Formula editor using the **SET ALLOWED METHODS** command, a syntax error is generated and you will not be able to validate the dialog box.
- The formula editor is not associated with any menu bar by default. You need to install a standard **Edit** menu in the calling process if you want users to be able to benefit from cut/copy/paste shortcuts in the formula editor.

Keep in mind that when the dialog box is validated, the command does not execute the *formula*; it only validates and updates the contents of the variable. If you want to execute the *formula*, you must use the **EXECUTE FORMULA** command.

## Example

Displaying the Formula editor with the [Employees] table and without a pre-entered formula:

```
$myFormula:=""
EDIT FORMULA([Employees];$myFormula)
If(OK=1)
   APPLY TO SELECTION([Employees];EXECUTE FORMULA($myFormula))
End if
```

## System variables and sets

If the user validates the dialog box, the system variable OK is set to 1. If the user cancels the dialog box, the system variable OK is set to 0.

# EXECUTE FORMULA

EXECUTE FORMULA ( statement )

| Parameter | Type | | Description |
|---|---|---|---|
| statement | String | ➡ | Code to be executed |

## Description

**EXECUTE FORMULA** executes *statement* as a line of code. The statement string must be one line. If *statement* is an empty string, **EXECUTE FORMULA** does nothing.

The rule of thumb is that if the *statement* can be executed as a one-line method, then it will execute properly. Use **EXECUTE FORMULA** sparingly, as it slows down execution speed. In a compiled database, the line of code is not compiled. This means that *statement* will be executed, but it will not have been checked by the compiler at compilation time.

**Note:** Executing formulas in compiled mode can be optimized using a cache (see **Cache for formulas in compiled mode** below).

The statement can include the following elements:

- a Call to a project method
- a Call to a 4D command
- an Assignment

The formula can include process variables and interprocess variables. However, the statement cannot contain control of flow statements (If, While, etc.), because it must be in one line of code.

To ensure that the *statement* will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

### Cache for formulas in compiled mode

For optimization purposes, each formula executed by **EXECUTE FORMULA** in compiled mode can be stored in a dedicated cache in memory. The formula is cached in tokenized form. Once it is placed in the cache, its subsequent executions are highly optimized since the tokenization step is bypassed.

The cache size is zero by default (no cache); it needs to be created or adjusted using the **SET DATABASE PARAMETER** command. For example:

```
SET DATABASE PARAMETER(Number of formulas in cache;0) //no cache for formulas
SET DATABASE PARAMETER(Number of formulas in cache;3) //up to three formulas can be cached for each process
```

The **EXECUTE FORMULA** command uses the cache only when called from a compiled database or component.

## Example

You want to execute formulas including calls to 4D commands and tables. Since these elements could potentially be renamed, you can ensure correct execution in future versions of your application by using the token syntax as shown here:

```
EXECUTE FORMULA("Year of:C25 ([Products:5]Creation_Date:2])+$add")
```

# GET ALLOWED METHODS

GET ALLOWED METHODS ( methodsArray )

| Parameter | Type | | Description |
|---|---|---|---|
| methodsArray | String array | ⇦ | Array of method names |

## Description

The **GET ALLOWED METHODS** command returns, in *methodsArray*, the names of methods that can be used to write formulas. These methods are listed at the end of the list of commands in the editor.

By default, methods cannot be used in the Formula editor. Methods must be explicitly authorized using the **SET ALLOWED METHODS** command. If this command has not been executed, **GET ALLOWED METHODS** returns an empty array.

**GET ALLOWED METHODS** returns exactly what was passed to the **SET ALLOWED METHODS** command, i.e. a string array (the command creates and sizes the array). Also, if the wildcard (@) character is used to set a group of methods, the string containing the @ character is returned (and not the names of the methods of the group).

This command is useful for storing the settings of the current set of authorized methods before the execution of a formula in a specific context (for instance, a quick report).

## Example

This example authorizes a set of specific methods to create a report:

```
 `Store current parameters
GET ALLOWED METHODS(methodsArray)

 `Define methods for quick report
methodsarr_Reports{1}:="Reports_@"
SET ALLOWED METHODS(methodsarr_Reports)
QR REPORT([People];"MyReport")

 `Re-establish current parameters
SET ALLOWED METHODS(methodsArray)
```

# SET ALLOWED METHODS

SET ALLOWED METHODS ( methodsArray )

| Parameter | Type | | Description |
|---|---|---|---|
| methodsArray | String array | ➡ | Array of method names |

## Description

The **SET ALLOWED METHODS** command sets the methods that are displayed in the Formula editor for the current session. The designated methods will appear at the end of the list of commands and can be used in formulas. By default (if this command is not used), no methods are visible in the Formula editor. If a formula uses an unauthorized method name, a syntax error is generated and the formula cannot be validated.

Pass the name of an array containing the list of methods to offer in the Formula editor in the *methodsArray* parameter. The array must have been set previously.
You can use the wildcard character (@) in method names to define one or more authorized method groups.

If you would like the user to be able to call 4D commands that are unauthorized by default or plug-in commands, you must use specific methods that handle these commands.

**Note:** The mechanism for restricting access to commands and methods in the Formula editor can be disabled for all users or for the Designer and Administrator by means of an option on the "Security" page of the Database Settings. If the "Disabled for all" option is checked, the **SET ALLOWED METHODS** command will have no effect.

## Example

This example authorizes all methods starting with “formula” and the “Total_general” method in the Formula editor:

```
ARRAY STRING(15;methodsArray;2)
methodsArray{1}:="formula@"
methodsArray{2}:="Total_general"
SET ALLOWED METHODS(methodsArray)
```

# Graphs

GRAPH
GRAPH SETTINGS
*_o_GRAPH TABLE*

# GRAPH

GRAPH ( graphPicture ; graphNumber | graphSettings ; xLabels {; yElements} {; yElements2 ; ... ; yElementsN} )

| Parameter | Type | | Description |
|---|---|---|---|
| graphPicture | Picture variable | ⇒ | Picture variable |
| graphNumber \| graphSettings | Longint, Object | ⇒ | Longint: Graph type number, Object (64-bits only): Graph settings |
| xLabels | Array | ⇒ | Labels for the x-axis |
| yElements | Array | ⇒ | Data to graph (up to eight allowed) |

## Description

***Compatibility note**: Beginning with 4D v14, the GRAPH command only works with a picture variable as its first parameter. The obsolete syntax using a graph area (4D Chart) is no longer supported.*

**GRAPH** draws a graph for a picture variable on the basis of values coming from arrays.

The graphs generated by this command are drawn using the integrated SVG rendering engine. They have interface functions associated with picture variables: a context menu in Application mode (to let you choose, more particularly, the display format), scrollbars, and so on.

**Note:** SVG (Scalable Vector Graphics) is a graphics file format (.svg extension). Based on XML, this format is widespread and can be displayed more particularly in Web browsers. For more information, please refer to the following address: http://www.w3.org.Graphics/SVG/. The **SVG EXPORT TO PICTURE** command can also be used to take advantage of the integrated SVG engine.

In the *graphPicture* parameter, pass the name of the picture variable that displays the graph in the form.

The second parameter specifies the type of graph that will be drawn. You have two options:

- pass a *graphNumber* parameter of the *Longint* type (all versions of 4D): In this case, you must pass a number from 1 to 8. The graph types are described in Example 1. After a graph has been drawn, you can change the type by changing *graphNumber* and executing the **GRAPH** command again. You can then modify certain graph characteristics by calling the **GRAPH SETTINGS** command. See Example 1.
- pass a *graphSettings* parameter of the *Object* type (64-bit versions of 4D only, except for 64-bit versions of 4D Server on Windows): In this case, you must pass an object that contains the various graph properties to define. To do this, you can use the constants found in the "**Graph Parameters**" theme (see below). This syntax allows you to define the graph type along with its specific settings (legend, xmin, etc.) in a single call. This allows users to save the generated graphs as regular SVG pictures and makes it possible to display them using a standard browser like FireFox, Chrome, IE, or Safari (the graphs generated have better compliance with the SVG standard implemented in browsers). Furthermore, this syntax gives you access to various extra settings, which allow you to customize, for example, spacing between bars, margins, bar colors, etc. See Examples 2, 3 and 4. **Warning**: If you use this syntax, the **GRAPH SETTINGS** command must NOT be called.

The *xLabels* parameter defines the labels that will be used to label the x-axis (the bottom of the graph). This data can be of string, date, time, or numeric type. There should be the same number of array elements in *xLabels* as there are subrecords or array elements in each of the *yElements*.

The data specified by *yElements* is the data to graph. The data must be numeric. Up to eight data sets can be graphed. Pie charts graph only the first *yElements*.

### Automatic IDs

Specific IDs are assigned automatically to elements found in the SVG graph:

| IDs | Description |
| --- | --- |
| ID_graph_1 to ID_graph_8 | Columns, lines, areas... |
| ID_graph_shadow_1 to ID_graph_shadow_8 | Shadows for columns, lines, areas... |
| ID_bullet_1 to ID_bullet_8 | Points (*Line and Scatter graphs only*) |
| ID_pie_label_1 to ID_pie_label_8 | Pie chart labels (*Pie chart graphs only*) |
| ID_legend | Legend |
| ID_legend_1 to ID_legend_8 | Legend titles |
| ID_legend_border | Legend borders |
| ID_legend_border_shadow | Shadows for legend borders |
| ID_x_values | Values of X axis |
| ID_y_values | Values of Y axis |
| ID_y0_axis | Values of Z axis |
| ID_background | Background |
| ID_background_shadow | Background shadow |
| ID_x_grid | Grid on X axis |
| ID_x_grid_shadow | Shadow for grid on X axis |
| ID_y_grid | Grid on Y axis |
| ID_y_grid_shadow | Shadow for grid on Y axis |

### graphSettings attributes

When you use the *graphSettings* parameter, you pass an object that contains the various graph properties to define. You can use the following constants, found in the "**Graph Parameters**" constant theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Graph background color | String | graphBackgroundColor | **Possible values:** SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph background opacity | String | graphBackgroundOpacity | **Possible values**: Integers, range 0-100<br>**Default value**: 100 |
| Graph background shadow color | String | graphBackgroundShadowColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph bottom margin | String | bottomMargin | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph colors | String | colors | **Possible values**: Text array. Colors for each graph series.<br>**Default values**: Blue-green (#19BAC9), Yellow (#FFC338), Purple (#573E82), Green (#4FA839), Orange (#D95700), Blue (#1D9DF2), Yellow-green (#B5CF32), Red (#D43A26) |
| Graph column gap | String | columnGap | **Possible value**s: Longints<br>**Default value**: 12<br>Sets spacing between bars |
| Graph column width max | String | columnWidthMax | **Possible values**: Real numbers<br>**Default value**: 200 |
| Graph column width min | String | columnWidthMin | **Possible values**: Real numbers<br>**Default value**: 10 |
| Graph default height | String | defaultHeight | **Possible values**: Real numbers<br>**Default value**: 400. If graphType=7 (Pie), then default value = 600 |
| Graph default width | String | defaultWidth | **Possible values**: Real numbers<br>**Default value**: 600. If graphType=7 (Pie), then default value = 800 |
| Graph display legend | String | displayLegend | **Possible value**s: Boolean<br>**Default value**: True |
| Graph document background color | String | documentBackgroundColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414". When a graph saved as an SVG picture is opened elsewhere, the document background color is only displayed if the SVG rendering engine supports the *SVG tiny 1.2* norm (supported on IE, Firefox, but not on Chrome). |
| Graph document background opacity | String | documentBackgroundOpacity | **Possible values**: Integer, range 0-100 (default value: 100). When a graph saved as an SVG picture is opened elsewhere, the document background opacity is only displayed if the SVG rendering engine supports the *SVG tiny 1.2* norm (supported on IE, Firefox, but not on Chrome). |
| Graph font color | String | fontColor | **Possible values:** SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph font size | String | fontSize | **Possible values**: Longints<br>**Default value**: 12. If graphType=7 (Pie), see Graph pie font size |
| Graph left margin | String | leftMargin | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph legend font color | String | legendFontColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Graph legend icon gap | String | legendIconGap | **Possible values**: Real numbers<br>**Default value**: Graph legend icon height/2 |
| Graph legend icon height | String | legendIconHeight | **Possible values**: Real numbers<br>**Default value**: 20 |
| Graph legend icon width | String | legendIconWidth | **Possible values**: Real numbers<br>**Default value**: 20 |
| Graph legend labels | String | legendLabels | **Possible values**: Text array. If missing, 4D displays icons without text. |
| Graph line width | String | lineWidth | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph pie font size | String | pieFontSize | **Possible values**: Real numbers<br>**Default value**: 16 |
| Graph pie shift | String | pieShift | **Possible values**: Real numbers<br>**Default value**: 8 |
| Graph plot height | String | plotHeight | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph plot radius | String | plotRadius | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph plot width | String | plotWidth | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph right margin | String | rightMargin | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph top margin | String | topMargin | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph type | String | graphType | **Possible values**: Longints [1 to 8] where 1 = bars, 2 = proportional, 3 = stacked, 4 = lines, 5 = surfaces, 6 = scatter, 7 = pie, 8 = pictures.<br>**Default value**: 1<br>If null, the graph is not drawn and no error message is displayed. If out of range, the graph is not drawn and an error message is displayed.<br>If you want to modify picture type graphs (value=8), you must copy the 4D/Resources/GraphTemplates/Graph_8_Pictures/ folder into the Resources folder of your database and perform the necessary modifications. Local picture files will be used instead of 4D files. There is no pattern for picture names; 4D sorts the files contained in the folder and assigns the first file to the first graph. These files can be of the SVG or image type. |
| Graph xGrid | String | xGrid | **Possible values**: Boolean<br>**Default value**: True.<br>Used only with proportional types 4 and 6. |
| Graph xMax | String | xMax | **Possible values**: Number, Date, Time (same type as *xLabels* parameter).<br>Only values lower than xMax are displayed on the graph. xMax is used only for graph types 4, 5, or 6 if xProp=true and if *xLabels* type is a number, date, or time. If missing or if xMin>xMax, 4D automatically calculates the xMax value. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Graph xMin | String | xMin | **Possible values**: Number, Date, Time (same type as *xLabels* parameter).<br>Only values higher than xMin are displayed on the graph. xMin is used only for graph types 4, 5, or 6 if xProp=true and if *xLabels* type is a number, date, or time. If missing or if xMin>xMax, 4D automatically calculates the xMin value. |
| Graph xProp | String | xProp | **Possible values**: Boolean<br>**Default value**: False<br>True for proportional x-axis; False for normal x-axis. xProp is used only for graph types 4, 5, or 6 |
| Graph yGrid | String | yGrid | **Possible values**: Boolean<br>**Default value**: True |
| Graph yMax | String | yMax | **Possible values**: Numbers<br>If missing, 4D automatically calculates the yMax value. |
| Graph yMin | String | yMin | **Possible values**: Numbers<br>If missing, 4D automatically calculates the yMin value. |

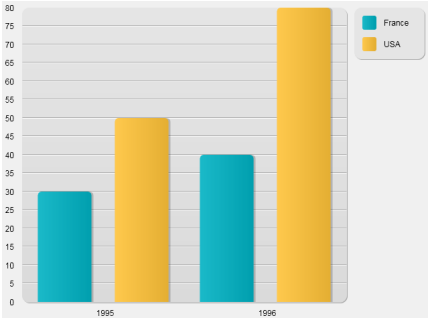
## Example 1

Syntax using *graphNumber*: The following example shows the different types of graphs that you can obtain. The code would be inserted in a form method or object method. It is not intended to be realistic, since the data is constant:

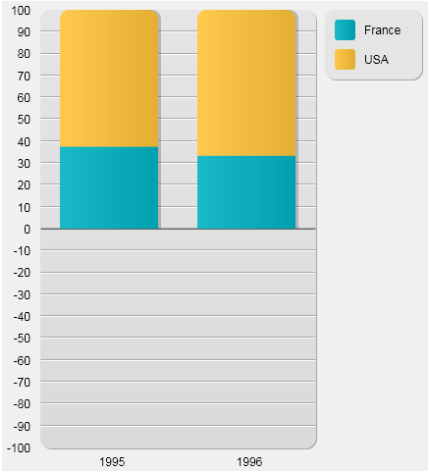
```
C_PICTURE(vGraph) //Variable of graph
ARRAY TEXT(X;2) //Create an array for the x-axis
X{1}:="1995" //X Label #1
X{2}:="1996" //X Label #2
ARRAY REAL(A;2) //Create an array for the y-axis
A{1}:=30 //Insert some data
A{2}:=40
ARRAY REAL(B;2) //Create an array for the y-axis
B{1}:=50 //Insert some data
B{2}:=80
vType:=1 //Initialize graph type
GRAPH(vGraph;vType;X;A;B) //Draw the graph
GRAPH SETTINGS(vGraph;0;0;0;0;False;False;True;"France";"USA") //Set the legends for the graph
```

The following figures show the resulting graph.

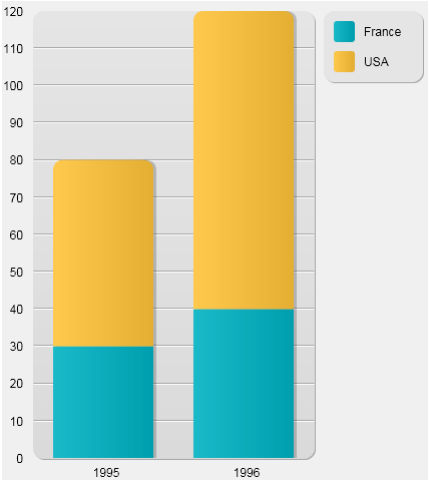
- With *vType* equal to 1, you obtain a **Column** graph:



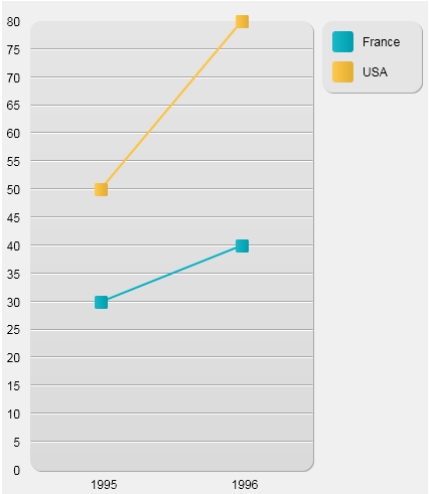
- With *vType* equal to 2, you obtain a **Proportional Column** graph:



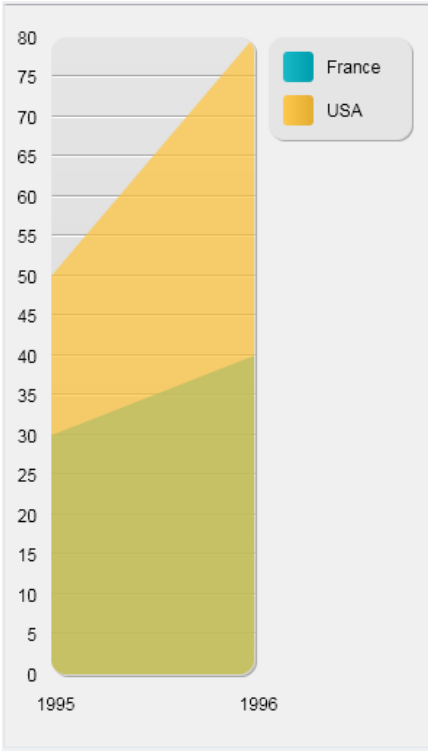
- With *vType* equal to 3, you obtain a **Stacked Column** graph:



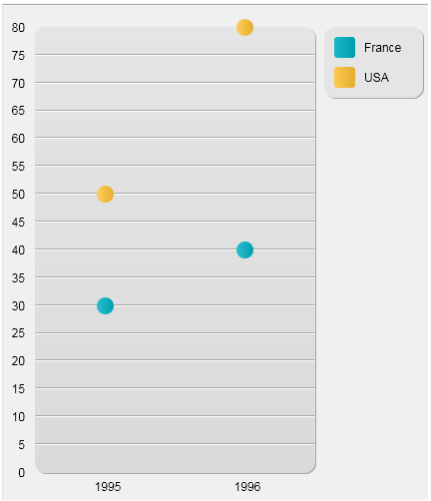
- With *vType* equal to 4, you obtain a **Line** graph:



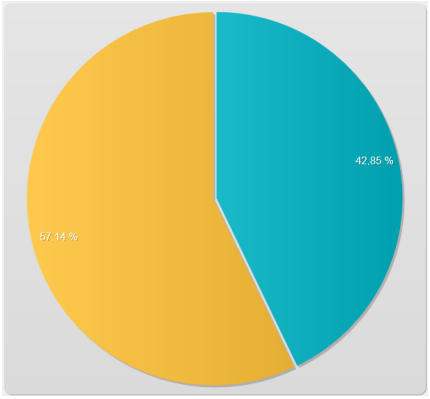
- With *vType* equal to 5, you obtain a **Area** graph:



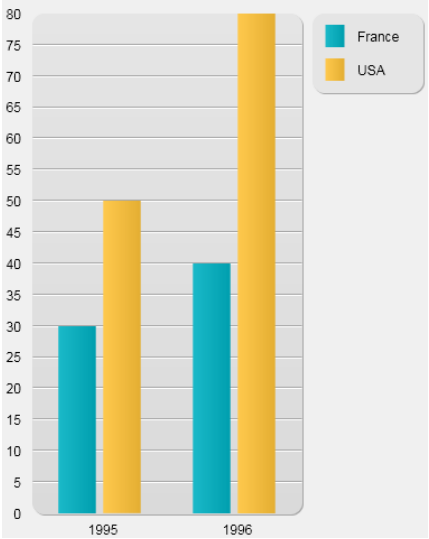
- With *vType* equal to 6, you obtain a **Scatter** graph:



- With *vType* equal to 7, you obtain a **Pie** graph:



- With *vType* equal to 8, you obtain a **Picture** graph:



**Note:** Pictures are simple rectangles by default.

## Example 2

Syntax using *graphSettings*: In the following example, you draw a simple line graph based on time values:

```
C_PICTURE(vGraph) //Graph variable
ARRAY TIME(X;3) //Create array for x-axis
X{1}:=?05:15:10? //X Label #1
X{2}:=?07:15:10? //X Label #2
X{3}:=?12:15:55? //X Label #3

ARRAY REAL(A;3) //Create array for y-axis
A{1}:=30 //Insert some data
A{2}:=22
A{3}:=50

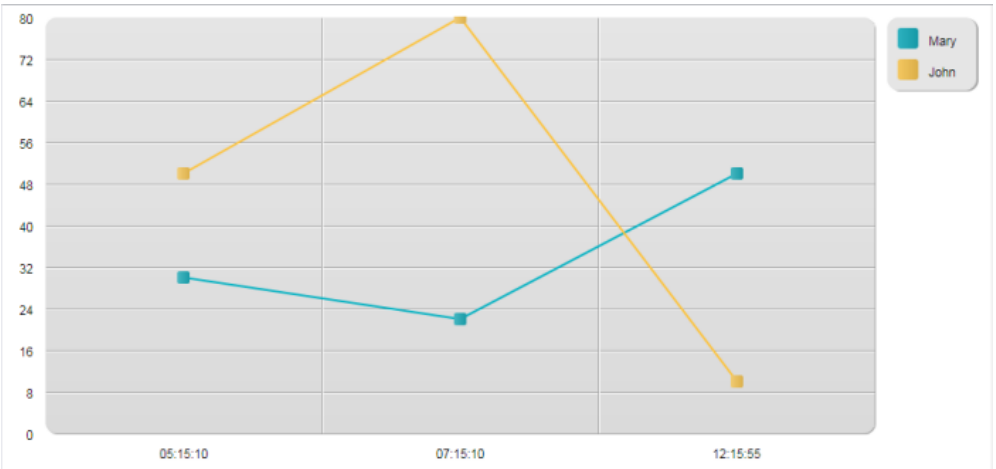
ARRAY REAL(B;3) //Create another array for y-axis
B{1}:=50 //Insert some data
B{2}:=80
B{3}:=10

C_OBJECT(vSettings) //Initialize graph settings

OB SET(vSettings;Graph type;4) //Line type

ARRAY TEXT(aLabels;2) //Set legends for graph
aLabels{1}:="Mary"
aLabels{2}:="John"
OB SET ARRAY(vSettings;Graph legend labels;aLabels)

GRAPH(vGraph;vSettings;X;A;B) //Draw graph
```



## Example 3

With the same values, you can add custom settings to obtain a different view:

```
C_PICTURE(vGraph) //Graph variable
ARRAY TIME(X;3) //Create an array for the x-axis
X{1}:=?05:15:10? //X Label #1
X{2}:=?07:15:10? //X Label #2
X{3}:=?12:15:55? //X Label #3

ARRAY REAL(A;3) //Create an array for the y-axis
A{1}:=30 //Insert some data
A{2}:=22
A{3}:=50

ARRAY REAL(B;3) //Create another array for the y-axis
B{1}:=50 //Insert some data
B{2}:=80
B{3}:=10

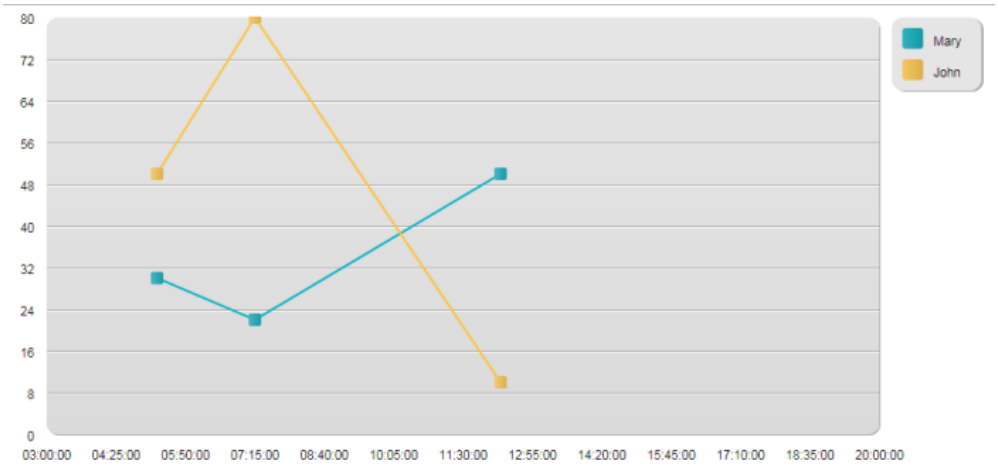
C_OBJECT(vSettings) //initializing graph settings

OB SET(vSettings;Graph type;4) //type Line

ARRAY TEXT(aLabels;2) //Set the legends for the graph
aLabels{1}:="Mary"
aLabels{2}:="John"
OB SET ARRAY(vSettings;Graph legend labels;aLabels)

 //options
OB SET(vSettings;Graph xProp;True) //set proportional
OB SET(vSettings;Graph xGrid;False) //remove the vertical grid
OB SET(vSettings;Graph xMin;?03:00:00?) //define boundaries
OB SET(vSettings;Graph xMax;?20:00:00?)

GRAPH(vGraph;vSettings;X;A;B) //Draw the graph
```



## Example 4

In this example, we customize a few settings:

```
C_PICTURE(vGraph) //Graph variable
ARRAY TEXT(X;5) //Create an array for the x-axis
X{1}:="Monday" //X Label #1
X{2}:="Tuesday" //X Label #2
X{3}:="Wednesday" //X Label #3
X{4}:="Thursday" //X Label #4
X{5}:="Friday" //X Label #5

ARRAY LONGINT(A;5) //Create an array for the y-axis
A{1}:=30 //Insert some data
```

```
A{2}:=22
A{3}:=50
A{4}:=45
A{5}:=55

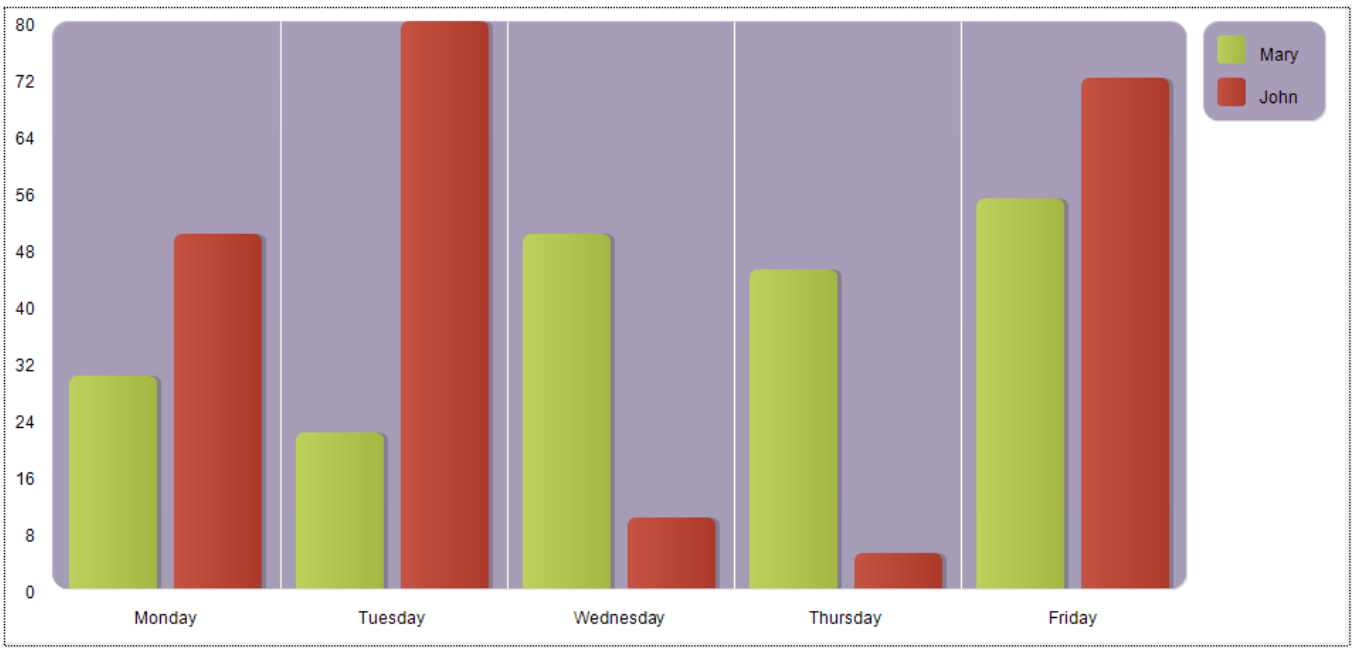
ARRAY LONGINT(B;5) //Create another array for the y-axis
B{1}:=50 //Insert some data
B{2}:=80
B{3}:=10
B{4}:=5
B{5}:=72

C_OBJECT(vSettings) //initializing graph settings

OB SET(vSettings;Graph type;1) //type Bars

ARRAY TEXT(aLabels;2) //Set the legends for the graph
aLabels{1}:="Mary"
aLabels{2}:="John"
OB SET ARRAY(vSettings;Graph legend labels;aLabels)

 //options
OB SET(vSettings;Graph yGrid;False) //remove the vertical grid
OB SET(vSettings;Graph background color;"#573E82") //set a background color
OB SET(vSettings;Graph background opacity;40)
ARRAY TEXT($aTcols;2) //Set the colors for the graph
$aTcols{1}:="#B5CF32"
$aTcols{2}:="#D43A26"
OB SET ARRAY(vSettings;Graph colors;$aTcols)
GRAPH(vGraph;vSettings;X;A;B) //Draw the graph
```



# GRAPH SETTINGS

GRAPH SETTINGS ( graphPicture ; xmin ; xmax ; ymin ; ymax ; xprop ; xgrid ; ygrid ; title {; title2 ; ... ; titleN} )

| Parameter | Type | | Description |
|---|---|---|---|
| graphPicture | Picture variable | ➡ | Picture variable |
| xmin | Longint, Date, Time | ➡ | Minimum x-axis value for proportional graph (line or scatter plot only) |
| xmax | Longint, Date, Time | ➡ | Maximum x-axis value for proportional graph (line or scatter plot only) |
| ymin | Longint | ➡ | Minimum y-axis value |
| ymax | Longint | ➡ | Maximum y-axis value |
| xprop | Boolean | ➡ | TRUE for proportional x-axis; FALSE for normal x-axis (line or scatter plot only) |
| xgrid | Boolean | ➡ | TRUE for x-axis grid; FALSE for no x-axis grid (only if xprop is TRUE) |
| ygrid | Boolean | ➡ | TRUE for y-axis grid; FALSE for no y-axis grid |
| title | String | ➡ | Title(s) for graph legend(s) |

## Description

**GRAPH SETTINGS** changes the graph settings for graph displayed in a form. The graph must have already been defined using the **GRAPH** command. **GRAPH SETTINGS** has no effect on a pie chart. This command must be called in the same process as the form.

**Note:** You must not call this command if the graph was generated using the **GRAPH** command with the *Object* type *graphSettings* parameter. Refer to the description of the **GRAPH** command for more information.

The *xmin*, *xmax*, *ymin*, and *ymax* parameters all set the minimum and maximum values for their respective axes of the graph. If the value of any pair of these parameters is a null value (0, ?00:00:00?, or !00/00/00!, depending on the data type), the default graph values will be used. The *xmin* and *xmax* parameters are only taken into account for proportional graphs (*xprop* is **True**).

The *xprop* parameter turns on proportional plotting for line graphs (type 4) and scatter graphs (type 6). When TRUE, it will plot each point on the x-axis according to the point's value, and then only if the values are numeric, time, or date.

**Note:** With the 4D Server 64-bit version for OS X, the *xprop* parameter is also taken into account for area graphs (type 5).

The *xgrid* and *ygrid* parameters display or hide grid lines. A grid for the x-axis will be displayed only when the plot is a proportional scatter or line graph.

The *title* parameter(s) labels the legend.

## Example

See example for the **GRAPH** command.

# _o_GRAPH TABLE

_o_GRAPH TABLE
Does not require any parameters

## Description

***Command deleted**: This command is no longer supported beginning with 4D v14*.

# Hierarchical Lists

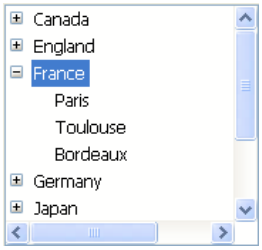
# Managing Hierarchical Lists

Hierarchical lists are form objects that can be used to display data as lists with one or more levels that can be expanded or collapsed.



In forms, hierarchical lists can be used for displaying or entering data. Each list item can contain up to 2 billion characters (maximum size of a text field) and be associated with an icon. They generally support clicks, double-clicks and keyboard navigation as well as drag and drop. It is possible to search the contents of a list (**Find in list** command).

## Creation and modification

Hierarchical lists can be created entirely by programming (via the **New list** or **Copy list** commands) or using lists defined in the List editor in Design mode (**Load list** command).

The contents and appearance of hierarchical lists are managed by programming using the commands of the "Hierarchical Lists" theme. Certain specific appearance characteristics can also be set using the generic commands of the **Object Properties** theme (see below).

You can associate hierarchical list references with form object choice lists (sources, required values and excluded values) dynamically using the **OBJECT SET LIST BY REFERENCE** or **OBJECT SET LIST BY NAME** commands. You can also associate choice lists defined in the List editor with form objects by means of the Property List.

## ListRef and object name

A hierarchical list is both a **language object** existing in memory and a **form object**.

The **language object** is referenced by an unique internal ID of the Longint type, designated by *ListRef* in this manual. This ID is returned by the commands that can be used to create lists: **New list**, **Copy list**, **Load list**, **BLOB to list**. There is only one instance of the language object in memory and any modification carried out on this object is immediately carried over to all the places where it is used.

The **form object** is not necessarily unique: there may be several representations of the same hierarchical list in the same form or in different ones. As with other form objects, you specify the object in the language using the syntax (*;"ListName", etc.).

You connect the hierarchical list "language object" with the hierarchical list "form object" by the intermediary of the variable containing the *ListRef* value. For example, if you write:

```
mylist:=New list
```

... you can simply associate the mylist variable name with the hierarchical list form object in the Property list so that it manages the language object whose *ListRef* is stored in mylist.

Each representation of the list has its own specific characteristics as well as sharing common characteristics with all the other representations.The following characteristics are specific to each representation of the list:

- The selection,
- The expanded/collapsed state of its items,
- The position of the scrolling cursor.

The other characteristics (font, font size, style, entry control, color, list contents, icons, etc.) are common to all the representations and cannot be modified separately.

Consequently, when you use commands based on the expanded/collapsed configuration or the current item, for example **Count list items** (when the final * parameter is not passed), it is important to be able to specify the representation to be used without any ambiguity.

You must use the *ListRef* ID with language commands when you want to specify the hierarchical list found in memory.

If you want to specify the representation of a hierarchical list object at the form level, you must use the object name (string type) in the command, via the syntax (*;"ListName", etc.).

This syntax is identical to that used in the commands of the "Object Properties" theme. It is accepted by most of the commands of the "Hierarchical Lists" theme that act on the properties of the lists (please see the description of the commands of this theme).

**Warning**: in the case of commands that set properties, the syntax based on the object name does not mean that only the form object specified will be modified by the command, but rather that the action of the command will be based on the state of this object. The common characteristics of hierarchical lists are always modified in all of their representations.

For example, if you pass the statement **SET LIST ITEM FONT**(*;"mylist1";*;thefont), you are indicating that you want to modify the font of the hierarchical list item associated with the mylist1 form object. The command will take the current item of the mylist1 object into account to specify the item to modify, but this modification will be carried over to all the representations of the list in all of the processes.

### Support of @

As with other object property management commands, it is possible to use the “@” character in the *ListName* parameter. As a rule, this syntax is used to designate a set of objects in the form. However, in the context of hierarchical list commands, this does not apply in every case. This syntax will have two different effects depending on the type of command:

- For commands that set properties, this syntax designates all the objects whose name corresponds (standard behavior). For example, the parameter "LH@" designates all objects of the hierarchical list type whose name begins with “LH.” These commands are:
  **DELETE FROM LIST**,
  **INSERT IN LIST**
  **SELECT LIST ITEMS BY POSITION**
  **SET LIST ITEM**
  **SET LIST ITEM FONT**
  **SET LIST ITEM ICON**
  **SET LIST ITEM PARAMETER**
  **SET LIST ITEM PROPERTIES**
- For commands retrieving properties, this syntax designates the first object whose name corresponds. These commands are:
  **Count list items**
  **Find in list**
  **GET LIST ITEM**
  **Get list item font**
  **GET LIST ITEM ICON**
  **GET LIST ITEM PARAMETER**
  **GET LIST ITEM PROPERTIES**
  **List item parent**
  **List item position**
  **Selected list items**

## Generic commands that can be used with hierarchical lists

It is possible to modify the appearance of a hierarchical list in a form using several generic 4D commands. You must pass to these commands either the object name of the hierarchical list (using the * parameter), or its variable name (standard syntax).

**Note:** In the case of hierarchical lists, the variable of the form contains the *ListRef* value. If you execute a command which modifies an attribute by passing the variable associated with the hierarchical list, it will not be possible to set the target list in the case of multiple representations. Therefore, only the object name allows you to differentiate individually between each different representation.

Here is a list of commands that can be used with hierarchical lists:
**OBJECT SET FONT**
**OBJECT SET FONT STYLE**
**OBJECT SET FONT SIZE**
**OBJECT SET COLOR**

**OBJECT SET FILTER**
**OBJECT SET ENTERABLE**
**OBJECT SET SCROLLBAR**
**OBJECT SET SCROLL POSITION**
**OBJECT SET RGB COLORS**

**Reminder:** Except for the **OBJECT SET SCROLL POSITION** command, these commands modify all the representations of the same list, even if you only specify a list via its object name

## Priority of property commands

Certain properties of hierarchical lists (for example, the Enterable attribute or the color) can be set in three different ways: via the Property list in Design mode, via a command of the "Object Properties" theme or via a command of the "Hierarchical Lists" theme.

When all three of these means are used to set list properties, the following order of priority is applied:

1. Commands of the "Hierarchical Lists" theme
2. Generic object property commands
3. Property list parameters

This principle is applied regardless of the order in which the commands are called. If an item property is modified individually via a hierarchical list command, the equivalent object property command will have no effect on this item even if it is called subsequently. For example, if you modify the color of an item via the **SET LIST ITEM PROPERTIES** command, the **OBJECT SET COLOR** command will have no effect on this item.

## Management of items by position or by reference

You can usually work in two ways with the contents of hierarchical lists: by position or by reference.

- When you work by position, 4D bases itself on the position in relation to the items of the list displayed on screen in order to identify them. The result will differ according to whether or not certain hierarchical items are expanded or collapsed. Note that in the case of multiple representations, each form object has its own configuration of expanded/collapsed items.
- When you work by reference, 4D bases itself on the *itemRef* ID number of the list items. Each item can thus be specified individually, regardless of its position or its display in the hierarchical list.

### Using item reference numbers (itemRef)

Each item of a hierarchical list has a reference number (*itemRef*) of the Longint type. This value is only intended for your own use: 4D simply maintains it.

**Warning:** You can use any type of Longint value as a reference number, except for 0. In fact, for most of the commands in this theme, the value 0 is used to specify the last item added to the list.

Here are a few tips for using reference numbers:

1. You do not need to identify each item with a unique number (beginner level).

- First example: you build a system of tabs by programming, for example, an address book. Since the system returns the number of the tab selected, you will probably not need more information than this. In this case, do not worry about item reference numbers: pass any value (except 0) in the *itemRef* parameter. Note that for an address book system, you can predefine a list A, B, ..., Z in Design mode, You can also create it by programming in order to eliminate any letters for which there are no records.

- Second example: while working with a database, you progressively build a list of keywords. You can save this list at the end of each session by using the **SAVE LIST** or **LIST TO BLOB** commands and reload it at the beginning of each new session using the **Load list** or **BLOB to list** commands. You can display this list in a floating palette; when each user clicks on a keyword in the list, the item chosen is inserted into the enterable area that is selected in the foreground process. You can also use drag and drop. In any case, the important thing is that you only process the item selected (by click or drag and drop), because the **Selected list items** (in the case of a click) and **DRAG AND DROP PROPERTIES** commands return the position of the item that you must process. When using this position value, you obtain the title of the item by means of the **GET LIST ITEM** command. Here again, you do not need to identify each item individually; you can pass any value (except 0) in the *itemRef* parameter.

2. You need to partially identify the list items (intermediary level).

You use the item reference number to store information needed when you must work with the item; this point is detailed in the example of the **APPEND TO LIST** command. In this example, we use the item reference numbers to store record numbers. However, we must be able to establish a distinction between items that correspond to the [Department] records and those that correspond to the [Employees] records.

3. You need to identify all the list items individually (advanced level).

You program an elaborate management of hierarchical lists in which you absolutely must be able to identify each item individually at every level of the list. A simple way of implementing this is to maintain a personal counter. Suppose that you create a hlList list using the **APPEND TO LIST** command. At this stage, you initialize a counter vhlCounter to 1. Each time you call **APPEND TO LIST** or **INSERT IN LIST**, you increment this counter (*vhlCounter:=vhlCounter+1*), and you pass the counter number as the item reference number. The trick consists in never decrementing the counter when you delete items — the counter can only increase. In this way, you guarantee the uniqueness of the item reference numbers. Since these numbers are of the Longint type, you can add or insert more than two billion items in a list that has been reinitialized... (however if you are working with such a great number of items, this usually means that you should use a table rather than a list.)

**Note**: If you use **Bitwise Operators**, you can also use item reference numbers for storing information that can be put into a Longint, i.e. 2 Integers, 4-byte values or, yet again, 32 Booleans.

### When do you need unique reference numbers?

In most cases, when using hierarchical lists for user interface purposes and when only dealing with the selected item (the one that was clicked or dragged), you will not need to use item reference numbers at all. Using **Selected list items** and **GET LIST ITEM** you have all you need to deal with the currently selected item. In addition, commands such as **INSERT IN LIST** and **DELETE FROM LIST** allow you to manipulate the list “relatively” with respect to the selected item.

Basically, you need to deal with item reference numbers when you want direct access to any item of the list programmatically and not necessarily the one currently selected in the list.

# APPEND TO LIST

APPEND TO LIST ( list ; itemText ; itemRef {; sublist ; expanded} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |
| itemText | String | ⇒ | Text of the new list item |
| itemRef | Longint | ⇒ | Unique reference number for the new list item |
| sublist | ListRef | ⇒ | Optional sublist to attach to the new list item |
| expanded | Boolean | ⇒ | Indicates if the optional sublist will be expanded or collapsed |

## Description

The **APPEND TO LIST** command appends a new item to the hierarchical list whose list reference number you pass in *list*.

You pass the text of the item in *itemText*. You can pass a string or text expression of up to 2 billion characters.

You pass the unique reference number of the item(of the Longint type) in *itemRef*. Although we qualify this item reference number as unique, you can actually pass the value you want. Refer to the **Managing Hierarchical Lists** section for more information about the *itemRef* parameter.

If you also want an item to have child items, pass a valid list reference to the child hierarchical list in *sublist*. In this case, you must also pass the *expanded* parameter. Pass **True** or **False** in this parameter so that the sublist is displayed expanded or collapsed respectively.

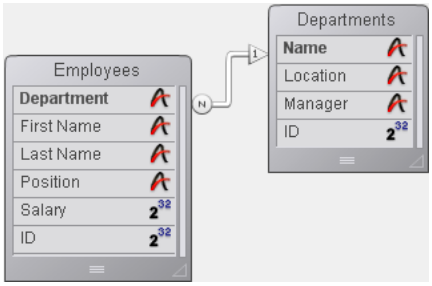
The list reference you pass in *sublist* must refer to an existing list. The existing list may be a one-level list or a list with sublists. If you do not want to attach a child list to the new item, omit the parameter or pass 0. Even though they are both optional, the *sublist* and *expanded* parameters must be passed jointly.

**Tips**

- To insert a new item in a list, use **INSERT IN LIST**. To change the text of an existing item or modify its child list as well as its expanded state, use **SET LIST ITEM**.
- To change the appearance of the new appended item use **SET LIST ITEM PROPERTIES**.

## Example

Here is a partial view of a database structure:



The [Departments] and [Employees] tables contain the following records:

| Name : | Location : | Manager : |
|---|---|---|
| Marine Biology | Aquarium B | Robert Masterson |
| Accounting | 3rd floor | Anne Weston |
| Sales | First floor-West | George Jackson |

| Department : | First Name : | Last Name : |
|---|---|---|
| Marine Biology | Andrew | Parker |
| Accounting | Jessica | Anders |
| Sales | Peter | Parker |
| Marine Biology | Jeffrey | Dalton |
| Accounting | Maria | Peterson |
| Sales | Jordan | Solomon |
| Sales | Patrick | McDonald |
| Marine Biology | Henry | Paulson |
| Sales | Marlo | Robertson |

You want to display a hierarchical list, named *hlList*, that shows the Departments, and for each Department, a child list that shows the Employees working in that Department. The object method of *hlList* is:

```
` hlList Hierarchical List Object Method

Case of

   :(Form event=On Load)
      C_LONGINT(hlList;$hSubList;$vlDepartment;$vlEmployee;$vlDepartmentID)
   ` Create a new empty hierarchical list
      hlList:=New list
   ` Select all the records from the [Departments] table
      ALL RECORDS([Departments])
   ` For each Department
      For($vlDepartment;1;Records in selection([Departments]))
   ` Select the Employees from this Department
         RELATE MANY([Departments]Name)
   ` How many are they?
         $vlNbEmployees:=Records in selection([Employees])
   ` Is there at least one Employee in this Department?
         If($vlNbEmployees>0)
   ` Create a child list for the Department item
            $hSubList:=New list
   ` For each Employee
            For($vlEmployee;1;Records in selection([Employees]))
   ` Add the Employee item to the sublist
   ` Note that ID field of the [Employees] record
   ` is passed as item reference number
               APPEND TO LIST($hSubList;[Employees]Last Name+", "+[Employees]First Name;[Employees]ID)
   ` Go the next [Employees] record
               NEXT RECORD([Employees])
            End for
         Else
   ` No Employees, no child list for the Department item
            $hSubList:=0
         End if
   ` Add the Department item to the main list
   ` Note that ID field of the [Departments] record
   ` is passed as item reference number. The bit #31
   ` of this item is forced to one so we'll be able
   ` to distinguish Department and Employee items. See note further
   ` below on why we can use this bit as supplementary information about
   ` the item.
         APPEND TO LIST(hlList;[Departments]Name;[Departments]ID?+31;$hSublist;$hSubList#0)
   ` Set the Department item in Bold to emphasize the hierarchy of the list
         SET LIST ITEM PROPERTIES(hlList;0;False;Bold;0)
   ` Go to the next Department
         NEXT RECORD([Departments])
      End for
   ` Sort the whole list in ascending order
      SORT LIST(hlList;>)
   ` Display the list using the Windows style
   ` and force the minimal line height to 14 Pts
      SET LIST PROPERTIES(hlList;Ala Windows;Windows node;14)

   :(Form event=On Unload)
   ` The list is no longer needed; do not forget to get rid of it!
      CLEAR LIST(hlList;*)

   :(Form event=On Double Clicked)
   ` A double-click occurred
   ` Get the position of the selected item
      $vlItemPos:=Selected list items(hlList)
   ` Just in case, check the position
      If($vlItemPos #0)
   ` Get the list item information
         GET LIST ITEM(hlList;$vlItemPos;$vlItemRef;$vsItemText;$vlItemSubList;$vbItemSubExpanded)
   ` Is the item a Department item?
         If($vlItemRef ?? 31)
   ` If so, it is a double-click on a Department Item
            ALERT("You double-clicked on the Department item "+Char(34)+$vsItemText+Char(34)+".")
         Else
```

```
      ` If not, it is a double-click on an Employee item
      ` Using the parent item ID to find the [Departments] record
                $vlDepartmentID:=List item parent(hlList;$vlItemRef)?-31
                QUERY([Departments];[Departments]ID=$vlDepartmentID)
      ` Tell where the Employee is working and to whom he or she is reporting
                ALERT("You double-clicked on the Employee item "+Char(34)+$vsItemText+Char(34)+
                " who is working in the Department "+Char(34)+[Departments]Name+Char(34)+
                " whose manager is "+Char(34)+[Departments]Manager+Char(34)+".")
             End if
          End if

   End case

      ` Note: 4D can store up to 1 billion records per table
      ` In our example, we use bit #31 of the unused high byte for
      ` distinguishing Employees and Departments items.
```

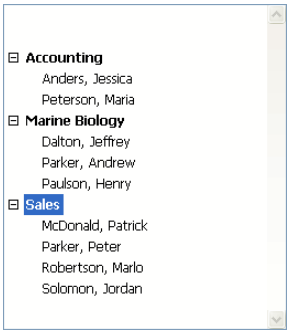
In this example, there is only one reason to distinguish [Departments] items and [Employees] items:

1. We store record IDs in the item reference numbers; therefore, we will probably end up with [Departments] items whose item reference numbers are the same as [Employees] items.

2. We use the **List item parent** command to retrieve the parent of the selected item. If we click on an [Employees] item whose associated record ID is #10, and if there is also a [Departments] item #10, the [Departments] item will be found first by **List item parent** when it browses the lists to locate the item with the item reference number we pass. The command will return the parent of the [Departments] item and not the parent of the [Employees] item.

Therefore, we made the item reference numbers unique, not because we wanted unique numbers, but because we needed to distinguish [Departments] and [Employees] records.

When the form is executed, the list will look like this:



**Note:** This example is useful for user interface purposes if you deal with a reasonably small number of records. Remember that lists are held in memory—do not build user interfaces with hierarchical lists containing millions of items.

# CLEAR LIST

CLEAR LIST ( list {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ➡ | List reference number |
| * | | ➡ | If specified, clear sublists from memory, if any. If omitted, sublists (if any) are not cleared. |

## Description

The **CLEAR LIST** command deletes the hierarchical list whose list reference number you pass in *list*.

Usually you will pass the optional * parameter, so all the sublists, if any, attached to items or subitems of the list will be deleted as well.

You do not need to clear a list attached to a form object via the Property List window. 4D loads and clears the list for you. On the other hand, each time you load, copy, extract from a BLOB, or create a list programmatically, call **CLEAR LIST** when you are through with the list.

To clear a sublist attached to an item (on any level) of another list currently displayed in a form, proceed as follows:

1. Call **GET LIST ITEM** on the parent item to get the list reference of the sublist.
2. Call **SET LIST ITEM** on the parent item to detach the sublist from the list item before clearing it.
3. Call **CLEAR LIST** to clear the sublist whose reference number you obtained with **GET LIST ITEM**.

## Example 1

Within a clean-up routine that clears all objects and data that you no longer need (i.e., when a window is closed and a form unloaded), you may end up clearing a hierarchical list that may have already been cleared, depending on the user actions within the form. Use **Is a list** to clear the list only if necessary:

```
  ` Extract of clean-up routine
If(Is a list(hlList))
   CLEAR LIST(hlList;*)
End if
```

## Example 2

See example for the **Load list** command.

## Example 3

See example for the **BLOB to list** command.

# Copy list

Copy list ( list ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | Reference to list to be copied |
| Function result | ListRef | ⇐ | List reference number to duplicated list |

## Description

The **Copy list** command duplicates the list whose reference number you pass in *list,* and returns the list reference number of the new list.

After you have finished with the new list, call **CLEAR LIST** to delete it.

# Count list items

Count list items ( {* ;} list {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| * | Operator | ⇒ | If omitted (default): Return visible list items (expanded) If specified: Return all list items |
| Function result | Longint | ⇐ | Number of visible (expanded) list items (if 2nd * omitted) or Total number of list items (if 2nd * present) |

## Description

The **Count list items** command returns either the number of items currently "visible" or the total number of items in the list whose reference number or object name you pass in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with all the items (the second * is passed), you can use either syntax. Conversely, if you use several representations of the same list and work with the visible items (the second * is omitted), the syntax based on the object name is required since each representation can have its own expanded/collapsed configuration.

**Note:** If you use the @ character in the name of the list object and the form contains several lists that match with this name, the **Count list items** command will only apply to the first object whose name corresponds.

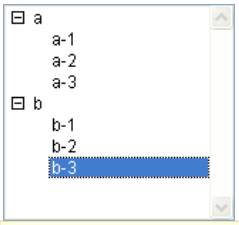
Use the second * parameter to determine which type of information will be returned. When this parameter is passed, the command returns the total number of items present in the list, regardless of whether it is expanded or collapsed.

When this parameter is omitted, the command returns the number of items that are visible, depending on the current expanded/collapsed state of the list and its sublists.

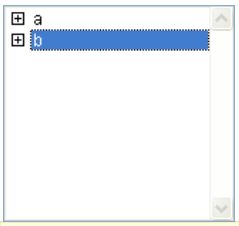
You apply this command to a list displayed in a form.

## Examples

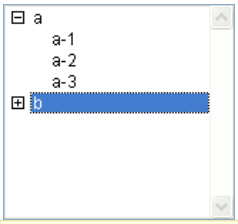
Here a list named *hList* shown in the Application environment:



```
$vlNbItems:=Count list items(hList) ` at this point $vlNbItems gets 8
$vlNbTItems:=Count list items(hList;*) `$vlNbTItems also gets 8
```



```
$vlNbItems:=Count list items(hList) ` at this point $vlNbItems gets 2
$vlNbTItems:=Count list items(hList;*) `$vlNbTItems still gets 8
```



```
$vlNbItems:=Count list items(hList) ` at this point $vlNbItems gets 5
$vlNbTItems:=Count list items(hList;*) `$vlNbTItems still gets 8
```

# DELETE FROM LIST

DELETE FROM LIST ( {* ;} list ; itemRef | * {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemRef \| * | Longint, Operator | ⇒ | Item reference number, or 0 for the last item added to the list or * for the currently selected list item |
| * | | ⇒ | If specified, erases sublists (if any) from memory If omitted, sublists (if any) are not erased |

## Description

The **DELETE FROM LIST** command deletes the item designated by the *itemRef* parameter of the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

If you pass * in *itemRef*, you delete the currently selected item in the list. You can also pass 0 in this parameter in order to request the deletion of the last item added to the list.

Otherwise, you specify the item reference number of the item you want to delete. If there is no item with the item reference number you passed, the command does nothing.

If you work with item reference numbers, build a list in which the items have unique reference numbers, otherwise you will not be able to distinguish the items. For more information, see the description of the **APPEND TO LIST** command.

No matter which item you delete, you should specify the optional * parameter to let 4D automatically delete the sublist attached to the item, if any. If you do not specify the * parameter, it is a good idea to have previously obtained the list reference number of the sublist (if any) attached to the item, so that you can delete it, if necessary, using the **CLEAR LIST** command.

## Example

The following code deletes the currently selected item of the list *hList*. If the item has an attached sublist, the sublist (as well as any sub-sublist) is deleted:

```
DELETE FROM LIST(hList;*;*)
```

# Find in list

Find in list ( {* ;} list ; value ; scope {; itemsArray {; *}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) Name of list type object (if * passed) |
| value | String | ⇒ | Value to be searched for |
| scope | Integer | ⇒ | 0=Main list, 1=Sublist |
| itemsArray | Longint array | ⇐ | - If 2nd * omitted: array of positions of items found - If 2nd * passed: array of reference numbers of items found |
| * | Operator | ⇒ | - If omitted: use position of items - If passed: use reference number of items |
| Function result | Longint | ⇐ | - If 2nd * omitted: position of item found - If 2nd * passed: reference number of item found |

## Description

The **Find in list** command returns the position or reference of the first item of the *list* that is equivalent to the string passed in *value*. If several items are found, the function can also fill an *itemsArray* array with the position or reference of each item.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with item reference numbers (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with item positions (the second * is passed), the syntax based on the object name is required since the position of items can vary from one representation to another.

**Note:** If you use the @ character in the object name of the list and the form contains several lists that match this name, the **Find in list** command will be applied to the first object whose name corresponds.

The second * parameter can be used to indicate whether you want to work with the current positions of the items (in which case, this parameter is omitted) or with the absolute references of the items (in which case, it must be passed).

Pass the character strings to be searched for in *value*. The search will be of the “is exactly” type; in other words, searching for “wood” will not find “wooden.” However, you can use the wildcard character (@ ) to set up searches of the “begins with,” “ends with” or “contains” types.

The *scope* parameter is used to set whether the search must only be carried out at the first level of the *list* or whether it should include all the sublists. Pass 0 to limit the search to the first level of the list and 1 to extend it to all the sublists.

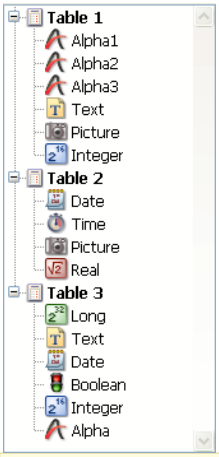
If you want to find out the position or number of all the items corresponding to *value*, pass a longint array in the optional *itemsArray* parameter. If necessary, the array will be created and resized by the command. The command will fill in the array with the positions (if the second * is omitted) or the reference numbers (if the second * is passed) of the items found.

Positions are expressed in relation to the top item of the main list, while taking into account the current expanded/collapsed state of the list and sublists.

If no item corresponds to the *value* searched for, the function returns 0 and the *itemsArray* array is returned empty.

## Example

Given the following hierarchical list:



```
$vlItemPos:=Find in list(hList;"P@";1;$arrPos)
  `$vlItemPos equals 6
  `$arrPos{1} equals 6 and $arrPos{2} equals 11
$vlItemRef:=Find in list(hList;"P@";1;$arrRefs;*)
  `$vlItemRef equals 7
  `$arrRefs{1} equals 7 and $arrRefs{2} equals 18
$vlItemPos:=Find in list(hList;"Date";1;$arrPos)
  `$vlItemPos equals 9
  `$arrPos{1} equals 9 and $arrPos{2} equals 16
$vlItemRefFind in list(hList;"Date";1;$arrRefs;*)
  `$vlItemRef equals 11
  `$arrRefs{1} equals 11 and $arrRefs{2} equals 23
$vlItemPos:=(hList;"Date";0;*)
  `$vlItemPos equals 0
```

# GET LIST ITEM

GET LIST ITEM ( {* ;} list ; itemPos | * ; itemRef ; itemText {; sublist ; expanded} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemPos \| * | Operator, Longint | ⇒ | Position of item in expanded/collapsed list(s) or * for the current item in the list |
| itemRef | Longint | ⇐ | Item reference number |
| itemText | String | ⇐ | Text of the list item |
| sublist | ListRef | ⇐ | Sublist list reference number (if any) |
| expanded | Boolean | ⇐ | If a sublist is attached: TRUE = sublist is currently expanded FALSE = sublist is currently collapsed |

## Description

The **GET LIST ITEM** command returns information about the item specified by *itemPos* of the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list, you can use either syntax. Conversely, if you use several representations of the same list, the syntax based on the object name is required since each representation can have its own expanded/collapsed configuration and its own current item.

**Note:** If you use the @ character in the name of the list object and the form contains several lists that match with this name, the **GET LIST ITEM** command will only apply to the first object whose name corresponds.

The position must be expressed relatively, using the current expanded/collapsed state of the list and its sublist. You pass a position value between 1 and the value returned by **Count list items**. If you pass a value outside this range, **GET LIST ITEM** returns empty values (0, "", etc.).

After the call, you retrieve:

- The item reference number of the item in *itemRef*.
- The text of the item in *itemText*.

If you passed the optional parameters *sublist* and *expanded*:

- *subList* returns the list reference number of the sublist attached to the item. If the item has no sublist, *subList* returns zero (0).
- If the item has a sublist, *expanded* returns TRUE if the sublist is currently expanded, and FALSE if it is collapsed.

## Example 1

*hList* is a list whose items have unique reference numbers. The following code programmatically toggles the expanded/collapsed state of the sublist, if any, attached to the current selected item:

```
$vlItemPos:=Selected list items(hList)
If($vlItemPos>0)
   GET LIST ITEM(hList;$vlItemPos;$vlItemRef;$vsItemText;$hSublist;$vbExpanded)
   If(Is a list($hSublist))
      SET LIST ITEM(hList;$vlItemRef;$vsItemText;$vlItemRef;$hSublist;Not($vbExpanded))
   End if
End if
```

## Example 2

Refer to the example of the **APPEND TO LIST** command.

# Get list item font

Get list item font ( {* ;} list ; itemRef | * ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Longint, Operator | ⇒ | Item reference number or 0 for the last item added to the list or * for the current item of the list |
| Function result | String | ⇐ | Font name |

## Description

The **Get list item font** command returns the current character font name of the item specified by the *itemRef* parameter of the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

**Note:** If you use the @ character in the object name of the list and the form contains several lists that match this name, the **Get list item font** command will be applied to the first object whose name corresponds.

You can pass a reference number in *itemRef*. If this number does not correspond to any item of the list, the command does nothing. You can also pass 0 in *itemRef* in order to get the font of the last item added to the list (using **APPEND TO LIST**).

Lastly, you can pass * in *itemRef*: in this case, the command will get the font of the current item of the list. If several items are selected manually, the current item is the one that was selected last. If no item is selected, the command does nothing.

# GET LIST ITEM ICON

GET LIST ITEM ICON ( {* ;} list ; itemRef | * ; icon )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number or 0 for the last item added to the list or * for the current item of the list |
| icon | Picture variable | ⇐ | Icon associated with item |

## Description

The **GET LIST ITEM ICON** command returns, in *icon*, the icon associated with the item whose reference number is passed in *itemRef* in the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

**Note:** If you use the @ character in the object name of the list and the form contains several lists that match this name, the **GET LIST ITEM ICON** command will be applied to the first object whose name corresponds.

You can pass a reference number in *itemRef*. If this number does not correspond to an item in the list, the command does nothing. You can also pass 0 in *itemRef* to indicate the last item added to the list (using **APPEND TO LIST**).
Lastly, you can pass * in *itemRef:* in this case, the command will apply to the current item of the list. If several items are selected manually, the current item is the one that was selected last. If no item is selected, the command does nothing.

Pass a picture variable in *icon*. After the command is executed, it will contain the icon associated with the item, regardless of the source of the icon (static picture, resource or picture expression).

If no icon is associated with the item, the icon variable is returned empty.

**Note:** When the icon associated with an item has been defined via a static reference (resource references or pictures from the picture library), it is possible to find out its number using the **GET LIST ITEM PROPERTIES** command.

# GET LIST ITEM PARAMETER

GET LIST ITEM PARAMETER ( {* ;} list ; itemRef | * ; selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number or 0 for the last item appended to the list or * for the current list item |
| selector | String | ⇒ | Parameter constant |
| value | String, Boolean, Real | ⇐ | Current value of parameter |

## Description

The **GET LIST ITEM PARAMETER** command is used to find out the current *value* of the *selector* parameter for the *itemRef* item of the hierarchical list whose reference or object name is passed in the *list* parameter.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second* is omitted), you can use either syntax. Conversely, if you use several representations of the same list and the second * is passed, the syntax based on the object name is required since each representation can have its own current item.

**Note:** If you use the @ character in the object name of the list and the form contains several lists that match this name, the **GET LIST ITEM PARAMETER** command will be applied to the first object whose name corresponds.

You can pass a reference number in *itemRef*. If this number does not correspond to an item in the list, the command does nothing. You can also pass 0 in *itemRef* to indicate the last item added to the list (using **APPEND TO LIST**).

Lastly, you can pass * in *itemRef*: in this case, the command is applied to the current item of the list. If several items are selected manually, the current item is the last one that was selected. If no item is selected, the command does nothing.

In *selector*, you can pass the Additional text constant (found in the "**Hierarchical Lists**" theme) or any custom value. For more information about the *selector* and *value* parameters, please refer to the description of the **SET LIST ITEM PARAMETER** command.

# GET LIST ITEM PARAMETER ARRAYS

GET LIST ITEM PARAMETER ARRAYS ( {* ;} list ; itemRef | * ; arrSelection {; arrValues} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, list is an object name (string)<br>If omitted, list is a list reference number |
| list | ListRef, String | ➡ | List reference number (if * omitted) or<br>Name of list type object (if * passed) |
| itemRef \| * | Longint, Operator | ➡ | Item reference number or<br>0 for the last item appended to the list or<br>* for the current list item |
| arrSelection | Text array | ⬅ | Array of parameter names |
| arrValues | Text array | ⬅ | Array of parameter values |

## Description

The **GET LIST ITEM PARAMETER ARRAYS** command lets you retrieve all the parameters in a single call (as well as, optionally, their values) that are associated with the *itemRef* item in the hierarchical list whose reference or object name is passed in the *list* parameter.

Parameters associated with items store additional information about each item. They are set using the **SET LIST ITEM PARAMETER** command.

If you pass the first optional * parameter, this indicates that *list* is an object name (string) corresponding to a list representation in the form. If you do not pass this parameter, this indicates that *list* is a hierarchical list reference (*ListRef*). If you use a single list representation or work with structural items (second * omitted), you can use either syntax. However, if you use several representations of the same list and work with the current item (second * passed), you must use the syntax based on the object name because each representation may have its own current item.

**GET LIST ITEM PARAMETER ARRAYS** returns parameters set for the *itemRef* item in the *arrSelectors* text array. When the *arrValues* text array is passed, the command uses it to return the values associated with these parameters.

*arrValues* must be a text type array. If you have associated values that are not Text (number or Boolean), they are converted to strings (True="1", False="0").

## Example

Given the following hierarchical list:

```
<>HL:=New list
$ID:=30
APPEND TO LIST(<>HL;"Martin";$ID)
 //5 parameters
SET LIST ITEM PARAMETER(<>HL;$ID;"Firstname";"Phil")
SET LIST ITEM PARAMETER(<>HL;$ID;"Birthday";"01/02/1978")
SET LIST ITEM PARAMETER(<>HL;$ID;"Male";True) //Boolean
SET LIST ITEM PARAMETER(<>HL;$ID;"Age";33) //number
SET LIST ITEM PARAMETER(<>HL;$ID;"City";"Dallas")
```

For more simplicity, the list was associated with a list object having the same name ("<>HL").
When the item "Martin" is selected in the list, you can retrieve its parameters by executing the following code:

```
ARRAY TEXT(arrParamNames;0)
GET LIST ITEM PARAMETER ARRAYS(*;"<>HL";*;arrParamNames)
 // arrParamNames{1} contains "Firstname"
 // arrParamNames{2} contains "Birthday"
 // arrParamNames{3} contains "Male"
 // arrParamNames{4} contains "Age"
 // arrParamNames{5} contains "City"
```

If you want to get the parameter values as well, you write:

```
ARRAY TEXT(arrParamNames;0)
ARRAY TEXT(arrParamValues;0)
GET LIST ITEM PARAMETER ARRAYS(*;"<>HL";*;arrParamNames;arrParamValues)
 // arrParamValues{1} contains "Phil"
 // arrParamValues{2} contains "01/02/1978"
 // arrParamValues{3} contains "1"
 // arrParamValues{4} contains "33"
 // arrParamValues{5} contains "Dallas"
```

# GET LIST ITEM PROPERTIES

GET LIST ITEM PROPERTIES ( {* ;} list ; itemRef | * ; enterable {; styles {; icon {; color}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number, or 0 for last list item added, or * for the current list item |
| enterable | Boolean | ⇐ | TRUE = Enterable, FALSE = Non-enterable |
| styles | Longint | ⇐ | Font style for the item |
| icon | Longint | ⇐ | 'cicn' Mac OS-based resource ID, or 65536 + 'PICT' Mac OS-based resource ID, or 131072 + Picture Reference Number |
| color | Longint | ⇐ | RGB color value |

## Description

The **GET LIST ITEM PROPERTIES** command returns the properties of the item designated by the *itemRef* parameterwithin the list whose list reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

**Note:** If you use the @ character in the object name of the list and the form contains several lists matching this name, the **GET LIST ITEM PROPERTIES** command will be applied to the first object whose name corresponds.

In *itemRef*, you can pass either a reference number, or the value 0 in order to designate the last item added to the list, or * in order to designate the current item of the list. If several items are selected, the current item is the last one selected.

If you pass * and no item is selected or if there is no item with the item reference number that is passed, the command leaves the parameters unchanged.

If you work with item reference numbers, build a list in which items have unique reference numbers, otherwise you will not be able to distinguish the items. For more information, refer to the description of the command **APPEND TO LIST**.

After the call:

- *enterable* returns TRUE if the item is enterable.
- *styles* returns the font style of the item.
- *icon* returns the icon or picture assigned to the item, *0* if none.
- *color* returns the color of the text of the item specified.

**Note:** You can retrieve, in a picture variable, the icon associated with an item using the **GET LIST ITEM ICON** command.

For details about these properties, see the description of the command **SET LIST ITEM PROPERTIES**.

# GET LIST PROPERTIES

GET LIST PROPERTIES ( list ; appearance {; icon {; lineHeight {; doubleClick {; multiSelections {; editable}}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |
| appearance | Longint | ⇐ | Graphical style of the list 1 = Hierarchical list a la Macintosh 2 = Hierarchical list a la Windows |
| icon | Longint | ⇐ | 'cicn' Mac OS-based resource ID |
| lineHeight | Longint | ⇐ | Minimal line height expressed in pixels |
| doubleClick | Longint | ⇐ | Expand/Collapse sublist on double-click? 0 = Yes, 1= No |
| multiSelections | Longint | ⇐ | Multiple selections: 0 = No, 1 = Yes |
| editable | Longint | ⇐ | List editable by user: 0 = No, 1 = Yes |

## Description

The **GET LIST PROPERTIES** command returns information about the list whose reference number you pass in *list*.

The *appearance* parameter returns the graphical style of the list.

The *icon* parameter returns the resource IDs of the node icons displayed in the list.

The *lineHeight* parameter returns the minimal line height.

If *doubleClick* is set to 1, double-clicking on a parent list item does not provoke its child list to expand or to collapse. If *doubleClick* is set to 0, this behavior is active (defaut value).

If the *multiSelections* parameter is set to 0, multiple selections of items (manually or by programming) are not possible in the list. If it is set to 1, multiple selections are allowed.

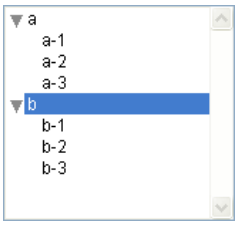
If the *editable* parameter is set to 1, the list is editable when it is displayed as a choice list in a record. If it is set to 0, the list is not editable.

These properties can be set using the **SET LIST PROPERTIES** command and/or in the Design environment List Editor, if the list was created there or saved using the **SAVE LIST** command.

For a complete description of the appearance, node icons, minimal line height and double-click management of a list, see the **SET LIST PROPERTIES** command.

## Example

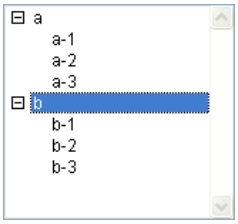
Given the list named *hList*, shown here in the Application environment:



The object method for a button:

```
   ` bMacOrWin button Object Method
GET LIST PROPERTIES(hList;$vlAppearance;$vlIcon;$vlLH;$vlClick;$vlSelect;$vlModif)
If($vlAppearance=Ala Macintosh)
   $vlAppearance:=Ala Windows
   $vlIcon:=Windows node
   $vlModif:=1
Else
   $vlAppearance:=A la Macintosh
   $vlIcon:=Macintosh node
   $vlModif:=1
End if
SET LIST PROPERTIES(hList;$vlAppearance;$vlIcon;$vlLH;$vlClick;$vlSelect;$vlModif)
```

This method lets you display the list as follows:



a
a-1
a-2
a-3
b
b-1
b-2
b-3

# INSERT IN LIST

INSERT IN LIST ( {* ;} list ; beforeItemRef | * ; itemText ; itemRef {; sublist ; expanded} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| beforeItemRef \| * | Longint, Operator | ⇒ | Item reference number or 0 for the last item added to the list or * for the currently selected list item |
| itemText | String | ⇒ | Text for the new list item |
| itemRef | Longint | ⇒ | Unique reference number for the new list item |
| sublist | ListRef | ⇒ | Optional sublist to attach to the new list item |
| expanded | Boolean | ⇒ | Indicates if the sublist will be expanded or collapsed |

## Description

The **INSERT IN LIST** command inserts the item designated by the *itemRef* parameter in the list whose reference number or object name you pass in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

The *beforeItemRef* parameter can be used to designate the item before which you wish to insert the new item:

- You can pass the value 0 in order to designate the last item added to the list. The newly inserted item will then become the selected item.
- You can pass * in order for the new item to be inserted before the currently selected item in the list. In this case, the newly inserted item will also become the selected item.
- Otherwise, if you want to insert an item before a specific item, you pass the item reference number of that item. In this case, the newly inserted item is not automatically selected. If there is no item with the corresponding item reference number, the command does nothing.

You pass the text and the item reference number of the new item in *itemText* and *itemRef*.

If you want for the item to include subitems, pass a valid list reference number in the *sublist* parameter. In this case, you must also pass the *expanded* parameter. Pass either **True** or **False** in this parameter so that this sublist is displayed either expanded or collapsed respectively.

## Example

The following code inserts an item (with no attached sublist) just before the currently selected item in the *hList* list:

```
vlUniqueRef:=vlUniqueRef+1
INSERT IN LIST(hList;*;"New Item";vlUniqueRef)
```

# Is a list

Is a list ( list ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | ListRef value to be tested |
| Function result | Boolean | ⇐ | TRUE if list is a hierarchical list FALSE if list is not a hierarchical list |

## Description

The **Is a list** command returns TRUE if the value you pass in *list* is a valid reference to a hierarchical list. Otherwise, it returns FALSE.

## Example 1

See example for the **CLEAR LIST** command.

## Example 2

See examples for the **DRAG AND DROP PROPERTIES** command.

# List item parent

List item parent ( {* ;} list ; itemRef | * ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number or 0 for the last item added to the list or * for the current item in the list |
| Function result | Longint | ⇐ | Item reference number of parent item or 0 if none |

## Description

The **List item parent** command returns the item reference number of a parent item.

Pass the reference number or object name of the list in *list* .

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

**Note:** If you use the @ character in the object name of the list and the form contains several lists matching this name, the **List item parent** command will be applied to the first object whose name corresponds.

You pass the item reference number of an item in the list or 0 or yet again *, in *itemRef*. If you pass 0, the command applies to the last item added to the list. If you pass *, the command applies to the current item of the list. If several items have been selected manually, the current item is the last one selected.

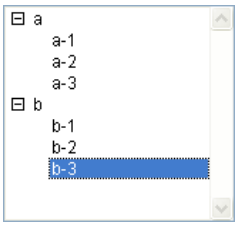
In return, if the corresponding item exists in the list and if this item is in a sublist (and therefore has a parent item), you obtain the item reference number of the parent item.

If there is no item with the item reference number you passed, or if you have passed * and no item is selected, or if the item has no parent, **List item parent** returns 0 (zero).

If you work with item reference numbers, be sure to build a list in which the items have unique reference numbers; otherwise you will not be able to distinguish the items. For more information, see the description of the **APPEND TO LIST** command.

## Example

Given the list named *hList* shown here in the Application environment:



The item reference numbers are set as follows:

| Item | Item Reference Number |
|---|---|
| *a* | *100* |
| *a - 1* | *101* |
| *a - 2* | *102* |
| *b* | *200* |
| *b - 1* | *201* |
| *b - 2* | *202* |
| *b - 3* | *203* |

- In the following code, if the item “b - 3” is selected, the variable *$vlParentItemRef* gets 200, the item reference number of the item “b”:

```
$vlItemPos:=Selected list items(hList)
GET LIST ITEM(hList;$vlItemPos;$vlItemRef;$vsItemText)
$vlParentItemRef:=List item parent(hList;$vlItemRef) ` $vlParentItemRef gets 200
```

- If the item “a - 1” is selected, the variable *$vlParentItemRef* gets 100, the item reference number of the item “a”.
- If the item “a” or “b” is selected, the variable *$vlParentItemRef* gets 0, because these items have no parent item.

# List item position

List item position ( {* ;} list ; itemRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemRef | Longint | ⇒ | Item reference number |
| Function result | Longint | ⇐ | Item position in expanded/collapsed lists |

## Description

The **List item position** command returns the position of the item whose item reference number is passed in *itemRef*, within the list whose list reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list, you can use either syntax. Conversely, if you use several representations of the same list, the syntax based on the object name is required since each representation can have its own expanded/collapsed configuration.

**Note:** If you use the @ character in the object name of the list and the form contains several lists matching this name, the **List item position** command will be applied to the first object whose name corresponds.

**Note:** Unlike the other commands of this theme, with this command it is not possible to pass the value 0 in *itemRef* to designate the last item added.

The position is expressed relative to the top item of the main list, using the current expanded/collapsed state of the list and its sublist.

The result is therefore a number between 1 and the value returned by **Count list items**.

If the item is not visible because it is located in a collapsed list, **List item position** expands the appropriate list to make the item visible.

If the item does not exist, **List item position** returns 0.

# LIST OF CHOICE LISTS

LIST OF CHOICE LISTS ( numsArray ; namesArray )

| Parameter | Type | | Description |
|---|---|---|---|
| numsArray | Longint array | ⇦ | Numbers of choice lists |
| namesArray | Text array | ⇦ | Names of choice lists |

## Description

The **LIST OF CHOICE LISTS** command returns, in the synchronized *numsArr* and *namesArr* arrays, the numbers and names of the choice lists defined by the list editor in Design mode.

The numbers of choice lists correspond to their order of creation. In the list editor, choice lists are displayed in alphabetical order.

# Load list

Load list ( listName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| listName | String | ⇒ | Name of a list created in the Design environment List Editor |
| Function result | ListRef | ⇐ | List reference number of newly created list |

## Description

**Load list** creates a new hierarchical list whose contents are copied from the list and whose name you pass in *listName*. It then returns the list reference number to the newly created list.

To find out the lists specified in the database, use the **LIST OF CHOICE LISTS** command.

To make sure that the list specified by *listName* exists, use the **Is a list** function.

Note that the new list is a copy of the list defined in the Design environment. Consequently, any modifications made to the new list will not affect the list defined in the Design environment. Conversely, any subsequent modifications made to the list defined in the Design environment will not affect the list that you just created.

If you modify the newly created list and want to permanently save the changes, call **SAVE LIST**.

Remember to call **CLEAR LIST** in order to delete the newly created list when you have finished with it. Otherwise, it will stay in memory until the end of the working session or until the process in which it was created ends or is aborted.

**Tip:** If you associate a list with a form object (hierarchical list, tab control, or hierarchical pop-up menu) using the Choice List property in the Property List window, you do not need to call **Load list** or **CLEAR LIST** from the method of the object. 4D loads and clears the list automatically for you.

## Example

You create a database for the international market and you need to switch to different languages while using the database. In a form, you present a hierarchical list, named *hlList*, that proposes a list of standard options. In the Design environment, you have prepared various lists, such as “Std Options US” for the English version, “Std Options FR” for the French version, “Std Options SP” for the Spanish version, and so on. In addition, you maintain an interprocess variable, named *◊gsCurrentLanguage*, where you store a 2-character language code, such as “US” for the English version, “FR” for the French version, “SP” for the Spanish version, and so on. To make sure that your list will always be loaded using the current selected language, you can write:

```
  ` hlList Hierarchical List Object Method
Case of
   :(Form event=On Load)
      C_LONGINT(hlList)
      hlList:=Load list("Std Options"+◊gsCurrentLanguage)
   :(Form event=On Unload)
      CLEAR LIST(hlList;*)
End case
```

# New list

New list -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | ListRef | | List reference number |

## Description

**New list** creates a new, empty hierarchical list in memory and returns its unique list reference number.

**WARNING:** Hierarchical lists are held in memory. When you are finished with a hierarchical list, it is important to dispose of it and free the memory, using the command **CLEAR LIST**.

Several other commands allow you to create hierarchical lists:

- **Copy list** duplicates a list from an existing list.
- **Load list** creates a list by loading a Choice List created (manually or programmatically) in the Design enviornment List Editor.
- **BLOB to list** creates a list from the contents of a BLOB in which a list was previously saved.

After you have created a hierarchical list using **New list**, you can:

- Add items to that list, using the command **APPEND TO LIST** or **INSERT IN LIST**.
- Delete items from that list, using the command **DELETE FROM LIST**.

## Example

See example for the **APPEND TO LIST** command.

## SAVE LIST

SAVE LIST ( list ; listName )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |
| listName | String | ⇒ | Name of the list as it will appear in the Design environment List Editor |

### Description

The **SAVE LIST** command saves the list whose reference number you pass in *list*, within the Design environment List Editor, under the name you pass in *listName*.

If there is already a list with this name, its contents are replaced.

# SELECT LIST ITEMS BY POSITION

SELECT LIST ITEMS BY POSITION ( {* ;} list ; itemPos {; positionsArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemPos | Longint | ⇒ | Position of item in expanded/collapsed list(s) |
| positionsArray | Longint array | ⇒ | Array of the positions in the expanded/collapsed list(s) |

## Description

The **SELECT LIST ITEMS BY POSITION** command selects the item(s) whose position is passed in *itemPos* and, optionally, in *positionsArray* within the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list, you can use either syntax. Conversely, if you use several representations of the same list, the syntax based on the object name is required since each representation can have its own expanded/collapsed configuration.

**Note:** If you use the @ character in the name of the list object and the form contains several lists that match with this name, the **SELECT LIST ITEMS BY POSITION** command will only apply to the first object whose name corresponds.

The position of items is always expressed using the current expanded/collapsed state of the list and its sublists. You pass a position value between 1 and the value returned by **Count list items**. If you pass a value outside this range, no item is selected.

If you do not pass the *positionsArray* parameter, the *itemPos* parameter represents the position of the item to be selected.

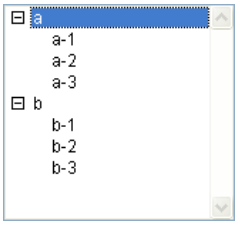
The optional *positionsArray* parameter lets you select several items simultaneously within the *list*. In *positionsArray*, you must pass an array where each line indicates the position of an item to be selected.

When you pass this parameter, the item designated by the *itemPos* parameter sets the new current item of the list among the resulting selection. It may or may not belong to the set of items defined by the array. The current item is, more particularly, the one that is edited if the **EDIT ITEM** command is used.

**Note:** In order for several items to be selected simultaneously in a hierarchical list (manually or by programming), the *multiSelections* property must have been enabled for this list. This property is set using the **SET LIST PROPERTIES** command.

## Example

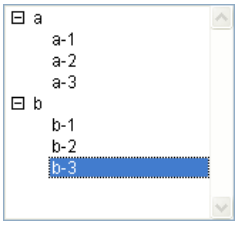
Given the hierarchical list named *hList,* shown here in the Application environment:



After the execution of this code:

```
SELECT LIST ITEMS BY POSITION(hList;Count list items(hList))
```

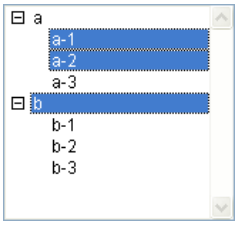
The last visible list item is selected:



After execution of the following lines of code:

```
SET LIST PROPERTIES(hList;0;0;18;0;1)
 `It is imperative to pass 1 as the last parameter in order to allow multiple selections
ARRAY LONGINT($arr;3)
$arr{1}:=2
$arr{2}:=3
$arr{3}:=5
SELECT LIST ITEMS BY POSITION(hList;3;$arr)
 `The 3rd item is designated as the current item
```

... the 2nd, 3rd and 5th items of the hierarchical list are selected:



# SELECT LIST ITEMS BY REFERENCE

SELECT LIST ITEMS BY REFERENCE ( list ; itemRef {; refArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ➡ | List reference number |
| itemRef | Longint | ➡ | Item reference number or 0 for the last item added to the list |
| refArray | Longint array | ➡ | Array of item reference numbers |

## Description

The **SELECT LIST ITEMS BY REFERENCE** command selects the item(s) whose item reference number is passed in *itemRef* and, optionally, in *refArray*, within the list whose reference number is passed in *list*.

If there is no item with the item reference number you passed, the command does nothing.

If an item is not currently visible (i.e., it is located in a collapsed sublist), the command expands the required sublist(s) so that it becomes visible.

If you do not pass the *refArray* parameter, the *itemRef* parameter represents the reference of the item to be selected. If the item number does not correspond to an item in the list, the command does nothing. You can also pass the value 0 in this parameter in order to designate the last item added to the list.

The optional *refArray* parameter lets you select several items simultaneously within the list. In *refArray*, you must pass an array where each line indicates the fixed reference of an item to be selected.

In this case, the item designated by the *itemRef* parameter sets the new current item of the list among the resulting selection. It may or may not belong to the set of items defined by the array. The current item is, more particularly, the one that is edited if the **EDIT ITEM** command is used.

**Note:** In order for several items to be selected simultaneously in a hierarchical list (manually or by programming), the *multiSelections* property must have been enabled for this list. This property is set using the **SET LIST PROPERTIES** command.

If you work with item reference numbers, be sure to build a list in which the items have unique reference numbers; otherwise you will not be able to distinguish them. For more information, see the description of the **APPEND TO LIST** command.

## Example

*hList* is a list whose items have unique reference numbers. The following object method for a button selects the parent item (if any) of the currently selected item:

```
$vlItemPos:=Selected list items(hList) ` Get position of selected item
GET LIST ITEM(hList;$vlItemPos;$vlItemRef;$vsItemText)
 ` Get item ref number of selected item
$vlParentItemRef:=List item parent(hList;$vlItemRef)
 ` Get item ref. number of parent item (if any)
If($vlParentItemRef>0)
   SELECT LIST ITEM BY REFERENCE(hList;List item parent(hList;$vlItemRef)) ` Select the parent item
End if
```

# Selected list items

Selected list items ( {* ;} list {; itemsArray {; *}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemsArray | Longint array | ⇐ | If 2nd * omitted: Array contains the positions of selected items in the list(s) If 2nd * passed: Array contains the selected item references |
| * | Operator | ⇒ | If omitted: Item position(s) If passed: Item reference(s) |
| Function result | Longint | ⇒ | If 2nd * omitted: Position of current selected list item in expanded/collapsed list(s) If 2nd * passed: Reference of the selected item |

## Description

The **Selected list items** command returns the position or reference of the selected item in the list whose reference number or object name you pass in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with item references (the second * is passed), you can use either syntax. Conversely, if you use several representations of the same list and work with the item positions (the second * is omitted), the syntax based on the object name is required since each representation can have its own expanded/collapsed item configuration.

**Note:** If you use the @ character in the name of the list object and the form contains several lists that match with this name, the **Selected list items** command will only apply to the first object whose name corresponds.

In the case of multiple selection, the command can also return in the *itemsArray* array, the position or reference of each item selected. You apply this command to a list displayed in a form to detect which item(s) the user has selected.

The second * parameter lets you indicate whether you want to work with current item positions (in this case, the * parameter should be omitted) or with fixed item references (in this case, the * parameter must be used).

You can pass a longint array in the *itemsArray* parameter. If necessary, the array will be created and resized by the command. Once the command has been executed, *itemsArray* will contain:

- the position of each item selected relative to the expanded/collapsed state of the list(s) if the * parameter is omitted.
- the fixed reference of each item selected if the * parameter is passed.
  If no items have been selected, the array is returned empty.

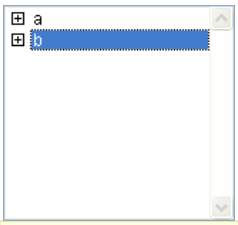
**Note:** In the event of multiple selections, the command returns the position or reference of the current item of *list*. The current item is the last item clicked by the user (manual selections) or the item set by the **SELECT LIST ITEMS BY POSITION** or **Selected list items** commands (programmed selection).

If the list has sublists, you apply the command to the main list (the one actually defined in the form), not one of its sublists. The positions are expressed relative to the top item of the main list, using the current expanded/collapsed state of the list and its sublist.

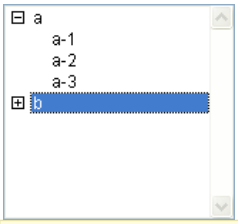
In any case, if no items are selected, the function returns 0.

## Example

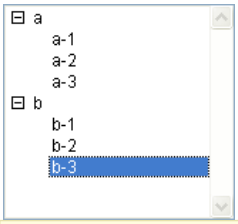
Here a list named *hList,* shown in the Application environment:



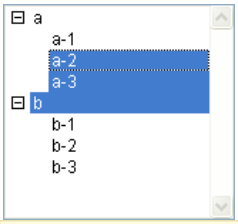
```
$vlItemPos:=Selected list items(hList) ` at this point $vlItemPos gets 2
```



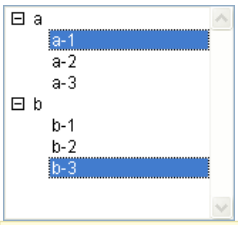
```
$vlItemPos:=Selected list items(hList) ` at this point $vlItemPos gets 5
$vlItemRef:=Selected list items(hList;*) ` $vlItemRef gets 200 (for instance)
```



```
$vlItemPos:=Selected list items(hList) ` at this point $vlItemPos gets 8
$vlItemRef:=Selected list items(hList;*) ` $vlItemRef gets 203 (for instance)
```



```
$vlItemPos:=Selected list items(hList;$arrPos) ` at this point, $vlItemPos gets 3
 ` $arrPos{1} gets 3, $arrPos{2} gets 4 and $arrPos{3} gets 5
```



```
$vlItemRef:=Selected list items(hList;$arrRefs;*) ` $vlItemRef gets 203 (for instance)
 ` $arrRefs{1} gets 101, $arrRefs{2} gets 203 (for instance)
```

# SET LIST ITEM

SET LIST ITEM ( {* ;} list ; itemRef | * ; newItemText ; newItemRef {; sublist ; expanded} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted), or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number, or 0 for last item appended to the list, or * for the current item in the list |
| newItemText | String | ⇒ | New item text |
| newItemRef | Longint | ⇒ | New item reference number |
| sublist | ListRef | ⇒ | New sublist attached to item, or 0 for no sublist (detaching current one, if any), or -1 for no change |
| expanded | Boolean | ⇒ | Indicates if the optional sublist will be expanded or collapsed |

## Description

The **SET LIST ITEM** command modifies the item designated by the *itemRef* parameter within the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

You can pass a reference number in *itemRef*. If there is no item with the item reference number you passed, the command does nothing. You can optionally pass *0* in *itemRef* to designate the last item added to the list using **APPEND TO LIST**.

Lastly, you can pass * in *itemRef*: in this case, the command will apply to the current item of the list. If several items are selected manually, the current item is the one that was selected last. If no item is selected, the command does nothing.

If you work with item reference numbers, build a list in which the items have unique reference numbers, otherwise you will not be able to distinguish the items. For more information, refer to the **Managing Hierarchical Lists** section.

You pass the new text for the item in *newItemText*. To change the item reference number, pass the new value in *newItemRef*; otherwise, pass the same value as *itemRef*.

To attach a list to the item, pass the list reference number in *subList*. In this case, you also specify if the newly sublist is expanded by passing TRUE in *expanded*; otherwise, pass FALSE.

To detach a sublist already attached to the item, pass *0* (zero) in *sublist*. In this case, it is a good idea to have previously obtained the reference number of that list using **APPEND TO LIST**, so you can later delete the sublist using **CLEAR LIST**, if you no longer need it.

If you do not want to change the sublist property of the item, pass *-1* in *sublist*.

**Note:** Even if they are optional, both the *sublist* and *expanded* parameters must be passed jointly.

## Example 1

*hList* is a list whose items have unique reference numbers. The following object method for a button adds a child item to the current selected list item.

```
$vlItemPos:=Selected list items(hList)
If($vlItemPos>0)
   GET LIST ITEM(hList;$vlItemPos;$vlItemRef;$vsItemText;$hSublist;$vbExpanded)
   $vbNewSubList:=Not(Is a list($hSublist))
   If($vbNewSubList)
      $hSublist:=New list
   End if
   vlUniqueRef:=vlUniqueRef+1
   APPEND TO LIST($hSubList;"New Item";vlUniqueRef)
   If($vbNewSubList)
      SET LIST ITEM(hList;$vlItemRef;$vsItemText;$vlItemRef;$hSublist;True)
   End if
   SELECT LIST ITEMS BY REFERENCE(hList;vlUniqueRef)
End if
```

## Example 2

See example for the **GET LIST ITEM** command.

## Example 3

See example for the **APPEND TO LIST** command.

# SET LIST ITEM FONT

SET LIST ITEM FONT ( {* ;} list ; itemRef | * ; font )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Longint, Operator | ⇒ | Item reference number or 0 for the last item added to the list or * for the current item of the list |
| font | String, Longint | ⇒ | Font name or number |

## Description

The **SET LIST ITEM FONT** command modifies the character font of the item specified by the *itemRef* parameter of the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

You can pass a reference number in *itemRef*. If this number does not correspond to any item of the list, the command does nothing. You can also pass 0 in *itemRef* in order to request the modification of the last item added to the list (using **APPEND TO LIST**).

Lastly, you can pass * in *itemRef*: in this case, the command will apply to the current item of the list. If several items are selected manually, the current item is the one that was selected last. If no item is selected, the command does nothing.

In the *font* parameter, pass the name or number of the font to be used. To reapply the default font of the hierarchical list, pass an empty string in *font*.

## Example

Apply the Times font to the current item of the list:

```
SET LIST ITEM FONT(*;"Mylist";*;"Times")
```

# SET LIST ITEM ICON

SET LIST ITEM ICON ( {* ;} list ; itemRef | * ; icon )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Longint, Operator | ⇒ | Item reference number or 0 for the last item added to the list or * for the current item of the list |
| icon | Picture | ⇒ | Icon to be associated with item |

## Description

The **SET LIST ITEM ICON** command modifies the icon associated with the item specified by the *itemRef* parameter of the list whose reference number or object name is passed in *list*.

**Note:** You can also modify the icon associated with an item using the **SET LIST ITEM PROPERTIES** command. However, this command only accepts static picture references (resource references or pictures from the picture library).

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

You can pass a reference number in *itemRef*. If this number does not correspond to an item in the list, the command does nothing. You can also pass 0 in *itemRef* to indicate the last item added to the list (using **APPEND TO LIST**).

Lastly, you can pass * in *itemRef*: in this case, the command is applied to the current item of the list. If several items are selected manually, the current item is the last one that was selected. If no item is selected, the command does nothing.

Pass a valid 4D picture expression (field, variable, pointer, etc.) in the *icon* parameter. The picture will be placed to the left of the item.

## Example

We want to assign the same picture to two different items. The following code is optimized since the picture is only loaded into memory once:

```
C_PICTURE($picture)
READ PICTURE FILE("myPict.png";$picture)
SET LIST ITEM ICON(mylist;ref1;$picture)
SET LIST ITEM ICON(mylist;ref2;$picture)
```

# SET LIST ITEM PARAMETER

SET LIST ITEM PARAMETER ( {* ;} list ; itemRef | * ; selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number or 0 for the last item appended to the list or * for the current list item |
| selector | String | ⇒ | Parameter constant |
| value | String, Boolean, Longint, Real | ⇒ | Value of the parameter |

## Description

The **SET LIST ITEM PARAMETER** command modifies the *selector* parameter for the *itemRef* item of the hierarchical list whose reference or object name is passed in the *list* parameter.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and the second * is passed, the syntax based on the object name is required since each representation can have its own current item.

You can pass a reference number in *itemRef*. If this number does not correspond to an item in the list, the command does nothing. You can also pass 0 in *itemRef* to indicate the last item added to the list (using **Hierarchical Lists**).

Lastly, you can pass * in *itemRef*: in this case, the command is applied to the current item of the list. If several items are selected manually, the current item is the last one that was selected. If no item is selected, the command does nothing.

In *selector*, you can pass the Additional text constant (found in the "**Hierarchical Lists**" theme) or any custom value:

- Additional text: This constant is used to add text to the right of the *itemRef* item. This additional title will always be displayed in the right part of the list, even when the user moves the horizontal scrolling cursor. When you use this constant, pass the text to be displayed in *value*.
- Custom selector: You can also pass custom text and associate it with a value of the Text, Number or Boolean type in *selector*. This value will be stored with the list item and may be retrieved using the **GET LIST ITEM PARAMETER** command. This lets you set up any type of interface associated with hierarchical lists. For example, in a list of customer names, you can store the age of each person and only display it when the corresponding item is selected.

# SET LIST ITEM PROPERTIES

SET LIST ITEM PROPERTIES ( {* ;} list ; itemRef | * ; enterable ; styles ; icon {; color} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, list is an object name (string) If omitted, list is a list reference number |
| list | ListRef, String | ⇒ | List reference number (if * omitted) or Name of list type object (if * passed) |
| itemRef \| * | Operator, Longint | ⇒ | Item reference number, or 0 for last item appended to the list, or * for the current list item |
| enterable | Boolean | ⇒ | TRUE = Enterable, FALSE = Non-enterable |
| styles | Longint | ⇒ | Font style for the item |
| icon | Longint | ⇒ | 'cicn' Mac OS-based resource ID, or 65536 + 'PICT' Mac OS-based resource ID, or 131072 + Picture Reference Number |
| color | Longint | ⇒ | RGB color value or -1 = reset to original color |

## Description

The **SET LIST ITEM PROPERTIES** command modifies the item designated by the *itemRef* parameter within the list whose reference number or object name is passed in *list*.

If you pass the first optional * parameter, you indicate that the *list* parameter is an object name (string) corresponding to a representation of the list in the form. If you do not pass this parameter, you indicate that the *list* parameter is a hierarchical list reference (*ListRef*). If you only use a single representation of the list or work with structural items (the second * is omitted), you can use either syntax. Conversely, if you use several representations of the same list and work with the current item (the second * is passed), the syntax based on the object name is required since each representation can have its own current item.

You can pass a reference number in *itemRef*. If there is no item with the item reference number that is passed, the command does nothing. You can optionally pass *0* in *itemRef* to modify the last item added to the list using **APPEND TO LIST**.

Lastly, you can pass * in *itemRef*: in this case, the command will apply to the current item of the list. If several items are selected manually, the current item is the one that was selected last. If no item is selected, the command does nothing.

If you work with item reference numbers, build a list in which items have unique reference numbers, otherwise you will not be able to distinguish the items. For more information, refer to the **Managing Hierarchical Lists** section.

**Note:** To change the text of the item or its sublist, use the command **SET LIST ITEM**.

To make an item enterable, pass TRUE in *enterable*; otherwise, pass FALSE.
**Important:** In order for an item to be enterable, it must belong to a list that is enterable. To make a whole list enterable, use the **OBJECT SET ENTERABLE** command. To make an individual list item enterable, use **SET LIST ITEM PROPERTIES**. Changing the enterable property at the list level does not affect the enterable properties of the items. However, an item can be enterable only if its list is enterable.

You specify the font style of the item in the *styles* parameter. You pass a combination (one or a sum) of the following predefined constants (**Font Styles** theme):

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

To associate an icon to the item, pass one of the following numeric values:

- N, where N is the resource ID of Mac OS-based 'cicn' resource
- Use PICT resource+N, where N is the the resource ID of a Mac OS-based 'PICT' resource
- Use PicRef+N, where N is the reference number of a Picture from the Design environment Picture Library

Pass zero (0), if you do not want any graphic for the item.

**Notes:**

- Use PICT resource and Use PicRef are predefined constants located in the **Hierarchical Lists** theme.

- If you want to use 4D picture expressions (fields, variables, etc.) to specify the icons of the items, use the **SET LIST ITEM ICON** command.

The *color* parameter (optional) lets you modify the color of the item text. The color must be specified in the form of an RGB color, i.e. a 4-byte longint in the 0x00RRGGBB format. For more information about this format, refer to the description of the **OBJECT SET RGB COLORS** command. Pass -1 in the *color* parameter to reset the original color of the item.

## Example 1

See the example for the **APPEND TO LIST** command.

## Example 2

The following example changes the text of the current item of *list* to bold and bright red:

```
SET LIST ITEM PROPERTIES(list;*;True;Bold;0;0x00FF0000)
```

# SET LIST PROPERTIES

SET LIST PROPERTIES ( list ; appearance {; icon {; lineHeight {; doubleClick {; multiSelections {; editable}}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |
| appearance | Longint | ⇒ | Graphical style of the list 1 = Hierarchical list a la Macintosh 2 = Hierarchical list a la Windows 0 = Auto appearance depending on platform |
| icon | Longint | ⇒ | 'cicn' Mac OS-based resource ID or 0 for default platform node icon |
| lineHeight | Longint | ⇒ | Minimal line height expressed in pixels |
| doubleClick | Longint | ⇒ | Expand/Collapse sublist on double-click 0 = Yes, 1= No |
| multiSelections | Longint | ⇒ | Multiple selections: 0 = No (default), 1 = Yes |
| editable | Longint | ⇒ | 0 = List is not editable by user, 1 = List is editable by user (default) |

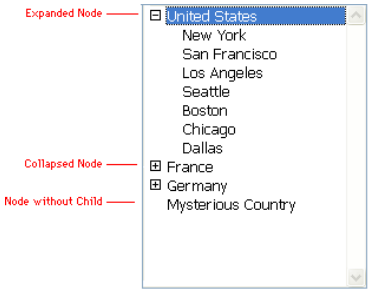
## Description

The **SET LIST PROPERTIES** command sets the appearance of the hierarchical list whose list reference you pass in *list*.

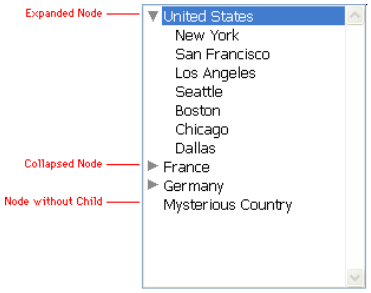
The parameter *appearance* can be one of the following predefined constants provided by 4D in the **Hierarchical Lists** theme:

| Constant | Type | Value |
|---|---|---|
| Ala Macintosh | Longint | 1 |
| Ala Windows | Longint | 2 |

In the Windows appearance, the icon (+) denotes collapsed nodes, and the icon (−) denotes expanded nodes. Nodes without child items have no icon. Here is a default hierarchical list in Windows appearance:



In the Macintosh appearance, a rightward-pointing arrow icon denotes the collapsed nodes, and a downward-pointing icon denotes the expanded nodes. Nodes without child items have no icon. Here is a default hierachical list in Macintosh appearance:



If you display a hierarchical list object without calling **SET LIST PROPERTIES** or pass 0 in the *appearence* parameter, the list appears with the default Windows or Macintosh appearances, depending on the Platform Interface property choosen for the object in the Design environment's Form Editor.

The parameter *icon* indicates the icons that will be displayed for each node. The value passed in *icon* sets the icon for collapsed nodes and *icon+1* sets the icon for expanded nodes.

For example, if you pass *15000*, the color icon *'cicn' ID=15000* will be displayed for each collapsed node and the color icon *'cicn' ID=15001* will be displayed for each expanded node.

It is therefore important to have these *'cicn'* color icon resources present in your database structure file. If a color icon resource is missing, the corresponding nodes are displayed with no icons. (You can actually take advantage of this to display a list with no icons.)

**WARNING:** When creating *'cicn'* color icon resources, use resource IDs greater than or equal to 15000. Resource IDs less than 15000 are reserved for 4D.

The resource IDs of the default Macintosh and Windows nodes are expressed by the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Macintosh node | Longint | 860 |
| Windows node | Longint | 138 |

In other words, 4D provides the following *'cicn'* resources:

| ID Number | Description |
|---|---|
| 860 | Collapsed node a la Macintosh |
| 861 | Expanded node a la Macintosh |
| 138 | Collapsed node a la Windows |
| 139 | Expanded node a la Windows |

If you do not pass the parameter *icon* or pass 0, the nodes are displayed with the default icons of the chosen appearance type.

Color icon resources can be of various sizes. For example, you can create *16x16* or *32x32* color icons.

If you do not pass the parameter *lineHeight*, the line height of a hierarchical list is determined by the font and font size used for the object. If you use a color icon that is too tall or too wide, it will be displayed truncated and/or will be overridden by the text of the nodes above or below it.

Choose color icon size, font, and font size accordingly, otherwise pass in the parameter *lineHeight* the minimal line height of the hierarchical list. If the value you pass is greater than the line height derived from the font and font size used, the line height of the hierarchical list will be forced to the value you pass.

**Note: SET LIST PROPERTIES** affects the way nodes are displayed in the hierarchical list. If you would rather customize the icon of each item in the list, use the command **SET LIST ITEM PROPERTIES**.

The optional parameter *doubleClick* allows you to define that a double-click on a parent list item will not provoke the sublist to expand or to collapse. By default, a double-click on a parent list item provokes its child list to expand or to collapse. However, some user interfaces may need to deactivate this behavior. To do this, the *doubleClick* parameter should be set to 1.
Only double-click will be deactivated. Users will still be able to expand or collapse sublists by clicking on the list node.
If you omit the *doubleClick* parameter or pass 0, default behavior will be applied.

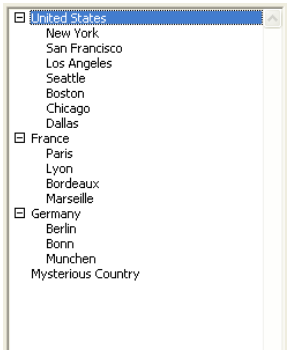
The optional *multiSelections* parameter lets you indicate whether the list must accept multiple selections.
By default, as in previous versions of 4D, you cannot simultaneously select several items of a hierarchical list. If you would like this function to be available for the list, pass the value 1 in the *multiSelections* parameter. In that case, multiple selections can be used:

- manually, using the **Shift**+**click** key combination for a continuous selection or **Ctrl**+**click** (Windows) / **Command**+**click** (Mac OS) for a discontinuous selection,
- by programming, using the **SELECT LIST ITEMS BY POSITION** and **SELECT LIST ITEMS BY REFERENCE** commands.
  If you pass 0 or omit the *multiSelections* parameter, the default behavior will be applied.

The optional *editable* parameter lets you indicate whether the list must be editable by the user when it is displayed as a choice list associated with a field or a variable during data entry. When the list is editable, a **Modify** button is added in the choice list window and the user can add, delete and sort the values through a specific editor.
If you pass 1 or omit the *editable* parameter, the list will be editable; if you pass 0, it will not be editable.

## Example

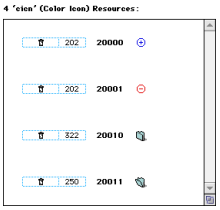
The following hierarchical list has been defined in the Design environment List Editor:



Within a form, the hierarchical list object *hlCities* reuses that list with this object method:

```
Case of
   :(Form event=On Load)
      hlCities:=Load list("Cities")
      SET LIST PROPERTIES(hlCities;vlAppearance;vlIcon)
   :(Form event=On Unload)
      CLEAR LIST(hlCities;*)
End case
```

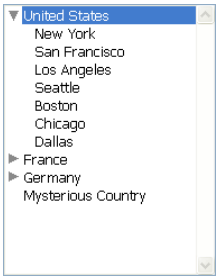
In addition, the structure file of the database has been edited so it contains the following *'cicn'* color icon resources:



1) With the following line:

```
SET LIST PROPERTIES(hlCities;Ala Macintosh;Macintosh node)
```

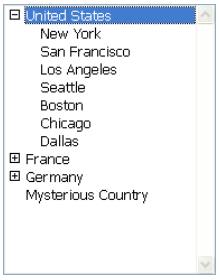
The hierarchical list will look like this:



2) With the following line:

```
SET LIST PROPERTIES(hlCities;Ala Windows;Windows node)
```

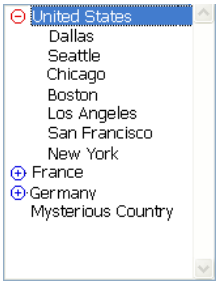
The hierarchical list will look like this:



3) With the following line:

```
SET LIST PROPERTIES(hlCities;Ala Windows;20000)
```

The hierarchical list will look like this:

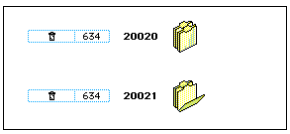


4) With the following line:

```
SET LIST PROPERTIES(hlCities;Ala Macintosh;20010)
```

The hierarchical list will look like this:

The *'cicn'* color icon resources shown are then added to the structure file of the database:



5) With the following line:

```
SET LIST PROPERTIES(hlCities;Ala Windows;20020;32)
```

The hierarchical list will look like this:

# SORT LIST

SORT LIST ( list {; > or <} )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |
| > or < | Operator | ⇒ | Sorting order: > to sort in ascending order, or < to sort in descending order |

## Description

The **SORT LIST** command sorts the list whose reference number is passed in *list*.

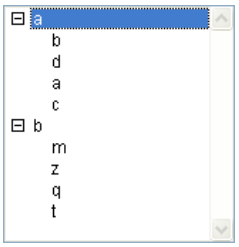
To sort in ascending order, pass >. To sort in descending order, pass <. If you omit the sorting order parameter, **SORT LIST** sorts in ascending order by default.

**SORT LIST** sorts all levels of the list; it first sorts the items of the list, then it sorts the items in each sublist (if any), and so on, through all the levels of the list. This is why you will usually apply **SORT LIST** to a list in a form. Sorting a sublist is of little interest because the order will be changed by a call to a higher level.

**SORT LIST** does not change the current list item nor the current expanded/collapsed state of the list and sublists. However, because the current item can be moved by the sorting operation, **Selected list items** may return a different position before and after the sort.

## Example

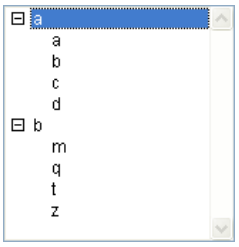
Given the list named *hList,* shown here in the Application environment:



After the execution of this code:

```
` Sort the list and it sublists in ascending order
SORT LIST(hList;>)
```

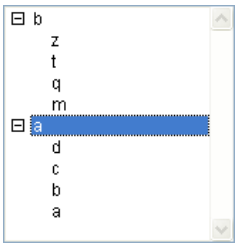
The list looks like:



After the execution of this code:

```
` Sort the list and it sublists in descending order
SORT LIST(hList;<)
```

The list looks like:



# _o_REDRAW LIST

_o_REDRAW LIST ( list )

| Parameter | Type | | Description |
|---|---|---|---|
| list | ListRef | ⇒ | List reference number |

## Description

This command serves no purpose since version 11 of 4D. All representations of hierarchical lists are now redrawn automatically.

# HTTP Client

- HTTP AUTHENTICATE
- HTTP Get
- HTTP Get certificates folder
- HTTP GET OPTION
- HTTP Request
- HTTP SET CERTIFICATES FOLDER
- HTTP SET OPTION

# HTTP AUTHENTICATE

HTTP AUTHENTICATE ( name ; password {; authMethod} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| name | Text | ⇒ | User name |
| password | Text | ⇒ | User password |
| authMethod | Longint | ⇒ | Authentication method: 0 or omitted=not specified, 1=BASIC, 2=DIGEST |
| * | Operator | ⇒ | If passed: authentication by proxy |

## Description

The **HTTP AUTHENTICATE** command enables HTTP requests to servers requiring authentication of the client application. The BASIC and DIGEST methods are supported, as well as the presence of a proxy.

In the *name* and *password* parameters, you pass the id information required (user name and password). This information is encoded and added to the next HTTP request sent using the **HTTP Request** or **HTTP Get** command, so you need to call the **HTTP AUTHENTICATE** command before each HTTP request.

The optional *authMethod* parameter indicates the authentication method to use. You pass one of the following constants, found in the **HTTP Client** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| HTTP basic | Longint | 1 | Use BASIC authentication method |
| HTTP digest | Longint | 2 | Use DIGEST authentication method |

If you omit the *authMethod* parameter (or pass 0), you let the program choose the appropriate method to use. In this case, 4D sends an additional request in order to negotiate the authentication method.

If you pass the * parameter, this indicates that the authentication information is intended for an HTTP proxy. This setting must be implemented when there is a proxy requiring authentication between the client and the HTTP server. If the server itself is authenticated, a double authentication is necessary.

By default, authentication information is stored temporarily and reused for each request in the current process. However, it is possible to reset this information after each request using an option set by the **HTTP SET OPTION** command. In this case, you will have to execute the **HTTP AUTHENTICATE** command before each call to **HTTP Request** or **HTTP Get**.

## Example

Examples of requests with authentication:

```
 // Authentication on HTTP server in DIGEST mode
HTTP AUTHENTICATE("httpUser";"123";2)
 // Authentication on proxy in default mode
HTTP AUTHENTICATE("ProxyUser";"456";*)
$httpStatus:=HTTP Get(...)
```

# HTTP Get

HTTP Get ( url ; response {; headerNames ; headerValues}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| url | Text | ⇒ | URL to which to send the request |
| response | Text, BLOB, Picture, Object | ⇐ | Result of request |
| headerNames | Text array | ⇒ | Header names of the request |
| | | ⇐ | Returned header names |
| headerValues | Text array | ⇒ | Header values of the request |
| | | ⇐ | Returned header values |
| * | Operator | ⇒ | If passed, connection is maintained (keep-alive)<br>If omitted, connection is closed automatically |
| Function result | Longint | ⇒ | HTTP status code |

## Description

The **HTTP Get** command sends an HTTP GET request directly to a specific URL and processes the HTTP server response.

Pass the URL where you want the request sent in the *url* parameter. The syntax to use is:

```
http://[{user}:[{password}]@]host[:{port}][/{path}][?{queryString}]
```

For example, you can pass the following strings:

```
http://www.myserver.com
http://www.myserver.com/path
http://www.myserver.com/path?name="jones"
https://www.myserver.com/login (*)
http://123.45.67.89:8083
http://john:smith@123.45.67.89:8083
```

*(*)* During HTTPS requests, authority of the certificate is not checked.

After command execution, the *response* parameter receives the result of the request returned by the server. This result corresponds to the body of the response, with no headers.
You can pass different types of variables in *response*:

- Text: When the result is expected to be text (see note below).
- BLOB: When the result is expected to be in binary form.
- Picture: When the result is expected to be a picture.
- Object: When the result is expected to be a **C_OBJECT** object.

**Note:** When a text variable is passed in *response*, 4D will try to decode the data returned from the server. 4D first tries to retrieve the charset from the *content-type* header, then from the content using a BOM, and finally looks for any *http-equiv charset* (in html content) or *encoding* (for xml) attribute. If no charset can be detected, 4D will attempt to decode the response in ANSI. If the conversion fails, the resulting text will be empty. If you are unsure whether the server returns a charset information or a BOM, but you know the encoding, it is more accurate to pass *response* in BLOB and call **Convert to text**.

If you pass a BLOB, it contains the text, picture or any type of contents (.wav, .zip, etc.) returned by the server. You must then manage the recovery of these contents (headers are not included in the BLOB). When you pass a **C_OBJECT** type object, if the request returns a result with an "application/json" (or "*something*/json") content-type, 4D attempts to parse the JSON content in order to generate the object.

In *headerNames* and *headerValues*, you pass arrays containing the names and values of the request headers.
After this method is executed, these arrays contain the names and values of headers returned by the HTTP server. More specifically, this lets you manage cookies.

The * parameter enables the keep-alive mechanism for the server connection. By default, if this parameter is omitted, keep-alive is not enabled.

The command returns a standard HTTP status code (200=OK and so on) as returned by the server. The list of HTTP status codes is provided in RFC 2616.
If you are unable to connect to the server for a reason related to the network (DNS Failed, Server not reachable...), the

command returns 0 and an error is generated. You can intercept errors using an error-handling method installed by the **ON ERR CALL** command.

## Example 1

Retrieval of the 4D logo on the 4D Web site:

```
C_TEXT(URLPic_t)
URLPic_t:="http://www.4d.com/sites/all/themes/dimention/images/home/logo4D.jpg"
ARRAY TEXT(HeaderNames_at;0)
ARRAY TEXT(HeaderValues_at;0)
C_PICTURE(Pic_i)
$httpResponse:=HTTP Get(URLPic_t;Pic_i;HeaderNames_at;HeaderValues_at)
```

## Example 2

Retrieval of an RFC:

```
C_TEXT(URLText_t)
C_TEXT(Text_t)
URLText_t:="http://tools.ietf.org/rfc/rfc1.txt"
ARRAY TEXT(HeaderNames_at;0)
ARRAY TEXT(HeaderValues_at;0)
$httpResponse:=HTTP Get(URLText_t;Text_t;HeaderNames_at;HeaderValues_at)
```

## Example 3

Retrieval of a video:

```
C_BLOB(vBlob)
$httpResponse:=HTTP Get("http://www.example.com/video.flv";vBlob)
BLOB TO DOCUMENT("video.flv";vBlob)
```

# HTTP Get certificates folder

HTTP Get certificates folder -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Text | ➲ | Complete pathname of active certificates folder |

## Description

The **HTTP Get certificates folder** command returns the complete pathname of the active client certificates folder.

By default, 4D uses the "ClientCertificatesFolder" folder that is created next to the structure file (folder only created if necessary). However, you can create a custom folder for the current process using the **HTTP SET CERTIFICATES FOLDER** command.

## Example

You want to change certificates folder temporarily:

```
C_TEXT($certifFolder)
$certifFolder :=HTTP Get certificates folder //save current folder
HTTP SET CERTIFICATES FOLDER("C:/temp/certifTempo/")
... // execution of specific requests
HTTP SET CERTIFICATES FOLDER($certifFolder) //restore previous folder
```

# HTTP GET OPTION

HTTP GET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇨ | Code of option to get |
| value | Longint | ⇦ | Current value of option |

## Description

The **HTTP GET OPTION** command returns the current value of the HTTP options (options used by client for next request triggered by the **HTTP Get** or **HTTP Request** commands). The current value of an option can be the default value or it can have been modified using the **HTTP SET OPTION** command.

**Note:** The options set are local to the current process. In a component, they are local to the component being executed.

In the *option* parameter, pass the number of the option whose value you want to get. You can use one of the following predefined constants, available in the **HTTP Client** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| HTTP compression | Longint | 6 | *value* = 0 (do not compress) or 1 (compress). Default value: 0<br>This option enables or disables the compression mechanism intended to accelerate exchanges for requests between the client and server. When this mechanism is enabled, the HTTP client uses deflate or gzip compression depending on the server response. |
| HTTP display auth dial | Longint | 4 | *value* = 0 (do not display dialogue box) or 1 (display dialogue box). Default value: 0<br>This option displays the authentication dialog box when the **HTTP Get** or **HTTP Request** command is executed. By default, this command never displays the dialog box and you must normally use the **HTTP AUTHENTICATE** command. However, if you want an authentication dialog box to appear so that users can enter their identifiers, then pass 1 in value. The dialog box only appears when the request requires authentication. |
| HTTP follow redirect | Longint | 2 | *value* = 0 (do not accept redirections) or 1 (accept redirections).<br>Default value = 1 |
| HTTP max redirect | Longint | 3 | *value* = Maximum number of redirections accepted<br>Default value = 2 |
| HTTP reset auth settings | Longint | 5 | *value* = 0 (do not delete information) or 1 (delete information). Default value: 0<br>This option indicates to 4D to reset the authentication information of the user (user name, password, method) after each execution of the **HTTP Get** or **HTTP Request** command in the same process. By default, this information is kept and reused for each request. Pass 1 in *value* to delete this information after each call. Note that regardless of the setting, this information is deleted when the process is killed. |
| HTTP timeout | Longint | 1 | *value* = timeout of client request, expressed in seconds. This timeout sets how long the HTTP client waits for the server to respond. After this period of time has passed, the client closes the session and the request is lost.<br>By default, this timeout is 120 seconds. It can be changed because of specific characteristics (network state, request characteristics, etc.). |

In the *value* parameter, pass a variable to receive the current value of the *option*.

# HTTP Request

HTTP Request ( httpMethod ; url ; contents ; response {; headerNames ; headerValues}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| httpMethod | Text | ➡ | HTTP method for request |
| url | Text | ➡ | URL to which to send the request |
| contents | Text, BLOB, Picture, Object | ➡ | Contents of request body |
| response | Text, BLOB, Picture, Object | ⬅ | Result of request |
| headerNames | Text array | ➡ | Header names of the request |
| | | ⬅ | Returned header names |
| headerValues | Text array | ➡ | Header values of the request |
| | | ⬅ | Returned header values |
| * | Operator | ➡ | If passed, connection is maintained (keep-alive)<br>If omitted, connection is closed automatically |
| Function result | Longint | ➲ | HTTP status code |

## Description

The **HTTP Request** command enables all types of HTTP requests to be sent to a specific URL and processes the HTTP server response.

Pass the HTTP method of the request in the *httpMethod* parameter. You can use one of the following constants, found in the **HTTP Client** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| HTTP DELETE method | String | DELETE | See RFC 2616 |
| HTTP GET method | String | GET | See RFC 2616. Same as using **HTTP Get** command. |
| HTTP HEAD method | String | HEAD | See RFC 2616 |
| HTTP OPTIONS method | String | OPTIONS | See RFC 2616 |
| HTTP POST method | String | POST | See RFC 2616 |
| HTTP PUT method | String | PUT | See RFC 2616 |
| HTTP TRACE method | String | TRACE | See RFC 2616 |

Pass the URL where you want the request sent in the *url* parameter. The syntax to use is:

```
http://[{user}:[{password}]@]host[:{port}][/{path}][?{queryString}]
```

For example, you can pass the following strings:

```
http://www.myserver.com
http://www.myserver.com/path
http://www.myserver.com/path?name="jones"
https://www.myserver.com/login (*)
http://123.45.67.89:8083
http://john:smith@123.45.67.89:8083
```

*(*)* During HTTPS requests, authority of the certificate is not checked.

Pass the body of the request in the *contents* parameter. Data passed in this parameter depends on the HTTP method of the request.
You can send data of the Text, BLOB, Picture or Object type. When the *content-type* is not specified, the following types are used:

- for text: text/plain - UTF8
- for BLOBs: application/byte-stream
- for pictures: known MIME type (best for Web).
- for **C_OBJECT** objects: application/json

After command execution, the *response* parameter receives the result of the request returned by the server. This result corresponds to the body of the response, with no headers.
You can pass different types of variables in *response*:

- Text: When the result is expected to be text (see note below).
- BLOB: When the result is expected to be in binary
- Picture: When the result is expected to be a picture.
- **C_OBJECT** Object: When the result is expected to be an object.

**Note:** When a text variable is passed in *response*, 4D will try to decode the data returned from the server. 4D first tries to retrieve the charset from the *content-type* header, then from the content using a BOM, and finally looks for any *http-equiv charset* (in html content) or *encoding* (for xml) attribute. If no charset can be detected, 4D will attempt to decode the response in ANSI. If the conversion fails, the resulting text will be empty. If you are unsure whether the server returns a charset information or a BOM, but you know the encoding, it is more accurate to pass *response* in BLOB and call **Convert to text**.

When you pass a **C_OBJECT** type variable in the *response* parameter, if the request returns a result with an "application/json" (or "*something*/json") content-type, 4D attempts to parse the JSON content in order to generate the object.

If the result returned by the server does not correspond to the *response* variable type, it is left blank and the OK system variable is set to 0.

In *headerNames* and *headerValues*, you pass arrays containing the names and values of the request headers.
After this method is executed, these arrays contain the names and values of headers returned by the HTTP server. More specifically, this lets you manage cookies.

The * parameter enables the keep-alive mechanism for the server connection. By default, if this parameter is omitted, keep-alive is not enabled.

The command returns a standard HTTP status code (200=OK and so on) as returned by the server. The list of HTTP status codes is provided in RFC 2616.
If you are unable to connect to the server for a reason related to the network (DNS Failed, Server not reachable...), the command returns 0 and an error is generated. You can intercept errors using an error-handling method installed by the **ON ERR CALL** command.

## Example 1

Requesting for a record deletion from a remote database:

```
C_TEXT($response)
$body_t:="{record_id:25}"
$httpStatus_l:=HTTP Request(HTTP_DELETE_method;"database.example.com";$body_t;$response)
```

**Note:** You have to process the request appropriately on the remote server, **HTTP Request** only handles the request and the returned result.

## Example 2

Requesting to add a record to a remote database:

```
C_TEXT($response)
$body_t:="{fName:'john',fName:'Doe'}"
$httpStatus_l:=HTTP Request(HTTP_PUT_method;"database.example.com";$body_t;$response)
```

**Note:** You have to process the request appropriately on the remote server, **HTTP Request** only handles the request and the returned result.

## Example 3

Request to add a record in JSON to a remote database::

```
C_OBJECT($content)
OB SET($content;"lastname";"Doe";"firstname";"John")
$result:=HTTP Request(HTTP_PUT_method;"database.example.com";$content;$response)
```

# HTTP SET CERTIFICATES FOLDER

HTTP SET CERTIFICATES FOLDER ( certificatesFolder )

| Parameter | Type | | Description |
|---|---|---|---|
| certificatesFolder | Text | ⇒ | Pathname and name of client certificates folder |

## Description

The **HTTP SET CERTIFICATES FOLDER** command modifies the active client certificates folder for all processes of the current session.

The client certificates folder is the one where 4D looks for the client certificate files that are required by Web servers. By default, as long as the **HTTP SET CERTIFICATES FOLDER** command is not executed, 4D uses a folder named "ClientCertificatesFolder" that is created next to the structure file. This folder is only created when necessary.

In 4D v14, it is now possible to use several client certificates.

In *certificatesFolder*, pass the pathname of the custom folder containing the client certificates. You can pass either a pathname relative to the application structure file, or an absolute pathname. The path must be expressed using the system syntax, for example:

- (OS X): Disk:Applications:myserv:folder
- (Windows): C:¥Applications¥myserv¥folder

Once this command has been executed, the new path is immediately taken into account by commands such as **HTTP Request** that are executed later on (you do not have to restart the application). It is used in all the processes of the database.

If the folder specified does not exist at the location defined, or if the pathname passed in *certificatesFolder* is not valid, an error is generated. You can intercept this error using an error-handling method installed by the **ON ERR CALL** command.

## About SSL certificates

As described in the **Using TLS Protocol** section, SSL certificates managed by 4D must be in the **PEM format**. If your certificate provider (for example, startssl) sends you a certificate that is in a binary format such as .crt, .pfx or .p12 (the format also depends on your browser), you have to convert it to PEM format in order to be able to use it. There are Web sites such as sslshopper where you can do this conversion on-line.

## Example

You want to change certificates folder temporarily:

```
C_TEXT($certifFolder)
$certifFolder :=HTTP Get certificates folder //save current folder
HTTP SET CERTIFICATES FOLDER("C:/temp/certifTempo/")
... // execution of specific requests
HTTP SET CERTIFICATES FOLDER($certifFolder) //restore previous folder
```

# HTTP SET OPTION

HTTP SET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇒ | Code of option to set |
| value | Longint | ⇒ | Value of option |

## Description

The **HTTP SET OPTION** command sets different options that are used during the next HTTP request triggered by the **HTTP Get** or **HTTP Request** commands. You call this command as many times as there are options to set.

**Note:** Options set are local to the current process. For components, they are local to the component being executed. .

In the *option* parameter, pass the number of the option to be set and in the *value* parameter, pass the new value of this option. For the *option* parameter, you can use one of the following predefined constants, available in the **HTTP Client** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| HTTP compression | Longint | 6 | *value* = 0 (do not compress) or 1 (compress). Default value: 0<br>This option enables or disables the compression mechanism intended to accelerate exchanges for requests between the client and server. When this mechanism is enabled, the HTTP client uses deflate or gzip compression depending on the server response. |
| HTTP display auth dial | Longint | 4 | *value* = 0 (do not display dialogue box) or 1 (display dialogue box). Default value: 0<br>This option displays the authentication dialog box when the **HTTP Get** or **HTTP Request** command is executed. By default, this command never displays the dialog box and you must normally use the **HTTP AUTHENTICATE** command. However, if you want an authentication dialog box to appear so that users can enter their identifiers, then pass 1 in value. The dialog box only appears when the request requires authentication. |
| HTTP follow redirect | Longint | 2 | *value* = 0 (do not accept redirections) or 1 (accept redirections).<br>Default value = 1 |
| HTTP max redirect | Longint | 3 | *value* = Maximum number of redirections accepted<br>Default value = 2 |
| HTTP reset auth settings | Longint | 5 | *value* = 0 (do not delete information) or 1 (delete information). Default value: 0<br>This option indicates to 4D to reset the authentication information of the user (user name, password, method) after each execution of the **HTTP Get** or **HTTP Request** command in the same process. By default, this information is kept and reused for each request. Pass 1 in *value* to delete this information after each call. Note that regardless of the setting, this information is deleted when the process is killed. |
| HTTP timeout | Longint | 1 | *value* = timeout of client request, expressed in seconds. This timeout sets how long the HTTP client waits for the server to respond. After this period of time has passed, the client closes the session and the request is lost.<br>By default, this timeout is 120 seconds. It can be changed because of specific characteristics (network state, request characteristics, etc.). |

You can call options in any order. If the same option is set more than once, only the value of the last call is taken into account.

# Import and Export

- EXPORT DATA
- EXPORT DIF
- EXPORT ODBC
- EXPORT SYLK
- EXPORT TEXT
- IMPORT DATA
- IMPORT DIF
- IMPORT ODBC
- IMPORT SYLK
- IMPORT TEXT

# EXPORT DATA

EXPORT DATA ( fileName {; project {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ⇒ | Full path name of the export file |
| project | Text variable, BLOB variable | ⇒ | Contents of the export project |
| | | ⇐ | New contents of the export project (if the * parameter has been passed) |
| * | Operator | ⇒ | Displays the export dialog box and updates the project |

## Description

The **EXPORT DATA** command exports data in the *fileName* file.4D can export data in the following formats: Text, Fixed length text, XML, SYLK, DIF, DBF (dBase), and 4D.

If you pass an empty string in *fileName*, **EXPORT DATA** displays the standard save file dialog box, allowing the user to define the name, type, and location of the export file. Once the dialog box has been accepted, the **Document** system variable contains the access path and the name of the file. If the user clicks **Cancel**, the execution of the command is stopped and the **OK** system variable is equal to 0.

The optional *project* parameter lets you use a project to export data. When you pass this parameter, the export is carried out directly, without any user intervention (unless you use the * option, see below). If you don't pass this parameter, the export dialog box is displayed. The user can define the export parameters or load an existing export project.

An export project contains all the export parameters such as the tables and fields to export, delimiters, etc. In the *project* parameter, you can pass either a Text variable containing XML or a Text variable containing a reference to a pre-existing DOM element, or a BLOB. Projects may have been created by programming (XML format projects only) or by loading parameters that were previously defined in the export dialog box.In the latter case, you have two solutions available:

- Use the **EXPORT DATA** command with an empty *project* parameter and the optional * parameter, then store the resulting *project* parameter in a Text or BLOB type field (see below). This solution allows you to save the project with the data file.
- Save the project to disk, then load it for example by using the **DOM Parse XML source** command, and pass its reference in the *project* parameter

**Compatibility note:** Beginning with version 12 of 4D, export projects are encoded in XML. 4D can open export projects generated with previous 4D versions (BLOB format) but any projects created starting with v12 can no longer be opened with v11 or earlier versions. We now recommend that you use Text variables for handling export files.

The optional parameter *, if it is specified, forces the display of the export dialog box with the parameters defined in *project*. This feature allows you to use a predefined project, while still having the possibility to modify one or more of the parameters. Furthermore, the project parameter contains, after closing the export dialog box, the parameters of the "new" project. You can then store the new project in a Text field, on disk, etc.

If the export was successful, the **OK** system variable is set to 1.

## Example 1

This example illustrates the use of the **EXPORT DATA** command to export data in binary format.

- This method makes a loop on all the database tables and calls the ***ExportBinary*** method:

```
C_TEXT($ExportPath)
C_LONGINT($i)
$ExportPath:=Select folder("Please select the export folder:")
If(Ok=1)
   For($i;1;Get last table number
      If(Is table number valid($i))
         ExportBinary(Table($i);$ExportPath+Table name($i);True)
      End if
   End for
End if
```

- Here is the code for the ***ExportBinary*** method:

```
C_POINTER($1) //table
C_TEXT($2) //path of destination file
C_BOOLEAN($3) //export all records
C_LONGINT($i)
C_TEXT($ref)
$ref:=DOM Create XML Ref("settings-import-export")
 // Export the table "$1" in '4D' binary format, all the records or only the current selection
DOM SET XML ATTRIBUTE($ref;"table_no";Table($1);"format";"4D";"all_records";$3)
 // Definition of fields to export
For($i;1;Get last field number($1))
   If(Is field number valid($1;$i))
      $elt:=DOM Create XML element($ref;"field";"table_no";Table($1);"field_no";$i)
   End if
End for
EXPORT DATA($2;$ref)
If(Ok=0)
   ALERT("Error during export of table "+Table name($1))
End if
DOM CLOSE XML($ref)
```

## Example 2

This example creates an empty project and stores the parameters set by the user in the export dialog box there:

```
C_TEXT($exportParams)
EXPORT DATA("DocExport.txt";$exportParams;*) //Display of the export dialog box
```

## System variables and sets

If the user clicks **Cancel** in the standard open file dialog box or in the export dialog box, the OK system variable is equal to 0. If the export was successful, the OK system variable is equal to 1.

# EXPORT DIF

EXPORT DIF ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to export data,or Default table, if omitted |
| document | String | ⇒ | DIF document to receive the data |

## Description

The **EXPORT DIF** command writes data from the records of the current selection of *aTable* in the current process. The data is written to *document*, a Windows or Macintosh DIF document on the disk.

The export operation is performed through the current output form. The export operation writes fields and variables based on the entry order of the output form. For this reason, you should use an output form that contains only the fields or enterable objects that you wish to export. Do not place buttons or other extraneous objects on the export form.Subform objects are ignored.

An On Load event is sent to the form method for each record that is exported. Use this event to set the variables you may use in the export form.

The *document* parameter can name a new or existing document. If *document* is given the same name as an existing document, the existing document is overwritten. The *document* can include a path that contains volume and folder names. If you pass an empty string, the standard Save File dialog box is displayed. If the user cancels this dialog, the export operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during export. The user can cancel the operation by clicking a Stop button. If the export is successfully completed, the OK system variable is set to 1. If the operation is canceled or an error occurs, the OK system variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses the UTF-8 character set. Since DIF format documents generally use the IBM437 character set, you may need to use the **USE CHARACTER SET** command to specify the appropriate character set.

When using **EXPORT DIF**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return (code 13). You can modify these values by assigning new values to the two **System Variables** *FldDelimit* and *RecDelimit*. The user can change these default values in the export dialog box of the Design mode. Since Text fields can contain carriage returns, be careful if you use the carriage return as the field delimiter for fields to be exported.

## Example

The following example exports data to a DIF document. The method first sets the output form so that the data will be exported through the correct form, then performs the export:

```
FORM SET OUTPUT([People];"Export")
EXPORT DIF([People];"NewPeople.dif"")  ` Export to the "NewPeople.dif" document
```

## System variables and sets

OK is set to 1 if the export is successfully completed; otherwise, it is set to 0.

# EXPORT ODBC

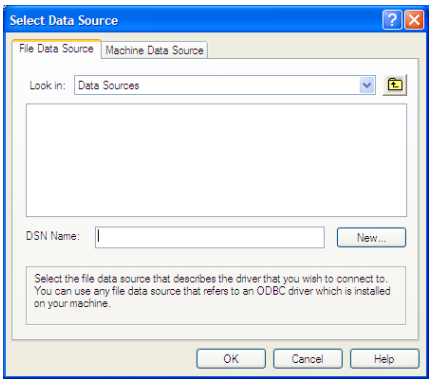
EXPORT ODBC ( sourceTable {; project {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| sourceTable | String | ⇒ | Name of table in ODBC data source |
| project | BLOB | ⇒ | Contents of export project |
| | | ⇐ | New contents of export project (if * is passed) |
| * | Operator | ⇒ | Display of export dialog box and project update |

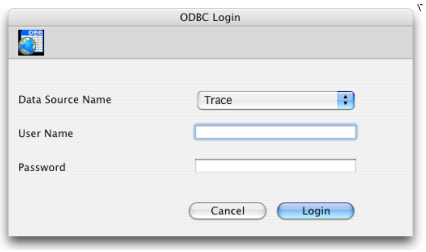
## Description

The **EXPORT ODBC** command is used to export data in the *sourceTable* table of an external ODBC source.
If you call the **EXPORT ODBC** command outside of a connection opened previously using the **SQL LOGIN** command, the ODBC data source selection dialog box is displayed:

**Windows**



**Mac OS**



If the user clicks **Cancel** in this dialog box, execution is stopped and the system variable OK is set to 0.

**Note:** This command cannot be used in the case of connections with the internal SQL kernel of 4D.

If you do not pass the optional *project* parameter, 4D displays the ODBC export dialog box, which allows the user to configure the operation. For more information about this dialog box, refer to the Design Reference manual.

If you pass a BLOB containing a valid ODBC export project in the *project* parameter, the export will be carried out directly, without any user intervention. To do this, you simply need to load a project that has been saved on disk beforehand into the field or the BLOB variable that you pass in the *project* parameter, using the **DOCUMENT TO BLOB** command. ODBC export projects are saved via the ODBC export dialog box.

You can also use the **EXPORT ODBC** command with an empty *project* parameter and the optional * parameter, then store the *project* parameter in a BLOB field (see below). On the one hand, this solution lets you store the project with the data file and, on the other, to avoid the phase of loading it from the disk into a BLOB.

**Note:** Refer to the **EXPORT DATA** command for an example concerning the definition of an empty project. Please note that projects generated in the ODBC export dialog box are not compatible with the commands or the standard export dialog box of 4D.

The optional * parameter, if it is set, displays the ODBC data export dialog box with the settings defined in *project* (if any). This allows you to use a predefined project while still being able to modify one or more parameters. Moreover, in this case, the *project* parameter contains the parameters of the “new” project after the dialog box is closed. You can then store it in a BLOB field, in a file on disk, etc.

## System variables and sets

If the user clicks **Cancel** in either of the two dialog boxes (for selecting the data source or the export settings), the system variable OK is set to 0. If the export is carried out correctly, the system variable OK is set to 1.

# EXPORT SYLK

EXPORT SYLK ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to export data, or Default table, if omitted |
| document | String | ⇒ | SYLK document to receive the data |

## Description

The **EXPORT SYLK** command writes data from the records of the current selection of *aTable* in the current process. The data is written to *document*, a Windows or Macintosh Sylk document on the disk.

The export operation is performed through the current output form. The export operation writes fields and variables based on the entry order of the output form. For this reason, you should use an output form that contains only the fields or enterable objects that you wish to export. Do not place buttons or other extraneous objects on the export form.Subform objects are ignored.

An On Load event is sent to the form method for each record that is exported. Use this event to set the variables you may use in the export form.

The *document* parameter can name a new or existing document. If *document* is given the same name as an existing document, the existing document is overwritten. The *document* can include a path that contains volume and folder names. If you pass an empty string, the standard Save File dialog box is displayed. If the user cancels this dialog, the export operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during export. The user can cancel the operation by clicking a Stop button. If the export is successfully completed, the OK system variable is set to 1. If the operation is canceled or an error occurs, the OK system variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses the UTF-8 character set. Since SYLK format documents generally use the ISO-8859-1 character set, you may need to use the **USE CHARACTER SET** command to specify the appropriate character set.

When using **EXPORT SYLK**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return (code 13) under OS X and the carriage return+line feed (code 13 + code 10) under Windows. You can modify these values by assigning new values to the two **System Variables** *FldDelimit* and *RecDelimit*. The user can change these default values in the export dialog box of the Design mode. Note that if exported fields contain characters defined as field or record delimiters, these characters are automatically replaced with spaces in the exported file, in order to avoid disrupting the importing process.

## Example

The following example exports data to a SYLK document. The method first sets the output form so that the data will be exported through the correct form, then performs the export:

```
FORM SET OUTPUT([People];"Export")
EXPORT SYLK([People];"NewPeople.slk") ` Export to the "NewPeople.slk" document
```

## System variables and sets

OK is set to 1 if the export is successfully completed; otherwise, it is set to 0.

# EXPORT TEXT

EXPORT TEXT ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to export data, or Default table, if omitted |
| document | String | ⇒ | Text document to receive the data |

## Description

The **EXPORT TEXT** command writes data from the records of the current selection of *aTable* in the current process. The data is written to *document*, a Windows or Macintosh text document on the disk.

The export operation is performed through the current output form. The export operation writes fields and variables based on the entry order of the output form. For this reason, use an output form that contains only the fields or enterable objects that you wish to export. Do not place buttons or other extraneous objects on the export form.Subform objects are ignored.

An On Load event is sent to the form method for each record that is exported. Use this event to set the variables you may use in the export form.

The *document* parameter can name a new or existing document. If *document* is given the same name as an existing document, the existing document is overwritten. The *document* can include a path that contains volume and folder names. If you pass an empty string, the standard Save File dialog box is displayed. If the user cancels this dialog, the export operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during export. The user can cancel the operation by clicking a Stop button. If the export is successfully completed, the OK system variable is set to 1. If the operation is canceled or an error occurs, the OK system variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses by default the UTF-8 character set. You can use the **USE CHARACTER SET** command to change this character set.

Using **EXPORT TEXT**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return character (code 13) under OS X and the carraige return+line feed (code 13 + code 10) under Windows. You can change these defaults by assigning values to the two delimiter **System Variables**: **FldDelimit** and **RecDelimit**. The user can change the default values in the Design environment Export Data dialog box. Note that if exported fields contain characters defined as field or record delimiters, these characters are automatically replaced with spaces in the exported file, in order to avoid disrupting the importing process.

## Example

This example exports data to a text document. The method first sets the output form so that the data will be exported through the correct form, changes the 4D delimiter variables, then performs the export:

```
FORM SET OUTPUT([People];"Export")
FldDelimit:=27 ` Set field delimiter to Escape character
RecDelimit:=10 ` Set record delimiter to Line Feed character
EXPORT TEXT([People];"NewPeople.txt") ` Export to the "NewPeople.txt" document
```

## System variables and sets

OK is set to 1 if the export is successfully completed; otherwise, it is set to 0.

# IMPORT DATA

IMPORT DATA ( fileName {; project {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ⇒ | Access path and name of the import file |
| project | Text variable, BLOB variable | ⇒ | Contents of the import project |
| | | ⇐ | New contents of the import project (if the * parameter has been passed) |
| * | Operator | ⇒ | Displays the import dialog box and updates the project |

## Description

The **IMPORT DATA** command imports the data located in the *fileName* file. 4D can import the data in the following formats: Text, Fixed length text, XML, SYLK, DIF, DBF (dBase), and 4D.

If you pass an empty string to *fileName*, **IMPORT DATA** displays the standard save file dialog box, allowing the user to define the name, type, and location of the import file. Once the dialog box has been accepted, the *Document* system variable contains the access path and the name of the file. If the user clicks **Cancel**, the execution of the command is stopped and the *OK* system variable is set to 0.

The optional *project* parameter lets you use a project to import data. When you pass this parameter, the import is carried out directly, without any user intervention (unless you use the * option, see below). If you don't pass this parameter, the import dialog box is displayed. The user can define the import parameters or load an existing import project.

An import project contains all the import parameters such as the tables and fields in which to import, the delimiters to use, and so on. In the *project* parameter, you can pass either a Text variable containing XML or a Text variable containing a reference to a pre-existing DOM element, or a BLOB. Projects may have been created by programming (XML format projects only) or by loading parameters that were previously defined in the import dialog box.In the latter case, you have two solutions available:

- Use the **IMPORT DATA** command with an empty project parameter and the optional parameter *, then store the resulting *project* parameter in a Text or BLOB field (see below). This solution allows you to save the project with the data file.
- Save the project to disk, then load it for example using the **DOM Parse XML source** command, and pass its reference in the *project* parameter.

**Compatibility note:** Beginning with version 12 of 4D, import projects are encoded in XML. 4D can open import projects generated with previous 4D versions (BLOB format) but any projects created starting with v12 can no longer be opened with v11 or earlier versions. We now recommend that you use Text variables for handling import files.

The optional * parameter, if it is specified, forces the display of the import dialog box with the import parameters set as they were defined in *project*. This feature allows you to use a predefined project, while still having the possibility to modify one or more of the parameters. Furthermore, the *project* parameter contains, after closing the import dialog box, the parameters of the "new" project. You can then store the new project in a BLOB field, on disk, and so on.

If the import was successful, the *OK* system variable is set to 1.

**Note:** Refer to the **EXPORT DATA** command for an example concerning the definition of an empty project.

## System variables and sets

If the user clicks **Cancel** in the standard save file dialog box or in the import dialog box, the OK system variable is set to 0. If the import was successful, the OK system variable is set to 1.

# IMPORT DIF

IMPORT DIF ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table into which to import data, or Default table, if omitted |
| document | String | ⇒ | DIF document from which to import data |

## Description

The **IMPORT DIF** command reads data from *document*, a Windows or Macintosh DIF document, into the table *aTable* by creating new records for that table.

The import operation is performed through the current input form. The import operation reads fields and variables based on the layering of objects in the input form. For this reason, you should be very careful about the front-to-back order of text objects (fields and variables) in the form. The first object into which data will be imported should be in the back of the form, and so on. If the number of fields or variables in the form does not match the number of fields being imported, the extra ones are ignored. An input form used for importing cannot contain any buttons. Subform objects are ignored.

**Note:** One way to ensure that the data is imported into the correct objects is to select the object into which the first field should be imported and move it to the front. Continue to move the fields and variables to the front, in order, making sure that you have one field or variable for each field being imported.

An On Validate event is sent to the form method for each record that is imported. Use this event to copy data from variables to fields, if you use variables in the import form.

The *document* parameter can include a path that contains volume and folder names. If you pass an empty string, the standard Open File dialog box is displayed. If the user cancels this dialog, the import operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during import. The user can cancel the operation by clicking a Stop button. Records that have already been imported will not be removed if the user presses the Stop button. If the import is successfully completed, the OK system variable is set to 1. If an error occurs or the operation was interrupted, the OK variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses the UTF-8 character set. Since DIF format documents generally use the IBM437 character set, you may need to use the **USE CHARACTER SET** command to specify the appropriate character set.

When using **IMPORT DIF**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return (code 13). You can modify these values by assigning new values to the two **System Variables** *FldDelimit* and *RecDelimit*. The user can change these default values in the export dialog box of the Design mode. Since Text fields can contain carriage returns, be careful if you use the carriage return as the field delimiter for fields to be exported.

## Example

The following example imports data from a DIF document. The method first sets the input form so that the data will be imported through the correct form, then performs the import:

```
FORM SET INPUT([People];"Import")
IMPORT DIF([People];"NewPeople.dif") ` Import from "NewPeople.dif" document
```

## System variables and sets

OK is set to 1 if the import is successfully completed; otherwise, it is set to 0.

# IMPORT ODBC

IMPORT ODBC ( sourceTable {; project {; *}} )

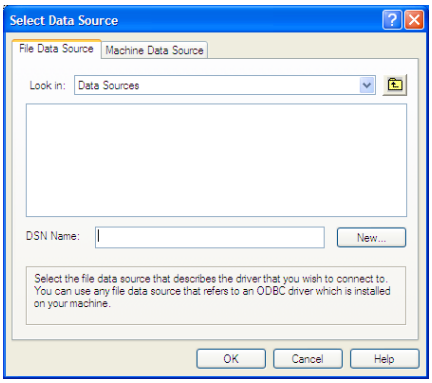
| Parameter | Type | | Description |
|---|---|---|---|
| sourceTable | String | ⇒ | Name of table in ODBC data source |
| project | BLOB | ⇒ | Contents of import project |
| | | ⇐ | New contents of import project (if * is passed) |
| * | Operator | ⇒ | Display of import dialog box and project update |

## Description

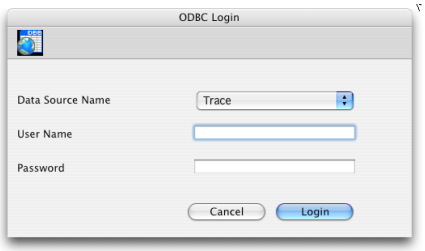
The **IMPORT ODBC** command is used to import data from the *sourceTable* table of an external ODBC source.

If you call the **IMPORT ODBC** command outside of a connection previously opened using the **SQL LOGIN**, command, the ODBC data source selection dialog box is displayed:

**Windows**



**Mac OS**



If the user clicks **Cancel** in the dialog box, execution is stopped and the system variable OK is set to 0.

**Note:** This command cannot be used in the case of connections with the internal SQL kernel of 4D.

If you do not pass the optional *project* parameter, 4D displays the ODBC import dialog box which allows the user to configure the operation. For more information about this dialog box, refer to the Design Reference manual.
If you pass a BLOB containing a valid ODBC import project in the *project* parameter, the import will be carried out directly, without any user intervention. To do this, you simply need to load a project that has been saved on disk beforehand into the field or the BLOB variable that you pass in the *project* parameter, using the **DOCUMENT TO BLOB** command. ODBC import projects are saved via the ODBC import dialog box.

You can also use the **IMPORT ODBC** command with an empty *project* parameter and the optional * parameter, then store the *project* parameter in a BLOB field (see below). On the one hand, this solution lets you store the project with the data file and, on the other, to avoid the phase of loading it from the disk into a BLOB.

**Note:** Refer to the **EXPORT DATA** command for an example concerning the definition of an empty project. Please note that projects generated in the ODBC import dialog box are not compatible with the commands or the standard import dialog box of 4D.

The optional * parameter, if it is set, displays the ODBC data import dialog box with the settings defined in *project* (if any). This allows you to use a predefined project while still being able to modify one or more parameters. Moreover, in this case, the *project* parameter contains the parameters of the “new” project after the dialog box is closed. You can then store it in a BLOB field, in a file on disk, etc.

## System variables and sets

If the user clicks **Cancel** in either of the two dialog boxes (for selecting the data source or the import settings), the system variable OK is set to 0. If the import is carried out correctly, the system variable OK is set to 1.

# IMPORT SYLK

IMPORT SYLK ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table into which to import data, or Default table, if omitted |
| document | String | ⇒ | SYLK document from which to import data |

## Description

The **IMPORT SYLK** command reads data from *document*, a Windows or Macintosh SYLK document, into the table *aTable* by creating new records for that table.

The import operation is performed through the current input form. The import operation reads fields and variables based on the layering of objects in the input form. For this reason, you should be very careful about the front-to-back order of text objects (fields and variables) in the form. The first object into which data will be imported should be in the back of the form, and so on. If the number of fields or variables in the form does not match the number of fields being imported, the extra ones are ignored. An input form used for importing cannot contain any buttons. Subform objects are ignored.

**Note:** One way to ensure that the data is imported into the correct objects is to select the object into which the first field should be imported and move it to the front. Continue to move the fields and variables to the front, in order, making sure that you have one field or variable for each field being imported.

An On Validate event is sent to the form method for each record that is imported. If you use variables in the import form, use this event to copy data from variables to fields.

The *document* parameter can include a path that contains volume and folder names. If you pass an empty string, the standard Open File dialog box is displayed. If the user cancels this dialog, the import operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during the import. The user can cancel the operation by clicking a Stop button. Records that have already been imported will not be removed if the user presses the Stop button. If the import is successfully completed, the OK system variable is set to 1. If an error occurs or the operation was interrupted, the OK variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses the UTF-8 character set. Since SYLK format documents generally use the ISO-8859-1 character set, you may need to use the **USE CHARACTER SET** command to specify the appropriate character set.

When using **IMPORT SYLK**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return (code 13). You can modify these values by assigning new values to the two **System Variables** *FldDelimit* and *RecDelimit*. The user can change these default values in the export dialog box of the Design mode. Since Text fields can contain carriage returns, be careful if you use the carriage return as the field delimiter for fields to be exported.

## Example

The following example imports data from a SYLK document. The method first sets the input form so the data will be imported through the correct form, then performs the import:

```
FORM SET INPUT([People];"Import")
IMPORT SYLK([People];"NewPeople.slk") ` Import from "NewPeople.slk" document
```

## System variables and sets

OK is set to 1 if the import is successfully complete; otherwise, it is set to 0.

# IMPORT TEXT

IMPORT TEXT ( {aTable ;} document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table into which to import data, or Default table, if omitted |
| document | String | ⇒ | Text document from which to import data |

## Description

The **IMPORT TEXT** command reads data from *document*, a Windows or Macintosh text document, into the table *aTable* by creating new records for that table.

The import operation is performed through the current input form. The import operation reads fields and variables based on the layering of objects in the input form. For this reason, you should be very careful about the front-to-back order of text objects (fields and variables) in the form. The first object into which data will be imported should be in the back of the form, and so on. If the number of fields or variables in the form does not match the number of fields being imported, the extra ones are ignored. An input form used for importing cannot contain any buttons. Subform objects are ignored.

**Note:** One way to ensure that the data is imported into the correct objects is to select the object into which the first field should be imported and move it to the front. Continue to move fields and variables to the front in order, making sure that you have one field or variable for each field being imported.

An On Validate event is sent to the form method for each record that is imported. If you use variables in the import form, use this event to copy data from variables to fields.

The *document* parameter can include a path that contains volume and folder names. If you pass an empty string, the standard Open File dialog box is displayed. If the user cancels this dialog, the import operation is canceled, and the OK system variable is set to 0.

A progress thermometer is displayed during import. The user can cancel the operation by clicking a button labeled Stop. Records that have already been imported will not be removed if the user presses the Stop button. If the import is successfully completed, the OK system variable is set to 1. If an error occurs or the operation was interrupted, the OK variable is set to 0. The thermometer can be hidden with the **MESSAGES OFF** command.

By default, the command uses the UTF-8 character set. You can use the **USE CHARACTER SET** command to change this character set.

Using **IMPORT TEXT**, the default field delimiter is the tab character (code 9). The default record delimiter is the carriage return character (code 13). You can change these defaults by assigning values to the two delimiter **System Variables**: *FldDelimit* and *RecDelimit*. The user can change the defaults in the Design environment's Import Data dialog box. Text fields may contain carriage returns, therefore, be careful when using a carriage return as a delimiter if you are importing text fields.

## Example

The following example imports data from a text document. The method first sets the input form so that the data will be imported through the correct form, changes the 4D delimiter variables, then performs the import:

```
FORM SET INPUT([People];"Import")
FldDelimit:=27 ` Set field delimiter to Escape character
RecDelimit:=10 ` Set record delimiter to Line Feed character
IMPORT TEXT([People];"NewPeople.txt") ` Import from "NewPeople.txt" document
```

## System variables and sets

OK is set to 1 if the import is successfully completed; otherwise, it is set to 0.

# Interruptions

- ABORT
- ASSERT
- Asserted
- FILTER EVENT
- Get assert enabled
- GET LAST ERROR STACK
- Method called on error
- Method called on event
- ON ERR CALL
- ON EVENT CALL
- SET ASSERT ENABLED

# ABORT

ABORT
Does not require any parameters

## Description

The **ABORT** command is used from within an error-handling project method installed using the command **ON ERR CALL**.

If you do not have an error-handling project method, when an error occurs (for example, a database engine error) 4D displays its standard error dialog box and then interrupts the execution of your code. If the code being executed is:

- an object method, form method (or a project method called by a form or object method), the control returns to the form currently being displayed.
- a method called from a menu, the control returns to the menu bar or to the form currently being displayed.
- the master method of a process, the process then ends.
- a method called directly or indirectly by an import or export operation, the operation is stopped. The same is true for sequential queries or order by operations.
- And so on...

If you use an error-handling project method to catch errors, 4D neither displays its standard error dialog box nor interrupts the execution of your code. Instead, 4D calls your error-handling project method (that you can see as an exception handler), and resumes the execution to the next line of code in the method that triggered the error.

There are errors you can treat programmatically; for example, during an import operation, if you catch a database engine duplicated value error, you can “cover” the error and pursue the import. However, there are errors that you cannot process and errors that you should not “cover.” In these cases, you need to stop the execution by calling **ABORT** from within the error-handling project method.

## Historical Note

Although the **ABORT** command is intended to be used only from within a error-handling project method, some members of the 4D community also use it to interrupt execution in other project methods. The fact that it works is only a side effect. We do not recommend the use of this command in methods other than error-handling methods.

# ASSERT

ASSERT ( boolExpression {; messageText} )

| Parameter | Type | | Description |
|---|---|---|---|
| boolExpression | Boolean | ➡ | Boolean expression |
| messageText | Text | ➡ | Text of error message |

## Description

The **ASSERT** command evaluates the *boolExpression* assertion passed in parameter and, if it returns false, stops the code execution with an error message. The command works in interpreted and compiled mode.

If *boolExpression* is true, nothing happens. If it is false, the command triggers the error -10518 and displays by default the text of the assertion preceded by the message "Assert failed:". You can intercept this error via a method installed using the **ON ERR CALL** command, in order, for example, to provide info for a log file.

Optionally, you can pass a *messageText* parameter to display a custom error message instead of the text of the assertion.

An assertion is an instruction inserted in the code that is responsible for detecting any anomalies during its execution. The principle consists in verifying that an expression is true at a given moment and, should the opposite occur, to cause an exception. Assertions are above all used to detect cases that should usually not ever occur. They are mainly used to detect programming bugs. It is possible to globally enable or disable all the assertions of an application (for example according to the type of version) via the **SET ASSERT ENABLED** command. For more information about assertions in programming, please refer to the article concerning them on Wikipedia: http://en.wikipedia.org/wiki/Assertion_(computing)

## Example 1

Before carrying out operations on a record, the developer wants to make sure that it is actually loaded in read/write mode:

```
READ WRITE([Table 1])
LOAD RECORD([Table 1])
ASSERT(Not(Locked([Table 1])))
 // triggers error -10518 if record is locked
```

## Example 2

An assertion can allow parameters passed to a project method to be tested in order to detect aberrant values. In this example, a custom warning message is used.

```
 // Method that returns the number of a client according to its name passed in $1
C_TEXT($1) // Name of client
ASSERT($1#"";"Search for a blank client name")
 // A blank name in this case is an aberrant value
 // If the assertion is false, the following will be displayed in the error dialog box:
 // "Assert failed: Search for a blank client name"
```

# Asserted

Asserted ( boolExpression {; messageText} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| boolExpression | Boolean | ⇒ | Boolean expression |
| messageText | Text | ⇒ | Text of error message |
| Function result | Boolean | ⇐ | Result of evaluation of boolExpression |

## Description

The **Asserted** command has an operation similar to that of the **ASSERT** command, with one difference in that it returns a value which is the result of the evaluation of the *boolExpression* parameter. It therefore allows the use of an assertion during the evaluation of a condition (see the example). For more information about the operation of assertions and the parameters of this command, please refer to the description of the **ASSERT** command.

**Asserted** accept a Boolean expression as a parameter and returns the result of the evaluation of this expression. If the expression is false and if the assertions are enabled (see the **SET ASSERT ENABLED** command), the error -10518 is generated, exactly as for the **ASSERT** command. If the assertions are disabled, **Asserted** returns the result of the expression that was passed without triggering an error.

**Note:** Like the **ASSERT** command, **Asserted** works in interpreted and compiled mode.

## Example

Insertion of an assertion in the evaluation of an expression:

```
READ WRITE([Table 1])
LOAD RECORD([Table 1])
If(Asserted(Not(Locked([Table 1]))))
 // This code triggers the error -10518 if the record is locked
   ...
End if
```

# FILTER EVENT

FILTER EVENT
Does not require any parameters

## Description

You call the **FILTER EVENT** command from within an event-handling project method installed using the **ON EVENT CALL** command.

If an event-handling method calls **FILTER EVENT**, the current event is not passed to 4D.

This command removes the current event (i.e., click, keystroke) from the event queue, so 4D will not perform any additional treatment to the one you made in the event-handling project method.

**WARNING:** Do not create an event-handling method that only calls the **FILTER EVENT** command, because all the events are going to be ignored by 4D. When you have an event-handling method with only the **FILTER EVENT** command, type Ctrl+Shift+Backspace (on Windows) or Command-Option-Shift-Control-Backspace (on Macintosh). This converts the On Event Call process into a normal process that does not get any events at all.

**Special case:** The **FILTER EVENT** command can also be used within a standard output form method when the form is displayed using the **DISPLAY SELECTION** or **MODIFY SELECTION** commands. In this specific case, the **FILTER EVENT** command allows you to filter double-clicks on the records (and in this way execute actions other than the opening of records in page mode).

To do this, place the following lines in the output form method:

```
If(Form event=On Double Clicked)
   FILTER EVENT
   ... `Process the double-click
End if
```

## Example

See example for the **ON EVENT CALL** command.

# Get assert enabled

Get assert enabled -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | True = assertions are enabled False = assertions are disabled |

## Description

The **Get assert enabled** command returns True or False according to whether or not assertions are enabled in the current process. For more information about assertions, please refer to the description of the **ASSERT** command.

By default, assertions are enabled but they may have been disabled using the **SET ASSERT ENABLED** command.

# GET LAST ERROR STACK

GET LAST ERROR STACK ( codesArray ; intCompArray ; textArray )

| Parameter | Type | | Description |
|---|---|---|---|
| codesArray | Longint array | ⇦ | Error numbers |
| intCompArray | String array | ⇦ | Internal component codes |
| textArray | String array | ⇦ | Text of errors |

## Description

The **GET LAST ERROR STACK** command returns information about the current stack of errors of the 4D application. When a 4D statement causes an error, the current error stack contains a description of the error as well as any series of errors generated. For example, a "disk full" type error causes a write error in the file then an error in the record saving command: the stack will therefore contain three errors. If the last 4D statement did not generate an error, the current error stack is empty.

This generic command can be used to process any type of error that may occur in the 4D application.

**Note:** However, to obtain detailed information concerning the errors generated by an ODBC source, it will be necessary to use the **SQL GET LAST ERROR** command.

This command must be called from an on error call method installed by the **ON ERR CALL** command.

The information is returned in three synchronized arrays:

- *codesArray*: This array receives the list of error codes generated.
- *intCompArray*: This array contains the codes of the internal components associated with each error.
- *textArray*: This array contains the text of each error.

The list of error codes and their text is provided in the sections of the **Error Codes** theme.

# Method called on error

Method called on error -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ⮌ | Name of method called on error |

## Description

The **Method called on error** command returns the name of the method installed by the **ON ERR CALL** command for the current process.

If no such method has been installed, an empty string ("") is returned.

## Example

This command is particularly useful in the context of components because it enables you to temporarily change and then restore the error-catching methods:

```
$methCurrent:=Method called on error
ON ERR CALL("NewMethod")
 ` If the document cannot be opened, an error is generated
$ref:=Open document("MyDocument")
 ` Reinstallation of previous method
ON ERR CALL($methCurrent)
```

# Method called on event

Method called on event -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | | Name of method called on event |

## Description

The **Method called on event** command returns the name of the method installed by the **ON EVENT CALL** command.
If no such method has been installed, an empty string ("") is returned.

# ON ERR CALL

ON ERR CALL ( errorMethod )

| Parameter | Type | | Description |
|---|---|---|---|
| errorMethod | String | ➡ | Error method to be invoked, or Empty string to stop trapping errors |

## Description

The **ON ERR CALL** command installs the project method, whose name you pass in *errorMethod*, as the method for catching (trapping) errors. This project method is called the **error-handling method** or **error-catching method**.

Once an error-handling project is installed, 4D calls the method each time an error occurs during the execution of a 4D language command.

The scope of this command is the current process. You can have only one error-handling method per process at a time, but you can have different error-handling methods for several processes.

**Notes:**

- In the context of the use of components, this command applies to the current database only. If an error is generated from a component, *errorMethod* is not called in the host database.
- If **ON ERR CALL** is called from a process for which you requested preemptive execution (in 64-bit compiled mode), the compiler checks whether *errorMethod* is thread-safe and returns errors if it is not compatible with the preemptive mode. For more information, refer to the **Preemptive 4D processes** section.

To stop the trapping of errors, call **ON ERR CALL** again and pass the empty string in *errorMethod*.

You can identify errors by reading the *Error* system variable, which contains the code number of the error. Error codes are listed in the **Error Codes** theme. For example, you can see the section **Syntax Errors (1 -> 81)**. The Error variable value is significant only within the error-handling method; if you need the error code within the method that provoked the error, copy the *Error* variable to your own process variable. You can also access the *Error method*, *Error line* and *Error formula* system variables which contain, respectively, the name of the method, the line number and the text of the formula where the error occurred (see **Error, Error method, Error line**).

You can use the **GET LAST ERROR STACK** command to obtain the error sequence (i.e., the error "stack") at the origin of the interruption.

The error-handling method should manage the error in an appropriate way or present an error message to the user. Errors can be generated during processing performed by:

- The 4D database engine; for example, when saving a record causes the violation of a trigger rule.
- The 4D environment; for example, when you do not have enough memory for allocating an array.
- The operating system on which the database is run; for example, disk full or I/O errors.

The **ABORT** command can be used to terminate processing. If you don't call **ABORT** in the error-handling method, 4D returns to the interrupted method and continues to execute the method. Use the **ABORT** command when an error cannot be recovered.

If an error occurs in the error-handling method itself, 4D takes over error handling. Therefore, you should make sure that the error-handling method cannot generate an error. Also, you cannot use **ON ERR CALL** inside the error-handling method.

## Example 1

The following project method tries to create a document whose name is received as parameter. If the document cannot be created, the project metod returns 0 (zero) or the error code:

```
 //Create doc project method
 //Create doc ( String ; Pointer ) -> LongInt
 //Create doc ( DocName ; ->DocRef ) -> Error code result

gError:=0
ON ERR CALL("IO ERROR HANDLER")
$2->:=Create document($1)
```

```
ON ERR CALL("")
$0:=gError
```

The ***IO ERROR HANDLER*** project method is listed here:

```
 //IO ERROR HANDLER project method
gError:=Error //just copy the error code to the process variable gError
```

Note the use of the *gError* process variable to get the error code result within the current executing method. Once these methods are present in your database, you can write:

```
 // ...
C_TIME(vhDocRef)
$vlErrCode:=Create doc($vsDocumentName;->vhDocRef)
If($vlErrCode=0)
 //...
   CLOSE DOCUMENT($vlErrCode)
Else
   ALERT("The document could not be created, I/O error "+String($vlErrCode))
End if
```

## Example 2

See example in the **Arrays and Memory** section.

## Example 3

While implementing a complex set of operations, you may end up with various subroutines that require different error-handling methods. You can have only one error-handling method per process at a time, so you have two choices:
- Keep track of the current one each time you call **ON ERR CALL**, or
- Use a process array variable (in this case, *asErrorMethod*) to "pile up" the error-handling methods and a project method (in this case, ***ON ERROR CALL***) to install and deinstall the error-handling methods.

You must initialize the array at the very beginning of the process execution:

```
 ` Do NOT forget to initialize the array at the beginning
 ` of the process method (the project method that runs the process)
ARRAY STRING(63;asErrorMethod;0)
```

Here is the custom ***ON ERROR CALL*** method:

```
 ` ON ERROR CALL project method
 ` ON ERROR CALL { ( String ) }
 ` ON ERROR CALL { ( Method Name ) }

C_STRING(63;$1;$ErrorMethod)
C_LONGINT($vlElem)

If(Count parameters>0)
   $ErrorMethod:=$1
Else
   $ErrorMethod:=""
End if

If($ErrorMethod#"")
   C_LONGINT(gError)
   gError:=0
   $vlElem:=1+Size of array(asErrorMethod)
   INSERT IN ARRAY(asErrorMethod;$vlElem)
   asErrorMethod{$vlElem}:=$1
   ON ERR CALL($1)
Else
   ON ERR CALL("")
   $vlElem:=Size of array(asErrorMethod)
   If($vlElem>0)
      DELETE FROM ARRAY(asErrorMethod;$vlElem)
```

```
      If($vlElem>1)
         ON ERR CALL(asErrorMethod{$vlElem-1})
      End if
   End if
End if
```

Then, you can call it this way:

```
gError:=0
ON ERROR CALL("IO ERRORS") ` Installs the IO ERRORS error-handling method
 ` ...
ON ERROR CALL("ALL ERRORS") ` Installs the ALL ERRORS error-handling method
 ` ...
ON ERROR CALL ` Deinstalls ALL ERRORS error-handling method and reinstalls IO ERRORS
 ` ...
ON ERROR CALL ` Deinstalls the IO ERRORS error-handling method
 ` ...
```

## Example 4

The following error-handling method ignores the user interruptions and displays the error text:

```
 //Show_errors_only project method
If(Error#1006) //this is not a user interruption
   ALERT("The error "+String(Error)+" occurred. The code in question is: ¥""+Error formula+"¥"")
End if
```

# ON EVENT CALL

ON EVENT CALL ( eventMethod {; processName} )

| Parameter | Type | | Description |
|---|---|---|---|
| eventMethod | String | ⇒ | Event method to be invoked, or Empty string to stop intercepting events |
| processName | String | ⇒ | Process name |

## Description

The **ON EVENT CALL** command installs the method, whose name you pass in *eventMethod*, as the method for catching (trapping) events. This method is called the **event-handling method** or **event-catching method**.

**Tip:** This command requires advanced programming knowledge. Usually, you do not need to use **ON EVENT CALL** for working with events. While using forms, 4D handles the events and sends them to the appropriate forms and objects.

**Tip:** Commands such as **GET MOUSE**, **Shift down,** etc., can be used for getting information about events. These commands can be called from within object methods to get the information you need about an event involving an object. Using them spares you the writing of an algorithm based on the **ON EVENT CALL** scheme.

The scope of this command is the current working session. By default, the method is run in a separate local process. You can have only one event-handling method at a time. To stop catching events with a method, call **ON EVENT CALL** again and pass an empty string in *eventMethod*.

Since the event-handling method is run in a separate process, it is constantly active, even if no 4D method is running. After installation, 4D calls the event-handling method each time an event occurs. An event can be a mouse click or a keystroke.

The optional *processName* parameter names the process created by the **ON EVENT CALL** command. If *processName* is prefixed with a dollar sign (*$*), a local process is started, which is usually what you want. If you omit the *processName* parameter, 4D creates, by default, a local process named *$Event Manager*.

**WARNING:** Be very careful in what you do within an event-handling method. Do NOT call commands that generate events, otherwise it will be extremely difficult to get out of the event-handling method execution. The key combination **Ctrl+Shift+Backspace** (on Windows) or **Command-Shift-Control-Backspace** (on Macintosh) allows you to kill the Event Manager process. You may want to use this technique to recover an event-handling gone wrong (i.e., one that has bugs triggering events).

In the event-handling method, you can read the following system variables—*MouseDown, KeyCode, Modifiers, MouseX, MouseY* and *MouseProc*. Note that these variables are process variables. Their scope is therefore the event-handling process. Copy them into interprocess variables if you want their values available in another process.

- The *MouseDown* system variable is set to 1 if the event is a mouse click, and to 0 if it is not.
- The *KeyCode* system variable is set to the code for a keystroke. This variable may return an character code or a function key code. These codes are listed in the sections **Unicode Codes** and **EXPORT TEXT** (and its subsections) as well as in the section **Function Key Codes**. 4D provides predefined constants for the major ASCII Codes and for Function Keys. In the Explorer window, look for the themes of these constants.
- The *Modifiers* system variable contains the modifier value. It indicates whether a modifier key was down when the event occurred. The following keys can be detected:

| Platform | Modifiers |
|---|---|
| Windows | Shift key, Caps Lock, Alt key, Ctrl key |
| Macintosh | Shift key, Caps Lock, Alt (or Option) key, Command key, Ctrl key |

The modifier keys do not generate an event on their own; another key or the mouse button must also be pressed. The **Modifiers** variable is a Long Integer variable containing a bit field. 4D provides predefined constants specifying the bit position or bit mask for each modifier key. For example, to detect if the Shift key was pressed for the event, you can write either:

```
If(Modifiers?? Shift key bit) //If the Shift key was down
```

or:

```
If((Modifiers & Shift key mask)#0) //If the Shift key was down
```

You can use one of the following constants, depending on the modifier key to be tested and the platform, which are found in the **Events (Modifiers)** theme:

| Modifier | Constant |
|---|---|
| Shift | Shift key bit / Shift key mask |
| Caps Lock | Caps lock key bit / Caps lock key mask |
| Alt (also called Option under OS X) | Option key bit / Option key mask |
| Ctrl under Windows | Command key bit / Command key mask |
| Ctrl under OS X | Control key bit / Control key mask |
| Command under OS X | Command key bit / Command key mask |
| Right click | Control key bit / Control key mask |

- The system variables *MouseX* and *MouseY* contain the horizontal and vertical positions of the mouse click, expressed in the local coordinate system of the window where the click occurred. The upper left corner of the window is position 0,0. These are meaningful only when there is a mouse click.
- The **MouseProc** system variable contains the process reference number of the process in which the event occurred (mouse click).

**Important:** The system variables **MouseDown**, **KeyCode**, **Modifiers**, **MouseX**, **MouseY**, and **MouseProc** contain significant values only within an event-handling method installed with **ON EVENT CALL**.

## Example

This example will cancel printing if the user presses **Ctrl+period**. First, the event-handling method is installed. Then a message is displayed, announcing that the user can cancel printing. If the interprocess variable *◊vbWeStop* is set to True in the event-handling method, the user is alerted to the number of records that have already been printed. Then the event-handling method is deinstalled:

```
PAGE SETUP
If(OK=1)
   ◊vbWeStop:=False
   ON EVENT CALL("EVENT HANDLER") ` Installs the event-handling method
   ALL RECORDS([People])
   MESSAGE("To interrupt printing press Ctrl+Period")
   $vlNbRecords:=Records in selection([People])
   For($vlRecord;1;$vlNbRecords)
      If(◊vbWeStop)
         ALERT("Printing cancelled at record "+String($vlRecord)+" of "+String($vlNbRecords))
         $vlRecord:=$vlNbRecords+1
      Else
         Print form([People];"Special Report")
      End if
   End for
   PAGE BREAK
   ON EVENT CALL("") ` Deinstalls the event-handling method
End if
```

If **Ctrl+period** has been pressed, the event-handling method sets *◊vbWeStop* to True:

```
 ` EVENT HANDLER project method
If((Modifiers?? Command key bit) & (KeyCode=Period))
   CONFIRM("Are you sure?")
   If(OK=1)
      ◊vbWeStop:=True
      FILTER EVENT ` Do NOT forget this call; otherwise 4D will also get this event
   End if
End if
```

Note that this example uses **ON EVENT CALL** because it performs a special printing report using the **PAGE SETUP**, **Print form** and **PAGE BREAK** commands with a **For...End for** loop.

If you print a report using **PRINT SELECTION**, you do NOT need to handle events that let the user interrupt the printing; this command does that for you.

# SET ASSERT ENABLED

SET ASSERT ENABLED ( assertions {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| assertions | Boolean | ⇒ | True = enable assertions False = disable assertions |
| * | Operator | ⇒ | If omitted = command applies to all the processes (existing or created subsequently) If passed= command applies to current process only |

## Description

The **SET ASSERT ENABLED** command can be used to disable or re-enable any assertions inserted into the 4D code of the application. For more information about assertions, please refer to the description of the **ASSERT** command.

By default, assertions added in the program are enabled in interpreted and compiled mode. This command is useful when you want to disable them since their evaluation can sometimes be costly in terms of execution time and you may also want them to be hidden from the final user of the application. Typically, the **SET ASSERT ENABLED** command could be used in the **On Startup database method** in order to enable or disable assertions according to whether the application is in "Test" mode or in "Production" mode.

By default, the **SET ASSERT ENABLED** command affects all the processes of the application. To restrict the effect of the command to the current process only, you can pass the * parameter.

Please note that when assertions are disabled, expressions passed to **ASSERT** commands are no longer evaluated. The lines of code that call this command no longer have any effect on the operation of the application, neither in terms of behavior, nor in terms of performance.

## Example

Disabling assertions:

```
SET ASSERT ENABLED(False)
ASSERT(TestMethod) // TestMethod will not be called since assertions are disabled
```

# Overview of JSON commands

JSON commands generate and parse JSON-format language objects. More particularly, JSON format makes it possible to access 4D databases (data and structure) using a Web browser.

Support for structured objects is a major new feature of the language in 4D v14, intended to facilitate the exchange of structured data. Thanks to the commands of the "JSON" theme, 4D can work directly with JSON objects. However, 4D can also work with "native" objects (whose structure is inspired by JSON), allowing exchanges with all types of language. For more information, refer to the **Objects (Language)** chapter.

## Introduction to JSON

"JSON or JavaScript Object Notation is a generic text-based data format derived from object notation of the ECMAScript language." (*source: Wikipedia*). JSON is independent from any other language, but uses conventions that are familiar to programmers using C++ or JavaScript, Perl, and so on. It is a format that is particularly suitable for data exchange.

This section summarizes the notation principles implemented in JSON. For a complete description of this format, refer the following site: www.json.org/index.html.

### JSON syntax

JSON syntax is based on the following principles:

- data consists of name/value pairs,
- data is separated by commas,
- objects are defined by braces {},
- arrays are defined by brackets [ ].

### JSON properties

JSON data is expressed in name/value (or key/value) pairs. A name/value pair contains a field name (in quotes), then a colon, followed by a value. For example:

```
"firstName":"John"
```

For information, this example is equivalent to the following in JavaScript:

```
firstName="John"
```

Keep in mind that property names are diacritical and case-sensitive. If you write "FirstName" instead of "firstName," this gives you a new name/value pair.

### JSON data types

The following types of values are supported in JSON:

| Type | Description | Comments |
| --- | --- | --- |
| string | Any Unicode character except for " and ¥<br>Values, like property names, are in quotes ("), for example, "city":"Paris" | ¥ is used for control characters:<br>¥" = quotes<br>¥¥ = backslash<br>¥/ = slash<br>¥b = backspace<br>¥f = formfeed<br>¥n = line break<br>¥r = carriage return<br>¥t = tab<br>¥u = four hexadecimal digits |
| number | Integer or floating point number | Number similar to a C or Java number, except that the octal and hexadecimal formats are not used |
| object | { } | |
| array | [ ] | |
| boolean | true or false | |
| null | null | |

### JSON objects

JSON objects are defined by braces and can contain an undefined number of name/value pairs, for example:

```
{ "firstName":"John" , "lastName":"Doe" }
```

### JSON arrays

JSON arrays are defined by brackets. Each array can contain an undefined number of objects:

```
{    "employees": [         { "firstName":"John" , "lastName":"Doe" },         { "firstName":"Anna" , "lastName":"Smith" },         { "firstName":"Peter" , "lastName":"Jones" }     ] }
```

## Time zone support

By default, when 4D dates are converted to and from JSON, they take into account the time zone of the machine where the conversion took place (in conformity with JavaScript). For example, in France (GMT+2), converting !23/08/2013! gives you "2013-08-22T22:00:00Z" and vice versa.

You can change this functioning and no longer take the time zone into account, during the implementation of export procedures for example, using the **SET DATABASE PARAMETER** command.

For more information about converting 4D/JSON dates, refer to **Conversion of JavaScript dates**.

# JSON Parse

JSON Parse ( jsonString {; type} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| jsonString | String | ➡ | JSON string to parse |
| type | Longint | ➡ | Type in which to convert the values |
| Function result | Boolean, Object, Pointer, Real, Text | ⬅ | Values extracted from JSON string |

## Description

The **JSON Parse** command parses the contents of a JSON-formatted string and extracts values that you can store in a 4D field or variable. This command deserializes JSON data; it performs the opposite action of the **JSON Stringify** command.

In *jsonString*, pass the JSON-formatted string whose contents you want to parse. This string must be formatted correctly, otherwise a parsing error is generated. **JSON Parse** can therefore be used to validate JSON strings.

**Note:** If you use pointers, you must call the **JSON Stringify** command before calling **JSON Parse**.

By default, if you omit the *type* parameter, 4D attempts to convert the value obtained into the type of the variable or field used to store the results (if one is defined). Otherwise, 4D attempts to infer its type. You can also force the type interpretation by passing the *type* parameter: pass one of the following constants, available in the **Field and Variable Types** theme:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is longint | Longint | 9 |
| Is object | Longint | 38 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |

**Notes:**

- Real type values must be included in the range ±10.421e±10
- In text type values, all special characters must be escaped, including quotes (see examples)
- JSON dates must be in the format "¥"YYYY-MM-DDTHH:mm:ssZ¥"". The command considers that the 4D date contains a local time and not GMT.

## Example 1

Examples of simple conversions:

```
C_REAL($r)
$r:=JSON Parse("42.17") //$r = 42,17 (Real)

C_LONGINT($el)
$el:=JSON Parse("120.13";Is longint) //$el=120

C_TEXT($t)
$t:=JSON Parse("¥"Year 42¥"";Is text) // $t="Year 42" (text)

C_OBJECT($o)
$o:=JSON Parse("{¥"name¥":¥"jean¥"}")
 // $o = {"name":"john"} (4D object)

C_BOOLEAN($b)
$b:=JSON Parse("{¥"manager¥":true}";Is Boolean) // $b=true
```

## Example 2

Example of converting date type data:

```
$test:=JSON Parse("¥"1990-12-25T12:00:00Z¥"")
 // $test=1990-12-25T12:00:00Z
C_DATE($date)
$date:=JSON Parse("¥"2008-01-01T12:00:00Z¥"";Is date)
 //$date=01/01/08
```

## Example 3

This example shows the combined use of the **JSON Stringify** and **JSON Parse** commands:

```
C_TEXT($MyContact)
C_OBJECT($Contact)

 // JSON Stringify: conversion of JSON object into a JSON string
$MyContact:=JSON Stringify("{¥"name¥":¥"Monroe¥",¥"firstname¥":¥"Alan¥"}")
 // $MyContact = "{¥¥"name¥¥":¥¥"Monroe¥¥",¥¥"firstname¥¥":¥¥"Alan¥¥"}"
 // JSON Parse: conversion of JSON string into a JSON object
$Contact:=JSON Parse("{¥"name¥":¥"Monroe¥",¥"firstname¥":¥"Alan¥"}")
 // $Contact = {"name":"Monroe","firstname":"Alan"}
```

# JSON PARSE ARRAY

JSON PARSE ARRAY ( jsonString ; objArray )

| Parameter | Type | | Description |
|---|---|---|---|
| jsonString | String | ➡ | JSON string to parse |
| objArray | Object array, Text array, Real array, Boolean array, Pointer array | ⬅ | Array containing result from parsing of JSON string |

## Description

The **JSON PARSE ARRAY** command parses the contents of a JSON-formatted string and puts the data extracted into the *objArray* array. This command deserializes the JSON data; it performs the opposite action of the **JSON Stringify array** array command.

In *jsonString*, pass the JSON-formatted string whose contents you want to parse. This string must be formatted correctly, otherwise a parsing error is generated.

In *objArray*, pass the object to receive the parsing results.

## Example

In this example, data from fields of the records in a table are extracted and then placed in object arrays:

```
C_OBJECT($ref)
ARRAY OBJECT($sel;0)
ARRAY OBJECT($sel2;0)
C_TEXT(v_String)

OB SET($ref;"name";->[Company]Company Name)
OB SET($ref;"city";->[Company]City)

While(Not(End selection([Company])))
   $ref_company:=OB Copy($ref;True)
   APPEND TO ARRAY($sel;$ref_company)
 // $sel{1}={"name":"4D SAS","city":"Clichy"}
 // $sel{2}={"name":"MyComp","city":"Lyon"}
 // ...
   NEXT RECORD([Company])
End while

v_String:=JSON Stringify array($sel)
 // v_String= [{"name":"4D SAS","city":"Clichy"},{"name":"MyComp","city":"Lyon"}...]
JSON PARSE ARRAY(v_String;$sel2)
 // $sel2{1}={"name":"4D SAS","city":"Clichy"}
 // $sel2{2}={"name":"MyComp","city":"Lyon"}
 //...
```

# JSON Stringify

JSON Stringify ( value {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| value | Object, Object array, String, Real, Date, Time | ➡ | Data to convert into JSON string |
| * | Operator | ➡ | Pretty printing |
| Function result | Text | ⮌ | String containing serialized JSON text |

## Description

The **JSON Stringify** command converts the *value* parameter into a JSON string. This command serializes data into JSON; it performs the opposite action of the **JSON Parse** command.

Pass the data to be serialized in *value*. It can be expressed in scalar form (string, number, date or time) or by means of a 4D object (or an object array).

In the case of an object, you can include all types of values (see the **JSON data types** paragraph). JSON formatting must respect the following rules:

- String values must be enclosed in quotes. All Unicode character can be used except for special characters that must be preceded by a backslash.
- Numbers: interval of ±10.421e±10
- Booleans: "true" or "false" strings
- Pointers to a field, variable or array (the pointer is evaluated when it is stringified)
- Dates: Text type
- Times: Real type

You can pass the optional * parameter to include formatting characters in the resulting string. This improves the presentation of JSON data (known as pretty formatting).

## Example 1

Conversion of scalar values:

```
$vc:=JSON Stringify("Eureka!") // "Eureka!"
$vel:=JSON Stringify(120) // "120"
$vd:=JSON Stringify(!28/08/2013!) //  "2013-08-27T22:00:00Z"
$vh:=JSON Stringify(?20:00:00?) // "72000000" seconds since midnight
```

## Example 2

Conversion of a string containing special characters:

```
$s:=JSON Stringify("{¥"name¥":¥"john¥"}")
 // $s="{¥¥"name¥¥":¥¥"john¥¥"}"
$p:=JSON Parse($s)
 // $p={"name":"john"}
```

## Example 3

Example using a pointer to a variable:

```
C_OBJECT($MyTestVar)
C_TEXT($name ;$jsonstring )
OB SET($MyTestVar;"name";->$name) // object definition
 // $MyTestVar= {"name":"->$name"}

$jsonstring :=JSON Stringify($MyTestVar)
```

```
 // $jsonstring ="{"name":""}"
 //...

$name:="Smith"
$jsonstring :=JSON Stringify($MyTestVar)
 //$jsonstring = "{"name" : "Smith"}"
```

## Example 4

Serialization of a 4D object:

```
C_TEXT($varjsonTextserialized)
C_OBJECT($Contact)
OB SET($Contact;"firstname";"Alan")
OB SET($Contact;"lastname";"Monroe")
OB SET($Contact;"age";40)
OB SET($Contact;"phone";"[555-0100,555-0120]")

$varjsonTextserialized:=JSON Stringify($Contact)

 // $varjsonTextserialized = "{"lastname":"Monroe","phone":"[555-0100,
 // 555-0120]","age":40,"firstname":"Alan"}"
```

## Example 5

Examples of serializing a 4D object with and without the * parameter:

```
C_TEXT($MyContact)
C_TEXT($MyPContact)
C_OBJECT($Contact;$Children)
OB SET($Contact;"lastname";"Monroe";"firstname";"Alan")
OB SET($Children;"firstname";"Jim";"age";"12")
OB SET($Contact;"children";$Children)
$MyContact:=JSON Stringify($Contact)
$MyPContact:=JSON Stringify($Contact;*)
 //$MyContact= {"lastname":"Monroe","firstname":"Alan","children":{"firstname":"John","age":"12"}}
 //$MyPContact= {¥n¥t"lastname": "Monroe",¥n¥t"firstname": "Alan",¥n¥t"children": {¥n¥t¥t"firstname": "John",¥n¥t¥t"age":
"12"¥n¥t}¥n}
```

The advantage of this formatting is clear when the JSON is shown in a Web area:

- Standard formatting:

```
{"Name":"Monroe","firstname":"Alan","children":{"firstname":"John","age":12}}
```

- Pretty formatting:

```
{
	"Name": "Monroe",
	"firstname": "Alan",
	"children": {
		"firstname": "John",
		"age": 12
	}
}
```

# JSON Stringify array

JSON Stringify array ( array {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| array | Text array, Real array, Boolean array, Pointer array, Object array | ➡ | Array whose contents must be serialized |
| * | Operator | ➡ | Pretty formatting |
| Function result | Text | ⮌ | String containing the serialized JSON array |

## Description

The **JSON Stringify array** command converts the 4D array *array* into a serialized JSON array. . This command performs the opposite action of the **JSON PARSE ARRAY** command.

In *array*, pass a 4D array containing the data to be serialized. This array may be of the text, real, Boolean, pointer or object type.

You can pass the optional * parameter to use pretty formatting in the resulting string. This improves the presentation of JSON data by including formatting characters when it is displayed in a Web page.

## Example 1

Conversion of a text array:

```
C_TEXT($jsonString)
ARRAY TEXT($ArrayFirstname;2)
$ArrayFirstname{1}:="John"
$ArrayFirstname{2}:="Jim"
$jsonString :=JSON Stringify array($ArrayFirstname)

 // $jsonString = "["John","Jim"]"
```

## Example 2

Conversion of a text array containing numbers:

```
ARRAY TEXT($phoneNumbers;0)
APPEND TO ARRAY($phoneNumbers ;"555-0100")
APPEND TO ARRAY($phoneNumbers ;"555-0120")
$string :=JSON Stringify array($phoneNumbers)
 // $string = "["555-0100","555-0120"]"
```

## Example 3

Conversion of an object array:

```
C_OBJECT($ref_john)
C_OBJECT($ref_jim)
ARRAY OBJECT($myArray;0)
OB SET($ref_john;"name";"John";"age";35)
OB SET($ref_jim;"name";"Jim";"age";40)
APPEND TO ARRAY($myArray ;$ref_john)
APPEND TO ARRAY($myArray ;$ref_jim)
$JsonString :=JSON Stringify array($myArray)
 // $JsonString = "[{"name":"John","age":35},{"name":"Jim","age":40}]"

 // If you want to view the result in a Web page,
 // pass the optional * parameter:
$JsonStringPretty :=JSON Stringify array($myArray;*)
```

```
[
  {
    "name": "John",
    "age": 35
  },
  {
    "name": "Jim",
    "age": 40
  }
]
```

## Example 4

Conversion of a 4D selection in an object array:

```
C_OBJECT($jsonObject)
C_TEXT($jsonString)

QUERY([Company];[Company]Company Name="a@")
OB SET($jsonObject;"company name";->[Company]Company Name)
OB SET($jsonObject;"city";->[Company]City)
OB SET($jsonObject;"date";[Company]Date_input)
OB SET($jsonObject;"time";[Company]Time_input)
ARRAY OBJECT($arraySel;0)

While(Not(End selection([Company])))
   $ref_value:=OB Copy($jsonObject;True)
 // If you do not copy them, the values will be empty strings
   APPEND TO ARRAY($arraySel;$ref_value)
 // Each element contains the selected values, for example:
 // $arraySel{1} = // {"company name":"APPLE","time":43200000,"city":
 // "Paris","date":"2012-08-02T00:00:00Z"}
   NEXT RECORD([Company])
End while

$jsonString:=JSON Stringify array($arraySel)
 // $jsonString = "[{"company name":"APPLE","time":43200000,"city":
 //"Paris","date":"2012-08-02T00:00:00Z"},{"company name":
 //"ALMANZA",...}]"
```

# JSON TO SELECTION

JSON TO SELECTION ( aTable ; jsonArray )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | 4D table into which elements are copied |
| jsonArray | Text | ⇒ | Array of objects in JSON |

## Description

The **JSON TO SELECTION** command copies the contents of an array of JSON objects *jsonArray* to the selection of records of *aTable*.

The *jsonArray* parameter is a *text* representing an array of objects formatted in JSON and containing one or more elements. The expected syntax is of the type:

```
"[{"attribute1":"value1","attribute2":"value2",...},...,{"attribute1":"valueN","attribute2":"valueN",...}]"
```

If a selection exists for *aTable* at the time of the call, the elements of the JSON array are copied into the records based on the order of the array and the order of the records. If the number of elements defined in the JSON array is greater than the number of records in the current selection, new records are created. The records, whether they are new or existing, are automatically saved.

**Note:** This command supports Object type fields: JSON data is converted automatically.

**Warning:** Since **JSON TO SELECTION** replaces any information found in the existing records, this command must be used with caution.

If a record is locked by another process during the execution of the command, it is not modified. All the locked records are placed in the **The LockedSet System Set**. After the execution of **JSON TO SELECTION**, you can test whether the *LockedSet* set contains any records that were locked.

## Example

Using the **JSON TO SELECTION** command to add records to the [Company] table:

```
C_OBJECT($Object1;$Object2;$Object3;$Object4)
C_TEXT($ObjectString)
ARRAY OBJECT($arrayObject;0)

OB SET($Object1;"ID";"200";"Company Name";"4D SAS";"City";"Clichy")
APPEND TO ARRAY($arrayObject;$Object1)

OB SET($Object2;"ID";"201";"Company Name";"APPLE";"City";"Paris")
APPEND TO ARRAY($arrayObject;$Object2)

OB SET($Object3;"ID";"202";"Company Name";"IBM";"City";"London")
APPEND TO ARRAY($arrayObject;$Object3)

OB SET($Object4;"ID";"203";"Company Name";"MICROSOFT";"City";"New York")
APPEND TO ARRAY($arrayObject;$Object4)

$ObjectString:=JSON Stringify array($arrayObject)

 // $ObjectString = "[{"ID":"200","City":"Clichy","Company Name":"4D
 // SAS"},{"ID":"201","City":"Paris","Company Name":"APPLE"},{"ID":"202",
 //"City":"London","Company Name":"IBM"},{"ID":"203","City":"New
 //York","Company Name":"MICROSOFT"}]"

JSON TO SELECTION([Company];$ObjectString)
 // You create 4 records in the [Company] table, filling the ID,
 //Company name and city fields
```

# Selection to JSON

Selection to JSON ( aTable {; aField}{; aField2 ; ... ; aFieldN}{; template}) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to serialize |
| aField | Field | ⇒ | Field(s) whose contents must be serialized |
| template | Object | ⇒ | Object for selection of labels and fields |
| Function result | Text | ⇐ | String containing serialized JSON array |

## Description

The **Selection to JSON** command returns a string containing a JSON array with as many elements as there are records in the current selection of *aTable*. Each element of the array is a JSON object containing the labels and values of the fields of the selection.

If you only pass the *aTable* parameter, the command includes, in the JSON array, the values of all the fields of the table that can be expressed in JSON. BLOB and Picture type fields are ignored.

If you do not want to include all the fields of *aTable*, you can use either the *aField* parameter or the *template* parameter:

- *aField*: pass one or more fields in this parameter. Only the values of the fields defined are included in the JSON array.
- *template*: pass a 4D object containing one or more *name/value* pairs where the *name* can be any valid attribute name and the *value* contains a pointer to a field you want to include. This syntax allows you to customize the labels of fields in the JSON array.

This command supports Object type fields: the data of these fields is automatically converted to the JSON format. Note that the following 4D statement will be interpreted as "produce JSON from all values of *objectField* in the current selection of the table":

```
Selection to JSON([aTable];objectField)
```

## Example 1

You want to create a JSON string representing this selection:

HierList - Members: 6 of 6

| Last name : | First name : | Address : | City : | Zip Code : |
|---|---|---|---|---|
| Durant | Mark | 25 Park St | Pittsburgh | 15205 |
| Smith | John | 24 Philadelphia Ave | Dallas | 75203 |
| Anderson | Adeline | 37 Market St | Cincinnati | 45205 |
| Peterson | Paul | 32 South Main St | Dallas | 75203 |
| Harper | Harry | 233 Southport Ave | Cincinnati | 45206 |
| Trace | Sandra | 332 Court St | Pittsburgh | 15205 |

1) You want to include the values of all the fields of the [Members] table:

```
$jsonString :=Selection to JSON([Members])
 // $jsonString =[{"LastName":"Durant","FirstName":"Mark","Address":
 //"25 Park St","Zip code":"15205","City":"Pittsburgh"},{"LastName":
 //"Smith","FirstName":"John","Address":"24 Philadelphia Ave","Zip code":
 //"75203","City":"Dallas"},{"LastName":"Anderson","FirstName"
 //:"Adeline","Address":"37 Market St","Zip code":"45205","City":"Cincinnati"},...]
```

2) You want to reduce the selection and only include two fields in the JSON string by using the syntax based on fields:

```
QUERY([Members];[Members]LastName="A@")
$jsonString :=Selection to JSON([Members];[Members]LastName;[Members]City)
 // $jsonString = [{"LastName":"Anderson","City":"Cincinnati"},{"LastName":"Albert","City":"Houston"}]
```

3) You only want to include one field in the JSON string and use a different label.
You can use the *template* syntax:

```
C_OBJECT($template)
OB SET($template;"Member";->[Members]LastName) //custom label and a single field
```

```
ALL RECORDS([Members])
$jsonString :=Selection to JSON([Members];$template)
 // $jsonString = [{"Member":"Durant"},{"Member":"Smith"},{"Member":"Anderson"},
 // {"Member":"Albert"},{"Member":"Leonard"},{"Member":"Pradel"}]
```

## Example 2

You can use the *template* syntax in order to export fields from different tables:

```
C_OBJECT($template)
C_TEXT($jsonString)
OB SET($template;"Last name";->[Emp]LastName)
OB SET($template;"First name";->[Emp]FirstName)
OB SET($template;"Company";->[Company]LastName) //custom label otherwise conflict with [Emp]LastName field
ALL RECORDS([Emp])
SET FIELD RELATION([Emp]UUID_Company;Automatic;Do not modify)
$jsonString:=Selection to JSON([Emp];$template)
SET FIELD RELATION([Emp]UUID_Company;Structure configuration;Do not modify)
```

# Language

# Command name

Command name ( command {; info {; theme}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| command | Longint | ⇒ | Command number |
| info | Longint | ⇐ | Thread-safety property of command |
| theme | Text | ⇐ | Language theme of command |
| Function result | String | ⇒ | Localized command name |

## Description

The **Command name** command returns the name as well as (optionally) the properties of the command whose command number you pass in *command*.

**Note:** The number of each command is indicated in the Explorer as well as in the Properties area of this documentation.

**Compatibility note:** Since a command name may vary from one 4D version to the next (commands renamed), this command was used in previous versions of the program to designate a command directly by means of its number, especially in non-tokenized portions of code. This need has diminished over time as 4D continues to evolve because, for non-tokenized statements (formulas), 4D now provides a token syntax. This syntax allows you to avoid potential problems due to variations in command names as well as other elements such as tables, while still being able to type these names in a legible manner (for more information about this point, refer to the **Using tokens in formulas** section). Furthermore, by default, the English language version is used starting with 4D v15; however, the "Use regional system settings" option on the **Methods Page** of the Preferences allows you to continue using the French language in a French version of 4D.

Two optional parameters are available:

- *info*: properties of the command. The returned value is a *bit field*, where currently only the first bit (bit 0) is meaningful. It is set to 1 if the command is thread-safe (i.e., compatible with execution in a preemptive process) and 0 if it is thread-unsafe. Only thread-safe commands can be used in preemptive processes. For more information about this point, refer to the [#title id="8733"/] section.
- *theme*: returns the name of the 4D language theme for the command.

The **Command name** command sets the *OK* variable to 1 if *command* corresponds to an existing command number, and to 0 otherwise. Note, however, that some existing commands have been disabled, in which case **Command name** returns an empty string (see last example).

## Example 1

The following code allows you to load all valid 4D commands in an array:

```
C_LONGINT($Lon_id)
C_TEXT($Txt_command)
ARRAY LONGINT($tLon_Command_IDs;0)
ARRAY TEXT($tTxt_commands;0)

Repeat
   $Lon_id:=$Lon_id+1
   $Txt_command:=Command name($Lon_id)
   If(OK=1) //command number exists
      If(Length($Txt_command)>0) //command is not disabled
         APPEND TO ARRAY($tTxt_commands;$Txt_command)
         APPEND TO ARRAY($tLon_Command_IDs;$Lon_id)
      End if
   End if
Until(OK=0) //end of existing commands
```

## Example 2

In a form, you want a drop-down list populated with the basic summary report commands. In the object method for that drop-down list, you write:

```
Case of
   :(Form event=On Before)
      ARRAY TEXT(asCommand;4)
      asCommand{1}:=Command name(1)
      asCommand{2}:=Command name(2)
      asCommand{3}:=Command name(4)
      asCommand{4}:=Command name(3)
 `...
End case
```

In the English version of 4D, the drop-down list will read: Sum, Average, Min, and Max. In the French version*, the drop-down list will read: Somme, Moyenne, Min, and Max.

*with a 4D application configured to use the French programming language (see compatibility note)

## Example 3

You want to create a method that returns **True** if the command, whose number is passed as parameter, is thread-safe, and **False** otherwise.

```
 //Is_Thread_Safe project method
 //Is_Thread_Safe(numCom) -> Boolean

C_LONGINT($1;$threadsafe)
C_TEXT($name)
C_BOOLEAN($0)
$name:=Command name($1;$threadsafe;$theme)
If($threadsafe ?? 0) //if the first bit is set to 1
   $0:=True
Else
   $0:=False
End if
```

Then, for the "SAVE RECORD" command (53) for example, you can write:

```
$isSafe:=Is_Thread_Safe(53)
 // returns True
```

# Count parameters

Count parameters -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | | Number of parameters actually passed |

## Description

The **Count parameters** command returns the number of parameters passed to a project method.

**WARNING: Count parameters** is meaningful only in a project method that has been called by another method (project method or other). If the project method calling this command is associated with a menu, it returns 0.

## Example 1

4D project methods accept optional parameters, starting from the right.
For example, you can call the method **MyMethod(a;b;c;d)** in the following ways:

```
MyMethod(a;b;c;d) ` All parameters are passed
MyMethod(a;b;c) ` The last parameter is not passed
MyMethod(a;b) ` The last two parameters are not passed
MyMethod(a) ` Only the first parameter is passed
MyMethod ` No Parameter is passed at all
```

Using **Count parameters** from within **MyMethod,** you can detect the actual number of parameters and perform different operations depending on what you have received. The following example displays a text message and can insert the text into a 4D Write area or send the text into a document on disk:

```
  ` APPEND TEXT Project Method
  ` APPEND TEXT ( Text { ; Long { ; Time } } )
  ` APPEND TEXT ( Text { ; 4D Write Area { ; DocRef } } )

C_TEXT($1)
C_TIME($2)
C_LONGINT($3)

MESSAGE($1)
If(Count parameters>=3)
   SEND PACKET($3;$1)
Else
   If(Count parameters>=2)
      WR INSERT TEXT($2;$1)
   End if
End if
```

After this project method has been added to your application, you can write:

```
APPEND TEXT(vtSomeText) ` Will only display the text message
APPEND TEXT(vtSomeText;$wrArea) ` Displays text message and appends it to $wrArea
APPEND TEXT(vtSomeText;0;$vhDocRef) ` Displays text message and writes it to $vhDocRef
```

## Example 2

4D project methods accept a variable number of parameters of the same type, starting from the right. To declare these parameters, you use a compiler directive to which you pass *${N}* as a variable, where **N** specifies the first parameter. Using **Count parameters** you can address those parameters with a For loop and the parameter indirection syntax. This example is a function that returns the greatest number received as parameter:

```
  ` Max of Project Method
  ` Max of ( Real { ; Real2... ; RealN } ) -> Real
```

```
` Max of ( Value { ; Value2... ; ValueN } ) -> Greatest value

C_REAL($0;${1}) ` All parameters will be of type REAL as well as the function result
$0:=${1}
For($vlParam;2;Count parameters)
   If(${$vlParam}>$0)
      $0:=${$vlParam}
   End if
End for
```

After this project method has been added to your application, you can write:

```
vrResult:=Max of(Records in set("Operation A");Records in set("Operation B"))
```

or:

```
vrResult:=Max of(r1;r2;r3;r4;r5;r6)
```

# Current method name

Current method name -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | | Calling method name |

## Description

The **Current method name** command returns the method name where it has been invoked. This command is useful for debugging generic methods.

According to the calling method type, the returned string can be as follows:

| Calling Method | Returned string |
|---|---|
| Database Method | MethodName |
| Trigger | Trigger on [TableName] |
| Project Method | MethodName |
| Table Form Method | [TableName].FormName |
| Project Form Method | FormName |
| Table Form Object Method | [TableName].FormName.ObjectName |
| Project Form Object Method | FormName.ObjectName |
| Component Project Method | MethodName |
| Component Project Form Method | FormName(ComponentName) |
| Component Project Form Object Method | FormName(ComponentName).ObjectName(ComponentName) |

This command cannot be called from within a 4D formula.

**Note:** For this command to be able to operate in compiled mode, the database must have been compiled with the **Range Checking** option (located in the Database Settings) selected.
In order to deactivate range checking in a method (or a part of a method) locally, you can use the following special comments:

```
`%R- to deactivate range checking
`%R+ to activate range checking
`%R* to restore the initial state of range checking (defined in the Preferences).
```

# EXECUTE METHOD

EXECUTE METHOD ( methodName {; result {; param}}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| methodName | String | ⇒ | Name of project method to be executed |
| result | Variable, Operator | ⇐ | Variable receiving the method result or * for a method not returning a result |
| param | Expression | ⇒ | Parameter(s) of the method |

## Description

The **EXECUTE METHOD** command executes the *methodName* project method while passing any parameters in *param1...paramN*. You can pass the name of any method that can be called from the database or the component executing the command.

In *result*, you can pass a variable which will receive the result of the execution of *methodName* (value placed in $0 inside *methodName*). If the method does not return a result, pass * as the second parameter. If the method does not return a result and does not require any parameters to be passed, pass only the *methodName* parameter.

The execution context is preserved in the called method, which means that the current form and any current form event remain defined.

If you call this command from a component and pass a method name belonging to the host database in *methodName* (or vice versa), the method must have been shared (“Shared by components and host database” option, in the Method properties).

## System variables and sets

If this command is executed correctly, the system variable OK is set to 1; otherwise, it is set to 0.

# EXECUTE METHOD IN SUBFORM

EXECUTE METHOD IN SUBFORM ( subformObject ; methodName {; return {; param} {; param2 ; ... ; paramN}} )

| Parameter | Type | | Description |
|---|---|---|---|
| subformObject | Text | ⇒ | Name of subform object |
| methodName | Text | ⇒ | Name of project method to be executed |
| return | Operator, Variable | ⇒ | * if method does not return a value |
| | | ⇐ | Value returned by method |
| param | Variable | ⇒ | Parameter(s) to pass to method |

## Description

The **EXECUTE METHOD IN SUBFORM** command can be used to execute the *methodName* project method in the context of the *subformObject* subform object.

The project method called can receive from 1 to X parameters in *param* and return a value in *return*. Pass * in the *return* parameter if the method does not return parameters.

You can pass the name of any project method that is accessible from the database or the component executing the command in *methodName*. The execution context is preserved in the method called, which means that the current form and current form event remain specified. If the subform comes from a component, the method must belong to the component and have the "Shared by components and host database" property.

This command must be called in the context of the parent form (containing the *subformObject* object), for example via the form method.

**Note:** The *methodName* method is not executed if the *subformObject* is not found in the current page or is not yet instantiated.

## Example 1

Given the "ContactDetail" form used as subform in the parent form "Company". The subform object that contains the ContactDetail form is named "ContactSubform". Imagine that we want to modify the appearance of certain elements of the subform according to the value of the field(s) of the company (for example, "contactname" must switch to red when [Company]City="New York" and to blue when [Company]City="San Diego"). This mechanism is implemented via the ***SetToColor*** method. To be able to get this result, the ***SetToColor*** method cannot be called directly from the process of the "On Load" form event of the Company parent form because the "contactname" object does not belong to the current form, but to the form displayed in the "ContactSubform" subform object. The method must therefore be executed using the **EXECUTE METHOD IN SUBFORM** command in order to function correctly.

```
Case of
   :(Form event=On Load)
      Case of
         :([Company]City="New York")
            $Color:=$Red
         :([Company]City="San Diego")
            $Color:=$Blue
         Else
            $Color:=$Black
      End case
      EXECUTE METHOD IN SUBFORM("ContactSubform";"SetToColor";*;$Color)
End case
```

## Example 2

You are developing a database that will be used as a component. It includes a shared project form (named, for instance, Calendar) that contains *dynamic variables* as well as a public project method that is used to adjust the calendar: ***SetCalendarDate(varDate)***.
If this method was used directly in the Calendar form method, you could call it directly in the "On Load" event:

```
SetCalendarDate(Current date)
```

But, in the context of the host database, imagine that a project form contains two "Calendar" subforms, in subform objects called "Cal1" and "Cal2". You must set the date of Cal1 to 01/01/10 and the date of Cal2 to 05/05/10. You cannot call ***SetCalendarDate*** directly because the method will not "know" which forms and variables it should apply. Therefore, you must call it via the following code:

```
EXECUTE METHOD IN SUBFORM("Cal1";"SetCalendarDate";*;!01/01/10!)
EXECUTE METHOD IN SUBFORM("Cal2";"SetCalendarDate";*;!05/05/10!)
```

## Example 3

Advanced example: in the same context as previously, this example provides a generic method:

```
 // Contents of the SetCalendarDate method
C_DATE($1)
C_TEXT($2)
Case of
   :(Count parameters=1)
 // Standard execution of method (as if it was executed from
 // the form itself) or specifically for a context (see case 2)

   :(Count parameters=2)
 // External call, needs a context
 // Recursive call with only one parameter
      EXECUTE METHOD IN SUBFORM($2;"SetCalendarDate";*;$1)
End case
```

## System variables and sets

If this command is executed correctly, the system variable OK is set to 1; otherwise, it is set to 0.

# Get pointer

Get pointer ( varName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| varName | String | ⇒ | Name of a process or interprocess variable |
| Function result | Pointer | ⇐ | Pointer to process or interprocess variable |

## Description

The **Get pointer** command returns a pointer to the process or interprocess variable whose name you pass in *varName*.

To get a pointer to a field, use **Field**. To get a pointer to a table, use **Table**.

**Note:** You can pass expressions such as, for example, *ArrName+"{3}"*, as well as 2D array elements (*ArrName+"{3}{5}"*) to **Get pointer**.
However, you cannot pass variable elements (*ArrName+"{myVar}"*).

## Example 1

In a form, you build a 5 x 10 grid of enterable variables named v1, v2... v50. To initialize all of these variables, you write:

```
  ` ...
For($vlVar;1;50)
   $vpVar:=Get pointer("v"+String($vlVar))
   $vpVar->:=""
End for
```

## Example 2

Using pointers to elements of two-dimensional arrays:

```
$pt:=Get pointer("a{1}{2}")
 //$pt=->a{1}{2}
$pt2:=Get pointer("atCities"+"{2}{6}")
 //$pt2=->atCities{2}{6}
```

# Is a variable

Is a variable ( aPointer ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aPointer | Pointer | ⇒ | Pointer to be tested |
| Function result | Boolean | ⇐ | TRUE = Pointer points to a variable FALSE = Pointer does not point to a variable |

## Description

The **Is a variable** command returns True if the pointer you pass in *aPointer* references a defined variable. It returns False in all other cases (pointer to field or table, Nil pointer, and so on).

When you want to know the name of the variable being pointed to or the field number, you can use the **RESOLVE POINTER** command.

# Nil

Nil ( aPointer ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aPointer | Pointer | ⇒ | Pointer to be tested |
| Function result | Boolean | ⇐ | TRUE = Nil pointer (->[]) FALSE = Valid pointer to an existing object |

## Description

The **Nil** command returns True if the pointer you pass in *aPointer* is Nil (*->[]*). It returns False in all other cases (pointer to field, table or variable).

If you want to find out the name of the variable or the number of the field that is being pointed to, you can use the **RESOLVE POINTER** command.

# NO TRACE

NO TRACE
Does not require any parameters

## Description

You use **NO TRACE** when checking the execution of methods during the development of a database.

**NO TRACE** turns off the debugger engaged by **TRACE**, by an error, or by the user. Using **NO TRACE** has the same effect as clicking the No Trace button in the debugger.

In compiled databases, the **NO TRACE** command is ignored.

# RESOLVE POINTER

RESOLVE POINTER ( aPointer ; varName ; tableNum ; fieldNum )

| Parameter | Type | | Description |
|---|---|---|---|
| aPointer | Pointer | ⇒ | Pointer for which to retrieve the referenced object |
| varName | String | ⇐ | Name of referenced variable or empty string |
| tableNum | Longint | ⇐ | Number of referenced table or array element or 0 or -1 |
| fieldNum | Longint | ⇐ | Number of referenced field or 0 |

## Description

The **RESOLVE POINTER** command retrieves the information of the object referenced by the pointer expression *aPointer* and returns it into the parameters *varName*, *tableNum,* and *fieldNum*.

Depending on the nature of the referenced object, **RESOLVE POINTER** returns the following values:

| Referenced object | Parameters | | |
|---|---|---|---|
| | varName | tableNum | fieldNum |
| None (NIL pointer) | "" (empty string) | 0 | 0 |
| Variable | Name of the variable | -1 | -1 |
| Array | Name of the array | -1 | -1 |
| Array element | Name of the array | Element number | -1 |
| 2D array element | Name of the 2D array | Element row number | Element column number |
| Table | "" (empty string) | Table number | 0 |
| Field | "" (empty string) | Table number | Field number |

**Notes:**

- If the value you pass in *pointer* is not a pointer expression, a syntax error occurs.
- The **RESOLVE POINTER** command does not work with pointers to local variables. In fact, by definition several local variables with the same name could exist in different locations, so it is not possible for the command to find the correct variable.

## Example 1

Within a form, you create a group of 100 enterable variables called v1, v2... v100. To do so, you perform the following steps:

a. Create one enterable variable that you name v.

b. Set the properties of the object.

c. Attach the following method to that object:

```
DoSomething(Self) ` DoSomething being a project method in your database
```

d. At this point, you can either duplicate the variable as many times as you need, or use the Objects on Grid feature in the Form Editor.

e. Within the **DoSomething** method, if you need to know the index of the variable for which the method is called, you write:

```
RESOLVE POINTER($1;$vsVarName;$vlTableNum;$vlFieldNum)
$vlVarNum:=Num(Substring($vsVarName;2))
```

Note that by constructing your form in this way, you write the methods for the 100 variables only once; you do not need to write **DoSomething (1), DoSomething (2)...,DoSomething (100)**.

## Example 2

For debugging purposes, you need to verify that the second parameter ($2) to a method is a pointer to a table. At the beginning of this method, you write:

```
  ` ...
If(◊DebugOn)
   RESOLVE POINTER($2;$vsVarName;$vlTableNum;$vlFieldNum)
   If(Not(($vlTableNum>0)&($vlFieldNum=0)&($vsVarName="")))
  ` WARNING: The pointer is not a reference to a table
      TRACE
      End
   End if
  ` ...
```

## Example 3

See example for the **DRAG AND DROP PROPERTIES** command.

## Example 4

Here is an example of a 2D array pointer:

```
ARRAY TEXT(atCities;100;50)
C_POINTER($city)
atCities{1}{2}:="Rome"
atCities{1}{5}:="Paris"
atCities{2}{6}:="New York"
 // ...other values
$city:=->atCities{1}{5}
RESOLVE POINTER($city;$var;$rowNum;$colNum)
 //$var="atCities"
 //$rowNum="1"
 //$colNum="5"
```

# Self

Self -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Pointer | Pointer to form object (if any) whose method is currently being executed. Otherwise Nil (->[]) if outside of context |

## Compatibility Note

This command is kept only for compatibility reasons. Starting with version 12 of 4D, it is recommended to use the **OBJECT Get pointer** command.

## Description

The **Self** command returns a pointer to the object whose object method is currently being executed.

**Self** is used to reference a variable within its own object method. It returns a valid pointer when it is called from within an object method or from within a project method that is called directly or indirectly by an object method.

If **Self** is called out of context, it returns a **Nil** pointer (*->[]*).

**Tip: Self** is useful when several objects on a form need to perform the same task, yet operate on themselves.

**Note:** When it is used in the context of a list box, the function returns a pointer to the list box or the column of the list box depending on the context. For more information, please refer to the **Managing List Box Objects** section.

## Example

See the example for the **RESOLVE POINTER** command.

# TRACE

TRACE
Does not require any parameters

## Description

You use **TRACE** to trace methods during the development of a database.

The **TRACE** command turns on the 4D debugger for the current process. The **Debugger** window is displayed before the next line of code is executed, and continues to be displayed for each line of code that is executed. You can also turn on the debugger by pressing **Alt+Shift+right-click** (Windows) or **Control+Option+Command+click** (Macintosh) while code is executing.

In compiled databases, the **TRACE** command is ignored.

**4D Server:** If you call **TRACE** from a project method executed within the context of a Stored Procedure, the debugger window appears on the Server machine.

**Tip:** Do not place **TRACE** calls when using a form whose On Activate and On Deactivate events have been enabled. Each time the debugger window appears, these events will be invoked; you will then loop infinitely between these events and the debugger window. If you end up in this situation, **Shift+click** on the **No Trace** button of the debugger in order to get out of it. Any subsequent calls to **TRACE** within the process will be ignored.

## Example

The following code expects the process variable **BUILD_LANG** to be equal to “US” or “FR”. If this is not the case, it calls the project method **DEBUG**:

```
  ` ...
Case of
   :(BUILD_LANG="US")
      vsBHCmdName:=[Commands]CM US Name
   :(BUILD_LANG="FR")
      vsBHCmdName:=[Commands]CM FR Name
   Else
      DEBUG("Unexpected BUILD_LANG value")
End case
```

The **DEBUG** project method is listed here:

```
  ` DEBUG Project Method
  ` DEBUG (Text)
  ` DEBUG (Optional Debug Information)

C_TEXT($1)

If(◊vbDebugOn) ` Interprocess variable set in the On Startup Method
   If(Is compiled mode)
      If(Count parameters>=1)
         ALERT($1+Char(13)+"Call Designer at x911")
      End if
   Else
      TRACE
   End if
End if
```

# Type

Type ( fieldVar ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| fieldVar | Field, Variable | ⇒ | Field or Variable to be tested |
| Function result | Longint | ⇐ | Data type number |

## Description

The **Type** command returns a numeric value that denotes the type of the field or variable you pass as *fieldVar*.

4D provides the following predefined constants found in the **Field and Variable Types** theme:

| Constant | Type | Value |
|---|---|---|
| Array 2D | Longint | 13 |
| Blob array | Longint | 31 |
| Boolean array | Longint | 22 |
| Date array | Longint | 17 |
| Integer array | Longint | 15 |
| Is alpha field | Longint | 0 |
| Is BLOB | Longint | 30 |
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is float | Longint | 35 |
| Is integer | Longint | 8 |
| Is integer 64 bits | Longint | 25 |
| Is JSON null | Longint | 255 |
| Is longint | Longint | 9 |
| Is object | Longint | 38 |
| Is picture | Longint | 3 |
| Is pointer | Longint | 23 |
| Is real | Longint | 1 |
| Is string var | Longint | 24 |
| Is subtable | Longint | 7 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |
| Is undefined | Longint | 5 |
| LongInt array | Longint | 16 |
| Object array | Longint | 39 |
| Picture array | Longint | 19 |
| Pointer array | Longint | 20 |
| Real array | Longint | 14 |
| String array | Longint | 21 |
| Text array | Longint | 18 |
| Time array | Longint | 32 |

**Notes**:

- **Type** returns *9* (Is longint) when applied to a Graph variable.
- Beginning with version 11 of 4D, **Type** returns the actual type of an array when it is applied to a "row" of a 2D array, rather than Array 2D as before (see example 4).
- Beginning with version 11 of 4D, **Type** returns the type Is text or Text array when it is applied, respectively, to an Alpha variable or an Alpha array (starting with this version, there is no difference between an Alpha variable and a Text variable).

You can apply **Type** to fields, interprocess variables, process variables, local variables, and dereferenced pointers referring to these types of objects.You can apply **Type** to parameters (*$1,$2..., ${...}*), or to project method or function results (*$0*).

## Example 1

See example for the **APPEND DATA TO PASTEBOARD** command.

## Example 2

See example for **DRAG AND DROP PROPERTIES** command.

## Example 3

The following project method empties some or all of the fields for the current record of the table whose a pointer is passed as parameter. It does this without deleting or changing the current record:

```
  ` EMPTY RECORD Project Method
  ` EMPTY RECORD ( Pointer {; Long } )
  ` EMPTY RECORD ( -> [Table] { ; Type Flags } )

C_POINTER($1)
C_LONGINT($2;$vlTypeFlags)

If(Count parameters>=2)
   $vlTypeFlags:=$2
Else
   $vlTypeFlags:=0xFFFFFFFF
End if
For($vlField;1;Get last field number($1))
   $vpField:=Field(Table($1);$vlField)
   $vlFieldType:=Type($vpField->)
   If($vlTypeFlags ??$vlFieldType )
      Case of
         :(($vlFieldType=Is alpha field)|($vlFieldType=Is text))
            $vpField->:=""
         :(($vlFieldType=Is real)|($vlFieldType=Is integer)|($vlFieldType=Is longint))
            $vpField->:=0
         :($vlFieldType=Is date)
            $vpField->:=!00/00/00!
         :($vlFieldType=Is time)
            $vpField->:=?00:00:00?
         :($vlFieldType=Is Boolean)
            $vpField->:=False
         :($vlFieldType=Is picture)
            C_PICTURE($vgEmptyPicture)
            $vpField->:=$vgEmptyPicture
         :($vlFieldType=Is subtable)
            Repeat
               ALL SUBRECORDS($vpField->)
               DELETE SUBRECORD($vpField->)
            Until(Records in subselection($vpField->)=0)
         :($vlFieldType=Is BLOB)
            SET BLOB SIZE($vpField->;0)
      End case
   End if
End for
```

After this project method is implemented in your database, you can write:

```
  ` Empty the whole current record of the table [Things To Do]
EMPTY RECORD(->[Things To Do])

  ` Empty Text, BLOB and Picture fields for the current record of the table [Things To Do]
EMPTY RECORD(->[Things To Do];0?+Is text?+Is BLOB?+Is picture)
```

```
` Empty the whole current record of the table [Things To Do] except Alphanumeric fields
EMPTY RECORD(->[Things To Do];-1?-Is alpha field)
```

## Example 4

In certain cases, for example when writing generic code, you may need to find out whether an array is a standard independent array or the “row” of a 2D array. In this case, you can use the following code:

```
ptrmyArr:=->myArr{6} ` Is myArr{6} the row of a 2D array?
RESOLVE POINTER(ptrmyArr;varName;tableNum;fieldNum)
If(varName#"")
   $ptr:=Get pointer(varName)
   $thetype:=Type($ptr->)
 ` If myArr{6} is the row of a 2D array, $thetype equals 13
End if
```

# LDAP

- Overview of LDAP commands
- LDAP LOGIN
- LDAP LOGOUT
- LDAP Search
- LDAP SEARCH ALL

## Overview of LDAP commands

The commands of the "LDAP" theme allow your 4D application to connect to a company directory server such as MS Active Directory using the LDAP protocol. You can access the server data and query it.

**Note:** LDAP or Lightweight Directory Access Protocol is an open standard for accessing and maintaining distributed information services. For more information, please refer to the Wikipedia page on LDAP or the OpenLDAP Software main page.

LDAP commands allow you to:

- use the Windows session login and password to grant access to your 4D application (if using MS Active directory) so that the end user only needs to remember a single password,
- query the corporate directory to retrieve user information such as full name, email, phone number, office building, groups the person belongs to, etc.

In 4D, an LDAP connection is opened using **LDAP LOGIN**. It is then bound to the current 4D process and must be closed using **LDAP LOGOUT**, or when the process terminates its execution.

### Glossary

Here is a list of the main acronyms used in the LDAP environment:

| Acronym | Definition |
|---|---|
| LDAP | Lightweight Directory Access Protocol |
| AD | Active Directory. AD is a directory services database implemented by Microsoft, and LDAP is one of the protocols you can use to talk to it. |
| CN | Common Name, for example "John Doe" |
| DN | Distinguished Name, for example "cn=John Doe,ou=users,dc=example,dc=com" |
| SAM-Account-Name | Security Account Manager, logon name for AD, for example "jdoe" |
| OU | Organizational unit, groups of the server tree |
| DC | Domain components, root and first branches of the server tree |
| uid | User identifier |

# LDAP LOGIN

LDAP LOGIN ( url ; login ; password {; digest} )

| Parameter | Type | | Description |
|---|---|---|---|
| url | String | ⇒ | URL of LDAP server to connect to |
| login | String | ⇒ | Login entry |
| password | String | ⇒ | Password of login entry |
| digest | Longint | ⇒ | 0 = send password in digest MD5 (default), 1 = send password without encryption |

## Description

The **LDAP LOGIN** command opens a read-only connection to the LDAP server specified in the *url* parameter with the *login* and *password* identifiers provided. If accepted by the server, this connection will be used for any LDAP searches executed subsequently in the current process until the **LDAP LOGOUT** command is executed (or until the process is closed).

In *url*, pass the full URL of the LDAP server you want to connect to, including the scheme and port (389 by default). This parameter should be compliant with rfc2255.
You can open secure connections over TLS by using a *url* that starts with "ldaps" and uses a specific port number (for example "ldaps://svr.ldap.acme.com:1389"). The LDAP server must have an SSL Certificate (at least for Microsoft Active Directory). Using a TLS connection is highly recommended when the password is sent in plain text (see below).

**Note:** If you pass an empty string in the *url* parameter, the command will try to connect to the default LDAP server available on the domain; (this feature is intended for testing purposes only, for performance reasons it should not be used in production).

In *login*, pass the user account on the LDAP server, and in *password*, pass the user password. By default, the *login* can be one of the following login strings, depending on the LDAP Server configuration:

- a Distinguished Name (DN), for example "CN=John Smith,OU=users,DC=example,DC=com"
- the user name (CN), for example "CN=John Smith"
- an e-mail address, for example "johnsmith@4d.fr"
- an SAM-Account-Name, for example "jsmith".

Note that accepted values for the *login* are related to the password transmission mode as defined by the *digest* parameter. For example, in a default MS Active Directory configuration:

- When the transmission mode is LDAP password MD5, the only accepted value for a login is the SAM-Account-Name.
- When the transmission mode is LDAP password plain text (clear text), the *login* parameter can be either DN, CN or an e-mail address. An SAM-Account-Name is also accepted but only when preceded by the domain name (for example, "dc-acme.com/jsmith").

The *digest* parameter allows you to modify the way the password is transmitted over the network. You can use one of the following constants, located in the "**LDAP**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| LDAP password MD5 | Longint | 0 | (Default) Send password encrypted in MD5 |
| LDAP password plain text | Longint | 1 | Send password with no encryption (TLS connection recommended) |

By default, the *password* is transmitted in digest MD5. Pass LDAP password plain text if necessary, for example if you want to use different login type values with the LDAP server. In a production environment, it is recommended to use a TLS connection for the *url*.

**Note:** Authentication with an empty password lets you enter the anonymous binding mode (if authorized by the LDAP server). However, in this mode, errors can be thrown if you try to perform any operation that is not allowed in this kind of bind.

If the login parameters are valid, a connection to the LDAP server is opened in the 4D process. You can then search and retrieve information using LDAP commands.

Do not forget to call the **LDAP LOGOUT** command when the connection to the LDAP server is no longer necessary.

## Example 1

You want to log in to an LDAP server and do a search:

```
ARRAY TEXT($_tabAttributes;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes;"phoneNumber")
LDAP LOGIN("ldap://srv.dc.acme.com:389";"John Smith";"qrnSurBret2elburg")
$vfound:=LDAP Search("OU=UO_Users,DC=ACME,DC=com";cn=John Doe";LDAP all levels;$_tabAttributes)
LDAP LOGOUT //do not forget to log out
```

## Example 2

This example tries to connect to an application:

```
ON ERR CALL("ErrHdlr") //handle errors
errOccurred:=False
errMsg:=""
If(ppBindMode=1) //if password mode is default
   LDAP LOGIN(vUrlLdap;vUserCN;vPwd;LDAP password MD5)
Else
   LDAP LOGIN(vUrlLdap;vUserCN;vPwd;LDAP password plain text)
End if

Case of
   :(Not(errOccurred))
      ALERT(" You are now connected to your LDAP server.  ")

   :(errOccurred)
      ALERT("Error in your parameters")
End case

LDAP LOGOUT
ON ERR CALL("")
```

# LDAP LOGOUT

LDAP LOGOUT
Does not require any parameters

## Description

The **LDAP LOGOUT** command closes the connection with an LDAP server in the current process (if applicable). If there is no connection, an error 1003 stating that you are not logged in is returned.

# LDAP Search

LDAP Search ( dnRootEntry ; filter {; scope {; attributes {; attributesAsArray}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| dnRootEntry | String | ➡ | Distinguished Name of root entry where search is to start |
| filter | String | ➡ | LDAP search filter |
| scope | String | ➡ | Scope of search: "base" (default), "one", or "sub" |
| attributes | Text array | ➡ | Attribute(s) to fetch |
| attributesAsArray | Boolean array | ➡ | True = force attributes to be returned as array; False = force attributes to be returned as a simple variable |
| Function result | Object | ⮌ | Key/value attributes |

## Description

The **LDAP Search** command searches in the target LDAP server for the first occurrence matching the criteria defined. This command must be executed within a connection to an LDAP server opened with **LDAP LOGIN**; otherwise a 1003 error is returned.

In *dnRootEntry*, pass the *Distinguished Name* of the LDAP server root entry; the search will start at this entry.

In *filter*, pass the LDAP search filter to execute. The filter string must be compliant with rfc2225. You can pass an empty string "" in order not to filter the search; the "*" is supported to search substrings.

In *scope*, pass one of the following constants from the "**LDAP**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| LDAP all levels | String | sub | Search in the root entry level defined by *dnRootEntry* and in all subsequent entries |
| LDAP root and next | String | one | Search in the root entry level defined by *dnRootEntry* and in the directly subsequent entries on one level |
| LDAP root only | String | base | Search only in the root entry level defined by *dnRootEntry* (default if omitted) |

In *attributes*, pass a text array which contains the list of all LDAP attributes to fetch from the matched entries. By default, if this parameter is omitted, all attributes are fetched.

**Note:** Keep in mind that LDAP attribute names are case-sensitive. For more information on LDAP attributes, you can refer to this page that lists all available attributes for the MS Active directory.

By default, the command returns attributes as an array if multiple results are found, or as a variable if a single result is found. The optional *attributesAsArray* parameter allows you to "force" returned attribute(s) to be formatted as an array or as a variable for each attribute defined:

- When you pass **true** in an element, the corresponding element of the *attributes* parameter will be returned in an array. If a single value is found, the command returns an array with a single element.
- When you pass **false** in an element, the corresponding element of the *attributes* parameter will be returned in a simple variable. If multiple entries are found, the command returns only the first element.

## Example 1

You want to get the phone number of the user "smith" in the company directory:

```
ARRAY TEXT($_tabAttributes;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes;"phoneNumber")
LDAP LOGIN($url;$dn;$pwd)
$filter:="cn=*smith*"
$vfound:=LDAP Search($dnSearchRootEntry;$filter;LDAP all levels;$_tabAttributes)
LDAP LOGOUT
```

## Example 2

We want to get an array of all entries found for the "memberOf" attribute:

```
C_OBJECT($entry)
ARRAY TEXT($_tabAttributes;0)
ARRAY BOOLEAN($_tabAttributes_asArray;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes_asArray;False)
APPEND TO ARRAY($_tabAttributes;"memberOf")
APPEND TO ARRAY($_tabAttributes_asArray;True)

LDAP LOGIN($url;$login;$pwd;LDAP password plain text)
$entry:=LDAP Search($dnSearchRootEntry;"cn=adrien*";LDAP all levels;$_tabAttributes;$_tabAttributes_asArray)
LDAP LOGOUT

ARRAY TEXT($_arrMemberOf;0)
OB GET ARRAY($entry;"memberOf";$_arrMemberOf)
 // in $_arrMemberOf we have an array containing all entry groups
```

# LDAP SEARCH ALL

LDAP SEARCH ALL ( dnRootEntry ; arrResult ; filter {; scope {; attributes {; attributesAsArray}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| dnRootEntry | String | ⇒ | Distinguished Name of root entry where search is to start |
| arrResult | Object array | ⇐ | Result of the search |
| filter | String | ⇒ | LDAP search filter |
| scope | String | ⇒ | Scope of the search: "base" (default), "one", or "sub" |
| attributes | Text array | ⇒ | Attribute(s) to fetch |
| attributesAsArray | Boolean array | ⇒ | True = force attributes to be returned as array; false = force attributes to be returned as a simple variable |

## Description

The **LDAP SEARCH ALL** command searches in the target LDAP server for all occurrences matching the criteria defined. This command must be executed within a connection to an LDAP server opened with **LDAP LOGIN**; otherwise a 1003 error is returned.

Note that LDAP servers usually impose a maximum number of entries that can be received from a search. For example, Microsoft Active directory limits this number to 1000 entries by default.

In *dnRootEntry*, pass the *Distinguished Name* of the LDAP server root entry; the search will start at this entry.

In *arrResult*, pass an object array that will be filled with all matching entries; in this array, each element is an object containing attribute/value pairs returned for a matching entry. You can use the *attributes* parameter to define the attributes to be returned.

In *filter*, pass the LDAP search filter to execute. The filter string must be compliant with rfc2225. You can pass an empty string "" in order not to filter the search; the "*" is supported to search substrings.

In *scope*, pass one of the following constants from the "**LDAP**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| LDAP all levels | String | sub | Search in the root entry level defined by *dnRootEntry* and in all subsequent entries |
| LDAP root and next | String | one | Search in the root entry level defined by *dnRootEntry* and in the directly subsequent entries on one level |
| LDAP root only | String | base | Search only in the root entry level defined by *dnRootEntry* (default if omitted) |

In *attributes*, pass a text array which contains the list of all LDAP attributes to fetch from the matched entries. By default, if this parameter is omitted, all attributes are fetched.

**Note:** Keep in mind that LDAP attribute names are case-sensitive. For more information on LDAP attributes, you can refer to this page that lists all available attributes for the MS Active directory.

By default, the command returns attributes as an array if multiple results are found, or as a variable if a single result is found. The optional *attributesAsArray* parameter allows you to "force" the attribute(s) returned to be formatted as an array or as a variable for each attribute defined:

- When you pass **true** in an element, the corresponding element of the *attributes* parameter will be returned in an array. If a single value is found, the command returns an array with a single element.
- When you pass **false** in an element, the corresponding element of the *attributes* parameter will be returned in a simple variable. If multiple entries are found, the command returns only the first element.

## Example 1

We want to get the phone number of all users named "smith" in the company directory:

```
ARRAY TEXT($_tabAttributes;0)
ARRAY BOOLEAN($_tabAttributes_asArray;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes_asArray;False)
APPEND TO ARRAY($_tabAttributes;"telephoneNumber")
APPEND TO ARRAY($_tabAttributes_asArray;False)
ARRAY OBJECT($_entry;0)
```

```
LDAP LOGIN($url;$myLogin;$pwd)
$filter:="cn=*smith*"
LDAP SEARCH ALL($dnSearchRootEntry;$_entry;$filter;LDAP all levels;$_tabAttributes)
LDAP LOGOUT

 //$_entry will contain for example
 // $_entry{1} = {"cn":"John Smith","telephoneNumber":"01 40 87 00 00"}
 // $_entry{2} = {"cn":"Adele Smith","telephoneNumber":"01 40 87 00 01"}
 // $_entry{3} = {"cn":"Adrian Smith","telephoneNumber":"01 23 45 67 89"}
 // ...
```

## Example 2

These examples illustrate the use of the *attributesAsArray* parameter:

```
ARRAY OBJECT($_entry;0)
ARRAY TEXT($_tabAttributes;0)
ARRAY BOOLEAN($_tabAttributes_asArray;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes_asArray;False)
APPEND TO ARRAY($_tabAttributes;"memberOf")
APPEND TO ARRAY($_tabAttributes_asArray;True)

LDAP LOGIN($url;$login;$pwd;LDAP password plain text)
LDAP SEARCH ALL($dnSearchRootEntry;$_entry;$filter;LDAP all levels;$_tabAttributes;$_tabAttributes_asArray)
LDAP LOGOUT

ARRAY TEXT($_arrMemberOf;0)
OB GET ARRAY($_entry{1};"memberOf";$_arrMemberOf)
 // in $_arrMemberOf we have an array containing all groups of the entry
```

```
ARRAY TEXT($_tabAttributes;0)
ARRAY BOOLEAN($_tabAttributes_asArray;0)
APPEND TO ARRAY($_tabAttributes;"cn")
APPEND TO ARRAY($_tabAttributes_asArray;False)
APPEND TO ARRAY($_tabAttributes;"memberOf")
APPEND TO ARRAY($_tabAttributes_asArray;False)

LDAP LOGIN($url;$login;$pwd;LDAP password plain text)
LDAP SEARCH ALL($dnSearchRootEntry;$_entry;$filter;LDAP all levels;$_tabAttributes;$_tabAttributes_asArray)
LDAP LOGOUT

$memberOf:=OB Get($_entry{1};"memberOf")
 // in $memberOf we have a variable containing the first group of the entry
```

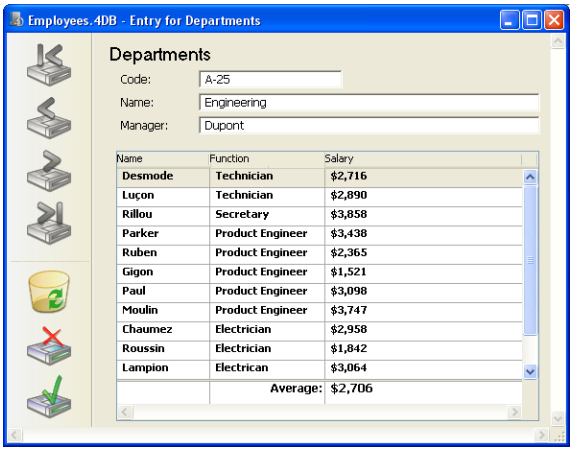
# Managing List Box Objects

The commands of this theme are dedicated to handling form objects of the List box type.

List boxes represent data in the form of columns and selectable rows and provide many interface functions such as the ability to enter values, sort columns, display a hierarchy, define alternating colors, and so on.



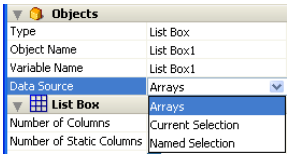
You can set up a List box completely in the 4D Form editor and can also manage it through programming. For more information on creating and setting List boxes in the Form editor as well as on their use, refer to the *Design Reference* manual of the 4D documentation.

Programming list box objects is done in the same way as other 4D list form objects. However, specific rules must be followed, as detailed in this section.

## Data sources and principles for managing values

A list box can contain one or more columns and can be associated either with 4D arrays or a selection of records. In the case of selection type list boxes, columns are associated with fields or expressions.

It is not possible to have both types of data sources (arrays and selections) combined in the same list box. The data source is set when the list box is created in the Form editor, via the Property list. It is then no longer possible to modify it by programming.



### Array type list boxes

In this type of list box, each column must be associated with a one-dimensional 4D array; all array types can be used, with the exception of pointer arrays. The display format for each column can be defined in the Form editor or by using the **OBJECT SET FORMAT** command.

Using the language, the values of columns (data entry and display) are managed using high-level List box commands (such as **LISTBOX INSERT ROWS** or **LISTBOX DELETE ROWS**) as well as array manipulation commands.
For example, to initialize the contents of a column, you can use the following instruction:

```
ARRAY TEXT(ColumnName;size)
```

You can also use a list:

```
LIST TO ARRAY("ListName";ColumnName)
```

**Warning** : When a list box contains several columns of different sizes, only the number of items of the smallest array (column) will be displayed. You should make sure that each array has the same number of elements as the others. Also, if a

list box column is empty (this occurs when the associated array was not correctly declared or sized using the language), the list box displays nothing.

### Selection type list boxes

In this type of list box, each column can be associated with a field or an expression. The contents of each row is then evaluated according to a selection of records: the current selection of a table or a named selection.

When the current selection is the data source, any modifications made on the database side are automatically carried over to the list box and vice versa. The current selection is thus always the same in both locations. Note that the **LISTBOX INSERT ROWS** and **LISTBOX DELETE ROWS** commands cannot be used with selection type list boxes.

You can associate a list box column with an expression. The expression could be based on one or more fields (for example *[Employees]LastName+" "+[Employees]FirstName*) or simply be a formula (for example **String**(Milliseconds)). The expression can also be a project method, a variable or an array element.

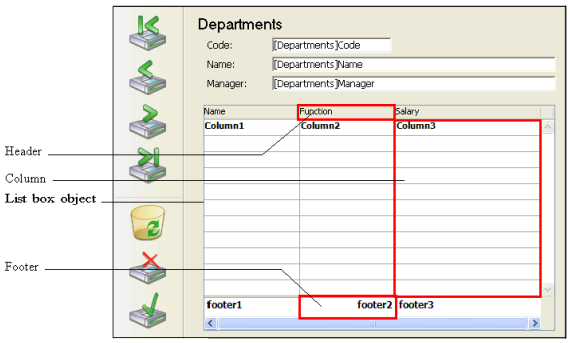
The **LISTBOX SET TABLE SOURCE** command can be used to modify the table associated with the list box by programming.

## Object, column, header and footer

A List box object is composed of four separate items:

- the **object** itself,
- the **columns**,
- the column **headers** (can be displayed or hidden, displayed by default),
- the column **footers** (can be displayed or hidden, hidden by default).

These items can be selected individually in the Form editor. Each one has its own object and variable name and can be handled separately.



By default, columns are named **Column1** to *n*, headers **Header1** to *n* and footers **Footer1** to *n* in the form, independently of the list box objects. Note that, by default, the same name is used for the objects and their associated variables, except in the case of footers (by default, footer variables are blank; 4D uses dynamic variables).

Each item type contains individual and shared characteristics with other items. For example, character fonts can be globally assigned to the list box object or separately to columns, headers and/or footers. On the other hand, entry properties can only be defined for columns.

These rules apply to the "**Object Properties**" theme commands that can be used with list boxes. Depending on its functionality, each command can be used with the list box, columns, column headers and/or footers. To set the type of item on which you want to work, simply pass the object name or the variable associated with it.

The following table details the scope of each command of the "**Object Properties**" theme that can be used with list boxes:

| Object Properties commands | Object | Columns | Column headers | Column footers |
|---|---|---|---|---|
| OBJECT MOVE | X | | | |
| OBJECT GET COORDINATES | X | X | X | X |
| OBJECT SET RESIZING OPTIONS | X | | | |
| OBJECT GET RESIZING OPTIONS | X | | | |
| OBJECT GET BEST SIZE | | X | | |
| OBJECT SET FILTER | | X | | |
| OBJECT SET FORMAT | | X | X | X |
| OBJECT SET ENTERABLE | | X | | |
| OBJECT SET LIST BY NAME | | X | | |
| OBJECT SET TITLE | | | X | |
| OBJECT SET COLOR | X | X | X | X |
| OBJECT SET RGB COLORS | X | X | X | X |
| OBJECT SET FONT | X | X | X | X |
| OBJECT SET FONT SIZE | X | X | X | X |
| OBJECT SET FONT STYLE | X | X | X | X |
| OBJECT SET HORIZONTAL ALIGNMENT | X | X | X | X |
| OBJECT Get horizontal alignment | X | X | X | X |
| OBJECT SET VERTICAL ALIGNMENT | X | X | X | X |
| OBJECT Get vertical alignment | X | X | X | X |
| OBJECT SET VISIBLE | X | X | X | X |
| OBJECT SET SCROLLBAR | X | | | |
| OBJECT SET SCROLL POSITION | X | | | |

**Note**: With array type list boxes, it is possible to specify the style, font color, background color and visibility of each row separately. This is managed via arrays associated with the list box in the Property List. You can retrieve the names of these arrays by programming using the **LISTBOX GET ARRAYS** command.

## List box and Language

### Object methods

It is possible to add an object method to the list box object and/or to each column of the list box. Object methods are called in the following order:

**1.** Object method of each column

**2.** Object method of the list box

The column object method gets events that occur in its header and footer.

### OBJECT SET VISIBLE and headers/footers

When the **OBJECT SET VISIBLE** command is used with a header or footer, it is used on all List box object headers or footers, regardless of the individual element set by the command. For example, the **OBJECT SET VISIBLE(*;"header3";False)** instruction will hide all headers in the List box object to which header3 belongs and not simply this header.

Note that in order for you to be able to manage the visibility of these objects using the **OBJECT SET VISIBLE** command, they must have been displayed in the list box at the level of the Form editor (the **Display Headers** and/or **Display Footers** option must be checked for the object).

### OBJECT Get pointer

The **OBJECT Get pointer** function used with the Object with focus or Object current constant (formerly the **Focus object** and **Self** functions) can be used in the object method of a list box or a list box column. They return a pointer to the list box, the list box column(1) or the header variable depending on the type of form event. The following table details this functioning:

| Event | Object with focus | Object current |
|---|---|---|
| On Clicked | list box | column |
| On Double Clicked | list box | column |
| On Before Keystroke | column | column |
| On After Keystroke | column | column |
| On After Edit | column | column |
| On Getting Focus | column or list box (*) | column or list box (*) |
| On Losing Focus | column or list box (*) | column or list box (*) |
| On Drop | list box source | list box (*) |
| On Drag Over | list box source | list box (*) |
| On Begin Drag Over | list box | list box (*) |
| On Mouse Enter | list box (**) | list box (**) |
| On Mouse Move | list box (**) | list box (**) |
| On Mouse Leave | list box (**) | list box (**) |
| On Data Change | column | column |
| On Selection Change | list box (**) | list box (**) |
| On Before Data Entry | column | column |
| On Column Moved | list box | column |
| On Row Moved | list box | list box |
| On Column Resize | list box | column |
| On Open Detail | Nil | list box (**) |
| On Close Detail | Nil | list box (**) |
| On Header Click | list box | header |
| On Footer Click | list box | footer |
| On After Sort | list box | header |

(*) When the focus is modified within a list box, a pointer to the column is returned. When the focus is modified at the overall form level, a pointer to the list box is returned. In the context of a column object method, a pointer to the column is returned.
(**) Not executed in the context of a column object method.

(1) When a pointer to a column is returned, the object pointed to depends on the type of list box. With an array type list box, the **OBJECT Get pointer** function (“User Interface” theme) returns a pointer to the column of the list box with the focus (i.e. to an array). The 4D pointer mechanism allows you to see the item number of the modified array. For example, supposing a user modified the 5th line of the column col2:

```
$Column:=OBJECT Get pointer(Object with focus)
` $Column contains a pointer to col2
$Row:=$Column-> `$Row equals 5
```

For a selection type list box, the **OBJECT Get pointer** function returns:

- For a column associated with a field, a pointer to the associated field,
- For a column associated with a variable, a pointer to the variable,
- For a column associated with an expression, the **Nil** pointer.

### OBJECT SET SCROLL POSITION

The **OBJECT SET SCROLL POSITION** command (“**Objects (Forms)**” theme) can be used with a list box. It scrolls the list box rows so that the first selected row or a specified row is displayed.

### EDIT ITEM

The **EDIT ITEM** command (“**Entry Control**” theme) allows you to pass a cell of a list box object into edit mode.

### REDRAW

When it is applied to a listbox in selection mode, the **REDRAW** command ("**User Interface**" theme) triggers the updating of the data displayed in the list box.

### Displayed line number

The **Displayed line number** command (“**Selection**” theme) functions in the context of the On Display Detail form event for a list box object.

### Form events

Specific form events are intended to facilitate list box management, in particular concerning drag and drop and sort operations. For more information, refer to the description of the **Form event** command.

### Drag and drop

Managing the drag and drop of data in list boxes is supported by the **Drop position** and **DRAG AND DROP PROPERTIES** commands. These commands have been specially adapted for list boxes.

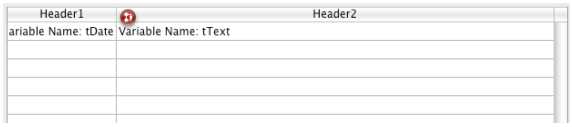
Be careful not to confuse drag and drop with the moving of rows and columns, supported by the **LISTBOX MOVED ROW NUMBER** and **LISTBOX MOVED COLUMN NUMBER** commands.

## Managing entry

For a list box cell to be enterable, both of the following conditions must be met:

- The cell’s column must have been set as **Enterable** (otherwise, the cells of the column can never be enterable).
- In the On Before Data Entry event, $0 does not return -1.
  When the cursor arrives in the cell, the On Before Data Entry event is generated in the column method. If, in the context of this event, $0 is set to -1, the cell is considered as not enterable. If the event was generated after **Tab** or **Shift+Tab** was pressed, the focus goes to either the next cell or the previous one respectively. If $0 is not -1 (by default $0 is 0), the cell is enterable and switches to editing mode.

Let’s consider the example of a list box containing two arrays, one date and one text. The date array is not enterable but the text array is enterable if the date has not already past.



Here is the method of the arrText column:

```
Case of
   :(Form event=On Before Data Entry) // a cell gets the focus
      LISTBOX GET CELL POSITION(*;"lb";$col;$row)
 // identification of cell
      If(arrDate{$row}<Current date) // if date is earlier than today
         $0:=-1 // cell is NOT enterable
      Else
 // otherwise, cell is enterable
      End if
End case
```

**Note:** Beginning with 4D v13, the On Before Data Entry event is returned before On Getting Focus.

In order to preserve data consistency for selection type list boxes, any modified record is saved as soon as the cell is validated (if it is set, the On saving an existing record trigger is called) then the On Data Change event is executed. The typical sequence of events generated during data entry or modification is as follows:

| Action | Sequence of events |
|---|---|
| A cell switches to edit mode | On Before Data Entry / On Getting Focus |
| Its value is modified | On Before Keystroke / On After Keystroke / On After Edit |
| A user validates and leaves the cell (tab, click, etc.) | *Save* (On saving an existing record trigger) / On Data Change / On Losing Focus |

## Managing sorts

By default, the list box automatically handles standard column sorts when the header is clicked. A standard sort is an alphanumeric sort of column values, alternately ascending/descending with each successive click. All columns are always synchronized automatically.
You can forbid standard user sorts by deselecting the “Sortable” property of the list box.

The developer can set up custom sorts using the **LISTBOX SORT COLUMNS** command and/or combining the On Header Click and On After Sort form events (see the **Form event** command) and array management 4D commands.

**Note**: The “Sortable” column property only affects the standard user sorts; the **LISTBOX SORT COLUMNS** command does not take this property into account.

The value of the variable related to the column header allows you to manage additional information: the current sort of the column (read) and the display of the sort arrow.

- If the variable is set to 0, the column is not sorted and the sort arrow is not displayed;

- If the variable is set to 1, the column is sorted in ascending order and the sort arrow is displayed;

- If the variable is set to 2, the column is sorted in descending order and the sort arrow is displayed.

You can set the value of the variable (for example, **Header2:=2**) in order to “force” the sort arrow display. The column sort itself is not modified in this case; it is up to the developer to handle it.

**Note:** The **OBJECT SET FORMAT** command offers specific support for icons in list box headers, which can be useful when you want to work with a customized sort icon.

## Managing selections

Selections are managed differently depending on whether the list box is based on an array or on a selection.

- **Selection type list box**: Selections are managed by a set, which you can modify if necessary, called *$ListboxSetX* by default (where *X* starts at 0 and is incremented based on the number of list boxes in the form). This set is defined in the properties of the list box. It is automatically maintained by 4D: If the user selects one or more rows in the list box, the set is immediately updated. On the other hand, it is also possible to use the commands of the "Sets" theme in order to modify the selection of the list box via programming.
- **Array type list box**: the **LISTBOX SELECT ROW** command can be used to select one or more rows of the list box by programming.
  The variable linked to the List box object is used to get, set or store selections of object rows. This variable corresponds to a Boolean array that is automatically created and maintained by 4D. The size of this array is determined by the size of the list box: it contains the same number of elements as the smallest array linked to the columns.
  Each element of this array contains **True** if the corresponding line is selected and **False** otherwise. 4D updates the contents of this array depending on user actions. Inversely, you can change the value of array elements to change the selection in the list box.
  On the other hand, you can neither insert nor delete rows in this array; you cannot retype rows either.

**Note**: The **Count in array** command can be used to find out the number of selected lines.

For example, this method allows inverting the selection of the first row of the (array type) list box:

```
ARRAY BOOLEAN(tBListBox;10)
 ` tBListBox is the name of the list box variable in the form
If(tBListBox{1}=True)
   tBListBox{1}:=False
Else
   tBListBox{1}:=True
End if
```

**Note**: The specificities of managing selections in list boxes that are in hierarchical mode are detailed in the **Managing Hierarchical List Boxes** section.

## Printing list boxes

It is possible to print list boxes beginning with 4D v12. Two printing modes are available: preview mode, which can be used to print a list box like a form object, and advanced mode, which lets you control the printing of the list box object itself within the form. Note that the "Printing" appearance is available for list box objects in the Form editor.

### Preview mode

Printing a list box in preview mode consists in directly printing the list box with the form that contains it using the standard print commands or the **Print** menu command. The list box is printed as it is in the form. This mode does not allow precise

control of the printing of the object; in particular, it does not allow you to print all the rows of a list box that contains more rows than it can display.

### Advanced mode

In this mode, the printing of list boxes is carried out by programming, via the **Print object** command (project forms and table forms are supported). The **LISTBOX GET PRINT INFORMATION** command is used to control the printing of the object.

In this mode:

- The height of the list box object is automatically reduced when the number of rows to be printed is less than the original height of the object (there are no "blank" rows printed). On the other hand, the height does not automatically increase according to the contents of the object. The size of the object actually printed can be obtained via the **LISTBOX GET PRINT INFORMATION** command.
- The list box object is printed "as is", in other words, taking its current display parameters into account: visibility of headers and gridlines, hidden and displayed rows, etc.
  These parameters also include the first row to be printed: if you call the **OBJECT SET SCROLL POSITION** command before launching the printing, the first row printed in the list box will be the one designated by the command.
- An automatic mechanism facilitates the printing of list boxes that contain more rows than it is possible to display: successive calls to **Print object** can be used to print a new set of rows each time. The **LISTBOX GET PRINT INFORMATION** command can be used to check the status of the printing while it is underway.

## Managing styles and colors

There are several different ways to set background colors, font colors and font styles for list boxes:

- at the level of the list box object properties,
- at the level of the column properties,
- using arrays or methods for the list box and/or for each column,
- at the level of the text of each cell (if multi-style text).

Priority and inheritance principles are observed.

### Priority

When the same property is set at more than one level, the following priority is applied:

| | |
|---|---|
| *high priority* | Cell (if multi-style text) |
| | Column arrays/methods |
| | List box arrays/methods |
| | Column properties |
| *low priority* | List box properties |

For example, if you set a font style in the list box properties and another using a style array for the column, the latter one will be taken into account.

Given a list box where the rows have an alternating gray/light gray color, defined in the properties of the list box. A background color array has also been set for the list box in order to switch the color of rows where at least one value is negative to light orange:

```
<>_BgndColors{$i}:=0x00FFD0B0 // orange
<>_BgndColors{$i}:=-255 // default value
```

| Header1 | Header2 | Header3 |
|---|---|---|
| 21483 | 9031 | 27290 |
| 24151 | 21990 | -923 |
| 21351 | 2982 | 18009 |
| 8089 | 12898 | 20941 |
| 13001 | -802 | 22059 |
| 4321 | 16826 | 11303 |
| 24082 | 26214 | 22380 |
| 16680 | 23651 | 20403 |
| -2678 | 24818 | 29896 |
| 25639 | 2691 | 9687 |
| 28794 | 26941 | 21486 |
| 26083 | 21092 | 13476 |
| 27928 | 4092 | 15441 |
| 19987 | 28211 | 21191 |
| 7996 | 6300 | 4089 |
| -1063 | 13388 | 23683 |
| 13008 | 7470 | 19897 |
| 5388 | 26918 | 13547 |
| 28559 | 27007 | 8365 |
| 28454 | 22646 | 13824 |

Next you want to color the cells with negative values in dark orange. To do this, you set a background color array for each column, for example *<>_BgndColor_1*, *<>_BgndColor_2* and *<>_BgndColor_3*. The values of these arrays have priority over the ones set in the list box properties as well as those of the general background color array:

```
<>_BgndColorsCol_3{2}:=0x00FF8000 // dark orange
<>_BgndColorsCol_2{5}:=0x00FF8000
<>_BgndColorsCol_1{9}:=0x00FF8000
<>_BgndColorsCol_1{16}:=0x00FF8000
```

| Header1 | Header2 | Header3 |
|---|---|---|
| 21483 | 9031 | 27290 |
| 24151 | 21990 | -923 |
| 21351 | 2982 | 18009 |
| 8089 | 12898 | 20941 |
| 13001 | -802 | 22059 |
| 4321 | 16826 | 11303 |
| 24082 | 26214 | 22380 |
| 16680 | 23651 | 20403 |
| -2678 | 24818 | 29896 |
| 25639 | 2691 | 9687 |
| 28794 | 26941 | 21486 |
| 26083 | 21092 | 13476 |
| 27928 | 4092 | 15441 |
| 19987 | 28211 | 21191 |
| 7996 | 6300 | 4089 |
| -1063 | 13388 | 23683 |
| 13008 | 7470 | 19897 |
| 5388 | 26918 | 13547 |
| 28559 | 27007 | 8365 |
| 28454 | 22646 | 13824 |

You can get the same result using the **LISTBOX SET ROW FONT STYLE** and **LISTBOX SET ROW COLOR** commands. They have the advantage of letting you skip having to predefine style/color arrays for the columns: instead they are created dynamically by the commands.

### Inheritance

For each attribute (style, color and background color), an inheritance is implemented when the default value is used:

- for cell attributes: attribute values of rows
- for row attributes: attribute values of columns
- for column attributes: attribute values of the list box

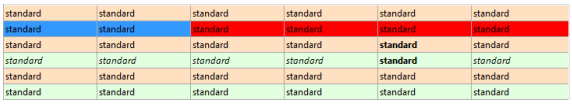
This way, if you want for an object to inherit the attribute value from a higher level, you can use pass the lk inherited constant (default value) to the definition command or directly in the element of the corresponding style/color array.

Given a list box containing a standard font style with alternating colors:

| | | | | | |
|---|---|---|---|---|---|
| standard | standard | standard | standard | standard | standard |
| standard | standard | standard | standard | standard | standard |
| standard | standard | standard | standard | standard | standard |
| standard | standard | standard | standard | standard | standard |
| standard | standard | standard | standard | standard | standard |
| standard | standard | standard | standard | standard | standard |

You perform the following modifications:

- change the background of row 2 to red using the **Row Background Color Array** property of the list box object,
- change the style of row 4 to italics using the **Row Style Array** property of the list box object,
- two elements in column 5 are changed to bold using the **Row Style Array** property of the column 5 object,
- the 2 elements for column 1 and 2 are changed to dark blue using the **Row Background Color Array** property for the column 1 and 2 objects:



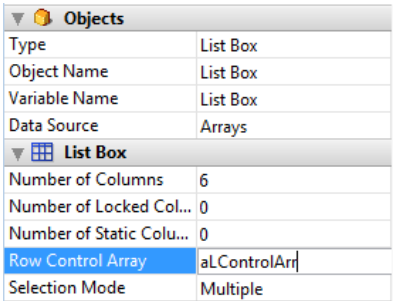
To restore the original appearance of the list box, you can:

- pass the lk inherited constant in element 2 of the background color arrays for columns 1 and 2: then they inherit the red background color of the row.
- pass the lk inherited constant in elements 3 and 4 of the style array for column 5: then they inherit the standard style, except for element 4, which changes to italics as specified in the style array of the list box.
- pass the lk inherited constant in element 4 of the style array for the list box in order to remove the italics style.
- pass the lk inherited constant in element 2 of the background color array for the list box in order to restore the original alternating color of the list box.

## Managing row display

You can set the "hidden", "disabled" and "selectable" interface properties for each row in an array-based list box.

These settings can be handled by means of the **Row Control Array**, which you can designate using the **LISTBOX SET ARRAY** command or through the Property list:



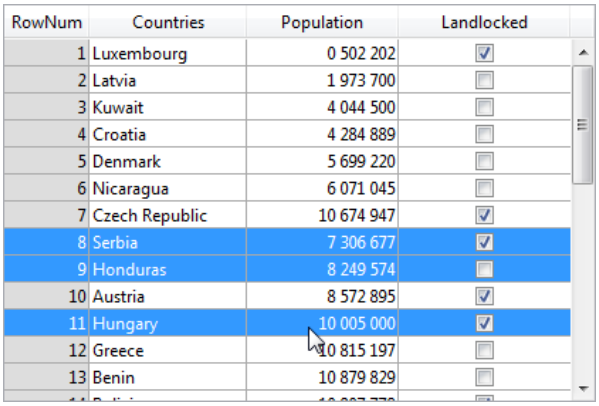
A row control array must be of the Longint type and include the same number of rows as the list box. For more information, refer to the **List box specific properties** section.

Each element of the **Row Control Array** array defines the interface status of its corresponding row in the list box. Three interface properties are available using constants in the "List Box" constant theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk row is disabled | Longint | 2 | The corresponding row is disabled. The text and controls such as check boxes are dimmed or grayed out. Enterable text input areas are no longer enterable. Default value: Enabled |
| lk row is hidden | Longint | 1 | The corresponding row is hidden. Hiding rows only affects the display of the list box. The hidden rows are still present in the arrays and can be managed by programming. The language commands, more particularly **LISTBOX Get number of rows** or **LISTBOX GET CELL POSITION**, do not take the displayed/hidden status of rows into account. For example, in a list box with 10 rows where the first 9 rows are hidden, **LISTBOX Get number of rows** returns 10. From the user's point of view, the presence of hidden rows in a list box is not visibly discernible. Only visible rows can be selected (for example using the Select All command). Default value: Visible |
| lk row is not selectable | Longint | 4 | The corresponding row is not selectable (highlighting is not possible). Enterable text input areas are no longer enterable unless the "Single-Click Edit" option is enabled. Controls such as check boxes and lists are still functional however. This setting is ignored if the list box selection mode is "None". Default value: Selectable |

To change the status for a row, you just need to set the appropriate constant(s) to the corresponding array element. For example, if you do not want row #10 to be selectable, you can write:

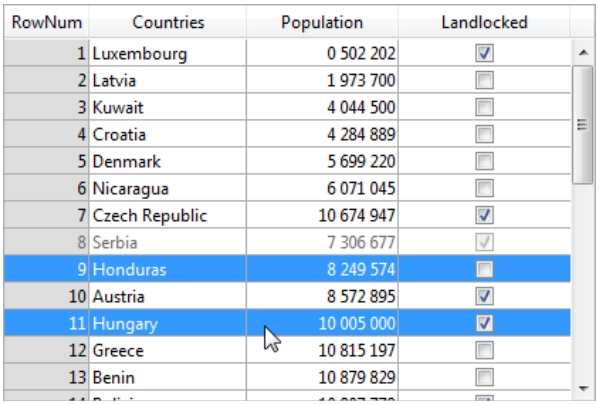
```
aLControlArr{10}:=lk row is not selectable
```



| RowNum | Countries | Population | Landlocked |
|---|---|---|---|
| 1 | Luxembourg | 0 502 202 | ☑ |
| 2 | Latvia | 1 973 700 | ☐ |
| 3 | Kuwait | 4 044 500 | ☐ |
| 4 | Croatia | 4 284 889 | ☐ |
| 5 | Denmark | 5 699 220 | ☐ |
| 6 | Nicaragua | 6 071 045 | ☐ |
| 7 | Czech Republic | 10 674 947 | ☑ |
| 8 | Serbia | 7 306 677 | ☑ |
| 9 | Honduras | 8 249 574 | ☐ |
| 10 | Austria | 8 572 895 | ☑ |
| 11 | Hungary | 10 005 000 | ☑ |
| 12 | Greece | 10 815 197 | ☐ |
| 13 | Benin | 10 879 829 | ☐ |

You can define several interface properties at once:

```
aLControlArr{8}:=lk row is not selectable+lk row is disabled
```



| RowNum | Countries | Population | Landlocked |
|---|---|---|---|
| 1 | Luxembourg | 0 502 202 | ☑ |
| 2 | Latvia | 1 973 700 | ☐ |
| 3 | Kuwait | 4 044 500 | ☐ |
| 4 | Croatia | 4 284 889 | ☐ |
| 5 | Denmark | 5 699 220 | ☐ |
| 6 | Nicaragua | 6 071 045 | ☐ |
| 7 | Czech Republic | 10 674 947 | ☑ |
| 8 | Serbia | 7 306 677 | ☑ |
| 9 | Honduras | 8 249 574 | ☐ |
| 10 | Austria | 8 572 895 | ☑ |
| 11 | Hungary | 10 005 000 | ☑ |
| 12 | Greece | 10 815 197 | ☐ |
| 13 | Benin | 10 879 829 | ☐ |

Note that setting properties for an element overrides any other values for this element (if not reset). For example:

```
aLControlArr{6}:=lk row is disabled+lk row is not selectable //sets row 6 as disabled AND not selectable
aLControlArr{6}:=lk row is disabled //sets row 6 as disabled but selectable again
```

## Displaying the result of an SQL query in a list box

It is possible to place the results of an SQL query directly in an array type list box. This offers a rapid means for viewing the results of SQL queries. Only queries of the **SELECT** type can be used. This mechanism cannot be used with an external SQL database.

It works according to the following principles:

- Create the list box which will receive the query results. The data source of the list box must be **Arrays**.
- Execute an SQL query of the **SELECT** type and assign the result to the variable associated with the list box. You can use the **Begin SQL**/**End SQL** keywords (see the 4D *Language Reference* manual).
- List box columns can be sorted or modified by the user.
- Each new execution of a **SELECT** query with the list box leads to the resetting of the columns (it is not possible to fill the same list box progressively using several **SELECT** queries).
- It is recommended to give the list box the same number of columns as there will be in the SQL query result. If the number of list box columns is less than that required by the **SELECT** query, columns are added automatically. If the number of columns is more than required by the **SELECT** query, the unnecessary columns are automatically hidden. **Note:** The columns added automatically are bound to **Dynamic variables** of the array type. These dynamic arrays last as long as the form does. A dynamic variable is also created for each header. When the **LISTBOX GET ARRAYS** command is called, the *arrColVars* parameter contains pointers to the dynamic arrays and the *arrHeaderVars* parameter contains pointers to the dynamic header variables. If the added column is, for example, the fifth column, its name is *sql_column5* and its header name is *sql_header5*.
- In interpreted mode, existing arrays that are used by the list box can be retyped automatically according to the data sent by the SQL query.

**Example**

We want to retrieve all the fields of the PEOPLE table and put their contents into the list box having the variable name *vlistbox*. In the object method of a button (for example), simply write:

```
Begin SQL
   SELECT * FROM PEOPLE INTO <<vlistbox>>
End SQL
```

# Managing Hierarchical List Boxes

4D lets you specify and use hierarchical list boxes. A hierarchical list box is a list box in which the contents of the first column appears in hierarchical form. This type of representation is adapted to the presentation of information including repeated values and/or values that are hierarchically dependent (country/region/city and so on).

Only **list boxes of the array type** can be hierarchical.

Hierarchical list boxes are a particular way of representing data but they do not modify the structure of these data (the arrays). Hierarchical list boxes are filled and managed exactly the same way as regular list boxes (see **Managing List Box Objects**).

To specify a hierarchical list box, there are three different possibilities:

- manually configure hierarchical elements using the Property list of the form editor or using the list box management pop-up menu. These points are covered in the *Design Reference* manual of 4D.
- use the **LISTBOX SET HIERARCHY** and **LISTBOX GET HIERARCHY** commands.

When a form containing a hierarchical list box is opened for the first time, by default all the rows are expanded.
A break row and a hierarchical "node" are automatically added in the list box when values are repeated in the arrays. For example, imagine a list box containing four arrays specifying cities, each city being characterized by a country, a region, a name and a number of inhabitants:

| Country | Region | City | Population |
|---|---|---|---|
| France | Brittany | Rennes | 200000 |
| France | Brittany | Quimper | 80000 |
| France | Brittany | Brest | 120000 |
| France | Normandy | Caen | 75000 |
| France | Normandy | Deauville | 35000 |

If this list box is displayed in hierarchical form (the first three arrays being included in the hierarchy), you will obtain:

| City | Population |
|---|---|
| France | |
| Brittany | |
| Rennes | 200000 |
| Quimper | 80000 |
| Brest | 120000 |
| Normandy | |
| Caen | 75000 |
| Deauville | 35000 |

The arrays are not sorted before the hierarchy is constructed. If, for example, an array contains the data AAABBAACC, the hierarchy obtained will be:

> A
> B
> A
> C

To expand or collapse a hierarchical "node", simply click on it. If you **Alt+click** (Windows) or **Option+click** (Mac OS) on the node, all its sub-elements will be expanded or collapsed. These operations can also be carried out by programming using the **LISTBOX EXPAND** and **LISTBOX COLLAPSE** commands.

## Management of selections and positions

A hierarchical list box displays a variable number of rows on screen according to the expanded/collapsed state of the hierarchical nodes. This does not however mean that the number of rows of the arrays vary. Only the display is modified, not the data.

It is important to understand this principle because programmed management of hierarchical list boxes is always based on the data of the arrays, not on the displayed data. In particular, the break rows added automatically are not taken into account in the display options arrays (see below).

Let’s look at the following arrays for example:

| | | |
|---|---|---|
| France | Brittany | Brest |
| France | Brittany | Quimper |
| France | Brittany | Rennes |

If these arrays are represented hierarchically, the row "Quimper" will not be displayed on the second row, but on the fourth, because of the two break rows that are added:

| |
|---|
| France |
| Brittany |
| Brest |
| Quimper |
| Rennes |

Regardless of how the data are displayed in the list box (hierarchically or not), if you want to change the row containing "Quimper" to bold, you must use the statement Style{2} = bold. Only the position of the row in the arrays is taken into account.

This principle is implemented for internal arrays that can be used to manage:

- colors
- background colors
- styles
- hidden rows
- selections

For example, if you want to select the row containing Rennes, you must pass:

```
->MyListbox{3}:=True
```

*Non-hierarchical representation:*

| | | |
|---|---|---|
| France | Brittany | Brest |
| France | Brittany | Quimper |
| France | Brittany | Rennes |

*Hierarchical representation:*

| |
|---|
| France |
| Brittany |
| Brest |
| Quimper |
| Rennes |

**Note:** If one or more rows are hidden because their parents are collapsed, they are no longer selected. Only the rows that are visible (either directly or by scrolling) can be selected. In other words, rows cannot be both hidden and selected.

As with selections, the **LISTBOX GET CELL POSITION** command will return the same values for a hierarchical list box and a non-hierarchical list box. This means that in both of the examples below, **LISTBOX GET CELL POSITION** will return the same position: (3;2).

*Non-hierarchical representation:*

| | | | |
|---|---|---|---|
| France | Brittany | Brest | 120000 |
| France | Brittany | Quimper | 80000 |
| France | Brittany | Rennes | 200000 |
| France | Normandy | Caen | 75000 |

*Hierarchical representation:*

| | |
|---|---|
| France | |
| Brittany | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| Normandy | |
| Caen | 75000 |

## Management of break rows

If the user selects a break row, **LISTBOX GET CELL POSITION** returns the first occurrence of the row in the corresponding array. In the following case:

| | |
|---|---|
| France | |
| Brittany | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| Normandy | |
| Caen | 75000 |

... **LISTBOX GET CELL POSITION** returns (2;4). To select a break row by programming, you will need to use the **LISTBOX SELECT BREAK** command.

Break rows are not taken into account in the internal arrays used to manage the graphic appearance of list boxes (styles and colors). It is however possible to modify these characteristics for break rows via the graphic management commands for objects (**Objects (Forms)** theme). You simply need to execute the appropriate commands on the arrays that constitute the hierarchy.

Given for example the following list box (the names of the associated arrays are specified in parentheses):

*Non-hierarchical representation:*

| (T1) | (T2) | (T3) | (T4) | (tStyle) | (tColor) |
|---|---|---|---|---|---|
| France | Brittany | Brest | 120000 | *Normal* | *0* |
| France | Brittany | Quimper | 80000 | *Underline* | *0* |
| France | Brittany | Rennes | 200000 | *Normal* | *0xFF0000* |
| France | Normandy | Caen | 220000 | *Normal* | *0* |
| France | Normandy | Deauville | 4000 | *Normal* | *0* |

*Hierarchical representation:*

| | |
|---|---|
| France | |
| Brittany | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| Normandy | |
| Caen | 75000 |
| Deauville | 4000 |

In hierarchical mode, break levels are not taken into account by the style modification arrays named *tStyle* and *tColors*. To modify the color or style of break levels, you must execute the following statements:

```
OBJECT SET RGB COLORS(T1;0x0000FF;0xB0B0B0)
OBJECT SET FONT STYLE(T2;Bold)
```

**Note:** In this context, only the syntax using the array variable can function with the object property commands because the arrays do not have any associated object.

Result:

| | |
|---|---|
| France | |
| **Brittany** | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| **Normandy** | |
| Caen | 75000 |
| Deauville | 4000 |

### Hidden rows

When all the rows of a sub-hierarchy are hidden, the break line is automatically hidden. In the above example, if rows 1 to 3 are hidden, the "Brittany" break row will not appear.

## Optimized management of expand/collapse

You can optimize hierarchical list boxes display and management using the On Expand and On Collapse form events.

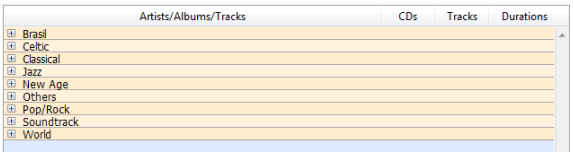
A hierarchical list box is built from the contents of its arrays so it can only be displayed when all these arrays are loaded into memory. This makes it difficult to build large hierarchical list boxes based on arrays generated from data (through the **SELECTION TO ARRAY** command), not only because of the display speed but also the memory used.

Using the On Expand and On Collapse form events can overcome these constraints: for example, you can now display only part of the hierarchy and load/unload the arrays on the fly, based on user actions.

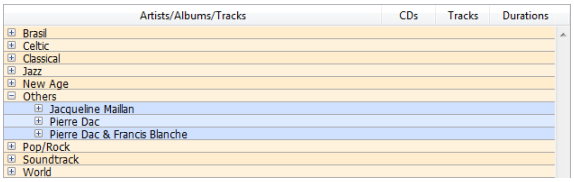
In the context of these events, the **LISTBOX GET CELL POSITION** command returns the cell where the user clicked in order to expand or collapse a row.

In this case, you must fill and empty arrays through the code. The principles to be implemented are:

- When the list box is displayed, only the first array must be filled. However, you must create a second array with empty values so that the list box displays the expand/collapse buttons:



- When a user clicks on an expand button, you can process the On Expand event. The **LISTBOX GET CELL POSITION** command returns the cell concerned and lets you build the appropriate hierarchy: you fill the first array with the repeated values and the second with the values sent from the **SELECTION TO ARRAY** command and you insert as many rows as needed in the list box using the **LISTBOX INSERT ROWS** command.

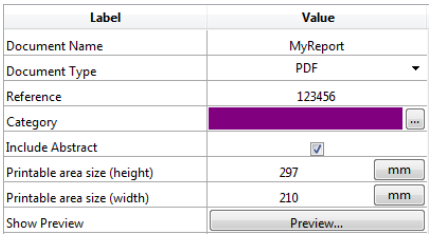


- When a user clicks on a collapse button, you can process the On Collapse event. The **LISTBOX GET CELL POSITION** command returns the cell concerned: you remove as many rows as needed from the list box using the **LISTBOX DELETE ROWS** command.

# Using object arrays in columns (4D View Pro)

List box columns can work with object arrays. Since object arrays can contain different kinds of data, this powerful feature allows you to enter and display various types of values in the rows of a single column, and use various widgets as well. For example, you could insert a text input in the first row, a check box in the second, and a drop-down list in the third. Object arrays also provide access to new kinds of widgets, such as buttons or color pickers.

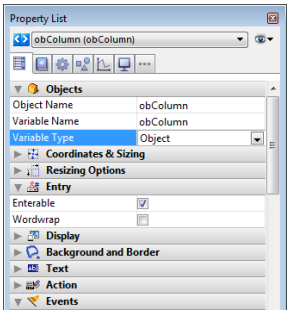
The following list box was designed using an object array:



**About 4D View Pro:** The ability to use object arrays in list boxes is a "4D View Pro" function, which means that its use requires you to have a valid 4D View license. 4D View Pro is a new tool being developed which includes a set of features related to arrays and list presentations. It is intended to progressively replace the 4D View plug-in. For more information, please refer to the 4D Web site.

## Configuring an object array column

To assign an object array to a list box column, you just need to set the object array name in either the Property list ("Variable Name" field), or using the **LISTBOX INSERT COLUMN** command, like with any array-based column. In the Property list, you can select **Object** as a "Variable Type" for the column:



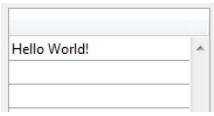
Standard properties related to coordinates, size, and style are available for object columns. You can define them using the Property list, or by programming the style, font color, background color and visibility for each row of an object-type list box column. These types of columns can also be hidden.

However, the **Data Source** theme is not available for object-type list box columns. In fact, the contents of each column cell are based on attributes found in the corresponding element of the object array. Each array element can define:

- the value type (*mandatory*): text, color, event, etc.
- the value itself (*optional*): used for input/output.
- the cell content display (*optional*): button, list, etc.
- additional settings (*optional*): depend on the value type

To define these properties, you need to set the appropriate attributes in the object (available attributes are listed below). For example, you can write "Hello World!" in an object column using this simple code:

```
ARRAY OBJECT(obColumn;0) //column array
C_OBJECT($ob) //first element
OB SET($ob;"valueType";"text") //defines the value type (mandatory)
OB SET($ob;"value";"Hello World!") //defines the value
APPEND TO ARRAY(obColumn;$ob)
```



**Note:** Display format and entry filters cannot be set for an object column. They automatically depend on the value type.

## valueType and data display

When a list box column is associated with an object array, the way a cell is displayed, entered, or edited, is based on the **valueType** attribute of the array element. Supported **valueType** values are:

- "text": for a text value
- "real": for a numeric value that can include separators like a <space>, <.>, or <,>
- "integer": for an integer value
- "boolean": for a True/False value
- "color": to define a background color
- "event": to display a button with a label.

4D uses default widgets with regards to the "valueType" value (i.e., a "text" is displayed as a text input widget, a "boolean" as a check box), but alternate displays are also available through options (e.g., a real can also be represented as a drop-down menu). The following table shows the default display as well as alternatives for each type of value:

| valueType | Default widget | Alternative widget(s) |
|---|---|---|
| text | text input | drop-down menu (required list) or combo box (choice list) |
| real | controlled text input (numbers and separators) | drop-down menu (required list) or combo box (choice list) |
| integer | controlled text input (numbers only) | drop-down menu (required list) or combo box (choice list) or three-states check box |
| boolean | check box | drop-down menu (required list) |
| color | background color | text |
| event | button with label | |
| | | All widgets can have an additional **unit toggle button** or **ellipsis button** attached to the cell. |

You set the cell display and options using specific attributes in each object (see below).

### Display formats and entry filters

You cannot set display formats or entry filters for columns of object-type list boxes. They are automatically defined according to the value type. These are listed in the following table:

| Value type | Default format | Entry control |
|---|---|---|
| text | same as defined in object | any (no control) |
| real | same as defined in object (using system decimal separator) | "0-9" and "." and "-" |
| | | "0-9" and "." if min>=0 |
| integer | same as defined in object | "0-9" and "-" |
| | | "0-9" if min>=0 |
| Boolean | check box | N/A |
| color | N/A | N/A |
| event | N/A | N/A |

## Attributes

Each element of the object array is an object that can contain one or more attributes that will define the cell contents and data display (see example above).

The only mandatory attribute is "valueType" and its supported values are "text", "real", "integer", "boolean", "color", and "event". The following table lists all the attributes supported in list box object arrays, depending on the "valueType" value (any other attributes are ignored). Display formats are detailed and examples are provided below.

| | valueType | text | real | integer | boolean | color | event |
|---|---|---|---|---|---|---|---|
| ***Attributes*** | ***Description*** | | | | | | |
| **value** | cell value (input or output) | x | x | x | | | |
| **min** | minimum value | | x | x | | | |
| **max** | maximum value | | x | x | | | |
| **behavior** | "threeStates" value | | | x | | | |
| **requiredList** | drop-down list defined in object | x | x | x | | | |
| **choiceList** | combo box defined in object | x | x | x | | | |
| **requiredListReference** | 4D list ref, depends on "saveAs" value | x | x | x | | | |
| **requiredListName** | 4D list name, depends on "saveAs" value | x | x | x | | | |
| **saveAs** | "reference" or "value" | x | x | x | | | |
| **choiceListReference** | 4D list ref, display combo box | x | x | x | | | |
| **choiceListName** | 4D list name, display combo box | x | x | x | | | |
| **unitList** | array of X elements | x | x | x | | | |
| **unitReference** | index of selected element | x | x | x | | | |
| **unitsListReference** | 4D list ref for units | x | x | x | | | |
| **unitsListName** | 4D list name for units | x | x | x | | | |
| **alternateButton** | add an alternate button | x | x | x | x | x | |

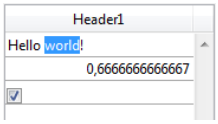
### value

Cell values are stored in the "value" attribute. This attribute is used for input as well as output. It can also be used to define default values when using lists (see below).

**Example:**

```
ARRAY OBJECT(obColumn;0) //column array
C_OBJECT($ob1)
$entry:="Hello world!"
OB SET($ob1;"valueType";"text")
OB SET($ob1;"value";$entry) // if the user enters a new value, $entry will contain the edited value
C_OBJECT($ob2)
OB SET($ob2;"valueType";"real")
OB SET($ob2;"value";2/3)
C_OBJECT($ob3)
OB SET($ob3;"valueType";"boolean")
OB SET($ob3;"value";True)

APPEND TO ARRAY(obColumn;$ob1)
APPEND TO ARRAY(obColumn;$ob2)
APPEND TO ARRAY(obColumn;$ob3)
```



**Note:** Null values are supported and result in an empty cell.

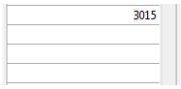
### min and max

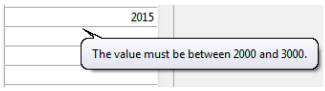
When the "valueType" is "real" or "integer", the object also accepts **min** and **max** attributes with appropriate values (values must be of the same type as the valueType).

These attributes can be used to control the range of input values. When a cell is validated (when it loses the focus), if the input value is lower than the **min** value or greater than the **max** value, then it is rejected. In this case, the previous value is maintained and a tip displays an explanation.

**Example:**

```
C_OBJECT($ob3)
$entry3:=2015
OB SET($ob3;"valueType";"integer")
OB SET($ob3;"value";$entry3)
OB SET($ob3;"min";2000)
OB SET($ob3;"max";3000)
```





### behavior

The **behavior** attribute provides variations to the regular representation of values. In the current version of 4D, a single variation is proposed:

| Attribute | Available value(s) | valueType(s) | Description |
|---|---|---|---|
| behavior | threeStates | integer | Represents a numeric value as a three-states check box. 2=semi-checked, 1=checked, 0=unchecked, -1=invisible, -2=unchecked disabled, -3=checked disabled, -4=semi-checked disabled |

**Example:**

```
C_OBJECT($ob3)
OB SET($ob3;"valueType";"integer")
OB SET($ob3;"value";-3)
C_OBJECT($ob4)
OB SET($ob4;"valueType";"integer")
OB SET($ob4;"value";-3)
OB SET($ob4;"behavior";"threeStates")
```

### requiredList and choiceList

When a "choiceList" or a "requiredList" attribute is present inside the object, the text input is replaced by a drop-down list or a combo box, depending of the attribute:

- If the attribute is "choiceList", the cell is displayed as a combo box. This means that the user can select or type a value.
- If the attribute is "requiredList" then the cell is displayed as a drop-down list and the user can only select one of the values provided in the list.

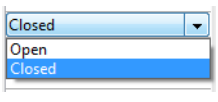
In both cases, a "value" attribute can be used to preselect a value in the widget.

**Note:** The widget values are defined through an array. If you want to assign an existing 4D list to the widget, you need to use the "requiredListReference", "requiredListName", "choiceListReference", or "choiceListName" attributes.

**Examples:**

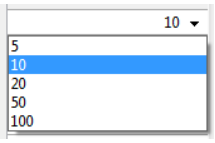
- You want to display a drop-down list with only two options: "Open" or "Closed". "Closed" must be preselected:

```
ARRAY TEXT($RequiredList;0)
APPEND TO ARRAY($RequiredList;"Open")
APPEND TO ARRAY($RequiredList;"Closed")
C_OBJECT($ob)
OB SET($ob;"valueType";"text")
OB SET($ob;"value";"Closed")
OB SET ARRAY($ob;"requiredList";$RequiredList)
```



- You want to accept any integer value, but display a combo box to suggest the most common values:

```
ARRAY LONGINT($ChoiceList;0)
APPEND TO ARRAY($ChoiceList;5)
APPEND TO ARRAY($ChoiceList;10)
APPEND TO ARRAY($ChoiceList;20)
APPEND TO ARRAY($ChoiceList;50)
APPEND TO ARRAY($ChoiceList;100)
C_OBJECT($ob)
OB SET($ob;"valueType";"integer")
OB SET($ob;"value";10) //10 as default value
OB SET ARRAY($ob;"choiceList";$ChoiceList)
```



### requiredListName and requiredListReference

The "requiredListName" and "requiredListReference" attributes allow you to use, in a list box cell, a list defined in 4D either in Design mode (in the **Lists** editor of the Tool box) or by programming (using the **New list** command). The cell will then be displayed as a drop-down list. This means that the user can only select one of the values provided in the list.

Use "requiredListName" or "requiredListReference" depending on the origin of the list: if the list comes from the Tool box, you pass a name; otherwise, if the list has been defined by programming, you pass a reference. In both cases, a "value" attribute can be used to preselect a value in the widget.

**Note:** If you want to define these values through a simple array, you need to use the "requiredList" attribute.

In this case, the "saveAs" attribute will define whether the selected item must be saved as a "value" or as a "reference".

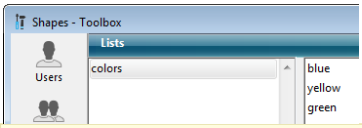
- If "saveAs" = "reference" then it will be saved as a reference and the "valueType" must be real or integer.
- If "saveAs" = "value" then the value is saved. In this case, the "valueType" must be the same type as the values of the list, usually "text" or "integer"; otherwise 4D will try to convert the value of the list into the "valueType" of the object (see examples below).

For more information about the "save as" option, please refer to the **Save as Value or Reference** section in the *Design Reference* manual.

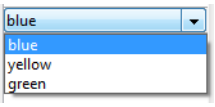
**Note:** If the list contains text items representing real values, the decimal separator must be a period ("."), regardless of the local settings, e.g.: "17.6" "1234.456".

**Examples:**

- You want to display a drop-down list based on a "colors" list defined in the Tool box (containing the values "blue", "yellow", and "green"), save it as a value and display "blue" by default:

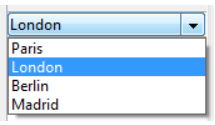


```
C_OBJECT($ob)
OB SET($ob;"valueType";"text")
OB SET($ob;"saveAs";"value")
OB SET($ob;"value";"blue")
OB SET($ob;"requiredListName";"colors")
```



- You want to display a drop-down list based on a list defined by programming and save it as a reference:

```
<>List:=New list
APPEND TO LIST(<>List;"Paris";1)
APPEND TO LIST(<>List;"London";2)
APPEND TO LIST(<>List;"Berlin";3)
APPEND TO LIST(<>List;"Madrid";4)
C_OBJECT($ob)
OB SET($ob;"valueType";"integer")
OB SET($ob;"saveAs";"reference")
OB SET($ob;"value";2) //displays London by default
OB SET($ob;"requiredListReference";<>List)
```



### choiceListName and choiceListReference

The "choiceListName" and "choiceListReference" attributes allow you to use, in a list box cell, a list defined in 4D either in Design mode (in the Tool box) or by programming (using the **New list** command). The cell is then displayed as a combo box, which means that the user can select or type a value.

Use "choiceListName" or "choiceListReference" depending on the origin of the list: if the list comes from the Tool box, you pass a name; otherwise, if the list has been defined by programming, you pass a reference. In both cases, a "value" attribute can be used to preselect a value in the widget.

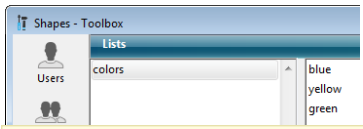
**Note:** If you want to define these values through a simple array, you need to use the "choiceList" attribute.

The "saveAs" attribute cannot be used in this case because selected items are automatically saved as a "value" (cf. for more information).

**Note:** If the list contains text items representing real values, the decimal separator must be a period ("."), regardless of the local settings, e.g.: "17.6" "1234.456".

**Example:**

You want to display a combo box based on a "colors" list defined in the Tool box (containing the values "blue", "yellow", and "green") and display "green" by default:



```
C_OBJECT($ob)
OB SET($ob;"valueType";"text")
OB SET($ob;"value";"blue")
OB SET($ob;"choiceListName";"colors")
```

### unitsList, unitsListName, unitsListReference and unitReference

You can use specific attributes to add units associated with cell values (e.g.: "10 cm", "20 pixels", etc.). To define the unit list, you can use one of the following attributes:

- "unitsList": an array containing the *x* elements used to define the available units (e.g.: "cm", "inches", "km", "miles", etc.). Use this attribute to define units within the object.
- "unitsListReference": a reference to a 4D list containing available units. Use this attribute to define units with a 4D list created with the **New list** command.
- "unitsListName": a name of a design-based 4D list that contains available units. Use this attribute to define units with a 4D list created in the Tool box.

Regardless of the way the unit list is defined, it can be associated with the following attribute:

- "unitReference": a single value that contains the index (from 1 to *x*) of the selected item in the "unitList", "unitsListReference" or "unitsListName" values list.

The current unit is displayed as a button that cycles through the "unitList", "unitsListReference" or "unitsListName" values each time it is clicked (e.g., "pixels" -> "rows" -> "cm" -> "pixels" -> etc.)

**Example:** We want to set up a numeric input followed by two possible units: "rows" or "pixels". The current value is "2" + "lines". We use values defined directly in the object ("unitsList" attribute):

```
ARRAY TEXT($_units;0)
APPEND TO ARRAY($_units;"lines")
APPEND TO ARRAY($_units;"pixels")
C_OBJECT($ob)
OB SET($ob;"valueType";"integer")
OB SET($ob;"value";2) // 2 "units"
OB SET($ob;"unitReference";1) //"lines"
OB SET ARRAY($ob;"unitsList";$_units)
```

### alternateButton

If you want to add an ellipsis button [**...**] to a cell, you just need to pass the "alternateButton" with the **True** value in the object. The button will be displayed in the cell automatically.

When this button is clicked by a user, an On Alternate Click event will be generated, and you will be able to handle it however you want (see the "**Event management**" section below for more information).

**Example:**

```
C_OBJECT($ob1)
$entry:="Hello world!"
OB SET($ob;"valueType";"text")
OB SET($ob;"alternateButton";True)
OB SET($ob;"value";$entry)
```

## color valueType

The "color" *valueType* allows you to display either a color or a text.

- If the value is a number, a colored rectangle is drawn inside the cell. Example:

```
C_OBJECT($ob4)
OB SET($ob4;"valueType";"color")
OB SET($ob4;"value";0x00FF0000)
```

- If the value is a text, then the text is displayed (e.g.: "value";"Automatic").

## event valueType

The "event" *valueType* displays a simple button that generates an On Clicked event when clicked. No data or value can be passed or returned.

Optionally, you can pass a "label" attribute.

Example:

```
C_OBJECT($ob)
OB SET($ob;"valueType";"event")
OB SET($ob;"label";"Edit...")
```

## Event management

Several events can be handled while using an object list box array:

- **On Data Change**: An On Data Change event is triggered when any value has been modified either:
  - in a text input zone
  - in a drop-down list
  - in a combo box area
  - in a unit button (switch from value x to value x+1)
  - in a check box (switch between checked/unchecked)
- **On Clicked**: When the user clicks on a button installed using the "event" *valueType* attribute, an On Clicked event will be generated. This event is managed by the programmer.
- **On Alternative Click**: When the user clicks on an ellipsis button ("alternateButton" attribute), an On Alternative Click event will be generated. This event is managed by the programmer.

**Compatibility note (4D v15): On Alternative Click** is the new name of the **On Arrow Click** event that was available in previous versions of 4D. This event has been renamed since its scope has been extended.

# 4D View Pro

## About 4D View Pro

4D View Pro is a new tool being developed by 4D. It provides a set of advanced features related to arrays and list presentations, and is essentially based upon list box objects. 4D View Pro offers 4D users a modern and integrated alternative to some of the legacy 4D View product features.

## 4D View Pro feature list

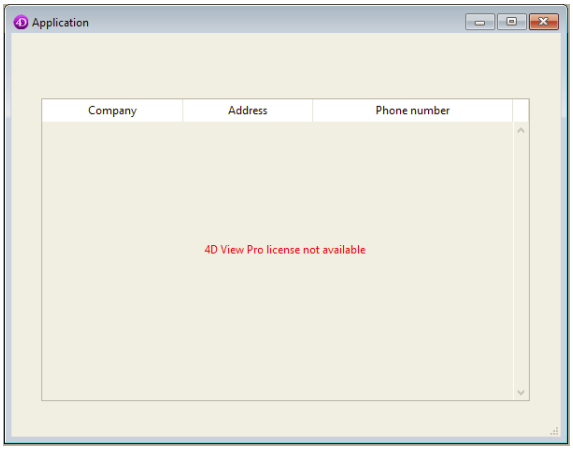
In the current version of the program, 4D View Pro provides the following features:

- Object arrays associated with a list box column (see **Using object arrays in columns (4D View Pro)**)
- Variable row height within a list box:
  - **Row Height Array** property
  - **LISTBOX Get row height** and **LISTBOX SET ROW HEIGHT** commands
  - lk row height array constant for **LISTBOX Get array** and **LISTBOX SET ARRAY** commands

## Installation and activation

Unlike with the legacy 4D View product, 4D View Pro features are directly included in 4D itself, making it easier to deploy and manage. No additional installation is required.

However, 4D View Pro requires the same license as 4D View. You need to have this license installed in your application in order to enable these features. When the 4D View license is not installed, the contents of a list box that uses a 4D View Pro feature are not displayed at runtime and an error message is displayed instead:



# LISTBOX COLLAPSE

LISTBOX COLLAPSE ( {* ;} object {; recursive {; selector {; line {; column}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| recursive | Boolean | ⇒ | True = collapse sublevels False = do not collapse sublevels |
| selector | Longint | ⇒ | Part of list box to collapse |
| line | Longint | ⇒ | Number of break row to collapse or<br>Number of list box level to collapse |
| column | Longint | ⇒ | Number of break column to collapse |

## Description

The **LISTBOX COLLAPSE** command is used to collapse the break rows of the list box object designated by the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

If the list box is not configured in hierarchical mode, the command does nothing. For more information about hierarchical list boxes, please refer to the **Managing Hierarchical List Boxes** section.

The optional *recursive* parameter is used to configure the collapsing of the hierarchical sublevels of the list box. Pass True or omit this parameter for the command to collapse all the levels and all the sublevels. If you pass False, only the first level will be collapsed.

The optional *selector* parameter is used to specify the scope of the command. You can pass one of the following constants, found in the **List Box** theme, in this parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk all | Longint | 0 | The command affects all sub-levels (default value, used when parameter is omitted). |
| lk selection | Longint | 1 | The command affects selected sub-levels. |
| lk break row | Longint | 2 | The command affects the sub-level to which the "cell" designated by the *row* and *column* parameters belongs. Note that these parameters represent the row and column numbers in the list box in standard mode and not in its hierarchical representation. If the *row* and *column* parameters are omitted, the command does nothing. |
| lk level | Longint | 3 | The command affects all the break rows corresponding to the *level* column. This parameter designates a column number in the list box in standard mode and not in its hierarchical representation. If the *level* parameter is omitted, the command does nothing. |

If the selection or list box does not contain a break row or if all the break rows are already collapsed, the command does nothing.

## Example

This example collapses the first level of the break rows of the selection in the list box:

```
LISTBOX COLLAPSE(*;"MyListbox";False;lk selection)
```

# LISTBOX DELETE COLUMN

LISTBOX DELETE COLUMN ( {* ;} object ; colPosition {; number} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| colPosition | Longint | ➡ | Column number to remove |
| number | Longint | ➡ | Number of columns to be removed |

## Description

The **LISTBOX DELETE COLUMN** command removes one or more columns (visible or invisible) in the list box set in the *object* and * parameters.

**Note:** This command does nothing if it is applied to the first column of a list box displayed in hierarchical mode.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

If you do not pass the optional *number* parameter, the command simply removes the column set in the *colPosition* parameter.

Otherwise, the *number* parameter indicates the number of columns to remove to the right starting from the column *colPosition* (this one included).

If the *colPosition* parameter is greater than the number of columns in the list box, the command does nothing.

# LISTBOX DELETE ROWS

LISTBOX DELETE ROWS ( {* ;} object ; rowPosition {; numRows} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| rowPosition | Longint | ⇒ | Position of the row to delete |
| numRows | Longint | ⇒ | Number of rows to delete |

## Description

The **LISTBOX DELETE ROWS** command deletes one or several row(s) starting at *rowPosition* row (visible or not) from the list box set in the *object* and * parameters.

**Note:** This command only works with list boxes based on arrays. When this command is used with a list box based on a selection, it does nothing and the OK system variable is set to 0.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

Keep in mind that after command execution, there will no longer be any element selected in the list box.

The *rowPosition* row is automatically removed from all the arrays used by the list box columns.

If the *rowPosition* value is higher than the total number of rows in the list box, or if it is less than 1, the command does nothing.

**Note:** This command does not take into account any hidden/displayed states of list box rows.

# LISTBOX DUPLICATE COLUMN

LISTBOX DUPLICATE COLUMN ( {* ;} object ; colPosition ; colName ; colVariable ; headerName ; headerVar {; footerName ; footerVar} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or **Variable (if * is omitted) of the column to be duplicated** |
| colPosition | Longint | ⇒ | Location of new duplicated column |
| colName | String | ⇒ | Name of new column |
| colVariable | Array, Field, Variable, Nil pointer | ⇒ | Name of the column array variable or field or variable |
| headerName | String | ⇒ | Column header object name |
| headerVar | Integer variable, Nil pointer | ⇒ | Column header variable |
| footerName | String | ⇒ | Column footer object name |
| footerVar | Variable, Nil pointer | ⇒ | Column footer variable |

## Description

The **LISTBOX DUPLICATE COLUMN** command duplicates the column designated by the *object* and * parameters by programming in the context of the form being executed (Application mode). The original form, generated in the Design mode, is not modified.

**Note:** This functionality was already found in 4D, in Design mode only, using the **Duplicate Column** command found in the context menu of the Form editor.

By default, all style options (size, color, formats, etc.) set for the source column by means of the Property list or using object management commands (**OBJECT SET COLOR**, etc.) are applied to the copy. The object method and the settings of the form events are also duplicated.
However, the data source (array or selection, depending on the source type set for the list box) as well as the style and color arrays are not duplicated. It is your responsibility to define them for each new column after duplication.

The *object* and * parameters designate the column to duplicate. Passing the optional * parameter indicates that the object parameter is an column name (string). If you do not pass this parameter, it indicates that the *object* parameter is a column variable. In this case, you pass a variable reference instead of a string.

**Note:** This command does nothing when it is applied to the first column of a list box displayed in hierarchical mode.

The new duplicated column is placed just before the column designated by the *colPosition* parameter. If the *colPosition* parameter is greater than the total number of columns, then the duplicated column is placed after the last column.

In the *colName* and *colVariable* parameters, pass the object name and the variable of the new duplicated column.

- For array type list boxes, the variable name corresponds to the name of the array whose contents will be displayed in the column. You can pass a Nil (->[]) pointer in a dynamic context (see below).
- For selection type list boxes, you can pass a field or variable in the *colVariable* parameter. So the contents of the column will be the value of this field or variable, evaluated for each record of the selection associated with the list box. This type of content can only be used when the "Data Source" property of the list box is set to Current Selection or Named Selection.

Remember that the data source of the original column is not duplicated: you must set a source variable, array or field for the new duplicated column.

In the *headerName* and *headerVariable* parameters, pass the object name and variable for the header of the new duplicated column. You can also pass the object name and variable for the footer of the inserted column in the *footerName* and *footerVariable* parameters. If you omit the *footerVariable* parameter, 4D uses a dynamic variable.

**Note:** Object names must be unique in a form. You must make sure that the names passed in the *colName*, *headerName* and *footerName* parameters have not already been used. Otherwise, the column is not duplicated and an error is generated.

This command must be used in the context of displaying a form. It is usually called in the On Load form event or following a user action (On Clicked event).

### Dynamic duplication

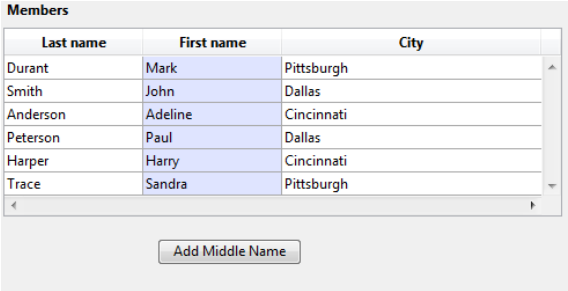
Starting with 4D v14 R3, you can duplicate list box columns dynamically and 4D will automatically handle the definition of the necessary variables (column, footer and header).

To do this, **LISTBOX DUPLICATE COLUMN** accepts a **Nil** (**->[]**) pointer as a value for the *colVariable* (array type list box only), *headerVar* and *footerVar* parameters. In this case, when the command is executed, 4D creates the required variables dynamically (for more information, refer to the **Dynamic variables** section).

Note that header and footer variables are always created with a specific type (longint and text, respectively). Conversely, column variables cannot be typed when created because list boxes accept different types of arrays for these variables (text array, integer array, and so on). This means you have to set the array type manually (see example 2). It is important to perform this typing before calling commands such as **LISTBOX INSERT ROWS** to insert new elements in the array. Alternatively, you can use **APPEND TO ARRAY** both for setting the type of the array and inserting elements.

## Example 1

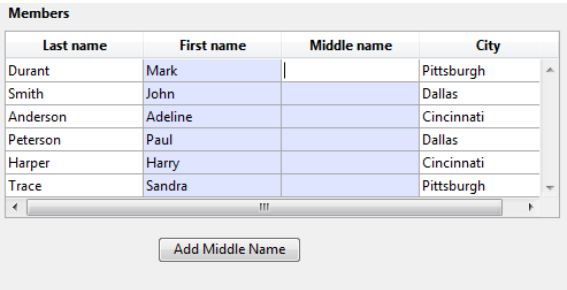
In an array type list box, we want to duplicate the "First Name" column, ready for input:



Here is the code of the button:

```
ARRAY TEXT(arrFirstNames2;Records in table([Members]))
LISTBOX DUPLICATE COLUMN(*;"column2";3;"col2bis";arrFirstNames2;"FirstNameA";vHead2A)
OBJECT SET TITLE(*;"FirstNameA";"Middle Name")
EDIT ITEM(*;"col2A";0)
```

When you click on the button, the list box appears as follows:



## Example 2

You want to duplicate a Boolean column and change its title:

```
C_POINTER($ptr)
LISTBOX DUPLICATE COLUMN(*;"boolCol";3;"duplBoolCol";$ptr;"duplBoolHeader";$ptr;"duplBoolFooter";$ptr)
colprt:=OBJECT Get pointer(Object named;"duplBoolCol")
ARRAY BOOLEAN(colprt->;10)
headprt:=OBJECT Get pointer(Object named;"duplBoolHeader")
OBJECT SET TITLE(headprt->;"New duplicated column")
```

# LISTBOX EXPAND

LISTBOX EXPAND ( {* ;} object {; recursive {; selector {; line {; column}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| recursive | Boolean | ➡ | True = expand sublevels False = do not expand sublevels |
| selector | Longint | ➡ | Part of list box to expand |
| line | Longint | ➡ | Number of break row to expand or<br>Number of list box level to expand |
| column | Longint | ➡ | Number of break column to expand |

## Description

The **LISTBOX EXPAND** command is used to expand the break rows of the list box object designated by the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

If the list box is not configured in hierarchical mode, the command does nothing. For more information about hierarchical list boxes, please refer to the **Managing Hierarchical List Boxes** section.

The optional *recursive* parameter is used to configure the expanding of the hierarchical sublevels of the list box. Pass True or omit this parameter for the command to expand all the levels and all the sublevels. If you pass False, only the first level specified will be expanded.

The optional *selector* parameter is used to specify the scope of the command. You can pass one of the following constants, found in the **List Box** theme, in this parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk all | Longint | 0 | The command affects all sub-levels (default value, used when parameter is omitted). |
| lk selection | Longint | 1 | The command affects selected sub-levels. |
| lk break row | Longint | 2 | The command affects the sub-level to which the "cell" designated by the *row* and *column* parameters belongs. Note that these parameters represent the row and column numbers in the list box in standard mode and not in its hierarchical representation. If the *row* and *column* parameters are omitted, the command does nothing. |
| lk level | Longint | 3 | The command affects all the break rows corresponding to the *level* column. This parameter designates a column number in the list box in standard mode and not in its hierarchical representation. If the *level* parameter is omitted, the command does nothing. |

The command does not select break rows.

If the selection or list box does not contain a break row or if all the break rows are already expanded, the command does nothing.

## Example

This example illustrates different ways of using the command. Given the following arrays shown in a list box:

| | | | |
|---|---|---|---|
| France | Brittany | Brest | 120000 |
| France | Brittany | Quimper | 80000 |
| France | Brittany | Rennes | 200000 |
| France | Normandy | Caen | 220000 |
| France | Normandy | Deauville | 4000 |
| France | Normandy | Cherbourg | 41000 |
| Belgium | Wallonia | Namur | 111000 |
| Belgium | Wallonia | Liege | 200000 |
| Belgium | Flanders | Antwerp | 472000 |
| Belgium | Flanders | Louvain | 95000 |

```
//Expand all the break rows and subrows of the list box
LISTBOX EXPAND(*;"MyListbox")
```

| | |
|---|---|
| V France | |
| V Brittany | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| V Normandy | |
| Caen | 220000 |
| Deauville | 4000 |
| Cherbourg | 41000 |
| V Belgium | |
| V Wallonia | |
| Namur | 111000 |
| Liege | 200000 |
| V Flanders | |
| Antwerp | 472000 |
| Louvain | 95000 |

```
//Expand the first level of break rows of the selection
LISTBOX EXPAND(*;"MyListbox";False;lk selection)
//If the "Belgium" row was selected
```

| |
|---|
| > France |
| V Belgium |
| > Wallonia |
| > Flanders |

```
//Expand the Brittany break row with recursion
LISTBOX EXPAND(*;"MyListbox";False;lk break row;1;2)
```

| | |
|---|---|
| V France | |
| V Brittany | |
| Brest | 120000 |
| Quimper | 80000 |
| Rennes | 200000 |
| > Normandy | |
| > Belgium | |

```
//Expand all the first columns (countries) without recursion
LISTBOX EXPAND(*;"MyListbox";False;lk level;1)
```

| |
|---|
| V France |
| > Brittany |
| > Normandy |
| V Belgium |
| > Wallonia |
| > Flanders |

# LISTBOX Get array

LISTBOX Get array ( {* ;} object ; arrType ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| arrType | Longint | ⇒ | Type of array |
| Function result | Pointer | ⇐ | Pointer to array associated with property |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX Get array** command returns a pointer to the *arrType* array of the list box or list box column designated by the *object* and * parameters.

Style, color, background color or row control arrays can be associated with array type list boxes or (except for row control arrays) with the columns of array type list boxes, using the Property list in Design mode or using the **LISTBOX SET ARRAY** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. You can designate a list box or a list box column in the *object* parameter.

In *arrType*, pass the type of array for the property you want to get. You can use one of the following constants, available in the "**List Box**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk background color array | Longint | 1 | |
| lk control array | Longint | 3 | |
| lk font color array | Longint | 0 | |
| lk row height array | Longint | 4 | (4D View Pro license required) |
| lk style array | Longint | 2 | |

The command returns one of the following values:

- **Nil** if no array for the requested property is associated with the column or the list box.
- a pointer to the array of the requested property, defined by the user.
- a pointer to the array of the requested property, defined dynamically when calling the **LISTBOX SET ROW COLOR** or **LISTBOX SET ROW FONT STYLE** command.

## Example

Typical examples of use:

```
vPtr:=LISTBOX Get array(*;"MyLB";lk font color array)
 // returns a pointer to the font color array
 // associated with the "MyLB" list box

vPtr:=LISTBOX Get array(*;"Col4";lk style array)
 // returns a pointer to the font style array
 // associated with the columns of the "Col4" list box
```

# LISTBOX GET ARRAYS

LISTBOX GET ARRAYS ( {* ;} object ; arrColNames ; arrHeaderNames ; arrColVars ; arrHeaderVars ; arrColsVisible ; arrStyles {; arrFooterNames ; arrFooterVars} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| arrColNames | String array | ⇐ | Column object names |
| arrHeaderNames | String array | ⇐ | Header object names |
| arrColVars | Pointer array | ⇐ | Pointers to column variables or Pointers to column fields or Nil |
| arrHeaderVars | Pointer array | ⇐ | Pointers to header variables |
| arrColsVisible | Boolean array | ⇐ | Visibility of each column |
| arrStyles | Pointer array | ⇐ | Pointers to arrays, or style, color and row control variables, or Nil |
| arrFooterNames | String array | ⇐ | Column footer object names |
| arrFooterVars | Pointer array | ⇐ | Pointers to column footer variables |

## Description

The **LISTBOX GET ARRAYS** command returns a set of synchronized arrays providing information on each column (visible or invisible) in the list box set in the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

Once the command is executed:

- The *arrColNames* array contains the list of object names for each column in the list box.
- The *arrHeaderNames* array contains the list of object names for each column header in the list box.
- The *arrColVars* array contains, for an array type list box, pointers toward variables (arrays) associated with each column of the list box. For a selection type list box, *arrColVars* contains:
  - For a column associated with a field, a pointer to the associated field,
  - For a column associated with a variable, a pointer to the variable,
  - For a column associated with an expression, a Nil pointer.
- The *arrHeaderVars* array contains pointers toward variables associated with each column header of the list box.
- The *arrColsVisible* array contains a Boolean value for each column, indicating whether the column is visible (**True**) or hidden (**False**) in the list box.
- The *arrStyles* array contains, for an array type list box, four pointers to four arrays that allow the applying of a specific style, font color, background color and custom display control to each row of the list box. These arrays are associated with the list box in the Property List of the Design environment or using the **LISTBOX SET ARRAY** command. If an array is not specified for the list box, the corresponding item in *arrStyles* will contain a Nil pointer.
  The fourth pointer corresponds either to a Boolean array (Hidden Rows Array), or to a longint array (array used to set hidden, disabled and non-selectable rows) based on the implementation used for the row control array (see **List box specific properties**).
  For a selection type list box, *arrStyles* contains:
  - For each configuration set via a variable, a pointer to the variable,
  - For each configuration set via an expression, a Nil pointer.

# LISTBOX GET CELL COORDINATES

LISTBOX GET CELL COORDINATES ( {* ;} object ; column ; row ; left ; top ; right ; bottom )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified = object is the name of the object (string)<br>If omitted = object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or variable (if * is omitted) |
| column | Longint | ⇒ | Column number |
| row | Longint | ⇒ | Row number |
| left | Longint | ⇐ | Left coordinate of the object |
| top | Longint | ⇐ | Top coordinate of the object |
| right | Longint | ⇐ | Right coordinate of the object |
| bottom | Longint | ⇐ | Bottom coordinate of the object |

## Description

The **LISTBOX GET CELL COORDINATES** command returns in variables or fields the *left*, *top*, *right* and *bottom* coordinates (in points) of the cell designated by the *column* and *row* parameters, in the list box defined by * and *object*.

If you pass the optional * parameter, it indicates that the *object* parameter is an object name (a string). If you don't pass the optional * parameter, this indicates that the object is a field or a variable. In this case, you pass a field or variable reference (only a field or variable of the object type) instead of a string

For consistency with the **OBJECT GET COORDINATES** command, the origin is the upper-left corner of the form which contains the cell. Also, the coordinates returned are theoretical; they take into account the scrolling state of the list box before any clipping occurs. As a result, the cell may be not visible (or only partially so) at its coordinates, and these coordinates may be outside the form limits (or even negative). To find out if the cell is displayed (and which part of it is visible) you need to compare the coordinates returned with the list box coordinates, while considering the following rules:

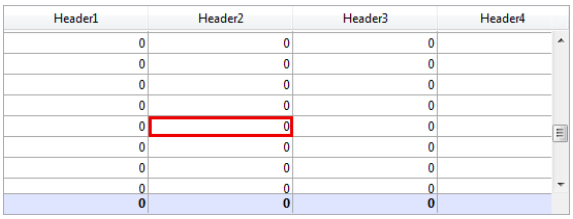
- All cells are clipped to the coordinates of their parent list box (as returned by the **OBJECT GET COORDINATES** command for the list box).
- Header and footer sub-objects are displayed on top column content: when the coordinates of a cell intersect the coordinates of the header or footer rows, then the cell is not displayed at this intersection.
- Elements of locked columns are displayed on top of elements of scrollable columns: when the coordinates of an element in a scrollable column intersect the coordinates of an element in a locked column, then it is not displayed at this intersection.

For more information, please refer to the **OBJECT GET COORDINATES** command description.

## Example

You want to draw a red rectangle around the selected cell of a list box:

```
OBJECT SET VISIBLE(*;"RedRect";False) //initialize a red rectangle
 //the rectangle is already defined somewhere in the form
LISTBOX GET CELL POSITION(*;"LB1";$col;$raw)
LISTBOX GET CELL COORDINATES(*;"LB1";$col;$raw;$x1;$y1;$x2;$y2)
OBJECT SET VISIBLE(*;"RedRect";True)
OBJECT SET COORDINATES(*;"RedRect";$x1;$y1;$x2;$y2)
```



# LISTBOX GET CELL POSITION

LISTBOX GET CELL POSITION ( {* ;} object ; column ; row {; colVar} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| column | Longint | ⇐ | Column number |
| row | Longint | ⇐ | Row number |
| colVar | Pointer | ⇐ | Pointer to column variable |

## Description

The **LISTBOX GET CELL POSITION** command returns the numbers of the *column* and the *row* that correspond to the location of the last mouse click or the last selection made via the keyboard in the listbox designated by * and *object*.

This command returns the coordinates of a click or a selection action even when data entry is not allowed in the list box.

**Notes:**

- The number returned in the *row* parameter does not take into account any hidden/displayed states of list box rows.
- If a cell in a fake column is clicked, the *row* parameter contains "X+1", where X is the number of existing columns. (A fake column can be added automatically when the "Column Auto-Resizing" option is selected; for more information refer to the **Resizing Options theme** paragraph).

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (a string). If you omit this parameter, you indicate that the *object* parameter is a variable.

The optional *colVar* parameter returns a pointer to the variable (i.e. array) associated with the column.

This command can only be called in the framework of a list box that generates one of the following form events:

- On Clicked and On Double Clicked
- On Before Keystroke and On After Keystroke
- On After Edit
- On Getting Focus and On Losing Focus
- On Data Change
- On Selection Change
- On Before Data Entry

When the command is called outside of this context, **LISTBOX GET CELL POSITION** returns 0 in both *column* and *row*.

This command takes into account any selection or deselection actions whether by mouse click, via keyboard keys, or using the **EDIT ITEM** command (which can generate the On Getting Focus event). If the selection is modified using the arrow keys of the keyboard, *column* returns 0. In this case, if it is passed, the *colVar* parameter returns **Nil**.

# LISTBOX Get column formula

LISTBOX Get column formula ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | String | ⇐ | Formula associated with column |

## Description

The **LISTBOX Get column formula** command returns the formula associated with the list box column designated by the *object* and * parameters. Formulas can only be used when the “Data Source” property of the list box is either **Current Selection** or **Named Selection**. If no formula is associated with the column, the command returns an empty string.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string. This parameter must designate a column of the list box.

# LISTBOX Get column width

LISTBOX Get column width ( {* ;} object {; minWidth {; maxWidth}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| minWidth | Longint | ⇐ | Minimum column width (in pixels) |
| maxWidth | Longint | ⇐ | Maximum column width (in pixels) |
| Function result | Longint | ⇒ | Column width (in pixels) |

## Description

The **LISTBOX Get column width** command returns the width (in pixels) of the column set in the *object* and * parameters. You can pass either a list box column or a column header in the *object* parameter.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

**LISTBOX Get column width** can return the resizing limits of the column in the *minWidth* and *maxWidth* parameters. These limits can be specified via the **LISTBOX SET COLUMN WIDTH** command.
If no minimum and/or maximum value has been set for the column, the corresponding parameter returns 0.

# LISTBOX Get footer calculation

LISTBOX Get footer calculation ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | Longint | ⇐ | Type of calculation |

## Description

The **LISTBOX Get footer calculation** command returns the type of calculation associated with the footer area of the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

The *object* parameter can designate:

- the variable or name of a footer area. In this case, the command returns the calculation associated with this area.
- the variable or name of a list box column. In this case, the command returns the calculation associated with footer area of this column.

You can compare the value returned with the constants of the **Listbox Footer Calculation** theme (see the **LISTBOX SET FOOTER CALCULATION** command).

# LISTBOX Get footers height

LISTBOX Get footers height ( {* ;} object {; unit} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| unit | Longint | ⇒ | Unit of height value:<br>0 or omitted = pixels, 1 = lines |
| Function result | Longint | ⇐ | Row height |

## Description

The **LISTBOX Get footers height** command returns the height of the footer row in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string. You can designate either the list box or any footer of the list box.

By default, if you omit the *unit* parameter, the height of the row returned is expressed in pixels. To set a different unit, you can pass one of the following constants (found in the **List Box** theme), in the *unit* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

**Note:** For more information about calculating the height of rows, refer to the *Design Reference* manual.

## LISTBOX GET GRID

LISTBOX GET GRID ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| horizontal | Boolean | ⇐ | True = shown, False = hidden |
| vertical | Boolean | ⇐ | True = shown, False = hidden |

### Description

The **LISTBOX GET GRID** command returns the shown/hidden status of the horizontal and/or vertical lines making up the grid of the list box object designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In *horizontal* and *vertical*, the command returns the value **True** or **False** depending on whether the corresponding lines are shown (True) or hidden (False). By default, the grid is shown.

# LISTBOX GET GRID COLORS

LISTBOX GET GRID COLORS ( {* ;} object ; hColor ; vColor )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| hColor | Longint | ⇐ | Value of RGB color for horizontal lines |
| vColor | Longint | ⇐ | Value of RGB color for vertical lines |

## Description

The **LISTBOX GET GRID COLORS** command returns the color of the horizontal and vertical lines making up the grid of the list box object designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In *hColor* and *vColor*, the command returns the values of the RGB colors. For more information about RGB colors, refer to the description of the **OBJECT SET RGB COLORS** command.

# LISTBOX Get headers height

LISTBOX Get headers height ( {* ;} object {; unit} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| unit | Longint | ⇒ | Unit of height value:<br>0 or omitted = pixels, 1 = lines |
| Function result | Longint | ⇐ | Row height |

## Description

The **LISTBOX Get headers height** command returns the height of the header row in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string. You can designate either the list box or any header of the list box.

By default, if you omit the *unit* parameter, the height of the row returned is expressed in pixels. To set a different unit, you can pass one of the following constants (found in the **List Box** theme), in the *unit* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

**Note:** For more information about calculating the height of rows, refer to the *Design Reference* manual.

# LISTBOX GET HIERARCHY

LISTBOX GET HIERARCHY ( {* ;} object ; hierarchical {; hierarchy} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| hierarchical | Boolean | ⇐ | True = hierarchical list box False = non-hierarchical list box |
| hierarchy | Pointer array | ⇐ | Array of pointers |

## Description

The **LISTBOX GET HIERARCHY** command lets you find out the hierarchical properties of the list box object designated by the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

The Boolean *hierarchical* parameter indicates whether or not the list box is in hierarchical mode:

- if the parameter returns True, the list box is in hierarchical mode,
- if the parameter returns False, the list box is displayed in non-hierarchical mode (standard array mode).

If the list box is in hierarchical mode, the command fills the *hierarchy* array with pointers to the arrays of the list box used to set the hierarchy.

**Note:** If the list box is in non-hierarchical mode, the command returns, in the first element of the *hierarchy* array, a pointer to the array of the first column of the list box.

# LISTBOX Get information

LISTBOX Get information ( {* ;} object ; info ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string). If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| info | Longint | ⇒ | Information to get |
| Function result | Longint | ⇐ | Current value |

## Description

The **LISTBOX Get information** command returns various information regarding the current visibility and size of headers, footers and scrollbars in the list box object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

In the *info* parameter, pass a value indicating the type of information that you want to get. You can use a value or one of the following constants from the "**List Box**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk display footer | Longint | 8 | **Display Footers** property<br>Applies to: List box<br>Possible values:<br>• lk no (0): hidden<br>• lk yes (1): shown |
| lk display header | Longint | 0 | **Display Headers** property<br>Applies to: List box<br>Possible values:<br>• lk no (0): hidden<br>• lk yes (1): shown |
| lk display hor scrollbar | Longint | 2 | 0=hidden, 1=shown |
| lk display ver scrollbar | Longint | 4 | 0=hidden, 1=shown |
| lk footer height | Longint | 9 | Height in pixels |
| lk header height | Longint | 1 | Height in pixels |
| lk hor scrollbar height | Longint | 3 | Height in pixels |
| lk hor scrollbar position | Longint | 6 | Position of the cursor in pixels |
| lk ver scrollbar position | Longint | 7 | Position of the cursor in pixels |
| lk ver scrollbar width | Longint | 5 | Width in pixels |

- The first constants are useful for calculating the actual size of a list box area in a form.
- When you use the constants lk hor scrollbar position or lk ver scrollbar position, the **LISTBOX Get information** command returns the position of the scrolling cursor in relation to its original position, i.e. the size of the hidden part of the window, expressed in pixels. By default, this position corresponds to 0. Combined, for example, with information concerning the row height, this value lets you find out the contents displayed in the listbox.
- The statement **LISTBOX Get information**(vLB;lk footer height) returns the same value as the **LISTBOX Get footers height** command when footers are displayed. However, if footers are not displayed, **LISTBOX Get information** returns 0 while **LISTBOX Get footers height** still returns the height, in this case theoretical, of the footers.

## Example

Given a list box containing rows with a height of 20 pixels each. You execute the following statement:

```
$scroll:=LISTBOX Get information(*;"Listbox";lk ver scrollbar position)
```

If, for instance, $scroll returns 200, you can conclude that the 11th row is currently the first one displayed in the list box (200/20=10, thus 10 rows are hidden).

# LISTBOX Get locked columns

LISTBOX Get locked columns ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | Longint | ⇐ | Number of locked columns |

## Description

The **LISTBOX Get locked columns** command returns the number of locked columns in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

Columns can be locked through the Property List or using the **LISTBOX SET LOCKED COLUMNS** command. For more information, refer to the *Design Reference* manual.

If a column is inserted or deleted by programming within the locked area, the number of columns returned by this command takes this change into account. For example, if you delete a locked column, the number of locked columns is decreased by 1. Similarly, if you insert a column by programming into a locked area, this column is locked automatically and the number of locked columns is increased by 1.

However, the command does not take into account the visible/invisible status of columns.

# LISTBOX Get number of columns

LISTBOX Get number of columns ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Longint | ⇐ | Number of columns |

## Description

The **LISTBOX Get number of columns** command returns the total number of columns (visible or invisible) present in the list box set in the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information on object names, refer to the **Object Properties** section.

# LISTBOX Get number of rows

LISTBOX Get number of rows ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Longint | ⇐ | Number of rows |

## Description

The **LISTBOX Get number of rows** command returns the number of rows in the list box set in the *object* and * parameters.

**Note:** This command does not take the hidden/displayed state of the rows into account. For example, in a list box with 10 rows where the first 9 rows are hidden, **LISTBOX Get number of rows** will return 10.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

**Note:** If the arrays associated with the columns of a List box do not all have the same size, only the number of items corresponding to the smallest array will appear in the list box and thus be returned by this command.

# LISTBOX GET OBJECTS

LISTBOX GET OBJECTS ( {* ;} object ; arrObjectNames )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| arrObjectNames | Text array | ⇐ | Names of sub-objects comprising list box (headers, columns, footers) |

## Description

The **LISTBOX GET OBJECTS** command returns an array containing the names of each object making up the list box designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

In *arrObjectNames*, you pass a text array that is automatically filled in by the command. Object names are returned in their display order, with the following sequence:

```
nameCol1
headerNameCol1
footerNameCol1
nameCol2
headerNameCol2
footerNameCol2
...
```

The array returns the object names for all the columns (including column footers), regardless of whether or not they are visible.

This command is useful in the context of the parsing of a form using the **FORM LOAD**, **FORM GET OBJECTS** and **OBJECT Get type** commands. You can use it, when needed, to obtain the names of list box sub-objects.

## Example

You want to load a form and get a list of all the objects of list boxes that it contains.

```
FORM LOAD("MyForm")
ARRAY TEXT(arrObjects;0)
FORM GET OBJECTS(arrObjects)
ARRAY LONGINT(ar_type;Size of array(arrObjects))
For($i;1;Size of array(arrObjects))
   ar_type{$i}:=OBJECT Get type(*;arrObjects{$i})
   If(ar_type{$i}=Object type listbox)
      ARRAY TEXT(arrLBObjects;0)
      LISTBOX GET OBJECTS(*;arrObjects{$i};arrLBObjects)
   End if
End for
FORM UNLOAD
```

# LISTBOX GET PRINT INFORMATION

LISTBOX GET PRINT INFORMATION ( {* ;} object ; selector ; info )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| selector | Longint | ⇒ | Information to get |
| info | Longint | ⇐ | Current value |

## Description

The **LISTBOX GET PRINT INFORMATION** command returns the current information relative to the printing of the list box object designated by the *object* and * parameters. This command can be used to control the printing of the list box contents.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

This command must be called in the context of the printing of a list box via the **Print object** command. Outside of this context, it will not return significant values.

Pass a value indicating the information you want to find out in *selector* and a variable of the number or BLOB type in *info*. In *selector*, you can pass one of the following constants, found in the "**List Box**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk last printed row number | Longint | 0 | Returns in *info* the number of the last row printed. Lets you find out the number of the next row to be printed.<br>The number returned may be greater than the number of rows actually printed if the list box contains invisible rows or if the **OBJECT SET SCROLL POSITION** command has been called. For example, if rows 1, 18 and 20 have been printed, *info* is 20. |
| lk printed height | Longint | 3 | Returns in *info* the height in pixels of the object actually printed (including headers, lines, etc.). Remember that if the number of rows to print is less than the "capacity" of the list box, its height is automatically reduced. |
| lk printed rows | Longint | 1 | Returns in *info* the number of rows actually printed during the last call to the **Print object** command. This number includes any break rows added in the case of a hierarchical list box. For example, *info* is 10 if the list box contains 20 rows and the odd-numbered rows were hidden. |
| lk printing is over | Longint | 2 | Returns in *info* a Boolean indicating whether the last (visible) row of the list box has actually been printed. True = row has been printed; Otherwise, False. |

For more information about the principles of printing list boxes, please refer to **Printing list boxes**.

## Example 1

Printing until all the rows have been printed:

```
OPEN PRINTING JOB
FORM LOAD("SalesForm")

$Over:=False
Repeat
   $Total:=Print object(*;"mylistbox")
   LISTBOX GET PRINT INFORMATION(*;"mylistbox";lk printing is over;$Over)
   PAGE BREAK
Until($Over)

CLOSE PRINTING JOB
```

## Example 2

Printing at least 500 rows of the list box, knowing that certain rows are hidden:

```
$GlobalPrinted:=0
Repeat
   $Total:=Print object(*;"mylistbox")
   LISTBOX GET PRINT INFORMATION(*;"mylistbox";lk printed rows;$Printed)
   $GlobalPrinted:=$GlobalPrinted+$Printed
   PAGE BREAK
Until($GlobalPrinted>=500)
```

# LISTBOX Get row color

LISTBOX Get row color ( {* ;} object ; row {; colorType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| row | Longint | ⇒ | Row number |
| colorType | Longint | ⇒ | Listbox font color (default) or Listbox background color |
| Function result | Longint | ⇐ | Color value |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX Get row color** command returns the color of a row or a cell in the list box designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. You can designate a list box or a list box column in the *object* parameter:

- When *object* designates a list box, the command returns the color of the row.
- When *object* designates a list box column, the command returns the color of the cell.

In *row*, pass the number of the row whose color you want to get.

**Note:** The command does not take any hidden/shown states of the list box rows into account.

In the *colorType* parameter, you can pass either the lk background color or lk font color constant ("**List Box**" theme) in order to find out the background or font color for the row. If you omit this parameter, the font color is returned.

**Warning:** a color assigned to a row is not necessarily displayed in every cell of the row (see example). If conflicting color values are set using properties for list boxes or list box columns, an order of priority is applied. For more information, refer to the *Design Reference* manual.

## Example

Given the following list box:

| | | | | | |
|---|---|---|---|---|---|
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |

```
vColor:=LISTBOX Get row color(*;"Col5";3)
vColor2:=LISTBOX Get row color(*;"List Box";3)
vColor3:=LISTBOX Get row color(*;"List Box";lk background color)
 // vColor contains 0xFFFF00 (yellow)
 // vColor2 contains 0x00FF (blue)
 // vColor3 contains 0x00FF0000 (red)
```

# LISTBOX Get row font style

LISTBOX Get row font style ( {* ;} object ; row ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| row | Longint | ⇒ | Row number |
| Function result | Longint | ⇐ | Style value |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX Get row font style** command returns the font style of a row or a cell in the list box designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. You can designate a list box or a list box column in the *object* parameter:

- When *object* designates a list box, the command returns the style of the row.
- When *object* designates a list box column, the command returns the style of the cell.

In *row*, pass the number of the row whose style you want to get.

**Note:** The command does not take any hidden/shown states of the list box rows into account.

**Warning:** a style assigned to a row is not necessarily displayed in every cell of the row (see example). If conflicting color values are set using properties for list boxes or list box columns, an order of priority is applied. For more information, refer to the *Design Reference* manual.

## Example

Given the following list box:

| | | | | | |
|---|---|---|---|---|---|
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| *text* | *text* | *text* | *text* | **text** | *text* |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |

```
vStyle:=LISTBOX Get row font style(*;"Col5";3)
vStyle2:=LISTBOX Get row font style(*;"List Box";3)
 // vStyle contains 1 (Bold)
 // vStyle2 contains 6 (Italic + Underline)
```

# LISTBOX Get row height

LISTBOX Get row height ( {* ;} object ; row ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| row | Longint | ⇒ | List box row whose height you want to get |
| Function result | Integer | ⇐ | Row height |

## 4D View Pro

This command requires a 4D View Pro license. If this license is not available, an error is displayed in the list box when the form is executed. For more information, please refer to the **4D View Pro** section.

## Description

The **LISTBOX Get row height** command returns the current height of the specified *row* in the list box object designated using the *object* and * parameters. Row height can be set globally using the Property List or the **LISTBOX SET ROWS HEIGHT** command, or individually by means of the **LISTBOX SET ROW HEIGHT** command.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

If the specified *row* does not exist in the list box, the command returns 0 (zero).

The row height is returned using the current unit defined for the list box rows globally, either in the Property list or by a prior call to the **LISTBOX SET ROWS HEIGHT** command.

# LISTBOX Get rows height

LISTBOX Get rows height ( {* ;} object {; unit} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| unit | Longint | ⇒ | Unit of height value: 0 or omitted = pixels, 1 = lines |
| Function result | Integer | ⇐ | Row height |

## Description

The **LISTBOX Get rows height** command returns the current row height for the list box object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

By default, if you omit the *unit* parameter, the row height returned is expressed in pixels. To set another unit, in the *unit* parameter you can pass one of the following constants, found in the **List Box** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

**Note:** For more information about calculating the height of rows, refer to the *Design Reference* manual.

# LISTBOX Get static columns

LISTBOX Get static columns ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | Longint | ⇐ | Number of static columns |

## Description

The **LISTBOX Get static columns** command returns the number of static columns in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

Static columns can be set through the Property List or using the **LISTBOX SET STATIC COLUMNS** command.

If a column is inserted or deleted by programming within a set of static columns, the number of columns returned by this command takes this change into account.
However, the command does not take into account the visible/invisible status of columns.

**Note:** Static columns and locked columns are two independent functions. For more information, refer to the *Design Reference* manual.

# LISTBOX GET TABLE SOURCE

LISTBOX GET TABLE SOURCE ( {* ;} object ; tableNum {; name {; highlightName}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| tableNum | Longint | ⇐ | Table number of selection |
| name | String | ⇐ | Name of named selection or "" for the current selection |
| highlightName | String | ⇐ | Name of highlight set |

## Description

The **LISTBOX GET TABLE SOURCE** command can be used to find out the current source of the data displayed in the list box that is designated by the * and *object* parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, please refer to the **Object Properties** section.

The command returns the number of the main table associated with the list box in the *tableNum* parameter and the name of any named selection used in the optional *name* parameter.

If the rows of the list box are linked with the current selection of the table, the *name* parameter, if passed, returns an empty string. If the rows of the list box are linked with a named selection, the *name* parameter returns the name of this named selection.

If the list box is associated with arrays, *tableNum* returns -1 and *name*, if passed, returns an empty string.

# LISTBOX INSERT COLUMN

LISTBOX INSERT COLUMN ( {* ;} object ; colPosition ; colName ; colVariable ; headerName ; headerVar {; footerName ; footerVar} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is set) or Variable (if * is omitted) |
| colPosition | Longint | ⇒ | Location of column to insert |
| colName | String | ⇒ | Name of the column object |
| colVariable | Array, Field, Variable, Nil pointer | ⇒ | Column array name or field or variable |
| headerName | String | ⇒ | Name of the column header object |
| headerVar | Integer variable, Nil pointer | ⇒ | Column header variable |
| footerName | String | ⇒ | Column footer object name |
| footerVar | Variable, Nil pointer | ⇒ | Column footer variable |

## Description

The **LISTBOX INSERT COLUMN** command inserts a column in the list box set by the *object* and * parameters.

**Note:** This command does nothing if it is applied to the first column of a list box displayed in hierarchical mode.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

The new column is inserted just in front of the column set using the *colPosition* parameter. If the *colPosition* parameter is greater than the total number of columns, the column is added after the last column.

Pass the name of the object and the variable of the inserted column in the *colName* and *colVariable* parameters.

- With an array type list box, the name of the variable must match the name of the array whose contents will be displayed in the column. You can pass a Nil (->[]) pointer if you use the command in a dynamic context when the form is executed (see below).
- With a selection type list box, you must pass a field or variable in the *colVariable* parameter. The contents of the column will thus be the value of the field or variable, evaluated for each record of the selection associated with the list box. This type of contents can only be used when the “Data Source” property of the list box is Current Selection or Named Selection (see the **Managing List Box Objects** section). You can use fields or variables of the string, number, Date, Time, Picture and Boolean types.

In the context of list boxes based on selections, **LISTBOX INSERT COLUMN** can be used to insert simple elements (fields or variables). If you want to handle more complex expressions (such as formulas or methods), you must use the **LISTBOX INSERT COLUMN FORMULA** command.

**Note:** It is not possible to combine columns of the array type (array data source) and those of the field or variable type (selection data source) in the same list box.

Pass the object name and the variable of the inserted column header in the *headerName* and *headerVar* parameters.

In the *footerName* and *footerVar* parameters, you can also pass the object name and variable of the footer of the inserted column.

**Note:** Object names must be unique in a form. You must be sure that the names passed in the *colName*, *headerName* and *footerName* parameters are not already used. Otherwise, the column is not created and an error is generated.

### Dynamic insertion

Starting with 4D v14 R3, you can use this command to insert columns into list boxes dynamically when the form is executed. 4D will automatically handle the definition of the necessary variables (column, footer and header).

To do this, **LISTBOX INSERT COLUMN** accepts a **Nil** (**->[]**) pointer as a value for the *colVariable* (array type list box only), *headerVar* and *footerVar* parameters. In this case, when the command is executed, 4D creates the required variables dynamically (for more information, refer to the **Dynamic variables** section).

Note that header and footer variables are always created with a specific type (longint and text, respectively). Conversely, column variables cannot be typed when created because list boxes accept different types of arrays for these variables (text array, integer array, and so on). This means you have to set the array type manually (see example 3). It is important to

perform this typing before calling commands such as **LISTBOX INSERT ROWS** to insert new elements in the array. Alternatively, you can use **APPEND TO ARRAY** both for setting the type of the array and inserting elements.

## Example 1

We would like to add a column at the end of the list box:

```
C_LONGINT(HeaderVarName;$Last;RecNum)
ALL RECORDS([Table 1])
$RecNum:=Records in table([Table 1])
ARRAY PICTURE(Picture;$RecNum)

$Last:=LISTBOX Get number of columns(*;"ListBox1")+1
LISTBOX INSERT COLUMN(*;"ListBox1";$Last;"ColumnPicture";Picture;"HeaderPicture";HeaderVarName)
```

## Example 2

We would like to add a column to the right of the list box and associate the values of the [Transport]Fees field with it:

```
$last:=LISTBOX Get number of columns(*;"ListBox1")+1
LISTBOX INSERT COLUMN(*;"ListBox1";$last;"FieldCol";[Transport]Fees;"HeaderName";HeaderVar)
```

## Example 3

You want to insert a column dynamically into an array type list box and define its header:

```
C_POINTER($NilPtr)
LISTBOX INSERT COLUMN(*;"MyListBox";1;"MyNewColumn";$NilPtr;"MyNewHeader";$NilPtr)
ColPtr:=OBJECT Get pointer(Object named;"MyNewColumn")
ARRAY TEXT(ColPtr->;10)
 //Definition of header
headprt:=OBJECT Get pointer(Object named;"MyNewHeader")
OBJECT SET TITLE(headprt->;"Inserted header")
```

# LISTBOX INSERT COLUMN FORMULA

LISTBOX INSERT COLUMN FORMULA ( {* ;} object ; colPosition ; colName ; formula ; dataType ; headerName ; headerVar {; footerName ; footerVar} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| colPosition | Longint | ⇒ | Location of column to insert |
| colName | String | ⇒ | Name of the column object |
| formula | String | ⇒ | 4D formula associated with column |
| dataType | Longint | ⇒ | Type of formula result |
| headerName | String | ⇒ | Name of the column header object |
| headerVar | Integer variable, Nil pointer | ⇒ | Column header variable |
| footerName | String | ⇒ | Column footer object name |
| footerVar | Variable, Nil pointer | ⇒ | Column footer variable |

## Description

The **LISTBOX INSERT COLUMN FORMULA** command inserts a column into the listbox designated by the *object* and * parameters.

The **LISTBOX INSERT COLUMN FORMULA** command is similar to the **LISTBOX INSERT COLUMN** command except that it can be used to enter a formula as the contents of a column.

This type of contents can only be used when the "Data Source" property of the list box is set to **Current Selection** or **Named Selection** (for more information about this, please refer to the **Managing List Box Objects** section).

**Note:** This command does nothing if it is applied to the first column of a list box displayed in hierarchical mode.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, please refer to the **Object Properties** section.

The new column is inserted just before the column designated by the *colPosition* parameter. If the *colPosition* parameter is greater than the total number of columns, the column will be added after the last column.

Pass the object name of the inserted column in the *colName* parameter.

The *formula* parameter can contain any valid expression, i.e.:

- An instruction,
- A formula generated using the Formula editor,
- A call to a 4D command,
- A call to a project method.

At the moment the command is called, the *formula* is parsed then executed.

**Note:** Use the **Command name** command in order to define formulas that are independent from the application language (when they call on 4D commands).

The *dataType* parameter can be used to designate the type of data resulting from the execution of the formula. You must pass one of the following constants of the "**Field and Variable Types**" theme in this parameter:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is picture | Longint | 3 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |

If the result of the *formula* does not correspond to the expected data type, an error is generated.

In the *headerName* and *headerVar* parameters, pass the object name and variable of the column header inserted.

In the *footerName* and *footerVar* parameters, you can also pass the object name and variable of the footer of the inserted column. If you omit the *footerVar* parameter, 4D uses a dynamic variable.

**Note:** Object names must be unique in a form. You need to make sure that the names passed in the *colName*, *headerName* and *footerName* parameters are not already used. Otherwise, the column is not created and an error is generated.

### Dynamic insertion

Starting with 4D v14 R3, you can use this command to insert columns into list boxes dynamically when the form is executed. 4D will automatically handle the definition of the necessary variables (footer and header).

To do this, **LISTBOX INSERT COLUMN FORMULA** accepts a **Nil** (**->[]**) pointer as a value for the *headerVar* and *footerVar* parameters. In this case, when the command is executed, 4D creates the required variables dynamically (for more information, refer to the **Dynamic variables** section).

Note that header and footer variables are always created with a specific type (longint and text, respectively).

## Example

We want to add a new column to the right of the list box that will contain a formula which calculates an empolyee's age:

```
vAge:="Current Date-[Employees]BirthDate)¥365"
$last:=LISTBOX Get number of columns(*;"ListBox1")+1
LISTBOX INSERT COLUMN FORMULA(*;"ListBox1";$last;"ColFormula";vAge;Is real;"Age";HeaderVar)
```

# LISTBOX INSERT ROWS

LISTBOX INSERT ROWS ( {* ;} object ; rowPosition {; numRows} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| rowPosition | Longint | ➡ | Position of the row to insert |
| numRows | Longint | ➡ | Number of rows to insert |

## Description

The **LISTBOX INSERT ROWS** command inserts one or several new row(s) in the list box set in the *object* and * parameters.

**Note:** This command only works with list boxes based on arrays. When this command is used with a list box based on a selection, it does nothing and the OK system variable is set to 0.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

By default, if *numRows* is omitted, only one row is inserted. Otherwise, the command inserts the number of rows defined in this parameter.

This command inserts the row(s) at the position set by the *rowPosition* parameter and these row(s) are automatically added at this position in all the arrays used by the list box columns, whatever their type and their visibility.

If the *rowPosition* value is higher than the total number of rows in the list box, the command adds the row(s) at the end of each array. If it is equal to 0, the command adds the row(s) at the beginning of each array. If it contains a negative value, the command does nothing.

# LISTBOX MOVE COLUMN

LISTBOX MOVE COLUMN ( {* ;} object ; colPosition )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or<br>Variable (if * is omitted) of the column to be moved |
| colPosition | Longint | ➡ | New location of column |

## Description

The **LISTBOX MOVE COLUMN** command moves the column designated by the *object* and * parameters by programming in the context of the form being executed (Application mode). The original form, generated in the Design mode, is not modified.

The *object* and * parameters designate the column to move. Passing the optional * parameter indicates that the *object* parameter is a column name (string). If you do not pass this parameter, this indicates that the *object* parameter is a column variable. In this case, you pass a variable reference instead of a string.

The column is moved to just in front of the one designated by the *colPosition* parameter. If the *colPosition* parameter is greater than the total number of columns, then the column is moved to just after the last column.

**Note:** This command does nothing when it is applied to the first column of a list box displayed in hierarchical mode.

The command takes the static and locked column properties into account: for example, if you try to move a static column, the command does nothing.

This functionality was already found in 4D in Application mode: the user can move non-static columns using the mouse. However, unlike columns moved by the user, this command does not generate the On Column Moved event.

## Example

You want to swap the 2nd and 3rd columns of the list box:

```
LISTBOX MOVE COLUMN(*;"column2";3)
```

# LISTBOX MOVED COLUMN NUMBER

LISTBOX MOVED COLUMN NUMBER ( {* ;} object ; oldPosition ; newPosition )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| oldPosition | Longint | ⇐ | Previous position of the moved column |
| newPosition | Longint | ⇐ | New position of the moved column |

## Description

The **LISTBOX MOVED COLUMN NUMBER** command returns two numbers in *oldPosition* and *newPosition* indicating respectively the previous position and the new position of the column moved in the list box, specified by the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

This command must be used with the form event On Column Moved (see the **Form event** command).

**Note:** This command takes invisible columns into account.

# LISTBOX MOVED ROW NUMBER

LISTBOX MOVED ROW NUMBER ( {* ;} object ; oldPosition ; newPosition )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| oldPosition | Longint | ⇐ | Previous position of the moved row |
| newPosition | Longint | ⇐ | New position of the moved row |

## Description

The **LISTBOX MOVED ROW NUMBER** command returns two numbers in *oldPosition* and *newPosition* indicating respectively the previous position and the new position of the row moved in the list box, specified by the *object* and * parameters.

**Note:** You can only move rows in array type list boxes.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

This command must be used with the form event On Row Moved (see the **Form event** command).

**Note:** This command does not take into account any hidden/displayed states of list box rows.

# LISTBOX SELECT BREAK

LISTBOX SELECT BREAK ( {* ;} object ; row ; column {; action} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| row | Longint | ➡ | Number of break row |
| column | Longint | ➡ | Number of break column |
| action | Longint | ➡ | Selection action |

## Description

The **LISTBOX SELECT BREAK** command can be used to select break rows in the list box object designated by the *object* and * parameters. The list box must be displayed in hierarchical mode.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

Break rows are added to represent the hierarchy but they do not correspond to existing rows in the array. To designate a break row to be selected, in the *row* and *column* parameters, you must pass the row and column number corresponding to the first occurrence in the corresponding array. These values are returned by the **LISTBOX GET CELL POSITION** command when the user has selected a break row. This principle is described in the “Management of break rows” paragraph of the **Managing Hierarchical List Boxes** section.

The *action* parameter, if it is passed, can set the selection action to be carried out when a selection of break rows already exists in the list box. You can pass a value or one of the following constants, found in the "**List Box**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk add to selection | Longint | 1 | The row selected is added to the existing selection. If the row specified already belongs to the existing selection, the command does nothing. |
| lk remove from selection | Longint | 2 | The row selected is removed from the existing selection. If the row specified does not belong to the existing selection, the command does nothing. |
| lk replace selection | Longint | 0 | The row selected becomes the new selection and replaces the existing selection. The command has the same effect as a user click on a row (however, the On Clicked event is not generated). This is the default action (if the *action* parameter is omitted). |

## Example

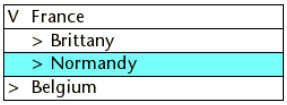
Given the following arrays shown in a list box:

| (T1) | (T2) | (T3) | (T4) |
|---|---|---|---|
| France | Brittany | Brest | 120000 |
| France | Brittany | Quimper | 80000 |
| France | Brittany | Rennes | 200000 |
| France | Normandy | Caen | 220000 |
| France | Normandy | Deauville | 4000 |
| France | Normandy | Cherbourg | 41000 |
| Belgium | Wallonia | Namur | 111000 |
| Belgium | Wallonia | Liege | 200000 |
| Belgium | Flanders | Antwerp | 472000 |
| Belgium | Flanders | Louvain | 95000 |

We want to select the "Normandy" break row:

```
$row:=Find in array(T2;"Normandy")
$column:=2
LISTBOX COLLAPSE(*;"MyListbox") `collapsing of all levels
LISTBOX SELECT BREAK(*;"MyListbox";$row;$column)
```

Here is the result:



V France
> Brittany
> Normandy
> Belgium

# LISTBOX SELECT ROW

LISTBOX SELECT ROW ( {* ;} object ; rowPosition {; action} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| rowPosition | Longint | ⇒ | Number of the row to select |
| action | Longint | ⇒ | Selection action |

## Description

The **LISTBOX SELECT ROW** command selects the row whose number is passed in *position* in the list box set in the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

The optional *action* parameter, if passed, is used to define the selection action to execute when a selection of rows already exists in the list box. You can pass a value or one of the following constants (located in the "**List Box**" theme):

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk add to selection | Longint | 1 | The row selected is added to the existing selection. If the row specified already belongs to the existing selection, the command does nothing. |
| lk remove from selection | Longint | 2 | The row selected is removed from the existing selection. If the row specified does not belong to the existing selection, the command does nothing. |
| lk replace selection | Longint | 0 | The row selected becomes the new selection and replaces the existing selection. The command has the same effect as a user click on a row (however, the On Clicked event is not generated). This is the default action (if the *action* parameter is omitted). |

When the *position* parameter does not correspond exactly to an existing row number, the command works as follows:

- If *position* is <0, the command does nothing, regardless of the *action* parameter value.
- If *position* is 0 and if the *action* parameter contains lk replace selection or is omitted, all the rows of the listbox are selected. If the *action* parameter contains lk remove from selection, all the listbox rows are deselected.
- If the *position* value is greater than the total number of rows contained in the listbox (only in the case of an array type listbox), the Boolean array associated with the listbox is automatically resized and the selection action is carried out. This mechanism means that you can use **LISTBOX SELECT ROW** with "standard" array management commands (such as **APPEND TO ARRAY**) that do not cause immediate synchronization of the listbox.
  After execution of the method, the arrays are synchronized: if the source array of the listbox has indeed been resized, the selection action is carried out. Otherwise, the Boolean array associated with the listbox returns to its initial size and the command does nothing.

**Notes:**

- If you want the list box to scroll automatically in order to display the row selected, use the **OBJECT SET SCROLL POSITION** command.
- To switch a row into editing mode (to allow data entry), use the **EDIT ITEM** command.
- If the number passed in *position* corresponds to a hidden row in the list box, the row is selected but not displayed.

# LISTBOX SET ARRAY

LISTBOX SET ARRAY ( {* ;} object ; arrType ; arrPtr )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| arrType | Longint | ➡ | Type of array |
| arrPtr | Pointer | ➡ | Array to associate with property |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX SET ARRAY** command associates an *arrType* array with the list box or list box column designated by the *object* and * parameters.

**Note:** Arrays of styles, colors, background colors or row controls can also be associated with array type list boxes using the Property list in the Design mode.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. You can designate a list box or a list box column in the *object* parameter.

In *arrType*, pass the type of array to associate with the list box or column. You can use one of the following constants, available in the "**List Box**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk background color array | Longint | 1 | |
| lk control array | Longint | 3 | |
| lk font color array | Longint | 0 | |
| lk row height array | Longint | 4 | (4D View Pro license required) |
| lk style array | Longint | 2 | |

In the *arrPtr* parameter, you pass a pointer to the array to use to support the property type.

## Example 1

You want to reuse the font color array of the 4th column for the 10th column:

```
 // retrieve a pointer to the array for column 4
$Pointer:=LISTBOX Get array(*;"Col4";lk font color array)
 // check that it exists
If(Not(Nil($Pointer)))
 //transfer to column 10
   LISTBOX SET ARRAY(*;"Col10";lk font color array;$Pointer)
End if
```

## Example 2

You want to set a row height array for a list box:

```
LISTBOX SET ARRAY(*;"LB";lk row height array;->RowHeightArray)
```

**Note**: The **Row Height Array** property for list boxes requires a 4D View Pro license. For more information, refer to **4D View Pro**.

# LISTBOX SET COLUMN FORMULA

LISTBOX SET COLUMN FORMULA ( {* ;} object ; formula ; dataType )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| formula | String | ⇒ | 4D formula associated with column |
| dataType | Longint | ⇒ | Type of formula result |

## Description

The **LISTBOX SET COLUMN FORMULA** command modifies the *formula* associated with the column of the list box designated by the *object* and * parameters. Formulas can only be used when the “Data Source” property of the list box is either **Current Selection** or **Named Selection**.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string. This parameter must designate a list box column.

The *formula* parameter can contain any valid expression, i.e.:

- an instruction,
- a formula generated using the formula editor,
- a call to a 4D command,
- a call to a project method.

When the command is called, the formula is parsed and then executed.

**Note:** Use the **Command name** command to specify formulas independent from the application language (when they call 4D commands).

The *dataType* parameter designates the type of data resulting from the execution of the formula. In this parameter, you pass one of the constants from the **Field and Variable Types** theme. If the formula result does not match the expected data type, an error is generated.

# LISTBOX SET COLUMN WIDTH

LISTBOX SET COLUMN WIDTH ( {* ;} object ; width {; minWidth {; maxWidth}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| width | Longint | ⇒ | Column width (in pixels) |
| minWidth | Longint | ⇒ | Minimum column width (in pixels) |
| maxWidth | Longint | ⇒ | Maximum column width (in pixels) |

## Description

The **LISTBOX SET COLUMN WIDTH** command allows you to modify through programming the width of one or all column(s) of the object (list box, column or header) set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (a string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

Pass the new width (in pixels) of the object in the *width* parameter.

If *object* sets the list box object, all columns of the list box are resized.

If *object* sets a column or a column header, only the column set is resized.

The optional *minWidth* and *maxWidth* parameters can be used to set limits for the manual resizing of the column You can pass, respectively, the minimum and maximum width expressed in pixels in the *minWidth* and *maxWidth* parameters. If you want users to be unable to resize the column, you can pass the same value in *width*, *minWidth* and *maxWidth*.

# LISTBOX SET FOOTER CALCULATION

LISTBOX SET FOOTER CALCULATION ( {* ;} object ; calculation )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| calculation | Longint | ⇒ | Calculation for footer area |

## Description

The **LISTBOX SET FOOTER CALCULATION** command sets the automatic calculation associated with the footer of the list box designated by the *object* and * parameters

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the object is a variable. In this case, you pass a variable reference instead of a string.
The *object* parameter can designate:

- the variable or name of a footer area. In this case, the command applies to this area.
- the variable or name of a list box column. In this case, the command applies to the footer area of this column.
- the variable or name of a list box. In this case, the command applies to all the footer areas of the list box.

In the *calculation* parameter, pass one of the following constants, found in the **Listbox Footer Calculation** theme, in order to set the calculation to be performed:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Listbox footer std deviation | Longint | 7 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |
| lk footer average | Longint | 6 | Used with number or time type columns<br>Default type of the result: Real |
| lk footer count | Longint | 5 | Used with number, text, date, time, Boolean or picture type columns<br>Default type of the result: Longint |
| lk footer custom | Longint | 1 | No calculation performed by 4D. The footer variable must be calculated by programming.<br>Default type of the result: Footer variable type |
| lk footer max | Longint | 3 | Used with number, date, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer min | Longint | 2 | Used with number, date, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer sum | Longint | 4 | Used with number, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer sum squares | Longint | 9 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |
| lk footer variance | Longint | 8 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |

Note that predefined calculations take all the values of the column into account, including those of any hidden rows. If you want to restrict a calculation to only visible rows, you must use the lk footer custom constant and perform a customized calculation.

If the data type of a column or of even one column of the list box (when object designate a whole list box) is not compatible with the *calculation* set, the footer is not modified and the error 18 is generated. If a column contains a formula (selection type list box), the error 10 is generated.

**Note:** Footer area variables are typed automatically (when there are not typed through the code) with regards to the calculation set in the Property List (see **List box footer specific properties**). If the variable data type does not correspond to the result expected by the **LISTBOX SET FOOTER CALCULATION** command, a typing error is generated. For example, for a column displaying dates, if the footer calculation is 'Maximum', the *footer* variable will be typed as Date. At this point, if

you execute the statement **LISTBOX SET FOOTER CALCULATION**(footer;lk footer count), an error is generated because the expected data type of the result (longint) differs from the actual variable data type.

# LISTBOX SET FOOTERS HEIGHT

LISTBOX SET FOOTERS HEIGHT ( {* ;} object ; height {; unit} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| height | Longint | ⇒ | Row height |
| unit | Longint | ⇒ | Unit of height value:<br>0 or omitted = pixels, 1 = lines |

## Description

The **LISTBOX SET FOOTERS HEIGHT** command modifies by programming the height of the footer row in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string. You can designate either the list box or any footer of the list box.

Pass the height to set in the *height* parameter. By default, if you omit the *unit* parameter, this height is expressed in pixels. To change the unit, you can pass one of the following constants (found in the **List Box** theme), in the *unit* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

**Note:** For more information about the calculation of row heights, refer to the *Design Reference* manual.

# LISTBOX SET GRID

LISTBOX SET GRID ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| horizontal | Boolean | ⇒ | True = show, False = hide |
| vertical | Boolean | ⇒ | True = show, False = hide |

## Description

The **LISTBOX SET GRID** command allows you to display or hide the horizontal and/or vertical grid lines that make up the grid in the list box object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

Pass the Boolean values in *horizontal* and *vertical* that indicate if the corresponding grid lines should be displayed (**True**) or hidden (**False**). The grid is displayed by default.

# LISTBOX SET GRID COLOR

LISTBOX SET GRID COLOR ( {* ;} object ; color ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| color | Longint | ⇒ | RGB color value |
| horizontal | Boolean | ⇒ | Use color for horizontal grid lines |
| vertical | Boolean | ⇒ | Use color for vertical grid lines |

## Description

The **LISTBOX SET GRID COLOR** command allows you to modify the color of the grid in the list box object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

Pass the RGB color value in *color*. For more information on RGB colors, refer to the description of the **OBJECT SET RGB COLORS** command.

The *horizontal* and *vertical* parameters allow you to set the grid lines to which you will apply a color:

- If you pass **True** in *horizontal*, the color will be applied to horizontal grid lines. If you pass **False**, their color is not changed.
- If you pass **True** in *vertical*, the color will be applied to vertical grid lines. If you pass **False**, their color is not changed.

# LISTBOX SET HEADERS HEIGHT

LISTBOX SET HEADERS HEIGHT ( {* ;} object ; height {; unit} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| height | Longint | ⇒ | Row height |
| unit | Longint | ⇒ | Unit of height value:<br>0 or omitted = pixels, 1 = lines |

## Description

The **LISTBOX SET HEADERS HEIGHT** command modifies by programming the height of the header row in the list box designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

You can designate either the list box or any header of the list box.

Pass the height to set in the *height* parameter. By default, if you omit the *unit* parameter, this height is expressed in pixels. To change the unit, you can pass one of the following constants (found in the **List Box** theme), in the *unit* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

Headers must respect the minimum height set by the system. This height is 24 pixels under Windows and 17 pixels under Mac OS. If you pass a lower value in the *height* parameter, the minimum height is applied.

**Note:** For more information about calculation row heights, refer to the *Design Reference* manual.

# LISTBOX SET HIERARCHY

LISTBOX SET HIERARCHY ( {* ;} object ; hierarchical {; hierarchy} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| hierarchical | Boolean | ⇒ | True = hierarchical list box False = non-hierarchical list box |
| hierarchy | Pointer array | ⇒ | Array of pointers |

## Description

The **LISTBOX SET HIERARCHY** command lets you configure the list box object designated by the *object* and * parameters in hierarchical or non-hierarchical mode.

**Note:** This command only functions with list boxes based on arrays. When this command is used with a list box based on selections, it does nothing.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

The Boolean *hierarchical* parameter lets you specify the list box mode:

- if you pass True, the list box is displayed in hierarchical mode,
- if you pass False, the list box is displayed in non-hierarchical mode (standard array mode).

When you pass a list box in hierarchical mode, certain properties are automatically restricted. For more information, please refer to the **Managing Hierarchical List Boxes** section.

The *hierarchy* parameter is used to designate the arrays of the list box to be used to construct the hierarchy (see example). If you display the list box in hierarchical mode and omit this parameter:

- if the list box is already in hierarchical mode, the command does nothing.
- if the list box is in non-hierarchical mode and has never been declared hierarchical, the first array is used as the hierarchy by default.
- if the list box is in non-hierarchical mode but has previously been declared hierarchical, the last hierarchy is re-established.

## Example

Definition of the aCountry, aRegion and aCity arrays as the hierarchy of a list box:

```
ARRAY POINTER($ArrHierarch;3)
$ArrHierarch{1}:=->aCountry `First break level
$ArrHierarch{2}:=->aRegion `Second break level
$ArrHierarch{3}:=->aCity `Third break level
LISTBOX SET HIERARCHY(*;"mylistbox";True;$ArrHierarch)
```

# LISTBOX SET LOCKED COLUMNS

LISTBOX SET LOCKED COLUMNS ( {* ;} object ; numColumns )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| numColumns | Longint | ⇒ | Number of columns to lock |

## Description

The **LISTBOX SET LOCKED COLUMNS** command locks *numColumns* columns (starting from the first on the left) in the list box designated by the *object* and * parameters.

Locked columns are shown in the left part of the list box and do not scroll with the rest of the list box columns. For more information, refer to the *Design Reference* manual.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In *numColumns*, you can pass any value included between 1 and the total number of columns in the list box minus 1. For a list box with X columns, if you pass a value > X-1 in *numColumns*, it will be reduced automatically to the value X-1.

To remove the column locking, pass 0 or a negative value in *numColumns*.

# LISTBOX SET ROW COLOR

LISTBOX SET ROW COLOR ( {* ;} object ; row ; color {; colorType} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| row | Longint | ➡ | Row number |
| color | Longint | ➡ | RGB color value |
| colorType | Longint | ➡ | Listbox font color (default) or Listbox background color |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX SET ROW COLOR** command sets the color for a row or a cell in the array list box designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the object parameter is a variable. In this case, you pass a variable reference instead of a string.

You can designate a list box or a list box column in the *object* parameter:

- When *object* designates a list box, the command applies to the row.
- When *object* designates a list box column, the command applies to the cell located at the column/row intersection.

In *row*, pass the number of the row where you want to apply the new color.

**Note:** The command does not take any hidden/shown states of the list box rows into account.

In *color*, pass an RGB color value. For more information about RGB colors, refer to the description of the **OBJECT SET RGB COLORS** command. If you want the row to inherit the color set for the higher level, you can pass the lk inherited constant in *color*.

In the *colorType* parameter, pass the lk background color or lk font color constants to indicate whether you want to apply the color as the background or the font color of the row. If you omit this parameter, the color is applied as the font color.

This command modifies values found in the array of colors that may have been defined for the column or list box. If these arrays are not already defined, the command dynamically creates arrays that you can access using the **LISTBOX Get array** command.

If conflicting color values are set using properties for list boxes or list box columns, an order of priority is applied. For more information, refer to the *Design Reference* manual.

## Example

In an array type list box, we want to set colors for a row and for one cell in this row:

```
 // Definition of font color for cell (yellow)
LISTBOX SET ROW COLOR(*;"Col5";3;0x00FFFF00)

 // Definition of background and font color for row 3
 // red background, blue font
LISTBOX SET ROW COLOR(*;"ListBox";3;0x00FF0000;lk background color)
LISTBOX SET ROW COLOR(*;"List Box";3;0x000000FF)
```

| | | | | | |
|---|---|---|---|---|---|
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |

# LISTBOX SET ROW FONT STYLE

LISTBOX SET ROW FONT STYLE ( {* ;} object ; row ; style )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or<br>Variable (if * is omitted) |
| row | Longint | ➡ | Row number |
| style | Longint | ➡ | Font style |

## Description

**Note:** This command only works with array type list boxes.

The **LISTBOX SET ROW FONT STYLE** command sets a font style for a row or a cell in the array type list box designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a is a variable. In this case, you pass a variable reference instead of a string.

You can designate a list box or a list box column in the *object* parameter:

- When *object* designates a list box, the command applies to the row.
- When *object* designates a list box column, the command applies to the cell located at the column/row intersection.

In *row*, pass the number of the row where you want to apply the new style.

**Note:** The command does not take any hidden/shown states of the list box rows into account.

In *style*, you pass a style value. You must use one (or a combination) of the constants found in the **Font Styles** theme:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

If an array of font styles has been associated with the list box or column, only the element matching the row is modified. In other words, executing the command has the same effect, in this case, as modifying an element of the font style array.
If there is no font style array associated with the list box or column, one will be created dynamically when this command is called. You can access them using the **LISTBOX Get array** command.

If conflicting style properties are set for the column or the list box, an order of priority is applied. For more information, refer to the *Design Reference* manual.

**Note:** Since style arrays for columns take priority over the ones for list boxes, when this command is applied to a list box, it will only have an effect if no style array has been assigned to the columns.

## Example

Given an array type list box with the following characteristics:

- a font style array associated with the list box (*ArrGlobalStyle*)
- a font style array associated with column 5 (*ArrCol5Style*)
- the other columns do not have any style arrays.

```
LISTBOX SET ROW FONT STYLE(*;"Col5";3;Bold)
 // equivalent to ArrCol5Style{3}:=Bold
```

| | | | | | |
|---|---|---|---|---|---|
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | **text** | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |

```
LISTBOX SET ROW FONT STYLE(*;"List Box";3;Italic+Underline)
 // equivalent toArrGlobalStyle{3}:=Italic+Underline
```

| | | | | | |
|---|---|---|---|---|---|
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| *text* | *text* | *text* | *text* | **text** | *text* |
| text | text | text | text | text | text |
| text | text | text | text | text | text |
| text | text | text | text | text | text |

After the second statement, all the cells of the third row change to underlined italic, except for the one in the 5th column which stays in bold only (column style arrays take priority over list box arrays).

# LISTBOX SET ROW HEIGHT

LISTBOX SET ROW HEIGHT ( {* ;} object ; row ; height )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| row | Longint | ➡ | List box row whose height you want to set |
| height | Longint | ➡ | Height of list box row |

## 4D View Pro

This command requires a 4D View Pro license. If this license is not available, an error is displayed in the list box when the form is executed. For more information, please refer to the **4D View Pro** section.

## Description

The **LISTBOX SET ROW HEIGHT** command allows you to modify the height of the specified *row* in the list box object designated using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

If the specified *row* does not exist in the list box, the command does nothing.

The unit used for the specified *height* corresponds to the one defined globally for the list box rows, either in the Property list or by a prior call to the **LISTBOX SET ROWS HEIGHT** command.

The **LISTBOX SET ROW HEIGHT** command modifies the row height array specified in the Property List, if any (for more information, please see the **Row Height Array** section in the *Design Reference* manual); otherwise, its creates a row height array dynamically. Using this command to set individual row heights produces the exact same visual result as associating a row height array using the Property List; however, filling a row height array with values is much faster than calling this command in a loop to set row heights one by one for the list box.

**Important note:** If the global **LISTBOX SET ROWS HEIGHT** command is called subsequently with a different unit than the one previously defined, the default value set by this command will replace and reinitialize any row heights set using **LISTBOX SET ROW HEIGHT** (see example 2).

## Example 1

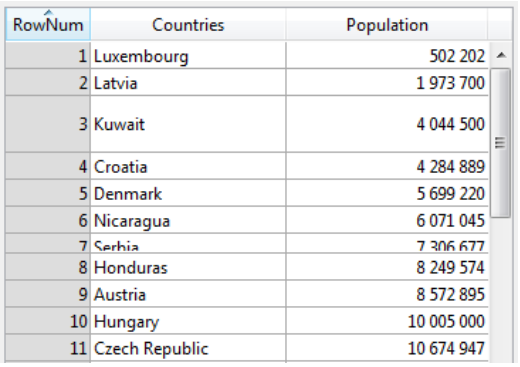
You want to change the height of a few rows in the following list box:

| RowNum | Countries | Population |
|---|---|---|
| 1 | Luxembourg | 502 202 |
| 2 | Latvia | 1 973 700 |
| 3 | Kuwait | 4 044 500 |
| 4 | Croatia | 4 284 889 |
| 5 | Denmark | 5 699 220 |
| 6 | Nicaragua | 6 071 045 |
| 7 | Serbia | 7 306 677 |
| 8 | Honduras | 8 249 574 |
| 9 | Austria | 8 572 895 |
| 10 | Hungary | 10 005 000 |
| 11 | Czech Republic | 10 674 947 |

If you execute this code:

```
 //current unit is pixels
LISTBOX SET ROW HEIGHT(*;"listboxname";3;40) //Kuwait
LISTBOX SET ROW HEIGHT(*;"listboxname";7;14) //Serbia
```

... you get the following result:



| RowNum | Countries | Population |
|---|---|---|
| 1 | Luxembourg | 502 202 |
| 2 | Latvia | 1 973 700 |
| 3 | Kuwait | 4 044 500 |
| 4 | Croatia | 4 284 889 |
| 5 | Denmark | 5 699 220 |
| 6 | Nicaragua | 6 071 045 |
| 7 | Serbia | 7 306 677 |
| 8 | Honduras | 8 249 574 |
| 9 | Austria | 8 572 895 |
| 10 | Hungary | 10 005 000 |
| 11 | Czech Republic | 10 674 947 |

## Example 2

You have set a default row height and then set several individual row height values using the **LISTBOX SET ROW HEIGHT** command:

```
LISTBOX SET ROWS HEIGHT(*;"listboxname";25;lk pixels) // global height set in pixels

LISTBOX SET ROW HEIGHT(*;"listboxname";1;30) // row 1: 30 pixels
LISTBOX SET ROW HEIGHT(*;"listboxname";5;40) // row 5: 40 pixels
LISTBOX SET ROW HEIGHT(*;"listboxname";11;50) // row 11: 50 pixels
```

Later, if the following code is executed…

```
LISTBOX SET ROWS HEIGHT(*;"listboxname";18;lk pixels)
```

…then the global row height is set to 18 pixels; however, since the unit has not changed, rows 1, 5 and 11 will keep their specific height values, i.e., 30, 40 and 50 pixels as defined above by the **LISTBOX SET ROW HEIGHT** command.

On the other hand, if the code below is executed subsequently…

```
LISTBOX SET ROWS HEIGHT(*;"listboxname";2;lk lines)
```

…then rows 1, 5 and 11 are reset to the global default row height set by **LISTBOX SET ROWS HEIGHT** (i.e., 2 lines) because the unit has changed from pixels to lines**.** Since there is no automatic conversion applied, changing units always results in row heights being reinitialized to the new default value defined.

# LISTBOX SET ROWS HEIGHT

LISTBOX SET ROWS HEIGHT ( {* ;} object ; height {; unit} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| height | Longint | ⇒ | Row height (in pixels) |
| unit | Longint | ⇒ | Unit of height value:<br>0 or omitted = pixels, 1 = lines |

## Description

The **LISTBOX SET ROWS HEIGHT** command allows you to modify by programming the row height in the list box object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

By default, if you omit the *unit* parameter, the height is expressed in pixels. To modify the unit, in the *unit* parameter you can pass one of the following constants, found in the **List Box** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |

**Note:** For more information about calculating the height of rows, refer to the *Design Reference* manual.

# LISTBOX SET STATIC COLUMNS

LISTBOX SET STATIC COLUMNS ( {* ;} object ; numColumn )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| numColumn | Longint | ⇒ | Number of columns to make static |

## Description

The **LISTBOX SET STATIC COLUMNS** command sets *numColumns* columns as static (starting from the first on the left) in the list box designated by the *object* and * parameters.

Static columns cannot be moved within the list box.

**Note:** Static columns and locked columns are two independent functions. For more information, refer to the *Design Reference* manual.

# LISTBOX SET TABLE SOURCE

LISTBOX SET TABLE SOURCE ( {* ;} object ; tableNum | selName {; highlightName} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| tableNum \| selName | Longint, String | ⇒ | Number of table whose current selection is to be used or Named selection to be used |
| highlightName | String | ⇒ | Name of highlight set |

## Description

The **LISTBOX SET TABLE SOURCE** command can be used to modify the source of the data displayed in the listbox that is designated by the * and *object* parameters.

**Note:** This command can only be used when the “Data Source” property of the list box is set to **Current Selection** or **Named Selection** (for more information about this, please refer to the **Managing List Box Objects** section). It does nothing if you use it with a listbox that is associated with an array.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, please refer to the **Object Properties** section.

If you pass a table number as the *tableNum* parameter, the listbox will be filled in with the data of the records in the current selection of the table.

If you pass a named selection as the *selName* parameter, the listbox will be filled in with the data of the records belonging to the named selection.

The optional *highlightName* parameter associates a highlight set with the list box. The highlight set manages record highlighting by the user in the list box.

If the listbox already contains columns, their contents will be updated after the command is executed.

**Note:** For optimization purposes, this command is processed in an asynchronous manner; in other words, the source of the listbox is changed only after the complete execution of the method in which the command is called.

# LISTBOX SORT COLUMNS

LISTBOX SORT COLUMNS ( {* ;} object ; colNum ; order {; colNum2 ; order2 ; ... ; colNumN ; orderN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| colNum | Longint | ⇒ | Column number(s) to sort |
| order | Operator | ⇒ | ">" to sort in ascending order or "<" to sort in descending order |

## Description

The **LISTBOX SORT COLUMNS** command sorts the rows of the list box set in the *object* and * parameters on the basis of one or more column value(s).

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string. For more information about object names, refer to the **Object Properties** section.

In *colNum*, pass the column number of the column whose values you want to use as the sort criteria. You can use any type of array data, except pictures and pointers.

In *order*, pass the symbol > or < to indicate the sort order. If *order* contains the “greater than” symbol (>), the sort order is ascending. If *order* contains the “less than” symbol (<), the sort oder is descending.

You can define multi-level sorts: to do so, pass as many pairs (*colNum;order*) as necessary. The sorting level is defined by the position of the parameter in the call.

In conformity with the principle of list box operation, the columns are synchronized which means that the sorting of a column is automatically passed on to all the other columns of the object.

# Math

- Abs

# Abs

Abs ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number for which to return the absolute value |
| Function result | Real | ⇐ | Absolute value of number |

## Description

**Abs** returns the absolute (unsigned, positive) value of *number*. If *number* is negative, it is returned as positive. If *number* is positive, it is returned unchanged.

## Example

The following example returns the absolute value of −10.3, which is 10.3:

```
vlVector:=Abs(-10.3)
```

# Arctan

Arctan ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Tangent for which to calculate the angle |
| Function result | Real | ⇒ | Angle in radians |

## Description

**Arctan** returns the angle, expressed in radians, of the tangent *number*.

**Note:** 4D provides the predefined constants Pi, Degree, and Radian. Pi returns the Pi number (3.14159...), Degree returns one degree expressed in radians (0.01745...), and Radian returns one radian expressed in degrees (57.29577...).

## Example

The following example shows the value of Pi:

```
ALERT("Pi is equal to: "+String(Arctan(1)*4))
```

# Cos

Cos ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number, in radians, whose cosine is returned |
| Function result | Real | ⇐ | Cosine of number |

## Description

**Cos** returns the cosine of *number*, where *number* is expressed in radians.

**Note:** 4D provides the predefined constants Pi, Degree, and Radian. Pi returns the Pi number (3.14159...), Degree returns one degree expressed in radians (0.01745...), and Radian returns one radian expressed in degrees (57.29577...).

# Dec

Dec ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number whose decimal portion is returned |
| Function result | Real | ⮌ | Decimal part of number |

## Description

**Dec** returns the decimal (fractional) portion of *number*.The value returned is always positive or zero.

## Example

The following example takes a monetary value expressed as a real number, and extracts the dollar part and the cents part. If *vrAmount* is 7.31, then *vlDollars* is set to 7 and *vlCents* is set to 31:

```
vlDollars:=Int(vrAmount) ` Get the dollars
vlCents:=Dec(vrAmount)*100 ` Get the fractional part
```

# Euro converter

Euro converter ( value ; fromCurrency ; toCurrency ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| value | Real | ⇒ | Value to convert |
| fromCurrency | String | ⇒ | Code of the currency in which the value is expressed |
| toCurrency | String | ⇒ | Code of the currency into which the value must be converted |
| Function result | Real | ⇐ | Converted value |

## Description

The **Euro converter** command converts any value from and to the different currencies belonging to “Euroland” and the Euro currency itself.

You can convert:

- a national currency into Euros,
- Euros into a national currency,
- a national currency into another national currency. In this case, the conversion is calculated by the intermediary of the Euro, as specified in the European reglementation. For example, to convert Belgian francs to Deutschemarks, 4D will perform the following calculations: Belgian francs -> Euros -> Deutchemarks.

Pass the value to convert in the first parameter.
The second parameter indicates the Currency code in which value is expressed.
The third parameter indicates the Currency code into which value must be converted.

To specify a Currency code, 4D proposes the following predefined constants, placed in the “**Euro Currencies**” theme:

| Constant | Type | Value |
|---|---|---|
| Austrian Schilling | String | ATS |
| Belgian Franc | String | BEF |
| Deutsche Mark | String | DEM |
| Euro | String | EUR |
| Finnish Markka | String | FIM |
| French Franc | String | FRF |
| Greek Drachma | String | GRD |
| Irish Pound | String | IEP |
| Italian Lira | String | ITL |
| Luxembourg Franc | String | LUF |
| Netherlands Guilder | String | NLG |
| Portuguese Escudo | String | PTE |
| Spanish Peseta | String | ESP |

If necessary, 4D performs rounding automatically on conversion results and keeps 2 decimals —except for conversions to Italian Lires, Belgian Francs, Luxembourg Francs and Spanish Pesetas, for which 4D keeps 0 decimal (the result is an integer number).

The conversion rates between the Euro and the currencies of the 11 participating Member States are fixed:

| Currency | Value for 1 Euro |
|---|---|
| Austrian Schilling | 13.7603 |
| Belgian Franc | 40.3399 |
| Deutschemark | 1.95583 |
| Finnish Markka | 5.94573 |
| French Franc | 6.55957 |
| Greek drachma | 340.750 |
| Irish Pound | 0.787564 |
| Italian Lire | 1936.27 |
| Luxembourg Franc | 40.3399 |
| Netherlands Guilder | 2.20371 |
| Portuguese Escudo | 200.482 |
| Spanish Peseta | 166.386 |

## Example

Here are some examples of conversions that can be done with this command:

```
$value:=10000 `Value expressed in French Francs
 `Convert the value into Euros
$InEuros:=Euro converter($value;French Franc;Euro)
 `Convert the value into Italian Lire
$InLires:=Euro converter($value;French Franc;Italian Lire)
```

# Exp

Exp ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number to evaluate |
| Function result | Real | ⇒ | Natural log base by the power of number |

## Description

**Exp** raises the natural log base (e = 2.71828...) by the power of *number*. **Exp** is the inverse function of **Log**.

**Note:** 4D provides the predefined constant *e number* (2.71828...).

## Example

The following example assigns the exponential of 1 to *vrE* (the log of *vrE* is 1):

```
vrE:=Exp(1) ` vrE gets 2.17828...
```

# Int

Int ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number whose integer portion is returned |
| Function result | Real | ⮌ | Integer portion of number |

## Description

**Int** returns the integer portion of *number*. **Int** truncates a negative *number* away from zero.

## Example

The following example illustrates how **Int** works for both positive and negative numbers. Note that the decimal portion of the number is removed:

```
vlResult:=Int(123.4) ` vlResult gets 123
vlResult:=Int(-123.4) ` vlResult gets -124
```

# Log

Log ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number for which to return the log |
| Function result | Real | ⇒ | Log of number |

## Description

**Log** returns the natural (Napierian) log of *number*. **Log** is the inverse function of **Exp**.

**Note:** 4D provides the predefined constant *e number* (2.71828...).

## Example

The following line displays 1:

```
ALERT(String(Log(Exp(1))))
```

# Mod

Mod ( number1 ; number2 ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number1 | Longint | ⇨ | Number to divide |
| number2 | Longint | ⇨ | Number to divide by |
| Function result | Real | ⇦ | Returns the remainder |

## Description

The **Mod** command returns the remainder of the Integer division of *number1* by *number2*.

**Notes:**

- **Mod** accepts Integer, Long Integer, and Real expressions. However, if *number1* or *number2* are real numbers, the numbers are first rounded and then **Mod** is calculated.
- Be careful when using **Mod** with real numbers of a large size (above 2^31) since, in this case, its operation may reach the limits of the calculation capacities of standard processors.

You can also use the % operator to calculate the remainder (see **Numeric Operators**).

**WARNING:** The % operator returns valid results with Integer and Long Integer expressions. To calculate the modulo of real values, you must use the **Mod** command.

## Example

The following example illustrates how the **Mod** function works with different arguments. Each line assigns a number to the *vlResult* variable. The comments describe the results:

```
vlResult:=Mod(3;2) ` vlResult gets 1
vlResult:=Mod(4;2) ` vlResult gets 0
vlResult:=Mod(3.5;2) ` vlResult gets 0
```

# Random

Random -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Random number |

## Description

**Random** returns a random integer value between 0 and 32,767 (inclusive).

To define a range of integers from which the random value will be chosen, use this formula:

```
(Random%(vEnd-vStart+1))+vStart
```

The value *vStart* is the first number in the range, and the value *vEnd* is the last.

## Example

The following example assigns a random integer between 10 and 30 to the *vlResult* variable:

```
vlResult:=(Random%21)+10
```

# Round

Round ( round ; places ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| round | Real | ⇒ | Number to be rounded |
| places | Longint | ⇒ | Number of decimal places used for rounding |
| Function result | Real | ⇐ | Number rounded to the number of decimal places specified by Places |

## Description

**Round** returns *number* rounded to the number of decimal places specified by *places*.

If *places* is positive, *number* is rounded to *places* decimal places. If *places* is negative, *number* is rounded on the left of the decimal point.

If the digit following *places* is 5 though 9, **Round** rounds toward positive infinity for a positive number, and toward negative infinity for a negative number. If the digit following *places* is 0 through 4, **Round** rounds toward zero.

## Example

The following example illustrates how **Round** works with different arguments. Each line assigns a number to the *vlResult* variable. The comments describe the results:

```
vlResult:=Round(16.857;2) ` vlResult gets 16.86
vlResult:=Round(32345.67;-3) ` vlResult gets 32000
vlResult:=Round(29.8725;3) ` vlResult gets 29.873
vlResult:=Round(-1.5;0) ` vlResult gets -2
```

# SET REAL COMPARISON LEVEL

SET REAL COMPARISON LEVEL ( epsilon )

| Parameter | Type | | Description |
|---|---|---|---|
| epsilon | Real | ⇒ | Epsilon value for real equality comparisons |

## Description

The **SET REAL COMPARISON LEVEL** command sets the epsilon value used by 4D to compare real values and expressions for equality.

A computer always performs approximative real computations; therefore, testing real numbers for equality should take this approximation into account. 4D does this when comparing real numbers by testing whether or not the difference between the two numbers exceeds a certain value. This value is called the **epsilon** and works this way:

Given two real numbers *a* and *b*, if **Abs***(a-b)* is greater than the epsilon, the numbers are considered not equal; otherwise, the numbers are considered equal.

By default, 4D, sets the epsilon value to 10 power minus 6 (10^-6). Please note that the *epsilon* value should always be positive. Examples:

- *0.00001=0.00002* returns False, because the difference *0.00001* is greater than *10^-6*.
- *0.000001=0.000002* returns True, because the difference *0.000001* is not greater than *10^-6*.
- *0.000001=0.000003* returns False, because the difference *0.000002* is greater than *10^-6*.

Using **SET REAL COMPARISON LEVEL**, you can increase or decrease the epsilon value as you require.

**WARNING:** Typically, you will not need to use this command to change the default epsilon value.

**IMPORTANT:** Changing the epsilon only affects real comparison for equality. It has no effect on other real computations nor on the display of real values.

**Note:** The **SET REAL COMPARISON LEVEL** command has no effect on queries and sorts performed with fields of the Real type. It only applies the 4D language.

# Sin

Sin ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number, in radians, whose sine is returned |
| Function result | Real | ⇐ | Sine of number |

## Description

**Sin** returns the sine of *number*, where *number* is expressed in radians.

**Note:** 4D provides the predefined constants Pi, Degree, and Radian. Pi returns the Pi number (3.14159...), Degree returns one degree expressed in radians (0.01745...), and Radian returns one radian expressed in degrees (57.29577...).

# Square root

Square root ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number whose square root is calculated |
| Function result | Real | ⇒ | Square root of the number |

## Description

**Square root** returns the square root of *number*.

## Example 1

The line:

```
$vrSquareRootOfTwo :=Square root(2)
```

assigns the value *1.414213562373* to the variable *$vrSquareRootOfTwo*.

## Example 2

The following method returns the hypotenuse of the right triangle whose two legs are passed as parameters:

```
  ` Hypotenuse method
  ` Hypotenuse ( real ; real ) -> real
  ` Hypotenuse ( legA ; legB ) -> Hypotenuse
C_REAL($0;$1;$2)
$0:=Square root(($1^2)+($2^2))
```

For instance, Hypotenuse (4;3) returns 5.

# Tan

Tan ( number ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number, in radians, whose tangent is returned |
| Function result | Real | ⇐ | Tangent of number |

## Description

**Tan** returns the tangent of *number*, where *number* is expressed in radians.

**Note:** 4D provides the predefined constants Pi, Degree, and Radian. Pi returns the Pi number (3.14159...), Degree returns one degree expressed in radians (0.01745...), and Radian returns one radian expressed in degrees (57.29577...).

# Trunc

Trunc ( number ; places ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| number | Real | ⇒ | Number to be truncated |
| places | Longint | ⇒ | Number of decimal places used for truncating |
| Function result | Real | ⇐ | Number with its decimal part truncated to the number of decimal places specified by Places |

## Description

**Trunc** returns *number* with its decimal part truncated to the number of decimal places specified by *places*. **Trunc** always truncates toward negative infinity.

If *places* is positive, *number* is truncated to *places* decimal places. If *places* is negative, number is truncated on the left of the decimal point.

## Example

The following example illustrates how **Trunc** works with different arguments. Each line assigns a number to the *vlResult* variable. The comments describe the results:

```
vlResult:=Trunc(216.897;1) ` vlResult gets 216.8
vlResult:=Trunc(216.897;-1) ` vlResult gets 210
vlResult:=Trunc(-216.897;1) ` vlResult gets -216.9
vlResult:=Trunc(-216.897;-1) ` vlResult gets -220
```

# Managing Menus

**Terminology:** The documentation of Menus commands uses the terms **menu command** and **menu item** interchangeably when describing a line in a menu.

## MenuRef and Menu Numbers

The language of 4D offers two ways of managing menus and menu bars: by references or by numbers.

- Managing menus by reference (MenuRef) is the new way of handling menus, introduced with version 11 of 4D. This mode gives access to advanced functions such as the creation of completely dynamic interfaces (menus created "on the fly" without necessarily existing in the Menu editor) and the managing of multi-level hierarchical submenus.
- Managing menus and menu bars by number is based on the menus created in the Menu editor in Design mode. Each menu bar and menu is assigned a fixed number (corresponding to its position in the editor). This number is used by the language commands to specify the menu bar or menu. The scope of language commands applied to menus managed by number is the current menu bar.
  This behavior corresponds to previous versions of 4D and complies with several rules (described below in the "Managing menus by number" paragraph). It can still be used but does not take advantage of the new functions offered starting with version 11, more particularly the dynamic management of menus and the use of hierarchical submenus: it is not possible to access a hiearchical submenu using a number.

Both menu management modes are compatible and can be used simultaneously in your interfaces. Most of the commands in the “Menus” theme accept both menu numbers and references indiscriminately.

However, managing menus by reference is recommended since it offers many more possibilities. Note that if your menu interface is partially or completely defined via the Menu editor, it remains entirely possible to work with it in the form of references using the **Get menu bar reference** and **GET MENU ITEMS** commands.

## Managing menus by reference

When menus are handled by means of MenuRef references, there is no difference per se between a menu and a menu bar. In both cases, it consists of a list of items. Only their use differs. In the case of a menu bar, each item corresponds to a menu which is itself composed of items. This is also the principle on which hierarchical menus are based: each item can itself be a menu, and so on.

When a menu is managed by reference, any changes made to this menu during the session are immediately passed on to every instance of this menu and in every process of the database.

### MenuRef

Like hierarchical lists, every menu has a unique reference, with which it can be identified during the entire session. This reference, named by convention *MenuRef*, is a 16-character alphanumeric. All the commands of the “Menus” theme accept either this reference, or a menu number, to specify a menu or menu bar.

Menu references can be obtained using the **Create menu**, **Get menu bar reference** or **GET MENU ITEMS** commands.

## Managing menus by number

### Menu Bars

Menu bars can be defined in the Menu editor in Design mode. When managed by number, each menu bar is identified by a number and by a name. The first menu bar (created automatically by 4D) has the number 1 and is named Menu Bar #1 by default. You can rename it in the Menu editor. The name of a menu bar may contain up to 31 characters and must be unique.

Menu Bar #1 is also the default menu bar. To open an application with a menu bar other than Menu Bar #1, you must use the **SET MENU BAR** command in the **On Startup database method**. It is not possible to modify the contents of a menu bar itself by programming; however, the menus comprising it can be modified. The scope of the language commands applied to

static menus is the current menu bar. On each call to the **SET MENU BAR** command (without the * parameter), all the menus and menu commands return to their original state as defined in the Menu editor.

Every menu bar comes equipped with three menus—the **File**, **Edit** and **Mode** menus.

- The **File** menu has only one menu command—Quit. The Quit standard action is assigned to it. This action displays an "Are you sure?" confirmation dialog box then quits the 4D application if this dialog box is validated. Otherwise, the operation is cancelled.

**Note:** Under Mac OS X, the created menu command associated with the Quit action is automatically placed in the application menu when the database is executed on this system.

You can rename the File menu, add menu commands to it or keep it as is. It is recommended that you always keep Quit as the last menu command in the File menu.

- The **Edit** menu contains the standard editing menu commands. A standard action (Cancel, Cut, Copy, etc.) is assigned to each command of this menu. You can add commands to this menu or use your own methods for managing editing actions.
- The **Mode** menu contains the Return to Design mode command. This command can be used to return to the Design mode (when it is available) from the Application mode.

**Note:** 4D automatically manages the **Help** and **application** (Mac OS X) system menus. These menus cannot be modified, except for the **About 4D** command, which can be managed using the **SET ABOUT** command.

**Warning:** Menu bars are "interprocess." Any modification carried out on a menu bar in the Design mode will be reflected in all the processes where the menu bar is used.

### Menu Numbers and Menu Command Numbers

Like menu bars, menus are numbered. The **File** menu is generally menu 1. Thereafter, menus are numbered sequentially from left to right (2, 3, 4, and so on). The **Application** menu (Mac OS ) is excluded from this numbering. On both platforms, the **Help** menu is also excluded. It should be noted that the **Count menus** command does not take these menus into account. If, for example, your menu bar consists of the File, Edit, Customers, Inoices and Help menus, **Count menus** will return 4 (ignoring the system menus maintained by 4D).

Menu numbering is important when you are working, for example, with the **Menu selected** function.

When a menu is associated with a form, the menu numbering scheme is different. The first appended menu begins with the number 2049. To refer to an appended menu, add 2048 to the normal menu number.

The menu commands within each menu are numbered sequentially from the top of the menu to the bottom including the separators. The topmost menu command is item 1.

### Associated Menu Bars

You can associate a menu bar with a form in the Form properties (General page). Such a menu bar is called a “form menu bar” in this document.

The menus on a form menu bar are appended to the current menu bar when the form is displayed as an output form in the Application environment.

Form menu bars are specified by a menu bar number and a name. If the number or name of the menu bar displayed with the current form is the same as that of the menu bar appended to the form, the menu bar is not appended.

By default, when a form is displayed with a custom menu bar, the commands of the current menu bar are deactivated, i.e. selecting them has no effect. You can modify this operation by checking the **Active Menu Bar** option in the Form properties: in this case, the commands of the current menu bar will remain usable.

In every case, the selection of a menu command causes an On Menu Selected event to be sent to the form method; you can then use the **Menu selected** command to test the selected menu.

### Attached Menus

Menus can be attached to menu bars. If an attached menu is modified using one of these commands, every other instance of the menu will reflect these changes. For more information about attaching menus, refer to the 4D Design Reference Manual.

## Standard actions and methods associated with menu commands

Each menu command can have a project method or a standard action attached to it. If you do not assign a method or a standard action to a menu command, choosing that menu command causes 4D to exit the Application environment and go to the Design environment. If only the Application environment is available or if the user does not have access to the Design environment, this means quitting to the Desktop.

Standard actions can be used to carry out various current operations linked to system functions (copy, quit, etc.) or to those of the 4D database (add record, select all, etc.).

You can assign both a standard action and a project method to a menu command. In this case, the standard action is never executed; however, 4D uses this action to activate/deactivate the menu command according to the current context and to associate a specific operation with it according to the platform (for example, the Preferences action is passed in the application menu under Mac OS). When a menu command is deactivated, the associated project method cannot be executed.

## menuItem=-1

In order to facilitate the managing of menu items, 4D provides a shortcut that can be used to specify the last item added to the menu: you simply need to pass -1 in the *menuItem* parameter.

This principle can be used in all the commands of the “Menus” theme that work with menu items.

# APPEND MENU ITEM

APPEND MENU ITEM ( menu ; itemText {; subMenu {; process {; *}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| itemText | Text | ⇒ | Text for the new menu items |
| subMenu | MenuRef | ⇒ | Reference of submenu associated with item |
| process | Longint | ⇒ | Process reference number |
| * | Operator | ⇒ | If passed: consider metacharacters as standard characters |

## Description

The **APPEND MENU ITEM** command appends new menu items to the menu whose number or reference is passed in *menu*.

If you omit the *process* parameter, **APPEND MENU ITEM** applies to the menu bar for the current process. Otherwise, **APPEND MENU ITEM** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purporse and will be ignored.

If you do not pass the * parameter, **APPEND MENU ITEM** allows you to append one or several menu items in one call.

You define the items to be appended with the parameter *itemText* as follows:

- Separate each item from the next one with a semi-colon (*;*). For example, *"ItemText1;ItemText2;ItemText3".*
- To disable an item: Place an opening parenthesis (*(*) in the item text.
- To specify a separation line: Pass "-" or "(-" as item text.
- To specify a font style for a line: In the item text, place a less than sign (<) followed by one of these characters:

| | |
|---|---|
| <B | Bold |
| <I | Italic |
| <U | Underline |

- To add a check mark to an item: In the item text, place an exclamation mark (*!*) followed by the character you want as a check mark. On Macintosh, the character is displayed; on Windows, a check mark is displayed no matter what character you passed.
- To add an icon to an item: In the item text, place a circumflex accent (^) followed by a character whose code plus 208 is the resource ID of a Mac OS-based icon resource.
- To add a shortcut to an item: In the item text, place a slash (*/*) followed by the shortcut character for the item.

**Note:** Use menus that have a reasonable number of items. For example, if you want to display more than 50 items, consider using a scrollable area in a form instead of a menu.

If you pass the * parameter, the "special" characters (*; ( !*...) included in the item text will be considered as standard characters and not as metacharacters. This means that you can create menu items like "**Copy (special)...**" or "**Find/Replace...**". Note that when the * parameter is passed, you cannot create several items in a single call since the ";" character is considered as a standard character.

**Note:** The **GET MENU ITEMS** and **Get menu item** commands will or will not return any metacharacters in the text of a menu item depending on how it was created: if it was created with the * option, metacharacters will be returned as standard characters.

The optional *subMenu* parameter can be used to indicate a menu as the added item and thus position a hierarchical submenu. You must pass a menu reference (*MenuRef* type string) specifying a menu created, for example, using the **Create menu** command. If the command adds more than one menu item, the submenu is associated with the first item.

**Important:** The new items do not have any associated methods or actions. These must be associated with the items using the **SET MENU ITEM PROPERTY** or **SET MENU ITEM METHOD** commands, or the items can also be managed from within a form method using the **Menu selected** command.

## Example

This example appends the names of the available fonts to the Font menu, which in this example is the sixth menu of the current menu bar:

```
  ` In the On Startup database method
  ` The font list is loaded and menu item text is built
FONT LIST(◊asAvailableFont)
◊atFontMenuItems:=""
For($vlFont;1;Size of array(◊asAvailableFont))
   ◊atFontMenuItems:=◊atFontMenuItems+";"+◊asAvailableFont{$vlFont}
End for
```

Then, in any form or project method, you can write:

```
APPEND MENU ITEM(6;◊atFontMenuItems)
```

# Count menu items

Count menu items ( menu {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| process | Longint | ⇒ | Process reference number |
| Function result | Longint | ⇐ | Number of menu items in the menu |

## Description

The **Count menu items** command returns the number of menu items present in the menu whose number or reference is passed in *menu.*

If you omit the *process* parameter, **Count menu items** applies to the menu bar for the current process. Otherwise, **Count menu items** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* parameter in *menu*, the *process* parameter serves no purpose and will be ignored.

# Count menus

Count menus {( process )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇒ | Process reference number |
| Function result | Longint | ⇐ | Number of menus in the current menu bar |

## Description

The **Count menus** command returns the number of menus present in the menu bar.

If you omit the *process* parameter, **Count menus** applies to the menu bar for the current process. Otherwise, **Count menus** applies to the menu bar for the process whose reference number is passed in *process*.

# Create menu

Create menu {{ menu )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | MenuRef, Longint, String | ⇒ | Menu reference or Number or Name of menu bar |
| Function result | MenuRef | ⇐ | Menu reference |

## Description

The **Create menu** command creates a new menu in memory. This menu will only exist in memory and will not be added in the Menu editor in Design mode. Any changes made to this menu during the session will be immediately carried over to all the instances of this menu and in all the processes of the database.

The command returns an ID of the *MenuRef* type for the new menu.

- If you do not pass the optional *menu* parameter, the menu is created blank. You must build and manage it using the **RELEASE MENU**, **SET MENU ITEM**, etc. commands.
- If you pass the *menu* parameter, the menu created will be an exact copy of the source menu designated by this parameter. All the properties of the source menu, including any associated submenus, will be applied to the new menu. Note that a new *MenuRef* reference is created for the source menu and for any existing submenus that are associated with it.

In the *menu* parameter, you can pass either a valid menu reference, or the number or name of a menu bar defined in Design mode. In this last case, the new menu will be made up of the menus and submenus of the source menu bar.

**Note:** If you pass an invalid value in *menu*, a blank menu is created.

A menu created by this command can be used as the menu bar using the **SET MENU BAR** command.

When you no longer need the menu created by **Create menu**, remember to call the **RELEASE MENU** command in order to free up the memory being used.

## Example

Refer to the example of the **SET MENU BAR** command.

# DELETE MENU ITEM

DELETE MENU ITEM ( menu ; menuItem {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for last item added |
| process | Longint | ⇒ | Process reference number |

## Description

The **DELETE MENU ITEM** command deletes the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If the menu item specified by *menu* and *menuItem* is itself a menu managed by reference and created, for example, using the **Create menu** command, **DELETE MENU ITEM** will only delete the instance of the *menuItem* in *menu*. The submenu referenced by the *menuItem* will continue to exist in memory. You must use the **RELEASE MENU** command in order to definitively delete a menu that is managed by reference.

This command also works with a menu bar created using the **Create menu** command and installed with the **SET MENU BAR** command.

If you omit the *process* parameter, **DELETE MENU ITEM** applies to the menu bar for the current process. Otherwise, **DELETE MENU ITEM** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

**Note:** For consistency in the user interface, do not keep a menu with no items.

# DISABLE MENU ITEM

DISABLE MENU ITEM ( menu ; menuItem {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for the last item added |
| process | Longint | ⇒ | Proces reference number |

## Description

The **DISABLE MENU ITEM** command disables the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem*.You can pass -1 in *menuItem* in order to designate the last item added to the *menu*.

If you omit the *process* parameter, **DISABLE MENU ITEM** applies to the menu bar for the current process. Otherwise, **DISABLE MENU ITEM** applies to the menu bar for the process whose reference number is passed in *process*.

If the *menuItem* parameter designates a hierarchical submenu, all the items of this menu and any submenus are disabled. This command also works with a menu bar created using the **Create menu** command and installed with the **SET MENU BAR** command.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

**Tip:** To enable/disable all items of a menu at once, pass 0 (zero) in *menuItem*.

# ENABLE MENU ITEM

ENABLE MENU ITEM ( menu ; menuItem {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for the last item added |
| process | Longint | ⇒ | Proces reference number |

## Description

The **ENABLE MENU ITEM** command enables the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem*. You can pass -1 in *menuItem* in order to designate the last item added to the *menu*.

If the *menuItem* parameter designates a hierarchical submenu, all the items of this menu and any submenus are enabled. This command also works with a menu bar created using the **Create menu** command and installed with the **SET MENU BAR** command.

If you omit the *process* parameter, **ENABLE MENU ITEM** applies to the menu bar for the current process. Otherwise, **ENABLE MENU ITEM** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

**Tip:** To enable/disable all items of a menu at once, pass 0 (zero) in *menuItem*.

# Get menu bar reference

Get menu bar reference {( process )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇒ | Reference number of process |
| Function result | MenuRef | ⇄ | Menu bar ID |

## Description

The **Get menu bar reference** command returns the ID of the current menu bar or the menu bar of a specific process.

If the menu bar was created by the **Create menu** command, this ID corresponds to the reference ID of the menu created. Otherwise, the command returns a specific internal ID. In all cases, this *MenuRef* ID may be used to reference the menu bar by all the other commands of the theme.

The *process* parameter can be used to designate the process where you want to get the current menu bar ID. If you omit this parameter, the command returns the menu bar ID of the current process.

## Example

Refer to the example of the **GET MENU ITEMS** command.

# Get menu item

Get menu item ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for last item added |
| process | Longint | ⇒ | Process reference number |
| Function result | String | ⇐ | Text of the menu item |

## Description

The **Get menu item** command returns the text of the menu item whose menu and item numbers are passed in *menu* and *menuItem*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If you omit the *process* parameter, **Get menu item** applies to the menu bar for the current process. Otherwise, **Get menu item** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

# GET MENU ITEM ICON

GET MENU ITEM ICON ( menu ; menuItem ; iconRef {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| iconRef | Text variable, Longint variable | ⇐ | Name or number of picture associated with menu item |
| process | Longint | ⇒ | Process number |

## Description

The **GET MENU ITEM ICON** command returns, in the *iconRef* variable, the reference of any icon that is associated with the menu item designated by the *menu* and *menuItem* parameters. This reference is the name or number of the picture.

You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the *process* parameter is unnecessary and will be ignored if it is passed. If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

If the icon has been specified using a library picture, the command returns either the name or number of the picture depending on the type of variable passed in this parameter. If the icon has been specified using a picture stored in the **Resources** folder of the database, the command returns the picture pathname in *iconRef*.

If you do not attribute a specific type to the *iconRef* variable, by default, the name of the picture is returned (text type).

If no icon is associated with the menu item, the command returns a blank value.

# Get menu item key

Get menu item key ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for the last item added |
| process | Longint | ⇒ | Process reference number |
| Function result | Longint | ⇐ | Character code of standard shortcut key associated with the menu item |

## Description

The **Get menu item key** command returns the code of the **Ctrl** (Windows) or **Command** (Macintosh) shortcut for the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If you omit the *process* parameter, **Get menu item key** applies to the menu bar for the current process. Otherwise, **Get menu item key** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

If the menu item has no associated shortcut or if the *menuItem* parameter designates a hierarchical submenu, **Get menu item key** returns *0* (zero).

## Example

To obtain the shortcut associated with a menu item, it is useful to implement a programming structure of the following type:

```
If(Get menu item key(mymenu;1)#0)
   $modifiers:=Get menu item modifiers(mymenu;1)
   Case of
      :($modifiers=Option key mask)
         ...
      :($modifiers=Shift key mask)
         ...
      :($modifiers=Option key mask+Shift key mask)
         ...
   End case
End if
```

# Get menu item mark

Get menu item mark ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ➡ | Menu number or Menu reference |
| menuItem | Longint | ➡ | Menu item number or -1 for last item added |
| process | Longint | ➡ | Process reference number |
| Function result | String | ⮌ | Current menu item mark |

## Description

The **Get menu item mark** command returns the check mark of the menu item whose number or reference is passed in *menu* and whose item number is passed in *menuItem*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If you omit the *process* parameter, **Get menu item mark** applies to the menu bar for the current process. Otherwise, **Get menu item mark** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

If the menu item has no mark or if the *menuItem* parameter specifies a hierarchical submenu, **Get menu item mark** returns an empty string.

**Note:** See discussion of check marks on Macintosh and Windows in the description of the **SET MENU ITEM MARK** command.

## Example

The following example toggles the check mark of a menu item:

```
SET MENU ITEM MARK($vlMenu;$vlItem;Char(18)*Num(Character code(Get menu item mark($vlMenu;$vlItem))#18))
```

# Get menu item method

Get menu item method ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| process | Longint | ⇒ | Process number |
| Function result | String | ⇐ | Method name |

## Description

The **Get menu item method** command returns the name of the 4D project method associated with the menu item designated by the *menu* and *menuItem* parameters.

You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the *process* parameter is unnecessary and will be ignored if it is passed. If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

The command returns the name of the 4D method as a character string (expression). If no method is associated with a menu item, the command returns an empty string.

# Get menu item modifiers

Get menu item modifiers ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| process | Longint | ⇒ | Process number |
| Function result | Longint | ⇐ | Modification key(s) associated with menu item |

## Description

The **Get menu item modifiers** command returns any additional modifier(s) associated with the standard shortcut of the menu item designated by the *menu* and *menuItem* parameters.

The standard shortcut is composed of the Command (Mac OS) or Ctrl (Windows) key plus a custom key. The standard shortcut is managed using the **SET MENU ITEM SHORTCUT** and **Get menu item key** commands.

The additional modifiers are the Shift key and the Option (Mac OS) /Alt (Windows) key. These modifiers can only be used when a standard shortcut has been specified beforehand.

The number value returned by the command corresponds to the codeof the additional modifier key(s). The key codes are as follows:

- **Shift**= 512
- **Option** (Mac OS) or **Alt** (Windows) = 2048
  If both keys are used, their values are combined.

**Note:** You can evaluate the value returned using the Shift key mask and Option key mask constants of the "**Events (Modifiers)**" theme.

If the menu item does not have an associated modifier key, the command returns 0.

You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number.

If you pass a menu reference, the *process* parameter serves no purpose and will be ignored if it is passed.

If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

## Example

Refer to the example of the **Get menu item key** command.

# Get menu item parameter

Get menu item parameter ( menu ; menuItem ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| Function result | String | ⇐ | Custom parameter of the menu item |

## Description

The **Get menu item parameter** command returns the custom character string associated with the menu item designated by the *menu* and *menuItem* parameters. This string must have been set beforehand using the **SET MENU ITEM PARAMETER** command.

# GET MENU ITEM PROPERTY

GET MENU ITEM PROPERTY ( menu ; menuItem ; property ; value {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| property | String | ⇒ | Property type |
| value | Expression | ⇐ | Property value |
| process | Longint | ⇒ | Process number |

## Description

The **GET MENU ITEM PROPERTY** command returns, in the *value* parameter, the current value of the property of the menu item designated by the *menu* and *menuItem* parameters.

You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the *process* parameter is unnecessary and will be ignored if it is passed. If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

In the *property* parameter, pass the property for which you want to get the value. You can use one of the constants of the "**Menu Item Properties**" theme or a string corresponding to a custom property. For more information about menu properties and their values, please refer to the description of the **SET MENU ITEM PROPERTY** command.

# Get menu item style

Get menu item style ( menu ; menuItem {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ➡ | Menu number or Menu reference |
| menuItem | Longint | ➡ | Menu item number or -1 for last item added |
| process | Longint | ➡ | Process reference number |
| Function result | Longint | ⮌ | Current menu item style |

## Description

The **Get menu item style** command returns the font style of the menu item whose number or reference is passed in *menu* and whose item number is passed in *menuItem*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If you omit the *process* parameter, **Get menu item style** applies to the menu bar for the current process. Otherwise, **Get menu item style** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

**Get menu item style** returns a combination (one or a sum) of the following predefined constants, found in the **Font Styles** theme:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

## Example

To test if a menu item is displayed in bold, you write:

```
If((Get menu item style($vlMenu;$vlItem)&Bold)#0)
   `...
End if
```

# GET MENU ITEMS

GET MENU ITEMS ( menu ; menuTitlesArray ; menuRefsArray )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇨ | Menu reference or Menu number |
| menuTitlesArray | String array | ⇦ | Array of menu titles |
| menuRefsArray | String array | ⇦ | Array of menu references |

## Description

The **GET MENU ITEMS** command returns, in the *menuTitlesArray* and *menuRefsArray* arrays, the titles and IDs of all the items of the menu or menu bar designated by the *menu* parameter.

In the *menu* parameter, you can pass a menu reference (*MenuRef*), a menu bar number or a menu bar reference obtained using the **Get menu bar reference** command.

If no menu reference is associated with an item, an empty string is returned in the corresponding array element.

## Example

You want to find out the contents of the menu bar of the current process:

```
ARRAY TEXT(menuTitlesArray;0)
ARRAY TEXT(menuRefsArray;0)
MenuBarRef:=Get menu bar reference(Frontmost process)
GET MENU ITEMS(MenuBarRef;menuTitlesArray;menuRefsArray)
```

# Get menu title

Get menu title ( menu {; process} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| process | Longint | ⇒ | Process reference number |
| Function result | String | ⇐ | Title of the menu |

## Description

The **Get menu title** command returns the title of the menu whose number or reference is passed in *menu.*

If you omit the *process* parameter, **Get menu title** applies to the menu bar for the current process. Otherwise, the command applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

# Get selected menu item parameter

Get selected menu item parameter -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String |  | Custom parameter of the menu item |

## Description

The **Get selected menu item parameter** command returns the custom character string assoaciated with the selected menu item. This parameter must have been set beforehand using the **SET MENU ITEM PARAMETER** command.

If no menu item has been selected, the command returns an empty string "".

# INSERT MENU ITEM

INSERT MENU ITEM ( menu ; afterItem ; itemText {; subMenu {; process}}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| afterItem | Longint | ⇒ | Menu item number |
| itemText | String | ⇒ | Text for the menu item to be inserted |
| subMenu | MenuRef | ⇒ | Reference of submenu associated with item |
| process | Longint | ⇒ | Process reference number |
| * | Operator | ⇒ | If passed: consider metacharacters as standard characters |

## Description

The **INSERT MENU ITEM** command inserts new menu items into the menu whose number or reference is passed in *menu* after the existing menu item whose number is passed in *afterItem*.

If you omit the *process* parameter, **INSERT MENU ITEM** applies to the menu bar for the current process. Otherwise, the command applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

If you do not pass the * parameter, **INSERT MENU ITEM** allows to you insert one or several menu items in one call.

**INSERT MENU ITEM** works like **APPEND MENU ITEM**, except that it enables you to insert items anywhere in the menu, while **APPEND MENU ITEM** always adds them at the end of the menu.

See the description of the **APPEND MENU ITEM** command for details about the item definition passed in *itemText* and about the action of the * parameter.

The optional *subMenu* parameter can be used to indicate a menu as the added item and thus position a hierarchical submenu. You must pass a menu reference (MenuRef type string) specifying a menu created, for example, using the **Create menu** command. If the command adds more than one menu item, the submenu is associated with the first item.

**Important:** The new items do not have any associated methods or actions. These must be associated with the items using the **SET MENU ITEM PROPERTY** or **SET MENU ITEM METHOD** commands, or the items can also be managed from within a form method using the **Menu selected** command.

## Example

The following example creates a menu consisting of two commands to which it assigns a method:

```
menuRef:=Create menu
APPEND MENU ITEM(menuRef;"Characters")
SET MENU ITEM METHOD(menuRef;1;"CharMgmtDial")
INSERT MENU ITEM(menuRef;1;"Paragraphs")
SET MENU ITEM METHOD(menuRef;2;"ParaMgmtDial")
```

# Menu selected

Menu selected {( subMenu )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| subMenu | MenuRef | ⇦ | Reference of menu containing item selected |
| Function result | Longint | ⇨ | Menu command selected Menu number in high word Menu item number in low word |

## Description

**Menu selected** is used only when forms are displayed. It detects which menu command has been chosen from a menu and, in the case of a hierarchical submenu, returns the reference of the submenu.

**Tip:** Whenever possible, use methods associated with menu commands in an associated menu bar (with a negative menu bar number) instead of using **Menu selected**. Associated menu bars are easier to manage, since it is not necessary to test for their selection.

The **Menu selected** command can be used to work with hierarchical submenus. When selecting a hierarchical menu item beyond the first level, the command returns, in the optional *subMenu* parameter, the reference (MenuRef type, 16-character string) of the submenu to which the selected item belongs. If the menu command does not contain a hierarchical submenu, this parameter receives an empy string.

**Menu selected** returns the menu-selected number, a long integer. To find the menu number, divide **Menu selected** by 65,536 and convert the result to an integer. To find the menu command number, calculate the modulo of **Menu selected** with the modulus 65,536. Use the following formulas to calculate the menu number and menu command number:

```
Menu:=Menu selected¥ 65536
menu command:=Menu selected% 65536
```

You can also extract these values using the *bitwise operators* as follows:

```
Menu:=(Menu selected & 0xFFFF0000)>>16
menu command:=Menu selected & 0xFFFF
```

If no menu commands are selected, **Menu selected** returns 0.

## Example

The following form method uses **Menu selected** to supply the menu and menu item arguments to **SET MENU ITEM MARK**:

```
Case of
   :(Form event=On Menu Selected)
      C_STRING(16;$refMenuIncludingItem)
      C_LONGINT($ref;$MenuNum;$MenuItemNum)
      $ref:=Menu selected($refMenuIncludingItem)
      $MenuNum:=$ref¥65536
      $MenuItemNum:=$ref%65536
      SET MENU ITEM MARK($refMenuIncludingItem;$MenuItemNum;Char(18))
End case
```

**Note:** The On Menu Selected form event is not activated if no item is selected, *$refMenuIncludingItem* is always given a value and *$MenuNum* equals 0 if the menu is not one of the menus of the menu bar.

# RELEASE MENU

RELEASE MENU ( menu )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | MenuRef | ➡ | Menu reference |

## Description

The **RELEASE MENU** command removes the menu whose ID is passed in *menu* from memory. This menu must have been created by the menu **Create menu** command. The following rule applies: for each **Create menu** there must be a corresponding **RELEASE MENU**.

The command removes every instance of the *menu* menu from every menu bar and every process. If the menu belongs to a menu bar which is in use, it will continue to work but can no longer be modified. It will only be truly removed from the memory when the last menu bar where it appears is no longer in use.

This command can be used with menus that are used as menu bars.

Any sub-menus used by *menu* are not removed if they were created directly using the **Create menu** command. In this case, you must remove them individually (see the rule mentioned above). However, if the submenus come from the duplication of an existing menu, do not call **RELEASE MENU** with them because 4D will erase them automatically.

## Example

This example shows different ways to use this command:

```
newMenu:=Create menu
APPEND MENU ITEM(newMenu;"Test1")
subMenu:=Create menu
APPEND MENU ITEM(subMenu;"SubTest1")
APPEND MENU ITEM(subMenu;"SubTest2") // Creation of items in submenu

APPEND MENU ITEM(newMenu;"Test2";subMenu) // Attaching submenu to menu

 //At this point, the submenu is attached to the menu and if we will not need it later on, this is right place to remove it.
 //Removing it does not immediately delete subMenu since it is still used by newMenu. subMenu is only deleted when newMenu
is.
 //Removing the submenu here lets you save memory
RELEASE MENU(subMenu)

$result1:=Dynamic pop up menu(newMenu) //Use of menu
copyMenu:=Create menu(newMenu) // Creation of menu by copying newMenu (and thus copying subMenu as well)
RELEASE MENU(newMenu) // We no longer need newMenu.

$result2:=Dynamic pop up menu(copyMenu)
RELEASE MENU(copyMenu)
 //You don't need to worry about deleting the submenus of copyMenu since it was not created directly using Create menu
 //The rule to follow is: each Create menu must have a corresponding RELEASE MENU
```

# SET MENU BAR

SET MENU BAR ( menuBar {; process}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| menuBar | Longint, String, MenuRef | ⇒ | Number or name of the menu bar or Menu reference |
| process | Longint | ⇒ | Process reference number |
| * | Operator | ⇒ | Save menu bar state |

## Description

**SET MENU BAR** replaces the current menu bar with the one specified by *menuBar* for the current process only. In the *menuBar* parameter, you can pass either the number or name of the new menu bar. You can also pass a menu ID (*MenuRef* type, 16-character string). When you work with references, the menus can be used as menu bars and vice versa (see the **Managing Menus** section).

**Note:** The name of a menu bar may contain up to 31 characters and must be unique.

The optional *process* parameter changes the menu bar of the specified process to *menuBar*.

**Note:** If you pass a *MenuRef* in *menuBar*, the *process* parameter serves no purpose and will be ignored.

The optional * parameter allows you to save the state of the menu bar. If this parameter is omitted, **SET MENU BAR** reinitializes the menu bar when the command is executed.

For example, suppose that **SET MENU BAR**(1) is executed. Next, several menu commands are disabled using the **DISABLE MENU ITEM** command.

If **SET MENU BAR(1)** is executed a second time, either from the same process or from a different process, all menu commands will revert to their initial enabled state.

If **SET MENU BAR(1;*)** is executed, the menu bar will retain the same state as before, and the menu commands that were disabled will remain disabled.

**Note:** If you pass a *MenuRef* in *menuBar*, the * parameter serves no purpose and will be ignored.

When a user enters the Application environment, the first menu bar is displayed (Menu Bar #1). You can change this menu bar when opening a database by specifying the desired menu bar in the **On Startup database method** or in the startup method for an individual user.

## Example 1

The following example changes the current menu bar to menu bar #3 and resets the states of the menu commands to their original states:

```
SET MENU BAR(3)
```

## Example 2

The following example changes the current menu bar to the menu bar named “FormMenuBar1” and saves the states of the menu commands. Menu commands that were previously disabled will appear disabled.

```
SET MENU BAR("FormMenuBar1";*)
```

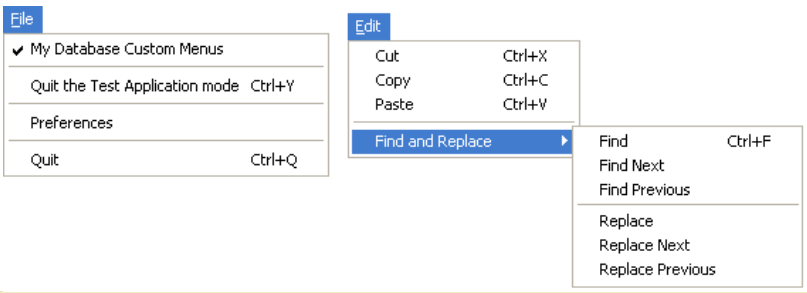
## Example 3

The following example sets the current menu bar to menu bar #3 while records are being modified. After the records have been modified, the menu bar is reset to menu bar #2, with the menu state saved:

```
SET MENU BAR(3)
ALL RECORDS([Customers])
MODIFY SELECTION([Customers])
SET MENU BAR(2;*)
```

## Example 4

In this comprehensive example, we will create, by programming, a menu bar including the following File and Edit menus:



```
 `Method for creating File menu
C_TEXT(FileMenu) ` FileMenu will contain the File menu reference
FileMenu:=Create menu
INSERT MENU ITEM(FileMenu;-1;"My Database "+Get indexed string(131;29))
SET MENU ITEM MARK(FileMenu;1;Char(18))
INSERT MENU ITEM(FileMenu;-1;"(-")
INSERT MENU ITEM(FileMenu;-1;"Quit the Test Application mode/Y")
SET MENU ITEM PROPERTY(FileMenu;3;Associated standard action;Return to Design mode)
INSERT MENU ITEM(FileMenu;-1;"(-")
INSERT MENU ITEM(FileMenu;-1;Get indexed string(131;26))
SET MENU ITEM PROPERTY(FileMenu;6;Associated standard action;Database settings action) `Settings
INSERT MENU ITEM(FileMenu;-1;"(-")
INSERT MENU ITEM(FileMenu;-1;Get indexed string(131;30))
SET MENU ITEM PROPERTY(FileMenu;7;Associated standard action;Quit action) `Quit
SET MENU ITEM SHORTCUT(FileMenu;7;Character code("Q"))

 `Method for creating Find and Replace menu
C_TEXT(FindAndReplaceMenu) `FindAndReplaceMenu will contain the Find and Replace menu reference
FindAndReplaceMenu:=Create menu
APPEND MENU ITEM(FindAndReplaceMenu;"Find;Find Next;Find Previous;(-;Replace;Replace Next;Replace Previous")
SET MENU ITEM SHORTCUT(FindAndReplaceMenu;1;Character code("F"))
SET MENU ITEM SHORTCUT(FindAndReplaceMenu;5;Character code("R"))
SET MENU ITEM METHOD(FindAndReplaceMenu;1;"MyFindMethod")

 `Method for creating Edit menu
C_TEXT(EditMenu) `EditMenu will contain the Edit menu reference
EditMenu:=Create menu
APPEND MENU ITEM(EditMenu;"Cut;Copy;Paste")
SET MENU ITEM SHORTCUT(EditMenu;1;Character code("X"))
SET MENU ITEM PROPERTY(EditMenu;1;Associated standard action;Cut action)
SET MENU ITEM SHORTCUT(EditMenu;2;Character code("C"))
SET MENU ITEM PROPERTY(EditMenu;2;Associated standard action;Copy action)
SET MENU ITEM SHORTCUT(EditMenu;3;Character code("V"))
SET MENU ITEM PROPERTY(EditMenu;3;Associated standard action;Paste action)
INSERT MENU ITEM(EditMenu;-1;"(-")
INSERT MENU ITEM(EditMenu;-1;"Find and Replace";FindAndReplaceMenu) ` item that will have submenu

main_Bar:=Create menu ` Create the menu bar made up of other menus
INSERT MENU ITEM(main_Bar;-1;Get indexed string(79;1);FileMenu)
APPEND MENU ITEM(main_Bar;"Edit";EditMenu)

SET MENU BAR(main_Bar)
```

# SET MENU ITEM

SET MENU ITEM ( menu ; menuItem ; itemText {; process}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for the last item added |
| itemText | String | ⇒ | New text for the menu item |
| process | Longint | ⇒ | Process reference number |
| * | Operator | ⇒ | If passed: consider metacharacters as standard characters |

## Description

The **SET MENU ITEM** command changes the text of the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem*, to the text passed in *itemText*. You can pass -1 in *menuItem* in order to designate the last item added to the *menu*.

If you do not pass the * parameter, any "special" characters included in *itemText* (such as ( ; or !) will be considered as instruction characters (metacharacters). For example, to set a menu item as a separator line, you insert the “-” character into *itemText*. If you pass the * parameter, the "special" characters will be considered as standard characters. Please refer to the description of the **APPEND MENU ITEM** command for more details about these characters.

If you omit the *process* parameter, **SET MENU ITEM** applies to the menu bar for the current process. Otherwise, **SET MENU ITEM** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

# SET MENU ITEM ICON

SET MENU ITEM ICON ( menu ; menuItem ; iconRef {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| iconRef | Text, Longint | ⇒ | Name or number of picture to be associated with menu item |
| process | Longint | ⇒ | Process number |

## Description

The **SET MENU ITEM ICON** command modifies the icon associated with the menu item designated by the *menu* and *menuItem* parameters.
You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the command will apply to all the instances of the menu in all the processes. In this case, the *process* parameter is ignored if it is passed. If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

In *iconRef*, you can pass the picture to be used as the icon. You can use a library picture or a picture reference.

- Library picture: You can pass either the name or number of the picture. It is generally preferable to use its number rather than its name since picture numbers are unique IDs, which is not the case with names.
- Picture reference: The picture must be located in the **Resources** folder of the database and you must use a "file:{pathname}fileName" type syntax in *iconRef*. For more information about the **Resources** folder, refer to the **Resources** section.

## Example

Use of a picture located in the Resources folder of the database:

```
SET MENU ITEM ICON($MenuRef;2;"File:English.lproj/spot.png")
```

# SET MENU ITEM MARK

SET MENU ITEM MARK ( menu ; menuItem ; mark {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Item number or -1 for last item added |
| mark | String | ⇒ | New menu item mark |
| process | Longint | ⇒ | Process reference number |

## Description

The **SET MENU ITEM MARK** command changes the check mark of the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem* to the first character of the string passed in *mark*. You can pass -1 in *menuItem* in order to designate the last item added to the *menu*.

If you omit the *process* parameter, **SET MENU ITEM MARK** applies to the menu bar for the current process. Otherwise, the command applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

If you pass an empty string, any mark is removed from the menu item. Otherwise:

- On Macintosh, the first character of the string becomes the mark of the menu item. Usually, you will pass **Char(18)**, which is the check mark character for Macintosh menus.
- On Windows, the menu item is assigned the standard check mark.

## Example

See example for the **Get menu item mark** command.

# SET MENU ITEM METHOD

SET MENU ITEM METHOD ( menu ; menuItem ; methodName {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| methodName | String | ⇒ | Method name |
| process | Longint | ⇒ | Process number |

## Description

The **SET MENU ITEM METHOD** command modifies the 4D project method associated with the menu item designated by the *menu* and *menuItem* parameters.

You can pass -1 in *menuItem* in order to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the command will apply to all the instances of the menu in all the processes. In this case, the *process* parameter is ignored if it is passed. If you pass a menu number, the command will be applied to the corresponding menu in the main menu bar of the current process. If you want to designate another process, pass its number in the optional *process* parameter.

In *method*, pass the name of the 4D method as a character string (expression).

**Note:** If the menu item corresponds to the title of a hierarchical sub-menu, the method will not be called when the menu item is selected.

## Example

Refer to the example of the **SET MENU BAR** command.

# SET MENU ITEM PARAMETER

SET MENU ITEM PARAMETER ( menu ; menuItem ; param )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or Menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| param | String | ⇒ | String to associate as parameter |

## Description

The **SET MENU ITEM PARAMETER** command associates a custom character string with a menu item designated by the *menu* and *menuItem* parameters.

This parameter is mainly used by the **Dynamic pop up menu** command.

## Example

This code provides a menu including the names of the open windows and lets you get the number of the window chosen:

```
WINDOW LIST($alWindow)
$tMenuRef:=Create menu
For($i;1;Size of array($alWindow))
   APPEND MENU ITEM($tMenuRef;Get window title($alWindow{$i})) // Title of menu item
   SET MENU ITEM PARAMETER($tMenuRef;-1;String($alWindow{$i})) // Value returned by menu item
End for
$tWindowRef:=Dynamic pop up menu($tMenuRef)
RELEASE MENU($tMenuRef)
```

# SET MENU ITEM PROPERTY

SET MENU ITEM PROPERTY ( menu ; menuItem ; property ; value {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu reference or menu number |
| menuItem | Longint | ⇒ | Number of menu item or -1 for the last item added to the menu |
| property | String | ⇒ | Property type |
| value | Expression | ⇒ | Property value |
| process | Longint | ⇒ | Process number |

## Description

The **SET MENU ITEM PROPERTY** command sets the *value* of the *property* for the menu item designated by the *menu* and *menuItem* parameters.

You can pass -1 in *menuItem* to specify the last item added to *menu*.

In *menu*, you can pass a menu reference (*MenuRef*) or a menu number. If you pass a menu reference, the command will apply to all the instances of the menu in all the processes. In this case, the *process* parameter is ignored if it is passed. If you pass a menu number, the command will take the corresponding menu in the main menu bar of the current process into account. If you want to designate another process, pass its number in the optional *process* parameter.

In the *property* parameter, pass the property whose value you want to modify and pass the new value in *value*. For the *property* parameter, you can use one of the constants of the "**Menu Item Properties**" theme or any custom value:
**Standard property**: The constants of the "**Menu Item Properties**" theme as well as their possible values are described below. Note that in the case of the Associated standard action property, you can pass one of the constants of the "**Value for Associated Standard Action**" theme in the *value* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Access privileges | String | 4D_access_group | Assign an access group to the command<br>0 = All Groups<br>>0 = Group ID |
| Associated standard action | String | 4D_standard_action | Associate a standard action with a menu item<br>See the constants of the **Value for Associated Standard Action** theme |
| Start a new process | String | 4D_start_new_process | Activate the "Start New Process" option<br>0 = No, 1 = Yes |

Here are the constants for the "**Value for Associated Standard Action**" theme:

| Constant | Type | Value |
|---|---|---|
| Accept action | Longint | 2 |
| Add subrecord action | Longint | 14 |
| Cancel action | Longint | 1 |
| Clear action | Longint | 21 |
| Copy action | Longint | 19 |
| Cut action | Longint | 18 |
| Database settings action | Longint | 32 |
| Delete record action | Longint | 7 |
| Delete subrecord action | Longint | 13 |
| Edit subrecord action | Longint | 12 |
| First page action | Longint | 10 |
| First record action | Longint | 5 |
| Last page action | Longint | 11 |
| Last record action | Longint | 6 |
| MSC action | Longint | 36 |
| Next page action | Longint | 8 |
| Next record action | Longint | 3 |
| No action | Longint | 0 |
| Paste action | Longint | 20 |
| Previous page action | Longint | 9 |
| Previous record action | Longint | 4 |
| Quit action | Longint | 27 |
| Redo action | Longint | 31 |
| Return to Design mode | Longint | 35 |
| Select all action | Longint | 22 |
| Show clipboard action | Longint | 23 |
| Test application action | Longint | 26 |
| Undo action | Longint | 17 |

For more information about standard menu item properties, refer to the "**Building menus**" section of the Design Reference manual.

**Custom property**: In *property*, you can pass any custom text and associate a *value* of the text, number or Boolean type with it. This *value* will be stored with the item and can be retrieved using the **GET MENU ITEM PROPERTY** command. You can use any custom string in the *property* parameter, simply make sure not to use a title used by 4D (by convention, properties set by 4D begin with "4D_").

**Note:** If the menu item corresponds to the title of a hierarchical sub-menu, the standard action will not be called when the menu item is selected.

# SET MENU ITEM SHORTCUT

SET MENU ITEM SHORTCUT ( menu ; menuItem ; itemKey ; modifiers {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for last item added |
| itemKey | String, Longint | ⇒ | Letter of keyboard shortcut or Character code of keyboard shortcut (former syntax) |
| modifiers | Longint | ⇒ | Modifier(s) to associate with shortcut (ignored if key code is passed) |
| process | Longint | ⇒ | Process reference number |

## Description

The **SET MENU ITEM SHORTCUT** command replaces the shortcut key associated with the menu command specified by *menu* and *menuItem*, by the character whose character code or text is passed in *itemKey*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*. This key is combined with the **Ctrl** (Windows) or **Command** (Macintosh) key in order to set the new keyboard shortcut.

You can pass the letter indicating the shortcut key in the *itemKey* parameter, for example “U” to specify the **Ctrl+U** (Windows) or **Command+U** (Mac OS) shortcut. You can pass additional modifiers to associate with the shortcut in the *modifiers* parameter. This way you can define shortcuts like **Ctrl+Alt+Shift+Z** (Windows) or **Cmd+Option+Shift+Z** (Mac OS).

You can pass the following values in *modifiers*:

- 256 for the **Command** (Mac OS) or **Ctrl** (Windows) key
- 512 for the **Shift** key
- 2048 for the **Option** (Mac OS) or **Alt** (Windows) key
- To associate several different keys, just combine their values.

**Note:** You can specify the value to pass using the Command key mask, Shift key mask and Option key mask constants of the **Events (Modifiers)** theme.

The **Ctrl** (Windows) and **Command** (Mac OS) keys are automatically added by 4D to the keyboard shortcut, regardless of whether or not you explicitly indicate it in the *modifiers* parameter. So you do not have to add the value 256 to this parameter, unless this key is the only modifier, in which case you must pass either the value 256 or the corresponding constant in *modifiers*.

**Note:** For compatibility, the command also accepts a character code in the *itemKey* parameter (former syntax). In this case, the *modifiers* parameter is not taken into account and can be omitted. The shortcut is only associated with the **Ctrl** (Windows) or **Command** (Mac OS) key.

If you omit the *process* parameter, **SET MENU ITEM SHORTCUT** applies to the menu bar for the current process. Otherwise, **SET MENU ITEM SHORTCUT** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

If you pass 0 (zero) in *itemKey*, any shortcut is removed from the menu item.

## Example 1

Definition of the Ctrl+Shift+U (Windows) and Cmd+Shift+U (Mac OS) shortcut for the “Underline” menu item:

```
SET MENU ITEM(menuRef;1;"Underline")
SET MENU ITEM SHORTCUT(menuRef;1;"U";Shift key mask)
```

## Example 2

Definition of the Ctrl+R (Windows) and Cmd+R (Mac OS) shortcut for the "Restart" menu item:

```
INSERT MENU ITEM(FileMenu;-1;"Restart")
SET MENU ITEM SHORTCUT(FileMenu;-1;"R";Command key mask)
```

# SET MENU ITEM STYLE

SET MENU ITEM STYLE ( menu ; menuItem ; itemStyle {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| menu | Longint, MenuRef | ⇒ | Menu number or Menu reference |
| menuItem | Longint | ⇒ | Menu item number or -1 for last item added |
| itemStyle | Longint | ⇒ | New menu item style |
| process | Longint | ⇒ | Process reference number |

## Description

The **SET MENU ITEM STYLE** command changes the font style of the menu item whose menu number or reference is passed in *menu* and whose item number is passed in *menuItem* according to the font style passed in *itemStyle*. You can pass -1 in *menuItem* in order to indicate the last item added to *menu*.

If you omit the *process* parameter, **SET MENU ITEM STYLE** applies to the menu bar for the current process. Otherwise, **SET MENU ITEM STYLE** applies to the menu bar for the process whose reference number is passed in *process*.

**Note:** If you pass a *MenuRef* in *menu*, the *process* parameter serves no purpose and will be ignored.

You specify the font style of the item in the *itemStyle* parameter. You pass a combination (one or a sum) of the following predefined constants, found in the **Font Styles** theme:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

# Messages

- ALERT
- CONFIRM
- DISPLAY NOTIFICATION
- GOTO XY
- MESSAGE
- MESSAGES OFF
- MESSAGES ON
- Request

# ALERT

ALERT ( message ; okButtonTitle ; test )

| Parameter | Type | | Description |
|---|---|---|---|
| message | String | ⇒ | Message to display in the alert dialog box |
| okButtonTitle | String | ⇒ | OK button title |
| test | 2D Text array | ⇒ | entrée plat dessert |

## Description

The **ALERT** command displays an alert dialog box composed of a note icon, a message, and an OK button.

You pass the message to be displayed in the parameter *message*. This message can be up to 255 characters long. However, if the message does not fit into the message area, it can appear truncated, depending on its length and the width of the characters.

By default, the title of the OK button is “OK.” To change the title of the OK button, pass the new custom title into the optional parameter *okButtonTitle*. If necessary, the OK button width is resized toward the left, according to the width of the custom title you pass.

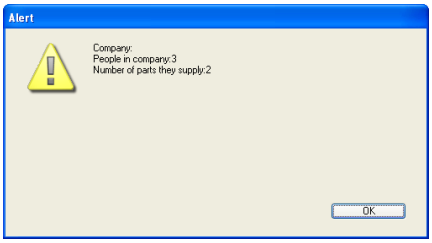
**Tip:** Do not call the **ALERT** command from the section of a form or object method that handles the On Activate or On Deactivate form events; this will cause an endless loop.

## Example 1

This example displays an alert showing information about a company. Note that the displayed string contains carriage returns, which cause the string to wrap to the next line:

```
ALERT("Company: "+[Companies]Name+Char(13)+"People in company: "+
String(Records in selection([People]))+Char(13)+"Number of parts they supply: "+
String(Records in selection([Parts])))
```

This line of code displays the following alert box (on Windows):

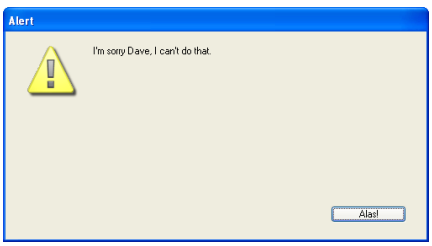


## Example 2

The line:

```
ALERT("I'm sorry Dave, I can't do that.";"Alas!")
```

displays the alert dialog box (on Windows) shown:

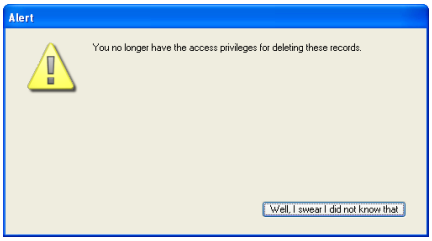


## Example 3

The line:

```
ALERT("You no longer have the access privileges for deleting these records.":"Well, I swear I did not know that")
```

displays the alert dialog box (on Windows) shown:



# CONFIRM

CONFIRM ( message {; okButtonTitle {; cancelButtonTitle}} )

| Parameter | Type | | Description |
|---|---|---|---|
| message | String | ⇒ | Message to display in the confirmation dialog box |
| okButtonTitle | String | ⇒ | OK button title |
| cancelButtonTitle | String | ⇒ | Cancel button title |

## Description

The **CONFIRM** command displays a confirm dialog box composed of a note icon, a message, an OK button, and a Cancel Button.

You pass the message to be displayed in the *message* parameter. This message can be up to 255 characters long. If the message does not fit into the message area, it can appear truncated, depending on its length and the width of the characters.

By default, the title of the OK button is “OK” and that of the Cancel button is “Cancel.” To change the titles of these buttons, pass the new custom titles into the optional parameters *okButtonTitle* and *cancelButtonTitle*. If necessary, the width of the buttons is resized toward the left, according to the width of the custom titles you pass.

The OK button is the default button. If the user clicks the OK button or presses Enter to accept the dialog box, the OK system variable is set to 1. If the user clicks the Cancel button to cancel the dialog box, the OK system variable is set to 0.

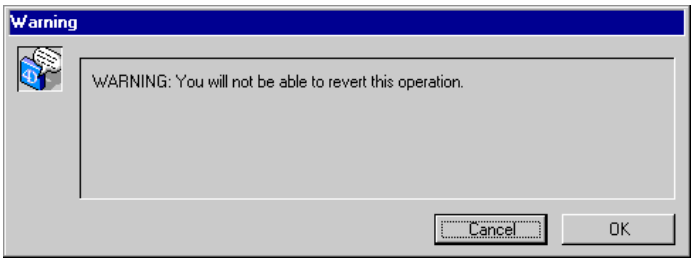
**Tip:** Do not call the **CONFIRM** command from the section of a form or object method that handles the On Activate or On Deactivate form events; this will cause an endless loop.

## Example 1

The line:

```
CONFIRM("WARNING: You will not be able to revert this operation.")
If(OK=1)
   ALL RECORDS([Old Stuff])
   DELETE SELECTION([Old Stuff])
Else
   ALERT("Operation canceled.")
End if
```

will display the confirm dialog box (on Windows) shown here:

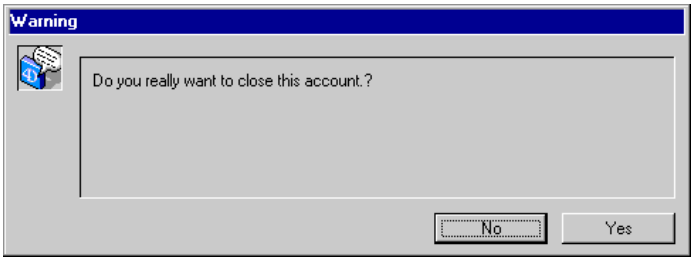


## Example 2

The line:

```
CONFIRM("Do you really want to close this account?";"Yes";"No")
```

will display the confirm dialog box (on Windows) shown here:

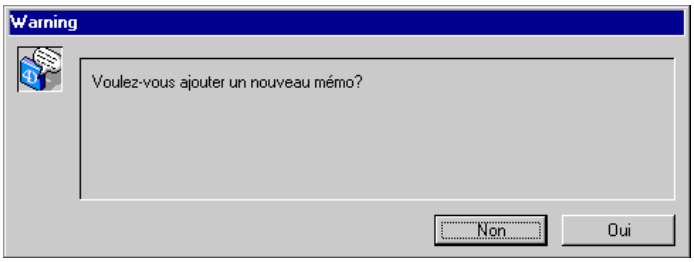


## Example 3

You are writing a 4D application for the international market. You wrote a project method that returns the correct localized text from its English version. You have also populated an array named *<>asLocalizedUIMessages,* where you store the most common words. In doing so, the line:

```
CONFIRM(INTL Text("Do you want to add a new Memo?");<>asLocalizedUIMessages{kLoc_YES};
<>asLocalizedUIMessages{kLoc_NO})
```

could display the French confirm dialog box (on Windows) shown here:

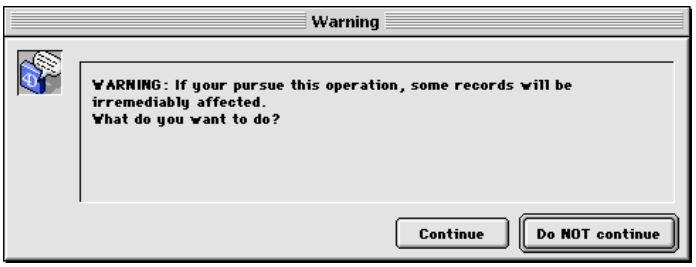


## Example 4

The line:

```
CONFIRM("WARNING: If your pursue this operation, some records will be "+"irremediably affected."+Char(13)+
"What do you want to do?";"Do NOT continue";"Continue")
```

will display the confirm dialog box (on Macintosh) shown here:



# DISPLAY NOTIFICATION

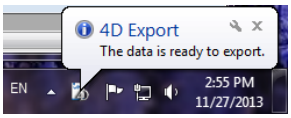
DISPLAY NOTIFICATION ( title ; text {; duration} )

| Parameter | Type | | Description |
|---|---|---|---|
| title | Alpha | ➡ | Notification title |
| text | Alpha | ➡ | Notification text |
| duration | Longint | ➡ | Display duration in seconds |

## Description

The **DISPLAY NOTIFICATION** command displays a notification message to the user.

Usually this kind of message is used by the OS or an application to inform the user of an external event (network disconnection, availability of an upgrade, etc.).

- Under Windows, the message appears in the notification area of the taskbar:
    


- Under OS X (version 10.8 minimum), the message appears in a small sliding window in the top right corner of the screen.
    
  Note that in compliance with Apple specifications, the notification is only displayed when the application is not in the foreground. However, the message still appears in the "notification center" list.

In *title* and *text*, pass the title and the text of the message to display (in our example, the title is “4D Export”). You can enter up to 255 characters.

Under Windows, the message window remains displayed as long as no activity has been detected on the machine, or until the user clicks on the close box. The optional *duration* parameter modifies the default display duration. Note that the display of notifications depends on the system configuration.

## Example

```
DISPLAY NOTIFICATION("4D Export";"The data is ready to export.")
```

# GOTO XY

GOTO XY ( x ; y )

| Parameter | Type | | Description |
|---|---|---|---|
| x | Longint | ⇒ | x (horizontal) position of cursor |
| y | Longint | ⇒ | y (vertical) position of cursor |

## Description

The **GOTO XY** command is used in conjunction with the **MESSAGE** command when you display messages in a window opened using **Open window**.

**GOTO XY** positions the character cursor (an invisible cursor) to set the location of the next message in the window.

The upper-left corner is position 0,0. The cursor is automatically placed at 0,0 when a window is opened and after **ERASE WINDOW** is executed.

After **GOTO XY** positions the cursor, you can use **MESSAGE** to display characters in the window.

## Example 1

See example for the **MESSAGE** command.

## Example 2

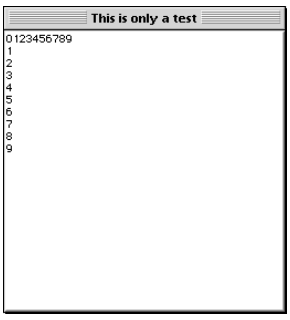
See example for the **Milliseconds** command.

## Example 3

The following example:

```
Open window(50;50;300;300;5;"This is only a test")
For($vlRow;0;9)
   GOTO XY($vlRow;0)
   MESSAGE(String($vlRow))
End for
For($vlLine;0;9)
   GOTO XY(0;$vlLine)
   MESSAGE(String($vlLine))
End for
$vhStartTime:=Current time
Repeat
Until((Current time-$vhStartTime)>?00:00:30?)
```

displays the following window (on Macintosh) for 30 seconds:



# MESSAGE

MESSAGE ( message )

| Parameter | Type | | Description |
|---|---|---|---|
| message | String | ➡ | Message to display |

## Description

The **MESSAGE** command is usually used to inform the user of some activity. It displays *message* on the screen in a special message window that opens and closes each time you call **MESSAGE**, unless you work with a window you previously opened using **Open window** (see the following details). The message is temporary and is erased as soon as a form is displayed or the method stops executing. If another **MESSAGE** is executed, the old message is erased.

If a window is opened with **Open window**, all subsequent calls to **MESSAGE** display the messages in that window. The window behaves like a terminal:

- Successive messages do not erase previous messages when displayed in the window. Instead, they are concatenated onto existing messages.
- If a message is wider than the window, 4D automatically performs text wrap.
- If a message has more lines than the window, 4D automatically scrolls the message window.
- To control line breaks, include carriage returns — **Char(13)** — into your message.
- To display the text at a particular place in the window, call **GOTO XY**.
- To erase the contents of the window, call **ERASE WINDOW**.
- The window is only an output window and does not redraw when other windows overlap it.
- You can modify the font and size of characters displayed in the window by means of the "Interface" page in the Database Settings.

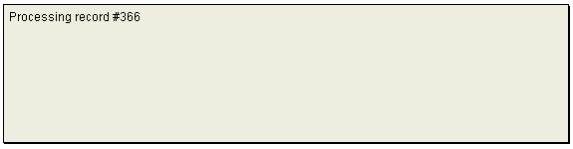
**Note: MESSAGE** is compatible with the **Open form window** command; however, in this context the second * parameter of **Open form window**, which saves the window's size and position, is not supported.

## Example 1

The following example processes a selection of records and calls **MESSAGE** to inform the user about the progress of the operation:

```
For($vlRecord;1;Records in selection([anyTable]))
   MESSAGE("Processing record #"+String($vlRecord))
   ` Do Something with the record
   NEXT RECORD([anyTable])
End for
```

The following window appears and disappears at each **MESSAGE** call:

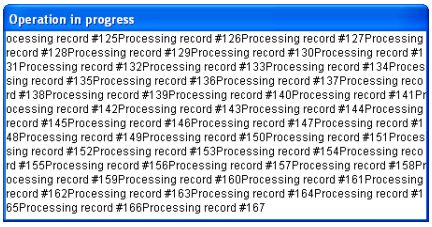


## Example 2

In order to avoid this "blinking" window, you can display the messages in a window opened using **Open window**, as in this example:

```
Open window(50;50;500;250;5;"Operation in Progress")
For($vlRecord;1;Records in selection([anyTable]))
   MESSAGE("Processing record #"+String($vlRecord))
   ` Do Something with the record
   NEXT RECORD([anyTable])
End for
CLOSE WINDOW
```

This provides the following result (shown here on Windows):

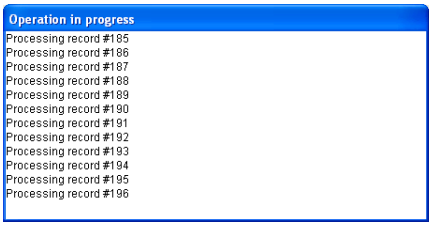


## Example 3

Adding a carriage return makes a better presentation:

```
Open window(50;50;500;250;5;"Operation in Progress")
For($vlRecord;1;Records in selection([anyTable]))
   MESSAGE("Processing record #"+String($vlRecord)+Char(Carriage return))
   ` Do Something with the record
   NEXT RECORD([anyTable])
End for
CLOSE WINDOW
```

This provides the following result (shown here on Windows):

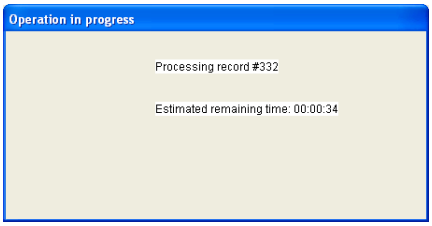


## Example 4

Using **GOTO XY** and writing some additional lines:

```
Open window(50;50;500;250;5;"Operation in Progress")
$vlNbRecords:=Records in selection([anyTable])
$vhStartTime:=Current time
For($vlRecord;1;$vlNbRecords)
   GOTO XY(5;2)
   MESSAGE("Processing record #"+String($vlRecord)+Char(Carriage return))
   ` Do Something with the record
   NEXT RECORD([anyTable])
   GOTO XY(5;5)
   $vlRemaining:=(($vlNbRecords/$vlRecord)-1)*(Current time-$vhStartTime)
   MESSAGE("Estimated remaining time: "+Time string($vlRemaining))
End for
CLOSE WINDOW
```

This provides the following result (shown here on Windows):



# MESSAGES OFF

MESSAGES OFF
Does not require any parameters

## Description

The **MESSAGES OFF** and **MESSAGES ON** commands turn on and off the progress meters displayed by 4D while executing time-consuming operations. By default, messages are on.

The following table shows operations that display the progress meter:

| | | |
|---|---|---|
| Apply Formula | Quick Report | Order by |
| Export Data | Import Data | Graph |
| Query by Form | Query by Formula | Query Editor |

The following table lists the commands that display the progress meter:

**APPLY TO SELECTION**
**Average**
**BUILD APPLICATION**
**DISTINCT VALUES**
**EXPORT DIF**
**EXPORT SYLK**
**EXPORT TEXT**
**_o_GRAPH TABLE**
**IMPORT DIF**
**IMPORT SYLK**
**IMPORT TEXT**
**Max**
**Min**
**ORDER BY**
**ORDER BY FORMULA**
**QR REPORT**
**QUERY**
**QUERY BY FORMULA**
**QUERY BY EXAMPLE**
**QUERY SELECTION**
**QUERY SELECTION BY FORMULA**
**REDUCE SELECTION**
**RELATE MANY SELECTION**
**RELATE ONE SELECTION**
**SCAN INDEX**
**Sum**

**Note for 4D Server:** Starting with 4D Server v14 R3, progress message windows are no longer shown on the server since these operations are automatically listed on the **Real Time Monitor Page** of the administration window. If you want to force these progress windows to be displayed, you must call the **MESSAGES ON** command on the server.

## Example

The following example turns off the progress meter before doing a sort, and then turns it back on after completing the sort:

```
MESSAGES OFF
ORDER BY([Addresses];[Addresses]ZIP;>;[Addresses]Name2;>)
MESSAGES ON
```

# MESSAGES ON

MESSAGES ON

Does not require any parameters

## Description

See the description of the **MESSAGES OFF** command.

# Request

Request ( message {; defaultResponse {; OKButtonTitle {; CancelButtonTitle}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| message | String | ➡ | Message to display in the request dialog box |
| defaultResponse | String | ➡ | Default data for the enterable text area |
| OKButtonTitle | String | ➡ | OK button title |
| CancelButtonTitle | String | ➡ | Cancel button title |
| Function result | String | ↩ | Value entered by user |

## Description

The **Request** command displays a request dialog box composed of a message, a text input area, an **OK** button, and a **Cancel** Button.

You pass the message to be displayed in the *message* parameter. If the message does not fit in the display area (usually around 50 characters, but it varies depending on the System and the font used), it can appear truncated.

By default, the title of the **OK** button is “OK” and that of the **Cancel** button is “Cancel.” To change the titles of these buttons, pass the new custom titles into the optional parameters *OKButtonTitle* and *CancelButtonTitle*. If necessary, the width of the buttons is resized toward the left, according to the width of the custom titles you pass.

The **OK** button is the default button. If you click the **OK** button or press **Enter** to accept the dialog box, the OK system variable is set to 1. If you click the **Cancel** button to cancel the dialog box, the OK system variable is set to 0.

The user can enter text into the text input area. To specify a default value, pass the default text in the *defaultResponse* parameter. If the user clicks **OK**, **Request** returns the text. If the user clicks **Cancel**, **Request** returns an empty string (""). If the response should be a numeric or a date value, convert the string returned by **Request** to the proper type with the **Num** or **Date** functions.

**Tip:** Do not call the **Request** command from the section of a form or object method that handles the On Activate or On Deactivate form event; this will cause an endless loop.

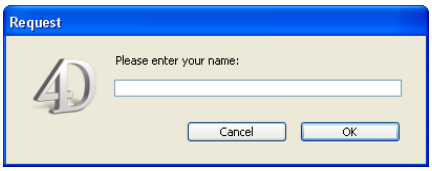
**Tip:** If you need to get several pieces of information from the user, design a form and present it with **DIALOG**, rather than presenting a succession of **Request** dialog boxes.

## Example 1

The line:

```
$vsPrompt:=Request("Please enter your name:")
```

will display the request dialog box (on Windows) shown here:

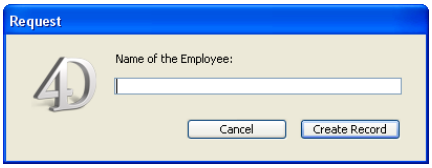


## Example 2

The line:

```
vsPrompt:=Request("Name of the Employee:";"";"Create Record";"Cancel")
If(OK=1)
   ADD RECORD([Employees])
   ` Note: vsPrompt is then copied into the field [Employees]Last name
   ` during the On Load event in the form method
End if
```

will display the request dialog box (on Windows) shown here:

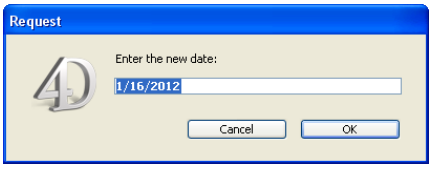


## Example 3

The line:

```
$vdPrompt:=Date(Request("Enter the new date:";String(Current date)))
```

will display the request dialog box (on Windows) shown here:



# Named Selections

- Named Selections
- CLEAR NAMED SELECTION
- COPY NAMED SELECTION
- CUT NAMED SELECTION
- USE NAMED SELECTION

# Named Selections

Named selections provide an easy way to manipulate several selections simultaneously. A named selection is an ordered list of records for a table in a process. This ordered list can be given a name and kept in memory. Named selections offer a simple means to preserve in memory the order of the selection and the current record of the selection.

The following commands enable you to work with named selections:

- **COPY NAMED SELECTION**
- **CUT NAMED SELECTION**
- **USE NAMED SELECTION**
- **CLEAR NAMED SELECTION**
- **CREATE SELECTION FROM ARRAY**

Named selections are created with the **COPY NAMED SELECTION**, **CUT NAMED SELECTION** and **CREATE SELECTION FROM ARRAY** commands. Named selections are generally used to work on one or more selections and to save and later restore an ordered selection. There can be many named selections for each table in a process. To reuse a named selection as the current selection, call **USE NAMED SELECTION**. When you are done with a named selection, use **CLEAR NAMED SELECTION**.

**Note:** Combining the statement **SET QUERY DESTINATION**(Into named selection;namedselection) with a search command (for example **QUERY**) can also be used to create a named selection. Refer to the description of the **SET QUERY DESTINATION** command.

Named selections can be local, process or interprocess in scope.

A named selection is local when its name is preceded by a dollar sign. When its name is not preceded by any symbol, it is a process named selection and it is an interprocess named selection if its name is preceded by the symbols (<>) — a “less than” sign followed by a “greater than” sign.

**Note**: This syntax can be used on both Windows and Macintosh. In addition, on Macintosh only, you can use the diamond (**Option-Shift-V** on US keyboard).

The scope of an interprocess named selection is identical to the scope of an interprocess variable. An interprocess named selection can be accessed from any process.
With 4D in remote mode and 4D Server, an interprocess named selection is available only to the processes of the client that created it. An interprocess named selection is not available to other client machines.

A process named selection is available only within the process in which it was created and on the server.

A local named selection is defined for the process that created it and is not visible on the server.

**Warning**: Creating a named selection requires access to the selection of the table. Since selections are kept on the server and a local process does not have access to server data, do not use named selections within local processes.

## Visibility of Sets

The following table indicates the principles concerning the visibility of named selections depending on their scope and where they were created:

| | Client Process | Other client processes | Other clients | Server process | Other server processes |
|---|---|---|---|---|---|
| **Creation in a client process** | | | | | |
| $test | x | | | | |
| test | x | | | x (Trigger) | |
| <>test | x | x | | | |
| **Creation in a server process** | | | | | |
| $test | | | | x | |
| test | | | | x | |
| <>test | | | | x | x |

## Named Selections and Sets

The differences between sets and named selections are:

- A named selection is an ordered list of records; a set is not.
- Sets are very memory efficient, because they require only one bit for each record in the file. Named selections require 4 bytes for each record in the selection.

- Unlike sets, named selections cannot be saved to disk.
- Sets have the standard **INTERSECTION**, **UNION** and **DIFFERENCE** operations; named selections cannot be combined with other named selections.

The similarities between named selections and sets are:

- Like a set, a named selection exists in memory.
- A named selection and a set store references to a record. If records are modified or deleted, the named selection or the set can become invalid.
- Like a set, a named selection “remembers” the current record as of the time the named selection was created.

# CLEAR NAMED SELECTION

CLEAR NAMED SELECTION ( name )

| Parameter | Type | | Description |
|---|---|---|---|
| name | String | ⇨ | Name of named selection to be cleared |

## Description

**CLEAR NAMED SELECTION** clears *name* from memory and frees the memory used by *name*. The command does not affect tables, selections, or records. Since named selections use memory, it is good practice to clear named selections when they are no longer needed.

If *name* was created using the **CUT NAMED SELECTION** command and then manipulated using the **USE NAMED SELECTION** command, *name* no longer exists in memory. In this case, the **CLEAR NAMED SELECTION** command does not need to be used.

# COPY NAMED SELECTION

COPY NAMED SELECTION ( {aTable ;} name )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to copy selection, or Default table, if omitted |
| name | String | ⇒ | Name of the named selection to create |

## Description

**COPY NAMED SELECTION** copies the current selection of *aTable* to the named selection *name*. The default table for the process is used if the optional *table* parameter is not specified. The parameter *name* contains a copy of the selection. The current selection and the current record of *aTable* for the process are not changed.

A named selection does not actually contain the records, but only an ordered list of references to records. Each reference to a record takes 4 bytes in memory. This means that when a selection is copied using the **COPY NAMED SELECTION** command, the amount of memory required is 4 bytes multiplied by the number of records in the selection. Since named selections reside in memory, you should have enough memory for the named selection as well as the current selection of the table in the process.

Use the **CLEAR NAMED SELECTION** command to free the memory used by *name*.

## Example

The following example allows you to check if there are other overdue invoices in the *[People]* table. The selection is sorted and then saved. We search for all records where invoices are due. Then we reuse the selection and clear the named selection in memory. Clearing the named selection in memory is optional, in case the database designer wants to keep the sorted selection for future use:

```
ALL RECORDS([People])
 `Allow the user to sort the selection
ORDER BY([People])
 ` Save the sorted selection as a named selection
COPY NAMED SELECTION([People];"UserSort")
 ` Search for records where invoices are due
QUERY([People];[People]InvoiceDue=True)
 ` If records are found
If(Records in selection([People])>0)
 ` Alert the user
   ALERT("Yes, there are overdue invoices on table.")
End if
 ` Reuse the sorted named selection
USE NAMED SELECTION("UserSort")
 ` Remove the selection from memory
CLEAR NAMED SELECTION("UserSort")
```

# CUT NAMED SELECTION

CUT NAMED SELECTION ( {aTable ;} name )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to cut selection, or Default table, if omitted |
| name | String | ⇒ | Name of the named selection to create |

## Description

**CUT NAMED SELECTION** creates a named selection *name* and moves the current selection of *aTable* to it. This command differs from **COPY NAMED SELECTION** in that it does not copy the current selection, but moves the current selection of *table* itself.

After the command has been executed, the current selection of *aTable* in the current process becomes empty. Therefore, **CUT NAMED SELECTION** should not be used while a record is being modified.

**CUT NAMED SELECTION** is more memory efficient than **COPY NAMED SELECTION**. With **COPY NAMED SELECTION**, 4 bytes times the number of selected records is duplicated in memory. With **CUT NAMED SELECTION**, only the reference to the list is moved.

## Example

The following method empties the current selection of a table *[Customers]*:

```
CUT NAMED SELECTION([Customers];"ToBeCleared")
CLEAR NAMED SELECTION("ToBeCleared")
```

# USE NAMED SELECTION

USE NAMED SELECTION ( name )

| Parameter | Type | | Description |
|---|---|---|---|
| name | String | ⇨ | Name of named selection to be used |

## Description

**USE NAMED SELECTION** uses the named selection *name* as the current selection for the table to which it belongs.

When you create a named selection, the current record is “remembered” by the named selection. **USE NAMED SELECTION** retrieves the position of this record and makes the record the new current record; this command loads the current record. If the current record was modified after *name* was created, the record should be saved before **USE NAMED SELECTION** is executed, in order to avoid losing the modified information.

- If **COPY NAMED SELECTION** was used to create *name*, the named selection *name* is copied to the current selection of the table to which *name* belongs. The named selection *name* exists in memory until it is cleared. Use the **CLEAR NAMED SELECTION** command to clear the named selection and free the memory used by *name*.
- If **CUT NAMED SELECTION** was used to create *name*, the current selection is set to *name* and *name* no longer exists in memory.

Remember that a named selection is a representation of a selection of records at the moment that the named selection is created. If the records represented by the named selection change, the named selection may no longer be accurate. Therefore, a named selection represents a group of records that does not change frequently. A number of things can invalidate a named selection: modifying a record of the named selection, deleting a record of the named selection, or changing the criterion that determined the named selection.

# Objects (Forms)

## 4D Write Pro areas

Most commands of the "**Objects (Forms)**" theme support 4D Write Pro areas. For more information about this, refer to the **Using commands from the Objects (Forms) theme** section in the 4D Write Pro Reference manual.

- Object Properties

- *_o_ENABLE BUTTON*

# Object Properties

The Object Properties commands act on the properties of objects present in forms. They enable you to change the appearance and behavior of the objects while using the forms to display records and in the Application environment.

**Important**: The scope of these commands is the form currently being used; changes disappear when you exit the form.

## Accessing Objects using their Object Names or their Data Source Names

The object property commands share the same generic syntax described here:

**COMMAND NAME**({*;} object { ; additional parameters specific to each command )

If you specify the optional * parameter, you indicate an object name (a string) in *object*.

You can use the @ character within that name if you want to address several objects of the form in one call. The following table shows examples of object names you can specify to this command.

| Object Names | Objects affected by the call |
|---|---|
| mainGroupBox | Only the object *mainGroupBox*. |
| main@ | The objects whose name starts with “main”. |
| @GroupBox | The objects whose name ends with “GroupBox”. |
| @Group@ | The objects whose name contains “Group”. |
| main@Btn | The objects whose name starts with “main” and ends with “Btn”. |
| @ | All the objects present in the form. |

Form object names can contain up 255 bytes, allowing you to define and apply custom naming rules, such as "xxxx_Button" or "xxx_Mac".

**Note**: You can configure the way the @ character is interpreted when it is included in a character string. This option affects the functioning of the commands in the "Objects (Forms)" theme. For more information, refer to the 4D *Design Reference* manual.

If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string.

## Interaction of generic commands with multi-style areas

Starting with 4D v14, a new way of interacting has been defined between generic commands such as **OBJECT SET RGB COLORS** or **OBJECT SET FONT STYLE** and multi-style text areas.

In previous versions of 4D, executing one of these commands modified the contents of any custom style tags inserted in the area. From now on, only default properties are affected by these commands (as well as any properties saved by means of default tags). Custom style tags remain as they are.

For example, given a multi-style area where default tags were saved:

The plain text of the area is as follows:

```
<span style="text-align:left;font-family:'Segoe UI';font-size:9pt;color:#009900">This is the word <span
style="color:#D81E05">red</span></span>
```

If you execute the following code:

```
OBJECT SET COLOR(*;"myArea";-(Blue+(256*Yellow)))
```

With 4D v14, the red color remains:

**4D v14 and higher**

```
<span style="text-align:left;font-
family:'Segoe UI';font-
size:9pt;color:#0000FF">This is the word
<span style="color:#D81E05">red</span>
</span>
```

**prior versions**

```
<span style="font-family:'Segoe UI';font-size:9pt;text-
align:left;font-weight:normal;font-style:normal;text-
decoration:none;color:#0000FF;"><span style="background-
color:#FFFFFF">This is the word red</span></span>
```

The following generic commands are concerned:

**OBJECT SET RGB COLORS**
**OBJECT SET COLOR**
**OBJECT SET FONT**
**OBJECT SET FONT STYLE**
**OBJECT SET FONT SIZE**

In the context of multi-style areas, generic commands should be used to set default styles only. To manage styles during database execution, we recommend using the commands of the "**Styled Text**" theme.

# GET STYLE SHEET INFO

GET STYLE SHEET INFO ( styleSheetName ; font ; size ; styles )

| Parameter | Type | | Description |
|---|---|---|---|
| styleSheetName | Text | ⇒ | Name of style sheet |
| font | Text | ⇐ | Character font |
| size | Longint | ⇐ | Font size |
| styles | Longint | ⇐ | Style value |

## Description

The **GET STYLE SHEET INFO** command returns the current configuration of the style sheet designated in the *styleSheetName* parameter.

In *styleSheetName*, you pass the name of the style sheet as defined in the Design mode. To designate an automatic style sheet, you can use one of the following constants, found in the "**Font Styles**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Automatic style sheet | String | __automatic__ | Used by default for all objects |
| Automatic style sheet_additional | String | __automatic_additional_text__ | Supported by static text, fields and variables only. Used for additional text in dialog boxes. |
| Automatic style sheet_main | String | __automatic_main_text__ | Supported by static text, fields and variables only. Used for main text in dialog boxes. |

In *font*, the command returns the name of the font associated with the style sheet for the current platform.

In *size*, the command returns the size in points of the font associated with the style sheet for the current platform.

In *styles*, the command returns a value corresponding to the style(s) associated with the style sheet for the current platform. You can compare the value received with the following constants, found in the "**Font Styles**" theme:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Bold and Italic | Longint | 3 |
| Bold and Underline | Longint | 5 |
| Italic | Longint | 2 |
| Italic and Underline | Longint | 6 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

If the command is executed correctly, the *OK* system variable is set to 1. Otherwise (for example, if the *styleSheetName* does not exist), it is set to 0.

## Example

You want to find out the current configuration of the "Automatic" style sheet:

```
C_LONGINT($size;$style)
C_TEXT($font)
GET STYLE SHEET INFO(Automatic style sheet;$font;$size;$style)
```

# LIST OF STYLE SHEETS

LIST OF STYLE SHEETS ( arrStyleSheets )

| Parameter | Type | | Description |
|---|---|---|---|
| arrStyleSheets | Text array | ⇦ | Names of style sheets defined in the application |

## Description

The **LIST OF STYLE SHEETS** command returns the list of application style sheets in the *arrStyleSheets* array.

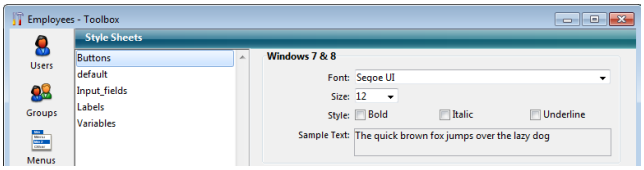
If it was not already defined previously, the *arrStyleSheets* text array is created by the command. It is automatically sized according to the number of style sheets defined.

After executing the command, each element of the array contains the name of a style sheet. These names are sorted alphabetically, as in the style sheet editor. The first array element always contains "__automatic__", which represents the "Automatic" style sheet.

**Note:** For compatibility reasons, the automatic style sheets "__automatic_main_text__" and "__automatic_additional_text__" are not returned by this command. However, they are still available in the forms.

## Example

In your application, the following style sheets are defined:



If you execute the following code:

```
LIST OF STYLE SHEETS($arrStyles)
 // $arrStyles{1} contains "__automatic__"
 // $arrStyles{2} contains "Buttons"
 // $arrStyles{3} contains "default"
 // $arrStyles{4} contains "Input_fields"
 // $arrStyles{5} contains "Labels"
 // $arrStyles{6} contains "Variables"
```

# OBJECT DUPLICATE

OBJECT DUPLICATE ( {* ;} object {; newName {; newVar {; boundTo {; moveH {; moveV {; resizeH {; resizeV}}}}}}} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| newName | Text | ⇒ | Name of new object |
| newVar | Pointer | ⇒ | Pointer to variable of new object |
| boundTo | Text | ⇒ | Name of previous enterable object (or radio button) |
| moveH | Longint | ⇒ | Horizontal shift of new object (>0 = to the right, <0 = to the left) |
| moveV | Longint | ⇒ | Vertical shift of new object (>0 = downwards, <0 = upwards) |
| resizeH | Longint | ⇒ | Value of the horizontal resize of the object |
| resizeV | Longint | ⇒ | Value of the vertical resize of the object |
| * | Operator | ⇒ | If specified= absolute coordinates If omitted= relative coordinates |

## Description

The **OBJECT DUPLICATE** command is used to create a copy of the object designated by the *object* parameter in the context of the form being executed (Application mode). The source form, generated in Design mode, is not modified.

By default, all the options specified in the Property list for the source object are applied to the copy (size, resizing options, color, etc.), including any associated object method.
However, the following exceptions should be noted:

- Default button: there can only be one default button in a form. When you duplicate a button having the "Default button" property, this property is assigned to the copy and is removed from the source object.
- Keyboard equivalents: the keyboard shortcut associated with a source object is not duplicated. This property is left blank in the copy.
- Object names: there cannot be several objects with the same name in a form. If you do not pass the *newName* parameter, the name of the source object is automatically incremented in the new object (see below).

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.
If you pass a field or variable reference and if the form contains several objects that use the same reference, the first occurrence found will be used. In this case, in order to avoid any ambiguity, it is recommended to work with object names, that are unique.

Pass the name assigned to the copy of the object in the *newName* parameter. This name must be in keeping with the rules for naming objects and be unique in the form. If it is not valid or already used by another object, the command does nothing and the *OK* variable returns 0.
If you omit this parameter or pass an empty string, the new name is automatically generated by incrementing the source object name (if this name is not already used). For example:

| Source name | Name of copy |
|---|---|
| Button | Button1 |
| Button20 | Button21 |
| Button21 | Button23 if Button22 already exists |

Pass a pointer to the variable to be associated with the new object in *newVar*. As a rule, you must point to a variable of the same type as the that of the source object but certain kinds of "retyping" are possible. The command provides automatic functions to facilitate writing generic code:

- Usually, all "enterable" variables can be retyped; for example, an object displaying a Date or Longint can be duplicated and used with a variable of the Text type. Any compatible properties will be kept. The command also permits changing types between Text objects and Picture objects. Note that a text object that is duplicated and associated with a Boolean variable or field will automatically appear as a check box.
- It is usually possible to dynamically transform a variable into a field and vice versa.
  On the other hand, graphic objects (buttons, check boxes, and so on) cannot be transformed into other types of controls.

If the variable type is not compatible with the object, the command does nothing and the *OK* variable is set to 0. If you omit this parameter, the variable is created dynamically by 4D (see the paragraph **Dynamic variables**). If you duplicate a static object (lines, rectangle, static picture, etc.), this parameter is ignored. Pass a Nil (->[]) pointer if you want to be able to use the other parameters.

You use the *boundTo* parameter in two cases:

- update of entry order: in this case, in *boundTo*, pass the name of the enterable object located just before the duplicated object. If you want for the new object to become the first object in the entry order of the page, pass the new Object First in entry order constant (see the **OBJECT Get pointer** command).
- association with a group of radio buttons: radio buttons function in a coordinated fashion when they are grouped. If the duplicated object is a radio button, in *boundTo* pass the name of a radio button of the group to which you want to attach the new object.

If you omit this parameter or pass an empty string, the new object becomes the last enterable object of the form page. In the case of a radio button, the object is attached to the group of the source button.

The new object can be moved and resized via the *moveH*, *moveV*, *resizeH* and *resizeV* parameters. As with the **OBJECT MOVE** command, the direction of the move or the resizing is specified by the sign of the values passed in the *moveH* and *moveV* parameters:

- If the value is positive, the move or resizing is carried out, respectively, to the right or downwards.
- If the value is negative, the move or resizing is carried out, respectively, to the left or upwards.

By default, the values of *moveH*, *moveV*, *resizeH* and *resizeV* modify the coordinates of the object in relation to its previous position. If you want for these parameters to specify absolute coordinates, pass the optional final * parameter.
If you omit these parameters, the new object is superimposed on top of the source object.

This command must be used in the context of the display of a form. It will generally be called in the On Load form event or following a user action (On Clicked event).

**Note:** If the On Load form event is associated with the source object, it is generated for the duplicated object when the command is executed. This allows, for example, the value of the object to be initialized.

For technical and logical reasons, **OBJECT DUPLICATE** cannot be called within the certain form events, in particular:

- On Load event generated in an object method
- On Unload event
- Event related to printing context (On Header, On Printing Detail, etc.). To print an object several times, you must use the **Print object** command.

When the command is called in a context that is not supported,the object is not duplicated and the *OK* variable is set to 0. If it is called in a printing context, the error -10601 is generated as well.

If the command was executed correctly, the *OK* variable is set to 1. Otherwise, it is set to 0.

## Example 1

Creation of a new button named "CancelButton" on top of the existing "OKButton" object and association with the *vCancel* variable:

```
OBJECT DUPLICATE(*;"OKButton";"CancelButton";vCancel)
```

## Example 2

Creation of a new radio button "bRadio6" based on the existing radio button "bRadio5". This button will be associated with the variable <>r6, integrated with the group of the "bRadio5" button and placed 20 pixels above it:

```
OBJECT DUPLICATE(*;"bRadio5";"bRadio6";<>r6;"bRadio5";0;20)
```

# OBJECT Get action

OBJECT Get action ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Text | ⇐ | Associated standard action |

## Description

The **OBJECT Get action** command returns the code of the standard action associated with the object(s) designated by the *object* and * parameters.

You can set a standard action for an object in the Design mode using the Property List (see **Standard actions** in the *Design Reference* manual), or using the **OBJECT SET ACTION** command.

The command returns a string containing the code for the standard action associated with the object. You can compare the value received with the constants of the "**Text Values for Associated Standard Action**" theme:

| Constant | Type | Value |
|---|---|---|
| Object Accept action | String | 2 |
| Object Add subrecord action | String | 14 |
| Object Automatic splitter action | String | 16 |
| Object Cancel action | String | 1 |
| Object Clear action | String | 21 |
| Object Copy action | String | 19 |
| Object Cut action | String | 18 |
| Object Database Settings action | String | 32 |
| Object Delete record action | String | 7 |
| Object Delete subrecord action | String | 13 |
| Object Edit subrecord action | String | 12 |
| Object First page action | String | 10 |
| Object First record action | String | 5 |
| Object Goto page action | String | 15 |
| Object Last page action | String | 11 |
| Object Last record action | String | 6 |
| Object MSC action | String | 36 |
| Object Next page action | String | 8 |
| Object Next record action | String | 3 |
| Object No standard action | String | 0 |
| Object Open back URL action | String | 37 |
| Object Open next URL action | String | 38 |
| Object Paste action | String | 20 |
| Object Previous page action | String | 9 |
| Object Previous record action | String | 4 |
| Object Quit action | String | 27 |
| Object Redo action | String | 31 |
| Object Refresh current URL action | String | 39 |
| Object Return to Design mode action | String | 35 |
| Object Select all action | String | 22 |
| Object Show Clipboard action | String | 23 |
| Object Stop loading URL action | String | 40 |
| Object Test Application action | String | 26 |
| Object Undo action | String | 17 |

## Example

You want to associate the "Cancel" action with all the objects in the form that do not already have any associated action:

```
ARRAY TEXT($arrObjects;0)

FORM GET OBJECTS($arrObjects)
For($i;1;Size of array($arrObjects))
   If(OBJECT Get action(*;$arrObjects{$i})=Object No standard action)
      OBJECT SET ACTION(*;$arrObjects{$i};Object Cancel action)
   End if
End for
```

# OBJECT Get auto spellcheck

OBJECT Get auto spellcheck ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| Function result | Boolean | ⇐ | True = automatic spell-checking,<br>False = no automatic spell-checking |

## Description

The **OBJECT Get auto spellcheck** command returns the status of the Auto spellcheck option for the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a reference instead of a name.

The command returns **True** when automatic spell-checking is enabled for the *object* and **False** when it is not.

# OBJECT GET BEST SIZE

OBJECT GET BEST SIZE ( {* ;} object ; bestWidth ; bestHeight {; maxWidth} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified = object is an object name (String) If omitted = object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Field or variable (if * is omitted) |
| bestWidth | Longint | ⬅ | Optimum object width |
| bestHeight | Longint | ⬅ | Optimum object height |
| maxWidth | Longint | ➡ | Maximum object width |

## Description

The **OBJECT GET BEST SIZE** command returns the *bestWidth* and *bestHeight* parameters, the “optimal” width and height of the form object designated by the * and *object* parameters. These values are expressed in pixels. This command is particularly useful for displaying or printing complex reports, associated with the **OBJECT MOVE** command.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a character string). If you do not pass the * parameter, this indicates that *object* is a field or a variable. In this case, do not pass a string but rather a field or variable reference (object type only).

The optimal values returned indicate the minimum size of the object so that its current contents are entirely included within the limits. Usually these values are only meaningful for objects containing text. This calculation takes the font, font size, font style and object contents into account. It also takes hyphenation and carriage returns into consideration. Note that in the case of 3D buttons, the command works even when button contains only an icon. If the object specified is empty, the *bestWidth* returned is 0.

The size returned does not take into account any graphic frame applied around the object, nor any scrollbars. To obtain the real size of an object on screen, it is necessary to add the width of these elements.

The optional *maxWidth* parameter enables you to attribute a maximum width to the object. If the optimal width of the object is greater than this value, **OBJECT GET BEST SIZE** returns *maxWidth* in the *bestWidth* parameter and increases the optimal height as a consequence.

The following objects are handled by this command:

- Static text areas
- Text inserted in the form of references
- Fields and variables of the following types: Alpha, Text, Real, Integer, Long Integer, Date, Time, Boolean (check boxes and radio buttons)
- Buttons
- List box columns in display context (only visible rows are taken into account).

For all other form object types (group areas, tabs, rectangles, straight lines, circles/ovals, external areas, etc.), the **OBJECT GET BEST SIZE** command returns the current object size (defined in the form editor and possibly using the **OBJECT MOVE** command).

## Example

Refer to the example in the **SET PRINT MARKER** command.

# OBJECT Get border style

OBJECT Get border style ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Longint | ⇐ | Border line style |

## Description

The **OBJECT Get border style** command returns the border line style of the object(s) designated by the *object* and * parameters.

You can set the border line style for an object in Design mode using the Property List, or using the **OBJECT SET BORDER STYLE** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The command returns a value corresponding to the border line style. You can compare the value received with the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Border Dotted | Longint | 2 | Objects appear framed with a dotted 1-pt. border line |
| Border Double | Longint | 5 | Objects appear framed with a double line, i.e., two continuous 1-pt. lines separated by a pixel |
| Border None | Longint | 0 | Objects appear with no border |
| Border Plain | Longint | 1 | Objects appear framed with a continuous 1-pt. border line |
| Border Raised | Longint | 3 | Objects appear framed with a 3D effect (raised) |
| Border Sunken | Longint | 4 | Objects appear framed with a sunken 3D effect |
| Border System | Longint | 6 | The border line is drawn based on the graphic specifications of the system |

# OBJECT Get context menu

OBJECT Get context menu ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Boolean | ⇐ | True = context menu enabled, False = context menu disabled |

## Description

The **OBJECT Get context menu** command returns the current state of the "Context Menu" option for the object(s) designated by the *object* and * parameters.

You can set the "Context Menu" option in Design mode using the Property List, or using the **OBJECT SET CONTEXT MENU** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, this indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The command returns **True** if the context menu is enabled for the object and **False** otherwise.

# OBJECT GET COORDINATES

OBJECT GET COORDINATES ( {* ;} object ; left ; top ; right ; bottom )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified = object is the name of the object (string) If omitted = object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| left | Longint | ⇐ | Left coordinate of the object |
| top | Longint | ⇐ | Top coordinate of the object |
| right | Longint | ⇐ | Right coordinate of the object |
| bottom | Longint | ⇐ | Bottom coordinate of the object |

## Description

The **OBJECT GET COORDINATES** command returns the coordinates *left*, *top*, *right* and *bottom* (in points) in variables or fields of the object(s) of the current form defined by the parameters * and *object*.

If you pass the optional parameter *, it indicates that the object parameter is an object name (a string). If you don't pass the optional parameter *, it indicates that object is a field or a variable. In this case, you don't pass a string but a field or variable reference (only a field or variable of type object).

If you pass an object name to *object* and use the wildcard character ("@") to select more than one object, the coordinates returned will be those of the rectangle formed by all the objects concerned.

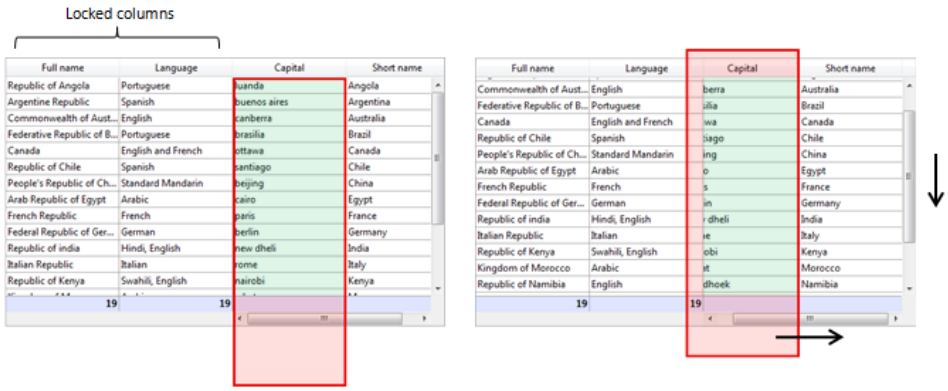
**Note:** Since 4D version 6.5, it is possible to set the interpretation mode of the wildcard character ("@"), when it is included in a string of characters. This option has an impact on the "Object Properties" commands. Please refer to the 4D Design Reference manual.

If the object doesn't exist or if the command is not called in a form, the coordinates (0;0;0;0) are returned.

In the context of list boxes, the **OBJECT GET COORDINATES** command can return the coordinates of specific list box parts, i.e. columns, headers, or footers, and not just those of the list box parent object. In 4D versions prior to v14 R5, this command always returned the parent list box coordinates, regardless of the area passed as parameter. From now on, when the referenced *object* is a list box header, column, or footer sub-object, the coordinates returned are those of the designated list box sub-object. You can use this new feature, for example, to display a small icon in the list box header cell when it is hovered over, which a user can then click to display a context menu.
For consistency, the reference frame used is the same when the object is a list box sub-object or a list box object: the origin is the upper-left corner of the form which contains the object. For list box sub-objects, the coordinates returned are theoretical; they take into account the scrolling state of the list box before any clipping occurs (i.e., the cutting carried out according to the coordinates of the parent list box). As a result, the sub-object may not be visible (or only partially so) at its coordinates, and these coordinates may be outside the form limits (or even negative). To find out whether the sub-object is visible (and which part of it is visible) you need to compare the coordinates returned with the list box coordinates, while considering the following rules:

- All sub-objects are clipped to the coordinates of their parent list box (as returned by **OBJECT GET COORDINATES** on the list box).
- Header and footer sub-objects are displayed on top of column content: when the coordinates of a column intersect the coordinates of the header or footer rows, then the column is not displayed at this intersection.
- Elements of locked columns are displayed on top of elements of scrollable columns: when the coordinates of an element in a scrollable column intersect the coordinates of an element in a locked column, then it is not displayed at this intersection.

For example, consider the following graphic where the coordinates of the *Capital* column are symbolized by the red rectangle:



As you can see in the first picture, the column is larger than the list box, so its coordinates go beyond the lower limit of the list box, including the footer. In the second picture, the list box has scrolled, so the column has also been moved "under" the *Language* column and header area. In any case, in order to calculate the actual visible part (green area), you need to subtract the red areas.

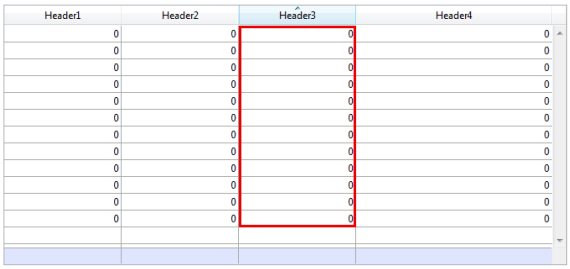
## Example 1

Let's assume that you want to obtain the coordinates of a rectangle formed by all the objects that begin with "button":

```
OBJECT GET COORDINATES(*;"button@";vLeft;vTop;vRight;vBottom)
```

## Example 2

For interface needs, you want to surround the clicked area with a red rectangle:

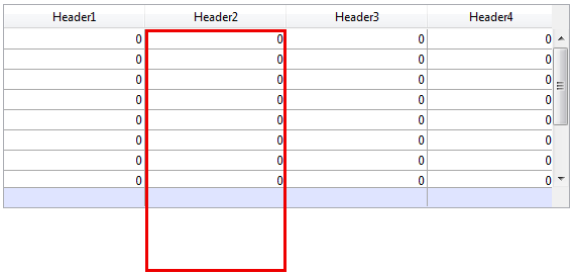


In the object method of the list box, you can write:

```
OBJECT SET VISIBLE(*;"rectangleInfo";False) //initialize a red rectangle
$ptr:=OBJECT Get pointer(Object current)
OBJECT GET COORDINATES($ptr->;$x1;$y1;$x2;$y2)
OBJECT SET VISIBLE(*;"RedRect";True)
OBJECT SET COORDINATES(*;"RedRect";$x1;$y1;$x2;$y2)

OBJECT GET COORDINATES(*;"LB1";$lbx1;$lby1;$lbx2;$lby2)
If($lby1>$y1)|($lby2<$y2) // if the clicked area is outside the list box
   OBJECT SET VISIBLE(*;"Alert";True) //display a warning
Else
   OBJECT SET VISIBLE(*;"Alert";False)
End if
```

The method returns theoretical coordinates. In cases where the list box has been resized, you may need to calculate the clipping to know which part is visible:



# OBJECT Get corner radius

OBJECT Get corner radius ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| Function result | Longint | ⇐ | Radius of rounded corners (in pixels) |

## Description

The **OBJECT Get corner radius** command returns the current value of the corner radius for the rounded rectangle object whose name is passed in the *object* parameter. This value may have been set at the form level using the Property list (see **Corner radius (rectangles)**), or for the current process using the **OBJECT SET CORNER RADIUS** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

**Note:** In the current version of 4D, this command only applies to rounded rectangles (which are static objects). As a result, only the syntax based on the object name (using the * parameter) is supported.

This command returns the radius of rounded corners in pixels. By default, this value is 5 pixels.

## Example

The following code could be added to a button method:

```
C_LONGINT($radius)
$radius:=OBJECT Get corner radius(*;"GreenRect") //get current value
OBJECT SET CORNER RADIUS(*;"GreenRect";$radius+1) //increase radius
 // Maximum value will be handled automatically:
 // when reached, the button no longer has any effect
```

# OBJECT Get data source

OBJECT Get data source ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Pointer | ⇐ | Pointer to current data source of object |

## Description

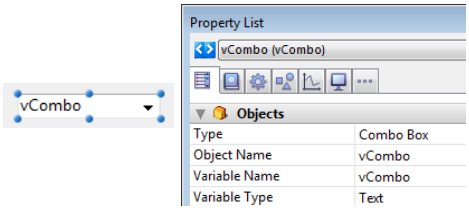
The **OBJECT Get data source** command returns the current data source of the object(s) designated by the *object* and * parameters.

You can define the data source for an object in Design mode using the Property List, or using the **OBJECT SET DATA SOURCE** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

## Example

Given a combo box object defined in a form:



You execute the following code:

```
$vPtr :=OBJECT Get data source(*;"vCombo")
 // $vPtr contains -> vCombo
```

# OBJECT GET DRAG AND DROP OPTIONS

OBJECT GET DRAG AND DROP OPTIONS ( {* ;} object ; draggable ; automaticDrag ; droppable ; automaticDrop )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| draggable | Boolean | ⇐ | Draggable = True; otherwise, False |
| automaticDrag | Boolean | ⇐ | Automatic Drag = True; otherwise, False |
| droppable | Boolean | ⇐ | Droppable = True; otherwise, False |
| automaticDrop | Boolean | ⇐ | Automatic Drop = True; otherwise, False |

## Description

The **OBJECT GET DRAG AND DROP OPTIONS** command returns the drag and drop options for the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

The command returns the current drag and drop options, as set in Design mode or for the current process using the **OBJECT SET DRAG AND DROP OPTIONS** command.

Each parameter returns True or False according to whether the corresponding option is enabled or disabled:

- *draggable* = True: Object draggable in programmed mode.
- *automaticDrag* = True (only used with text fields and variables, combo boxes and list boxes): Object draggable in automatic mode.
- *droppable* = True: Object accepts drops in programmed mode.
- *automaticDrop* = True (only used with picture fields and variables, text, combo boxes and list boxes): Object accepts drops in automatic mode.

# OBJECT Get enabled

OBJECT Get enabled ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Boolean | ⇐ | True = object(s) enabled; Otherwise, false |

## Description

The **OBJECT Get enabled** command returns True if the object or group of objects designated by *object* is enabled in the form and False if it is not enabled.

An enabled object reacts to mouse clicks and to keyboard shortcuts.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference (object variable only) instead of a string.

This command can be applied to the following types of objects:

- Button, Default button, 3D button, Invisible button, Highlight button
- Radio button, 3D radio button, Picture button
- Check Box, 3D Check Box
- Pop-up menu, Drop-down List, Combo Box, Menu/Drop-down List
- Thermometer, Ruler

# OBJECT Get enterable

OBJECT Get enterable ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Boolean | ⇐ | True = object(s) enterable; Otherwise, false |

## Description

The **OBJECT Get enterable** command returns True if the object or group of objects designated by *object* has the **enterable** attribute; otherwise, it returns False.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT GET EVENTS

OBJECT GET EVENTS ( {* ;} object ; arrEvents )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name or "" to designate the form (if * is specified) or<br>Field or variable (if * is omitted) |
| arrEvents | Longint array | ⇐ | Array of enabled events |

## Description

The **OBJECT GET EVENTS** command gets the current configuration of the form events for the object(s) designated by the *object* and * parameters.

Form events can be enabled/disabled either using the Property List, or using the **OBJECT SET EVENTS** command if it is called in the current process.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).
To get the configuration of events for the form itself, pass the optional * parameter and an empty string "" in object: in this case, you designate the current form.

**Note:** If you want to get events for a subform related to a table, you can only use the syntax based on the object name.

Pass a longint array in the *arrEvents* parameter. When the command is executed, this array is automatically sized and receives all the predefined or custom form events that are enabled for the object or the form. You can compare the values received with the constants of the "**Form Events**" theme.

Note that the *arrEvents* array is returned empty if no object method is associated with the object or if no form method is associated with the form.

## Example

You want to enable two events and get the list of events for an object:

```
ARRAY LONGINT($ArrCurrentEvents;0)
ARRAY LONGINT($ArrEnabled;2)
$ArrEnabled{1}:=On Header Click
$ArrEnabled{2}:=On Footer Click
OBJECT SET EVENTS(*;"Col1";$ArrEnabled;Enable events others unchanged)
OBJECT GET EVENTS(*;"Col1";$ArrCurrentEvents)
```

# OBJECT Get filter

OBJECT Get filter ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Text | ⇐ | Name of filter |

## Description

The **OBJECT Get filter** command returns the name of any filter associated with the object or group of objects designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT Get focus rectangle invisible

OBJECT Get focus rectangle invisible ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| Function result | Longint | ⇐ | True = focus rectangle hidden,<br>False = focus rectangle shown |

## Description

The **OBJECT Get focus rectangle invisible** command returns the status of the visibility option for the focus rectangle of the object(s) designated by the *object* and * parameters for the current process . This setting corresponds to the **Hide focus rectangle** option that is available for enterable objects in the Property List in the Design mode. This command returns the current status of the option, as it is defined in Design mode or using the **OBJECT SET FOCUS RECTANGLE INVISIBLE** command.

**Note:** You can only use this option under Mac OS. It has no effect under Windows.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a variable reference instead of a string.

The command returns **True** when the focus rectangle is hidden and **False** when it is shown.

# OBJECT Get font

OBJECT Get font ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Text | ⇐ | Name of font |

## Description

The **OBJECT Get font** command returns the name of the character font used by the form object(s) designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT Get font size

OBJECT Get font size ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Longint | ⇐ | Size of font in points |

## Description

The **OBJECT Get font size** command returns the size (in points) of the character font used by the form object(s) designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT Get font style

OBJECT Get font style ( * ; object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Longint | ⇐ | Font style |

## Description

The **OBJECT Get font style** command returns the current style of the character font used by the form object(s) designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

You can compare the value returned with the value of one or more of the following predefined constants, placed in the "**Font Styles**" theme:

| Constant | Type | Value |
|---|---|---|
| Plain | Longint | 0 |
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Underline | Longint | 4 |

# OBJECT Get format

OBJECT Get format ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a field or a variable |
| object | Form object | ➡ | Object name (if * is specified) or Field or variable (if * is omitted) |
| Function result | String | ⮌ | Object display format |

## Description

The **OBJECT Get format** command returns the current display format applied to the object specified in the *object* parameter.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (in this case, pass a string in *object*). If you do not pass this parameter, you indicate that the *object* parameter is a field or variable. In this case, you do not pass a string, but a field or variable reference.

This command returns the current display format of the object; in other words, the format as defined in the Design environment or using the **OBJECT SET FORMAT** command. **OBJECT Get format** works with all types of form objects (fields or variables) that accept a display format: Boolean, date, time, picture, string, number, as well as button grids, dials, thermometers, rulers, picture pop-up menus, picture buttons, 3D buttons, and list box headers. For more information on the display formats of these objects, refer to the documentation for the **OBJECT SET FORMAT** command.

**Note:** If you apply the command to a set of objects, the form of the last object selected is returned.

When the **OBJECT Get format** command is applied to date, time or picture objects (formats defined as constants), the string returned corresponds to the character code of the constant. To obtain the value of the constant, simply apply the **Character code** function to the result (see below).

## Example 1

This example allows you to obtain the value of the format constant applied to the picture variable named “myphoto”:

```
C_STRING(2;$format)
OBJECT SET FORMAT(*;"myphoto";Char(On background))
 `Apply background format (value = 3)
$format:=OBJECT Get format(*;"myphoto")
ALERT("Format number:"+String(Character code($format)))
 `Display value "3"
```

## Example 2

This example allows you to obtain the format applied to the Boolean field [Members]Marital_status:

```
C_STRING(30;$format)
$format:=OBJECT Get format([Members]Marital_status)
ALERT($format) `Display format, for example "Married;Single"
```

# OBJECT Get help tip

OBJECT Get help tip ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | Text | ⇐ | Help message of object |

## Description

The **OBJECT Get help tip** command returns the help message associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

The command returns the current help message associated with the object, as it is defined in Design mode or for the process using the **OBJECT SET HELP TIP** command. The string returned shows the message as it appears when the form is executed. If it contains variable items (xliff *resname* or 4D references), they are interpreted according to the context.

## Example

The title of a picture button is stored as a help message. This title is stored in an xliff file and differs according to the current language of the application:

```
OBJECT SET HELP TIP(*;"button1";":xliff:btn_discover")
$helpmessage:=OBJECT Get help tip(*;"button1")
 // $helpmessage contains for example "Découvrir" with a French 4D and "Discover" with an English 4D.
```

# OBJECT Get horizontal alignment

OBJECT Get horizontal alignment ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object name (String) If omitted, object is a field or a variable |
| object | Form object | ⇒ | Object name (if * specified), or Field or variable (if * omitted) |
| Function result | Longint | ⇐ | Alignment code |

## Description

The **OBJECT Get horizontal alignment** command returns a code indicating the type of horizontal alignment applied to the object designated by the *object* and * parameters.

If you specify the optional * parameter, you indicate an object name (a string) in the *object* parameter. If you omit the * parameter, you indicate a field or variable in the *object* parameter. In this case, you specify a field or variable reference (field or variable objects only) instead of a string.

**Note:** If you apply the command to a group of objects, only the alignment value of the last object is returned.

The returned code corresponds to one of the following constants located in the **Form Objects (Properties)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Align center | Longint | 3 | |
| Align default | Longint | 1 | |
| Align left | Longint | 2 | |
| Align right | Longint | 4 | |
| wk justify | Longint | 5 | Available for 4D Write Pro areas only |

The form objects to which alignment can be applied are as follows:

- Scrollable areas
- Combo boxes
- Static text
- Group areas
- Pop up menu/Drop-down lists
- Fields
- Variables
- List boxes
- List box columns
- List box headers

# OBJECT Get indicator type

OBJECT Get indicator type ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Longint | ⇐ | Indicator type |

## Description

The **OBJECT Get indicator type** command returns the current indicator type assigned to the thermometer(s) designated by the *object* and * parameters.

You can set the indicator type using the Property List in Design mode, or using the **OBJECT SET INDICATOR TYPE** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

You can compare the value returned by the command with the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Asynchronous progress bar | Longint | 3 | Circular indicator displaying continuous animation |
| Barber shop | Longint | 2 | Bar displaying continuous animation |
| Progress bar | Longint | 1 | Standard progress bar |

# OBJECT Get keyboard layout

OBJECT Get keyboard layout ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| Function result | String | ⇐ | Language code of layout, "" = no layout |

## Description

The **OBJECT Get keyboard layout** command returns the current keyboard layout associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a reference instead of a name.

The command returns a string indicating the language code used, based on RFC3066, ISO639 and ISO3166. For more information, refer to the description of the **SET DATABASE LOCALIZATION** command.

# OBJECT Get list name

OBJECT Get list name ( {* ;} object {; listType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| listType | Longint | ⇒ | Type of list: Choice list, Required list or Excluded list |
| Function result | Text | ⇐ | Name of list (specified in Design mode) |

## Description

The **OBJECT Get list name** command returns the name of the choice list associated with the object or group of objects designated by *object*. 4D lets you associate a choice list (created with the choice list editor in Design mode) with form objects using the form editor or the **OBJECT SET LIST BY NAME** command.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

You can use the optional *listType* parameter to designate the type of list that you want to get. By default, if you omit this parameter, the command returns the name of the choice list (list of values) associated with the object. You can also get the names of required lists or excluded lists by passing, in *listType*, one of the following constants found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Choice list | Longint | 0 | Simple list of values to choose from ("Choice List" option in the Property List) (default) |
| Excluded list | Longint | 2 | Lists values not accepted for entry ("Excluded List" option in the Property List) |
| Required list | Longint | 1 | Lists only values accepted for entry ("Required List" option in the Property List) |

If there is no list of the type defined associated with the *object*, the command returns an empty string ("").

# OBJECT Get list reference

OBJECT Get list reference ( {* ;} object {; listType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| listType | Longint | ⇒ | Type of list: Choice list, Required list or Excluded list |
| Function result | ListRef | ⇐ | List reference number |

## Description

The **OBJECT Get list reference** command returns the reference number (ListRef) of the hierarchical list associated with the object or group of objects designated by *object* and *.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, this indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

By default, if you omit the *listType* parameter, the command returns the name of the choice list (list of values) associated with the object. You can also get the reference number for required lists or excluded lists by passing, in *listType*, one of the following constants found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Choice list | Longint | 0 | Simple list of values to choose from ("Choice List" option in the Property List) (default) |
| Excluded list | Longint | 2 | Lists values not accepted for entry ("Excluded List" option in the Property List) |
| Required list | Longint | 1 | Lists only values accepted for entry ("Required List" option in the Property List) |

If there is no hierarchical list associated with the object for the *listType* defined, the command returns 0.

# OBJECT GET MAXIMUM VALUE

OBJECT GET MAXIMUM VALUE ( {* ;} object ; maxValue )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| maxValue | Date, Time, Number | ⇐ | Current maximum value for object |

## Description

The **OBJECT GET MAXIMUM VALUE** command returns, in the *maxValue* variable, the current maximum value of the object(s) designated by the *object* and * parameters.

You can set the "Maximum Value" property using the Property List in Design mode, or using the **OBJECT SET MAXIMUM VALUE** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

# OBJECT GET MINIMUM VALUE

OBJECT GET MINIMUM VALUE ( {* ;} object ; minValue )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| minValue | Date, Time, Number | ⇐ | Current minimum value for object |

## Description

The **OBJECT GET MINIMUM VALUE** command returns, in the *minValue* variable, the current minimum value of the object(s) designated by the *object* and * parameters.

You can set the "Minimum Value" property using the Property List in Design mode, or using the **OBJECT SET MINIMUM VALUE** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

# OBJECT Get multiline

OBJECT Get multiline ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Longint | ⇐ | Multiline status of object |

## Description

The **OBJECT Get multiline** command returns the current state of the "Multiline" option for the object(s) designated by the *object* and * parameters.

You can set the "Multiline" option for an object using the Property List, or using the **OBJECT SET MULTILINE** command option.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The value returned corresponds to one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Multiline Auto | Longint | 0 | In single-line areas, words located at the end of lines are truncated and there are no line returns.<br>In multiline areas, 4D carries out automatic line returns. |
| Multiline No | Longint | 2 | There are never line returns: the text is always displayed on a single row. If the Alpha or Text field or variable contains carriage returns, the text located after the first carriage return is removed as soon as the area is modified. |
| Multiline Yes | Longint | 1 | In single-line areas, the text is displayed up to the first carriage return or until the last word that can be displayed entirely. 4D inserts line returns; it is possible to scroll the contents of the area by pressing the down arrow key.<br>In multiline areas, 4D carries out automatic line returns. |

**Note:** If you apply the **OBJECT Get multiline** command to an object that does not support the "Multiline" option, the command returns 0.

# OBJECT Get name

OBJECT Get name {( selector )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ➡ | Object category |
| Function result | Text | ⮌ | Name of object |

## Description

The **OBJECT Get name** command returns the name of a form object.

The command can be used to designate two types of objects according to the value of the *selector* parameter. In this parameter, you can pass one of the following constants (placed in the "**Form Objects (Access)**" theme:

- Object current or *selector* omitted: If you pass this selector or omit the *selector* parameter, the command returns the name of the object from which it was called (object method or submethod called by the object method). In this case, the command must be called in the context of a form object, otherwise it returns an empty string.
- Object with focus: If you pass this selector, the command returns the name of the object that has the focus in the form.

## Example

Object method for "bValidateForm" button:

```
$btnName:=OBJECT Get name(Object current)
```

After the execution of this object method, the *$btnName* variable contains the "bValidateForm" value.

# OBJECT Get placeholder

OBJECT Get placeholder ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Text | ⇐ | Placeholder text associated with object |

## Description

The **OBJECT Get placeholder** command returns the placeholder text associated with the object(s) designated by the *object* and * parameters. If there is no placeholder text associated with the object, the command returns an empty string.

You can define the placeholder text either using the Property List, or using the **OBJECT SET PLACEHOLDER** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

If the placeholder is an xliff reference defined using the Property List, the command returns the original reference in the form ":xliff:*resname*", and not its calculated value.

## Example

You want to get the field placeholder text:

```
$txt:=OBJECT Get placeholder([People]LastName)
```

# OBJECT Get pointer

OBJECT Get pointer ( {selector }{;}{ objectName {; subformName}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ⇒ | Object category |
| objectName | Text | ⇒ | Object name |
| subformName | Text | ⇒ | Subform object name |
| Function result | Pointer | ⇐ | Pointer to object variable |

## Description

The **OBJECT Get pointer** command returns a pointer to the variable of a form object.

This command can be used to designate different objects according to the value of the *selector* parameter. You can pass one of the following constants (found in the "**Form Objects (Access)**" theme) in this parameter:

- Object current or *selector* omitted: If you omit the *selector* parameter or pass this selector, the command returns a pointer to the variable associated with the current object (object whose method is executing).
  **Note:** This is strictly equivalent to the previous functioning of the **Self** command. This command is only kept for compatibility reasons.
- Object with focus: If you pass this selector, the command returns a pointer to the variable associated with the object that has the focus in the form. The last two optional parameters are ignored if they are passed.
  **Note:** This is strictly equivalent to the functioning of the **Focus object** command. This command is now obsolete beginning with 4D v12.
- Object subform container: If you pass this selector, the command returns a pointer to the variable bound with the subform container. The last two optional parameters are ignored if they are passed. This selector can therefore only be used in the context of a form used as a subform, so as to access the variable bound with the container object.
- Object named: If you pass this selector, you must also pass the second parameter, *objectName*. In this case, the command returns a pointer to the variable associated with the object whose name was passed in this parameter.
  **Note:** If *objectName* corresponds to a subform and the "Output subform" option is checked, the command returns a pointer to the table of the subform if a source table is specified; otherwise it returns Nil.

The optional *subformName* parameter lets you retrieve a pointer to an *objectName* object that does not belong to the current context, in other words, in the parent form. To be able to use this parameter, you must have passed the Object named selector.
When the *subformName* parameter is passed, the **OBJECT Get pointer** command first looks for the subform object named *subformName* in the current form, then looks inside this subform for an object named *objectName*. If this object is found, it returns a pointer to the variable of this object.

## Example

Given a form "SF" used twice as a subform in the same parent form. The subform objects are named "SF1" and "SF2". The "SF" form contains an object named *CurrentValue*. In the "On Load" form event of the form method of the parent form, we want to initialize the *CurrentValue* object of SF1 to "January" and that of SF2 to "February":

```
C_POINTER($Ptr)
$Ptr:=OBJECT Get pointer(Object named;"CurrentValue";"SF1")
$Ptr->:="January"
$Ptr:=OBJECT Get pointer(Object named;"CurrentValue";"SF2")
$Ptr->:="February"
```

# OBJECT GET PRINT VARIABLE FRAME

OBJECT GET PRINT VARIABLE FRAME ( {* ;} object ; variableFrame {; fixedSubform} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| variableFrame | Boolean | ⇐ | True = Variable frame printing, False = Fixed frame printing |
| fixedSubform | Longint | ⇐ | Option for printing subforms in fixed size |

## Description

The **OBJECT GET PRINT VARIABLE FRAME** command gets the current configuration of the variable frame print options for the object(s) designated by the *object* and * parameters.

Variable frame printing properties can be defined using the Property List, or using the **OBJECT SET PRINT VARIABLE FRAME** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, this indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *variableFrame* parameter, the command returns a Boolean variable whose value indicates the enabled (**True**) or disabled (**False**) state of variable frame printing.

If the *object* is a subform and if variable frame printing is disabled (**False**), the command also returns, in the *fixedSubform* parameter, the fixed frame print option of the subform. You can compare the value returned with the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Print Frame fixed with multiple records | Longint | 2 | The frame remains the same size, but 4D prints the form several times to include all the records. |
| Print Frame fixed with truncation | Longint | 1 | 4D prints only the records that fit into the area of the subform. The form is printed only once and those records that are not printed are ignored. |

# OBJECT GET RESIZING OPTIONS

OBJECT GET RESIZING OPTIONS ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| horizontal | Longint | ⇐ | Horizontal resizing option |
| vertical | Longint | ⇐ | Vertical resizing option |

## Description

The **OBJECT GET RESIZING OPTIONS** command returns the current resizing options for the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

The command returns the current resizing options, as set in the Design mode or for the process using the **OBJECT SET RESIZING OPTIONS** command. These options specify the display of the object when the form window is resized.

The *horizontal* parameter returns a value indicating the horizontal resizing option that is set for the object. You can compare the value received with the following constants, found in the **Form Objects (Properties)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Resize horizontal grow | Longint | 1 | If the window grows by 50% in width, the object is expanded by 50% to the right. |
| Resize horizontal move | Longint | 2 | If the window grows by 100 pixels in width, the object is moved 100 pixels to the right. |
| Resize horizontal none | Longint | 0 | If the window is expanded in width, neither the width nor the position of the object changes. |

The *vertical* parameter returns a value indicating the vertical resizing option that is set for the object. You can compare the value received with the following constants, found in the **Form Objects (Properties)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Resize vertical grow | Longint | 1 | If the window grows by 50% in height, the object is lengthened by 50% towards the bottom. |
| Resize vertical move | Longint | 2 | If the window grows by 100 pixels in height, the object is moved 100 pixels towards the bottom. |
| Resize vertical none | Longint | 0 | If the window is expanded in height, neither the height nor the position of the object changes. |

# OBJECT GET RGB COLORS

OBJECT GET RGB COLORS ( {* ;} object ; foregroundColor {; backgroundColor {; altBackgrndColor}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| foregroundColor | Longint | ⇐ | RGB color value for foreground |
| backgroundColor | Longint | ⇐ | RGB color value for background |
| altBackgrndColor | Longint | ⇐ | RGB color value for alternating background |

## Description

The **OBJECT GET RGB COLORS** command returns the foreground and background colors of the object or group of objects designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

When the command is applied to a List box type object, the alternating background color for the rows can be returned in the *altBackgrndColor* parameter. In this case, the value of *backgroundColor* is used for the background of odd-numbered rows only.

The RGB color values returned in the *foregroundColor*, *backgroundColor* and *altBackgrndColor* parameters can be 4-byte longints of the format (0x00RRGGBB) or negative values corresponding to the "system" colors. In the latter case, you can compare the value obtained with the constants of the **SET RGB COLORS** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Background color | Longint | -2 | |
| Background color none | Longint | -16 | This constant can only be used with the *backgroundColor* and *altBackgrndColor* parameters. |
| Dark shadow color | Longint | -3 | |
| Disable highlight item color | Longint | -11 | |
| Foreground color | Longint | -1 | |
| Highlight menu background color | Longint | -9 | |
| Highlight menu text color | Longint | -10 | |
| Highlight text background color | Longint | -7 | |
| Highlight text color | Longint | -8 | |
| Light shadow color | Longint | -4 | |

**Note:** The "system" colors are applied using the **OBJECT SET RGB COLORS** command.

For more information about the format of the *foregroundColor*, *backgroundColor* and *altBackgrndColor* parameters, refer to the description of the **OBJECT SET RGB COLORS** command.

# OBJECT GET SCROLL POSITION

OBJECT GET SCROLL POSITION ( {* ;} object ; vPosition {; hPosition} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field or table (if * is omitted) |
| vPosition | Longint | ⇐ | Number of first line displayed or Vertical scrolling in pixels (pictures) |
| hPosition | Longint | ⇐ | Number of first column displayed or Horizonal scrolling in pixels (pictures) |

## Description

The **OBJECT GET SCROLL POSITION** returns, in the *vPosition* and *hPosition* parameters, information related to the position of the scroll bars of the form object designated by the * and *object* parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is the name of an object of the subform, hierarchical list, scrollable area, list box or picture type (in this case, pass a string in object). If you do not pass this parameter, you indicate that the *object* parameter is a variable (*ListRef* of hierarchical list, picture or list box variable) or a field.

**Note:** With subform type objects, only the syntax using an * is supported.

If *object* designates a list type object (subform, list form, hierarchical list, scrollable area or list box), *vPosition* returns the number of the first line displayed in the object. *hPosition* (list box only) returns the number of the first column that is completely visible in the left part of the list box. With other types of objects, this parameter returns 0.

If *object* designates a picture (variable or field), *vPosition* returns the vertical movement and *hPosition* the horizontal movement of the picture. These values are expressed in pixels with respect to the origin of the picture in the local coordinate system.

# OBJECT GET SCROLLBAR

OBJECT GET SCROLLBAR ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| horizontal | Boolean, Longint | ⇐ | Visibility of horizontal scrollbar |
| vertical | Boolean, Longint | ⇐ | Visibility of vertical scrollbar |

## Description

The **OBJECT GET SCROLLBAR** command is used to find out the displayed/hidden status of the horizontal and vertical scrollbars of the object or group of objects designated by *object*.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

In the *horizontal* and *vertical* parameters, you can pass Boolean or longint type variables:

- When you pass Boolean variables, the value returned reflects the **current** state of the scrollbar:
  - If the scrollbar has been defined as hidden, the parameter receives False,
  - If the scrollbar has been defined as displayed, the parameter receives True,
  - If the scrollbar has been set to automatic mode, the parameter receives either True or False depending on the current display state of the object.
- When you pass longint variables, the value returned reflects the visibility defined for the scrollbar:
  - If the scrollbar has been defined as hidden, the parameter receives 0,
  - If the scrollbar has been defined as displayed, the parameter receives 1,
  - If the scrollbar has been set to automatic mode, the parameter receives 2.

This command can be used with the following form objects:

- Picture or text object fields and variables
- List boxes,
- Hierarchical lists,
- Subforms.

For more information, refer to the description of the **OBJECT SET SCROLLBAR** command.

# OBJECT GET SHORTCUT

OBJECT GET SHORTCUT ( {* ;} object ; key ; modifiers )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| key | String | ⇐ | Key associated with object |
| modifiers | Longint | ⇐ | Modifier key mask or combination of masks |

## Description

The **OBJECT GET SHORTCUT** command returns the keyboard shortcut associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

The *key* parameter returns the character associated with the key (in the case of a standard key) or a string enclosed in brackets designating the key (in the case of a function key). You can compare this value with the constants of the **Shortcut and Associated Keys** theme (see the **OBJECT SET SHORTCUT** command).

The *modifiers* parameter returns a value indicating the modifier key(s) associated with the shortcut. If there are several modifier keys combined, the command returns the sum of their values. You can compare the value returned with the following constants of the **Events (Modifiers)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Command key mask | Longint | 256 | Ctrl key under Windows, Command key under OS X |
| Control key mask | Longint | 4096 | Ctrl key under OS X, or right click under Windows and OS X |
| Option key mask | Longint | 2048 | Alt key (also called Option under OS X) |
| Shift key mask | Longint | 512 | Windows and OS X |

If there are no modifier keys for the shortcut, *modifiers* returns 0.

**Note:** If the *object* parameter designates several objects in the form that have different settings, the command returns "" in *key* and 0 in *modifiers*.

# OBJECT Get style sheet

OBJECT Get style sheet ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Text | ⇐ | Name of style sheet |

## Description

The **OBJECT Get style sheet** command returns the name of the style sheet associated with the object(s) designated by the *object* and * parameters.

Style sheets may have been assigned in Design mode using the Property List, or for the current process using the **OBJECT SET STYLE SHEET** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The command can return either:

- a style sheet name,
- an empty string ("") if no style sheet is assigned, or
- if an automatic style sheet is assigned, one of the following constants found in the "**Font Styles**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Automatic style sheet | String | __automatic__ | Used by default for all objects |
| Automatic style sheet_additional | String | __automatic_additional_text__ | Supported by static text, fields and variables only. Used for additional text in dialog boxes. |
| Automatic style sheet_main | String | __automatic_main_text__ | Supported by static text, fields and variables only. Used for main text in dialog boxes. |

If the command designates several objects, the style sheet returned is only meaningful if the style sheet is assigned to all of the objects.

# OBJECT GET SUBFORM

OBJECT GET SUBFORM ( {* ;} object ; tablePtr ; detailSubform {; listSubform} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| tablePtr | Table | ⇐ | Pointer to table of form |
| detailSubform | Text | ⇐ | Name of detail form of subform |
| listSubform | Text | ⇐ | Name of list form of subform (table form) |

## Description

The **OBJECT GET SUBFORM** command gets the name(s) of the form(s) associated with the subform object designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In the *tablePtr* parameter, the command returns a pointer to the table of the form(s) used. If the subform uses a project form, this parameter contains **Nil**.
In the *detailSubform* parameter, the command returns the name of the detail form used in the subform.
In the *listSubform* parameter, the command returns the name of the list form used in the subform. If there is no list form, an empty string is returned.

# OBJECT GET SUBFORM CONTAINER SIZE

OBJECT GET SUBFORM CONTAINER SIZE ( width ; height )

| Parameter | Type | | Description |
|---|---|---|---|
| width | Longint | ⇦ | Width of subform object |
| height | Longint | ⇦ | Height of subform object |

## Description

The **OBJECT GET SUBFORM CONTAINER SIZE** command returns the *width* and *height* (in pixels) of a "current" subform object, displayed in the parent form.

This command must be called from the method of a form used as a subform and displayed in a subform object. It returns the *width* and *height* of the object containing the subform.

This command is useful, for example, in the case where subform objects must be resized according to the characteristics of the subform object itself. In the On Load form event, the subform can call this command to calculate the space at its disposal in order to display its contents.

**Note:** It is not possible to use the On Resize event directly in the subform method. Since this event is linked to the resizing of a window, it is generated only in the method of the parent form. You can, however, explicitly call the subform from this event of the parent form using, for instance, the **EXECUTE METHOD IN SUBFORM** command.

- If the command is called from a form that is not being used as a subform, it returns the current size of the form window.
- If the command is called outside of the context of screen display (for example, during form printing), it returns 0 in *width* and *height*.

# OBJECT Get text orientation

OBJECT Get text orientation ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Longint | ⇐ | Angle of text rotation |

## Description

The **OBJECT Get text orientation** command returns the current orientation value applied to the text of the object(s) designated by the *object* and * parameters.

You can set the "Orientation" option for an object in Design mode using the Property List, or using the **OBJECT SET TEXT ORIENTATION** command.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The value returns corresponds to one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Orientation 0° | Longint | 0 | No rotation (default value) |
| Orientation 180° | Longint | 180 | Orientation of text to 180° clockwise |
| Orientation 90° left | Longint | 270 | Orientation of text to 90° counter-clockwise |
| Orientation 90° right | Longint | 90 | Orientation of text to 90° clockwise |

## Example

Given the following object (where a "90° left" orientation was applied in the Form editor):

When the form is executed, if you call the following statement:

```
OBJECT SET TEXT ORIENTATION(*;"myText";Orientation 180° )
```

... then the object appears as follows:

```
$vOrt:=OBJECT Get text orientation(*;"myText") //$vOrt=180
```

# OBJECT Get three states checkbox

OBJECT Get three states checkbox ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Boolean | ⇐ | True = three-states checkbox, False = standard checkbox |

## Description

The **OBJECT Get three states checkbox** command returns the current state of the "Three-States" property for the checkbox(es) designated by the *object* and * parameters.

You can set the "Three-States" property either using the Property List, or using the **OBJECT SET THREE STATES CHECKBOX** command if it was called in the current process.

# OBJECT Get title

OBJECT Get title ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Text | ⇐ | Title of button |

## Description

The **OBJECT Get title** command returns the title (label) of the form object(s) designated by *object*. You can use this command with all types of simple objects that contain a label:

- buttons,
- check boxes
- radio buttons
- static texts
- group areas.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT Get type

OBJECT Get type ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Longint | ⇐ | Type of object |

## Description

The **OBJECT Get type** command returns the type of the object designated by the *object* and * parameters in the current form.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). This syntax is mandatory if you are processing static objects such as lines or rectangles.
If you do not pass this parameter, it indicates that the *object* parameter is a variable. In this case, you pass a variable reference instead of a string.

**Note:** If you apply this command to a set of objects, the type of the last object is returned.

The value returned corresponds to one of the following constants, available in the "**Form Object Types**" theme:

| Constant | Type | Value |
|---|---|---|
| Object type 3D button | Longint | 16 |
| Object type 3D checkbox | Longint | 26 |
| Object type 3D radio button | Longint | 23 |
| Object type button grid | Longint | 20 |
| Object type checkbox | Longint | 25 |
| Object type combobox | Longint | 11 |
| Object type dial | Longint | 28 |
| Object type group | Longint | 21 |
| Object type groupbox | Longint | 30 |
| Object type hierarchical list | Longint | 6 |
| Object type hierarchical popup menu | Longint | 13 |
| Object type highlight button | Longint | 17 |
| Object type invisible button | Longint | 18 |
| Object type line | Longint | 32 |
| Object type listbox | Longint | 7 |
| Object type listbox column | Longint | 9 |
| Object type listbox footer | Longint | 10 |
| Object type listbox header | Longint | 8 |
| Object type matrix | Longint | 35 |
| Object type oval | Longint | 34 |
| Object type picture button | Longint | 19 |
| Object type picture input | Longint | 4 |
| Object type picture popup menu | Longint | 14 |
| Object type picture radio button | Longint | 24 |
| Object type plugin area | Longint | 38 |
| Object type popup dropdown list | Longint | 12 |
| Object type progress indicator | Longint | 27 |
| Object type push button | Longint | 15 |
| Object type radio button | Longint | 22 |
| Object type radio button field | Longint | 5 |
| Object type rectangle | Longint | 31 |
| Object type rounded rectangle | Longint | 33 |
| Object type ruler | Longint | 29 |
| Object type splitter | Longint | 36 |
| Object type static picture | Longint | 2 |
| Object type static text | Longint | 1 |
| Object type subform | Longint | 39 |
| Object type tab control | Longint | 37 |
| Object type text input | Longint | 3 |
| Object type unknown | Longint | 0 |
| Object type web area | Longint | 40 |
| Object type write pro area | Longint | 41 |

## Example

You want to load a form and get a list of all the objects of list boxes that it contains.

```
FORM LOAD("MyForm")
ARRAY TEXT(arrObjects;0)
FORM GET OBJECTS(arrObjects)
ARRAY LONGINT(ar_type;Size of array(arrObjects))
For($i;1;Size of array(arrObjects))
```

```
      ar_type{$i}:=OBJECT Get type(*;arrObjects{$i})
      If(ar_type{$i}=Object type listbox)
         ARRAY TEXT(arrLBObjects;0)
         LISTBOX GET OBJECTS(*;arrObjects{$i};arrLBObjects)
      End if
   End for
   FORM UNLOAD
```

# OBJECT Get vertical alignment

OBJECT Get vertical alignment ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| Function result | Longint | ⇐ | Type of alignment |

## Description

The **OBJECT Get vertical alignment** command returns a value indicating the type of vertical alignment applied to the object designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

**Note:** If you apply this command to a set of objects, only the alignment value for the last object is returned.

The value returned corresponds to one of the following constants, found in the **Form Objects (Properties)** theme:

| Constant | Type | Value |
|---|---|---|
| Align bottom | Longint | 4 |
| Align center | Longint | 3 |
| Align top | Longint | 2 |

Vertical alignment can be applied to the following types of form objects:

- list boxes,
- list box columns,
- list box headers and footers.

# OBJECT Get visible

OBJECT Get visible ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| Function result | Boolean | ⇐ | True = object(s) visible; Otherwise, False |

## Description

The **OBJECT Get visible** command returns True if the object or group of objects designated by *object* has the visible attribute and False otherwise.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

# OBJECT Is styled text

OBJECT Is styled text ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| Function result | Boolean | ⇐ | True if object is a multi-style text, False otherwise |

## Description

The **OBJECT Is styled text** command returns **True** when the "Multi-style" option is checked for the object(s) designated by the *object* and * parameters.

The "Multi-style" option lets you use rich test areas including individual style variations. For more information, refer to **GET DATA SOURCE LIST** in the *Design Reference* manual.

Multi-style objects can be managed by programming using the commands of the "**Styled Text**" theme.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

**Note:** The **OBJECT Is styled text** command returns **True** when it is applied to a 4D Write Pro area.

## Example

A form contains a field represented by two different objects; one of the objects has the "Multi-style" property checked, and the other one does not. You can write:

```
$Style:=OBJECT Is styled text(*;"Styled_text")
 // returns True ("Multi-style" option is checked)

$Style:=OBJECT Is styled text(*;"Plain_text")
 // returns False ("Multi-style" option is not checked)
```

# OBJECT MOVE

OBJECT MOVE ( {* ;} object ; moveH ; moveV {; resizeH {; resizeV {; *}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified= object is an object name (string) If omitted = object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| moveH | Longint | ⇒ | Value of the horizontal move of the object (>0 = to the right, <0 = to the left) |
| moveV | Longint | ⇒ | Value of the vertical move of the object (>0 = to the bottom, <0 = to the top) |
| resizeH | Longint | ⇒ | Value of the horizontal resize of the object |
| resizeV | Longint | ⇒ | Value of the vertical resize of the object |
| * | Operator | ⇒ | If specified = absolute coordinates If omitted = relative coordinates |

## Description

The **OBJECT MOVE** command allows you to move the object(s) in the current form, defined by the * and *object* parameters *moveH* pixels horizontally and *moveV* pixels vertically.

It is also possible (optionally) to resize the object(s) *resizeH* pixels horizontally and *resizeV* pixels vertically.

The direction to move and resize depend on the values passed to the *moveH* and *moveV* parameters:

- If the value is positive, objects are moved and resized to the right and to the bottom, respectively.
- If the value is negative, objects are moved and resized to the left and to the top, respectively.

If you pass the first optional parameter *, you indicate that the *object* parameter is a parameter name (a string of characters). If you don't pass the * parameter, *object* is a field or a variable. In this case, you don't pass a string but a field or variable reference (only a field or variable of type object).

If you pass an object name to object and use the wildcard character ("@") to select more than one object, all the objects concerned will be moved or resized.

**Note:** Since 4D version 6.5, it is possible to set the interpretation mode of the wildcard character ("@"), when it is included in a string of characters. This option has an impact on the "Object Properties" commands. Please refer to the 4D Design Mode manual.

By default, the values *moveH*, *moveV*, *resizeH* and *resizeV* modify the coordinates of the object relative to its previous position. If you want the parameters to define the absolute parameters, pass the last optional parameter *.

This command works in the following contexts:

- Data entering in Input forms,
- Forms displayed using the **DIALOG** command,
- Headers and footers of Output forms displayed with **MODIFY SELECTION** or **DISPLAY SELECTION** commands,
- Form printing events.

## Example 1

The following statement moves "button_1" 10 pixels to the right, 20 pixels to the top and resizes it to 30 pixels in width and 40 in height:

```
OBJECT MOVE(*;"button_1";10;-20;30;40)
```

## Example 2

The following statement moves "button_1" to the following coordinates (10;20) (30;40):

```
OBJECT MOVE(*;"button_1";10;20;30;40;*)
```

# OBJECT SET ACTION

OBJECT SET ACTION ( {* ;} object ; action )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| action | Text | ⇒ | Action to associate |

## Description

The **OBJECT SET ACTION** command modifies, for the current process, the standard action associated with the object(s) designated by the *object* and * parameters.

**Note:** Standard actions can also be set using the Property list in the Design mode.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *action* parameter, pass an action code (string) indicating the standard action to associate with the object. You can pass one of the following constants, found in the "**Text Values for Associated Standard Action**" theme:

| Constant | Type | Value |
| --- | --- | --- |
| Object Accept action | String | 2 |
| Object Add subrecord action | String | 14 |
| Object Automatic splitter action | String | 16 |
| Object Cancel action | String | 1 |
| Object Clear action | String | 21 |
| Object Copy action | String | 19 |
| Object Cut action | String | 18 |
| Object Database Settings action | String | 32 |
| Object Delete record action | String | 7 |
| Object Delete subrecord action | String | 13 |
| Object Edit subrecord action | String | 12 |
| Object First page action | String | 10 |
| Object First record action | String | 5 |
| Object Goto page action | String | 15 |
| Object Last page action | String | 11 |
| Object Last record action | String | 6 |
| Object MSC action | String | 36 |
| Object Next page action | String | 8 |
| Object Next record action | String | 3 |
| Object No standard action | String | 0 |
| Object Open back URL action | String | 37 |
| Object Open next URL action | String | 38 |
| Object Paste action | String | 20 |
| Object Previous page action | String | 9 |
| Object Previous record action | String | 4 |
| Object Quit action | String | 27 |
| Object Redo action | String | 31 |
| Object Refresh current URL action | String | 39 |
| Object Return to Design mode action | String | 35 |
| Object Select all action | String | 22 |
| Object Show Clipboard action | String | 23 |
| Object Stop loading URL action | String | 40 |
| Object Test Application action | String | 26 |
| Object Undo action | String | 17 |

## Example

You want to associate the **Validate** standard action with a button:

```
OBJECT SET ACTION(*;"bValidate";Object Accept action)
```

# OBJECT SET AUTO SPELLCHECK

OBJECT SET AUTO SPELLCHECK ( {* ;} object ; autoSpellcheck )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| autoSpellcheck | Boolean | ⇒ | True = automatic spell-checking,<br>False= no automatic spell-checking |

## Description

The **OBJECT SET AUTO SPELLCHECK** command sets or dynamically modifies the status of the **Auto spellcheck** option for the object(s) designated by the *object* and * parameters for the current process. This option enables or disables the automatic spellcheck when data is entered for the object (Text type objects only).

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a reference instead of a name.

Pass **True** in *autoSpellcheck* to enable this function for the object, and **False** to disable it.

# OBJECT SET BORDER STYLE

OBJECT SET BORDER STYLE ( {* ;} object ; borderStyle )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| borderStyle | Longint | ⇒ | Border line style |

## Description

The **OBJECT SET BORDER STYLE** command modifies the border line style of the object(s) designated by the *object* and * parameters.

The "Border Line Style" property modifies the appearance of the object outlines. For more information, refer to **Border Line Style** in the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *borderStyle* parameter, pass the value of the border line style that you want to apply to the object. You can pass one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Border Dotted | Longint | 2 | Objects appear framed with a dotted 1-pt. border line |
| Border Double | Longint | 5 | Objects appear framed with a double line, i.e., two continuous 1-pt. lines separated by a pixel |
| Border None | Longint | 0 | Objects appear with no border |
| Border Plain | Longint | 1 | Objects appear framed with a continuous 1-pt. border line |
| Border Raised | Longint | 3 | Objects appear framed with a 3D effect (raised) |
| Border Sunken | Longint | 4 | Objects appear framed with a sunken 3D effect |
| Border System | Longint | 6 | The border line is drawn based on the graphic specifications of the system |

# OBJECT SET COLOR

OBJECT SET COLOR ( {* ;} object ; color {; altColor} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Field, Variable | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| color | Longint | ⇒ | New colors for the object |
| altColor | Longint | ⇒ | Alternating colors for a list box |

## Description

The **OBJECT SET COLOR** command sets the foreground and background colors of the form objects specified by *object*. If *object* is a list box, an additional parameter is used to set the foreground and background colors for even-numbered rows (alternating colors).

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

The *color* parameter specifies both foreground and background colors. The color is calculated as:

**Color:=-(Foreground+(256 * Background))**

where **Foreground** and **Background** are color numbers (from 0 to 255) within the color palette.

**Color** is always a negative number. For example, if the foreground color is to be 20 and the background color is to be 10, then *color* is – (20 + (256 * 10)) or –2580.

*altColor* is used to specify an alternative background color for the even-numbered rows of a list box or a list box column. In *altColor*, you must pass only the "background" part of the color formula, i.e. **AltColor:=-(256 * Background)**.
When this parameter is passed, the *color* parameter will be applied only to odd-numbered rows. Using alternating colors makes lists easier to read. If *object* specifies the list box object, alternating colors are used throughout the entire list box. If *object* specifies a column, only the column will use the colors set.

**Note:** You can see the color palette in the Form Editor's Property List window.

The numbers of the commonly used colors are provided by the following predefined constants, located in the "**Colors**" theme:

| Constant | Type | Value |
|---|---|---|
| Black | Longint | 15 |
| Blue | Longint | 6 |
| Brown | Longint | 13 |
| Dark blue | Longint | 5 |
| Dark brown | Longint | 10 |
| Dark green | Longint | 9 |
| Dark grey | Longint | 11 |
| Green | Longint | 8 |
| Grey | Longint | 14 |
| Light blue | Longint | 7 |
| Light grey | Longint | 12 |
| Orange | Longint | 2 |
| Purple | Longint | 4 |
| Red | Longint | 3 |
| White | Longint | 0 |
| Yellow | Longint | 1 |

**Note:** While **OBJECT SET COLOR** works with indexed colors within the default 4D color palette, the **OBJECT SET RGB COLORS** command allows you to work with any RGB color. To reestablish automatic colors for an object, use the **OBJECT SET RGB COLORS** command with the Default foreground color and Default background color constants.

## Example 1

The following example sets the color of the text area shown below in the form editor:

After executing the following statement:

```
OBJECT SET COLOR(*;"Mytext";-(Yellow+(256*Red)))
```

... the area appears as follows:

## Example 2

You want to set an alternating background color for a column in the list box. You can write:

```
OBJECT SET COLOR(*;"countryCol";-(Dark blue+(256*Red));-(256*Orange))
```

# OBJECT SET CONTEXT MENU

OBJECT SET CONTEXT MENU ( {* ;} object ; contextMenu )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| contextMenu | Boolean | ⇒ | True = enable context menu, False = disable context menu |

## Description

The **OBJECT SET CONTEXT MENU** command enables or disables, for the current process, the association of a context menu by default with the object(s) designated by the *object* and * parameters.

The "Context Menu" option is available for text type entry areas, Web areas and pictures. You can use it to associate a standard action menu with these objects depending on their type (for example Copy/Paste for text objects). For more information, refer to the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

Pass **True** in the *contextMenu* parameter to enable the context menu, and **False** to disable it.

# OBJECT SET COORDINATES

OBJECT SET COORDINATES ( {* ;} object ; left ; top {; right ; bottom} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Longint | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| left | Longint | ⇒ | Left coordinate of object in pixels |
| top | Longint | ⇒ | Top coordinate of object in pixels |
| right | Longint | ⇒ | Right coordinate of object in pixels |
| bottom | Longint | ⇒ | Bottom coordinate of object in pixels |

## Description

The **OBJECT SET COORDINATES** command modifies the location and, optionally, the size of the object(s) designated by the *object* and * parameters for the current process.

**Note:** This command is the equivalent of using the **OBJECT MOVE** command and passing its 2nd * parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *left* and *top* parameters, pass the new absolute coordinates of the object in the form. These coordinates must be expressed in pixels with respect to the top left corner of the form.

You can also pass absolute coordinate values in the *right* and *bottom* parameters, indicating the bottom right corner of the object. If this corner does not correspond to the corner of the object after application of the *left* and *top* parameters, the object is resized accordingly.

**Note:** If you want to move an object relative to its initial position, we recommend using the existing **OBJECT MOVE** command.

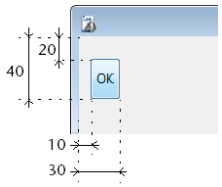
This command only functions in the following contexts:

- Input forms in entry mode,
- Forms displayed using the **DIALOG** command,
- Headers and footers of output forms displayed by the **MODIFY SELECTION** or **DISPLAY SELECTION** command,
- Forms being printed.

## Example

The following statement places the "button_1" object at the (10,20) (30,40) coordinates:

```
OBJECT SET COORDINATES(*;"button_1";10;20;30;40)
```



# OBJECT SET CORNER RADIUS

OBJECT SET CORNER RADIUS ( {* ;} object ; radius )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| radius | Longint | ⇒ | New radius of rounded corners (in pixels) |

## Description

The **OBJECT SET CORNER RADIUS** command modifies the radius of corners for the rounded rectangle object(s) whose name(s) you passed in the *object* parameter. The new radius is only set for the process and is not saved in the form itself.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

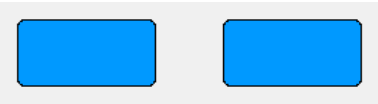
**Note:** In the current version of 4D, this command only applies to rounded rectangles (which are static objects). As a result, only the syntax based on the object name (using the * parameter) is supported.

In the *radius* parameter, you pass a new radius value in pixels to be applied to the corners of the object. By default, this value is 5 pixels.

**Note:** You can also modify this value at the form level using the Property list (see **Corner radius (rectangles)**).

## Example

You have the following rectangles in your form, named respectively "Rect1" and "Rect2":



You can execute the following code to change their corners:

```
OBJECT SET CORNER RADIUS(*;"Rect@";20)
```

# OBJECT SET DATA SOURCE

OBJECT SET DATA SOURCE ( {* ;} object ; dataSource )

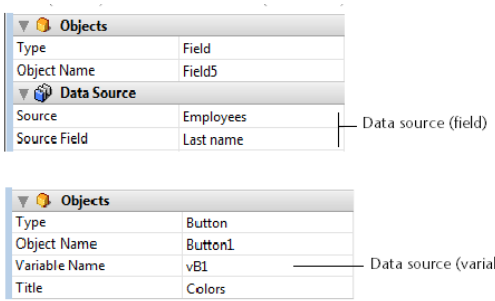
| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| dataSource | Pointer | ⇒ | Pointer to new data source for object |

## Description

The **OBJECT SET DATA SOURCE** command modifies the data source of the object(s) designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The data source is the field or variable whose value is represented by the object when the form is executed. In Design mode, the data source is defined in the Property list, usually through the Source and Source Field (fields) or Variable Name (variables) row:



Except for list boxes (see below), all data sources of the form can be modified by this command. It is up to the developer to ensure the consistency of the changes made.

In the case of list boxes, the following points must be considered:

- Data source modifications must take the list box type into account: for example, it is not possible to use a field as the data source for a column in an array type list box.
- For selection type list boxes, it is not possible to modify or read the data source of the list box object itself: in this case, it is an internal reference and not a data source.
- This command is mainly used in the context of array type list boxes. For selection type list boxes, you can use the **LISTBOX SET COLUMN FORMULA** command instead.

If this command is applied to a data source that is not modifiable, it does nothing.

## Example

Modification of the data source for an entry area:

```
C_POINTER($ptrField)
$ptrField:=Field(3;2)
OBJECT SET DATA SOURCE(*;"Input";$ptrField)
```

# OBJECT SET DRAG AND DROP OPTIONS

OBJECT SET DRAG AND DROP OPTIONS ( {* ;} object ; draggable ; automaticDrag ; droppable ; automaticDrop )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| draggable | Boolean | ⇒ | Draggable = True; otherwise, False |
| automaticDrag | Boolean | ⇒ | Automatic Drag = True; otherwise, False |
| droppable | Boolean | ⇒ | Droppable = True; otherwise, False |
| automaticDrop | Boolean | ⇒ | Automatic Drop = True; otherwise, False |

## Description

The **OBJECT SET DRAG AND DROP OPTIONS** command sets or dynamically modifies the drag and drop options for the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In each parameter, you pass a Boolean indicating whether the corresponding option is enabled or disabled:

- *draggable* = True: Object draggable in programmed mode.
- *automaticDrag* = True (only used with text fields and variables, combo boxes and list boxes): Object draggable in automatic mode.
- *droppable* = True: Object accepts drops in programmed mode.
- *automaticDrop* = True (only used with picture fields and variables, text, combo boxes and list boxes): Object accepts drops in automatic mode.

## Example

Setting a text area to automatic drag and drop:

```
OBJECT SET DRAG AND DROP OPTIONS(*;"Comments";False;True;False;True)
```

# OBJECT SET ENABLED

OBJECT SET ENABLED ( {* ;} object ; active )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| active | Boolean | ⇒ | True = object(s) enabled; otherwise, False |

## Description

The **OBJECT SET ENABLED** command can be used to enable or disable the object or group of objects specified by *object* in the current form. An enabled object reacts to mouse clicks and to keyboard shortcuts.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you pass a variable reference (object variable only) instead of a string.

Pass True in the *active* parameter to enable the objects and False to disable them.

This command can be applied to the following types of objects:

- Button, Default button, 3D button, Invisible button, Highlight button
- Radio button, 3D radio button, Picture button
- Check Box, 3D Check Box
- Pop-up menu, Drop-down List, Combo Box, Menu/Drop-down List
- Thermometer, Ruler

**Note:** This command has no effect with an object to which a standard action has been assigned (4D looks after modifying the state of this object when necessary), except in the case of the **Validate** and **Cancel** actions.

# OBJECT SET ENTERABLE

OBJECT SET ENTERABLE ( {* ;} object ; enterable )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Table or Field or Variable (if * is omitted) |
| enterable | Boolean | ⇒ | True for enterable; False for non-enterable |

## Description

The **OBJECT SET ENTERABLE** command makes the form objects specified by *object* either enterable or non-enterable.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a table, field or variable in *object*. In this case, specify a table, field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

Using this command is equivalent to selecting Enterable for a field or variable in the Form Editor's Property List window. This command works in subforms only if it is in the form method of the subform.

When the *entryArea* is enterable (TRUE), the user can move the cursor into the area and enter data. When the *entryArea* is non-enterable (FALSE), the user cannot move the cursor into the area and cannot enter data.

The **OBJECT SET ENTERABLE** command can also be used to enable the "Enter in List" mode by programming for subforms and list forms displayed using the **MODIFY SELECTION** and **DISPLAY SELECTION** commands:

- For subforms, in the *entryArea* parameter, pass either the name of the subform table or the name of the subform object itself, for example: **OBJECT SET ENTERABLE**(*;"Subform";True).
- For list forms, you must pass the name of the form table in the *entryArea* parameter, for example: **OBJECT SET ENTERABLE**([MyTable];True).

Making an object non-enterable does not prevent you from changing its value programmatically.

**Note:** To make a list box cell non-enterable, you pass the value -1 to $0 in the On Before Data Entry event, see **Managing entry**.

## Example 1

The following example sets a shipping field, depending on the weight of the shipment. If the shipment is 1 ounce or less, then the shipper is set to US Mail and the field is set to be non-enterable. Otherwise, the field is set to be enterable.

```
If([Shipments]Weight<=1)
   [Shipments]Shipper:="US Mail"
   OBJECT SET ENTERABLE([Shipments]Shipper;False)
Else
   OBJECT SET ENTERABLE([Shipments]Shipper;True)
End if
```

## Example 2

Here is the object method of a checkbox located in the header of a list in order to control the Enter in List mode:

```
C_BOOLEAN(bEnterable)
OBJECT SET ENTERABLE([Table1];bEnterable)
```

# OBJECT SET EVENTS

OBJECT SET EVENTS ( {* ;} object ; arrEvents ; mode )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name or "" to designate the form (if * is specified) or<br>Field or variable (if * is omitted) |
| arrEvents | Longint array | ⇒ | Array of events to set |
| mode | Longint | ⇒ | Activation mode for events defined in arrEvents |

## Description

The **OBJECT SET EVENTS** command modifies, for the current process, the configuration of the form events of the form or object(s) designated by the *object* and * parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).
To define the configuration of events for the form itself, pass the optional * parameter and an empty string "" in *object*: in this case, you designate the current form.

**Note:** If you want to modify the events of a subform related to a table, you can only use the syntax based on the object name.

In the *arrEvents* parameter, pass a Longint array containing the list of predefined or custom form events that you want to modify (you can use the *mode* parameter to specify whether the modification consists of enabling or disabling the events). To designate a predefined event to modify, you can pass, in each element of the *arrEvents* array, one of the following constants, found in the "**Form Events**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| On Activate | Longint | 11 | The form’s window becomes the frontmost window |
| On After Edit | Longint | 45 | The contents of the enterable object that has the focus has just been modified |
| On After Keystroke | Longint | 28 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text including this character. |
| On After Sort | Longint | 30 | (*List box only*) A standard sort has just been carried out in a list box column |
| On Arrow Click | Longint | 38 | (*3D buttons only*) The “arrow” area of a 3D button is clicked |
| On Before Data Entry | Longint | 41 | (*List box only*) A list box cell is about to change to editing mode |
| On Before Keystroke | Longint | 17 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text without this character. |
| On Begin Drag Over | Longint | 46 | An object is being dragged |
| On Begin URL Loading | Longint | 47 | (*Web areas only*) A new URL is loaded in the Web area |
| On bound variable change | Longint | 54 | The variable bound to a subform is modified. |
| On Clicked | Longint | 4 | A click occurred on an object |
| On Close Box | Longint | 22 | The window’s close box has been clicked |
| On Close Detail | Longint | 26 | You left the detail form and are going back to the output form |
| On Collapse | Longint | 44 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been collapsed using a click or a keystroke |
| On Column Moved | Longint | 32 | (*List box only*) A list box column is moved by the user via drag and drop |
| On Column Resize | Longint | 33 | (*List box only*) The width of a list box column is modified by a user with the mouse |
| On Data Change | Longint | 20 | Object data has been modified |
| On Deactivate | Longint | 12 | The form’s window ceases to be the frontmost window |
| On Delete Action | Longint | 58 | (*Hierarchical lists and List boxes*) The user attempts to delete an item |
| On Display Detail | Longint | 8 | A record is about to be displayed in a list or a row is about to be displayed in a list box. |
| On Double Clicked | Longint | 13 | A double click occurred on an object |
| On Drag Over | Longint | 21 | Data could be dropped onto an object |
| On Drop | Longint | 16 | Data has been dropped onto an object |
| On End URL Loading | Longint | 49 | (*Web areas only*) All the resources of the URL have been loaded |
| On Expand | Longint | 43 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been expanded using a click or a keystroke |
| On Footer Click | Longint | 57 | (*List boxes only*) A click occurs in the footer of a list box or a list box column |
| On Getting Focus | Longint | 15 | A form object is getting the focus |

| Constant | Type | Value | Comment |
|---|---|---|---|
| On Header | Longint | 5 | The form's header area is about to be printed or displayed |
| On Header Click | Longint | 42 | (*List box only*) A click occurs in a column header of the list box |
| On Load Record | Longint | 40 | During entry in list, a record is loaded during modification (the user clicks on a record line and a field changes to editing mode) |
| On Long Click | Longint | 39 | (*3D buttons only*) A 3D button is clicked and the mouse button remains pushed for a certain lapse of time |
| On Losing Focus | Longint | 14 | A form object is losing the focus |
| On Mac toolbar button | Longint | 55 | The user clicks on the tool bar management button under Mac OS. |
| On Menu Selected | Longint | 18 | A menu item has been chosen |
| On Mouse Enter | Longint | 35 | The mouse cursor enters the graphic area of an object |
| On Mouse Leave | Longint | 36 | The mouse cursor leaves the graphic area of an object |
| On Mouse Move | Longint | 37 | The mouse cursor moves at least one pixel OR a modifier key (Shift, Alt, Shift Lock) was pressed. If the event is checked for an object only, it is generated only when the cursor is within the graphic area of the object |
| On Open Detail | Longint | 25 | The detail form associated with the output form or with the listbox is about to be opened |
| On Open External Link | Longint | 52 | (*Web areas only*) An external URL has been opened in the browser |
| On Outside Call | Longint | 10 | The form received a **CALL PROCESS** call |
| On Picture Scroll | Longint | 59 | The user scrolls the contents of a picture field or variable using the mouse or keyboard. |
| On Plug in Area | Longint | 19 | An external object requested its object method to be executed |
| On Printing Break | Longint | 6 | One of the form's break areas is about to be printed |
| On Printing Detail | Longint | 23 | The form's detail area is about to be printed |
| On Printing Footer | Longint | 7 | The form's footer area is about to be printed |
| On Resize | Longint | 29 | The form window is resized |
| On Row Moved | Longint | 34 | (*List box only*) A list box row is moved by the user via drag and drop |
| On Selection Change | Longint | 31 | • *List box*: The current selection of rows or columns is modified<br>• *Records in list*: The current record or the current selection of rows is modified in a list form or subform<br>• *Hierarchical list*: The selection in the list is modified following a click or a keystroke<br>• *Enterable field or variable*: The text selection or the position of the cursor in the area is modified following a click or a keystroke |
| On Timer | Longint | 27 | The number of ticks defined by the **SET TIMER** command has passed |
| On Unload | Longint | 24 | The form is about to be exited and released |
| On URL Filtering | Longint | 51 | (*Web areas only*) A URL was blocked by the Web area |
| On URL Loading Error | Longint | 50 | (*Web areas only*) An error occurred when the URL was loading |

| Constant | Type | Value | Comment |
|---|---|---|---|
| On URL Resource Loading | Longint | 48 | (*Web areas only*) A new resource is loaded in the Web area |
| On Validate | Longint | 3 | The record data entry has been validated |
| On Window Opening Denied | Longint | 53 | (*Web areas only*) A pop-up window has been blocked |

It is important to note that the On Load event is not included in this list: this event cannot be defined because it has already been generated during the execution of the command.

In *arrEvents*, you can also pass any value corresponding to a custom event. In this case, we recommend using negative values (see the **CALL SUBFORM CONTAINER** command).

You use the *mode* parameter to set the overall processing to be carried out for the array elements. To do this, you can pass one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Disable events others unchanged | Longint | 2 | All the events listed in the *arrEvents* array are disabled; the status of other events remain unchanged |
| Enable events disable others | Longint | 0 | All the events listed in the *arrEvents* array are enabled; all the other events are disabled |
| Enable events others unchanged | Longint | 1 | All the events listed in the *arrEvents* array are enabled; the status of other events remain unchanged |

The **OBJECT SET EVENTS** command can lead to the enabling of events that are not supported by the *object* (depending on its type). In this case, the events will simply be ignored.

If an *object* is duplicated after a call to the **OBJECT SET EVENTS** command, the resulting enabled/disabled configuration is also duplicated.

## Example 1

Enabling three form events for a set of list box objects and disabling other events:

```
ARRAY LONGINT($MyEventsOnLB;3)
$MyEventsOnLB{1}:=On After Sort
$MyEventsOnLB{2}:=On Column Moved
$MyEventsOnLB{3}:=On Column Resize
OBJECT SET EVENTS(*;"MyLB@";$MyEventsOnLB;Enable events disable others)
 // enables 3 events and disables all others
```

## Example 2

Disabling three form events for a set of list box objects, without modifying the other events:

```
ARRAY LONGINT($MyEventsOnLB;3)
$MyEventsOnLB{1}:=On After Sort
$MyEventsOnLB{2}:=On Column Moved
$MyEventsOnLB{3}:=On Column Resize
OBJECT SET EVENTS(*;"MyLB@";$MyEventsOnLB;Disable events others unchanged)
 // disables only these 3 events
```

## Example 3

Enabling a form event for an object, without modifying the other events:

```
ARRAY LONGINT($MyEventsOnLB;1)
$MyEventsOnLB{1}:=On Column Moved
OBJECT SET EVENTS(*;"Col1";$MyEventsOnLB;Enable events others unchanged)
 // only enables this event
```

## Example 4

Disabling all events of the form:

```
ARRAY LONGINT($MyFormEvents;0)
OBJECT SET EVENTS(*;"";$MyFormEvents;Enable events disable others)
 // disables all events
```

## Example 5

Disables a single event of the form without modifying the others:

```
ARRAY LONGINT($MyFormEvents;1)
$MyFormEvents{1}:=On Timer
OBJECT SET EVENTS(*;"";$MyFormEvents;Disable events others unchanged)
 // only disables this event
```

# OBJECT SET FILTER

OBJECT SET FILTER ( {* ;} object ; entryFilter )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| entryFilter | String | ⇒ | New data entry filter for the enterable area |

## Description

**OBJECT SET FILTER** sets the entry filter for the objects specified by *object* to the filter you pass in *entryFilter*.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

**OBJECT SET FILTER** can be used for input and dialog forms and can be applied to fields and enterable variables that accept an entry filter in the Design environment.

Passing an empty string in *entryFilter* removes the current entry filter for the objects.

**Note:** This command cannot be used with fields located in a subform's list form.

**Note:** In *entryFilter*, to use entry filters you may have predefined using the Tool Box, prefix the name of the filter with a vertical bar (|).

## Example 1

The following example sets the entry filter for a postal code field. If the address is in the U.S., the filter is set to ZIP codes. Otherwise, it is set to allow any entry:

```
If([Companies]Country="US") ` Set the filter to a ZIP code format
   OBJECT SET FILTER([Companies]ZIP Code:"&9#####")
Else ` Set the filter to accept alpha and numeric and uppercase the alpha
   OBJECT SET FILTER([Companies]ZIP Code:"~@")
End if
```

## Example 2

The following example allows only the letters "a," "b," "c," or "g" to be entered in two places in the field Field:

```
OBJECT SET FILTER([Table]Field ;"&"+Char(Double quote)+"a;b;c;g"+Char(Double quote)+"##")
```

**Note:** This example sets the entry filter to *&"a;b;c;g"##*.

# OBJECT SET FOCUS RECTANGLE INVISIBLE

OBJECT SET FOCUS RECTANGLE INVISIBLE ( {* ;} object ; invisible )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| invisible | Boolean | ⇒ | True = focus rectangle hidden,<br>False = focus rectangle shown |

## Description

The **OBJECT SET FOCUS RECTANGLE INVISIBLE** command sets or dynamically modifies the visibility option for the focus rectangle of the object(s) designated by the *object* and * parameters for the current process. This setting corresponds to the **Hide focus rectangle** option that is available for enterable objects in the Property List in the Design mode.

**Note:** You can only use this option under Mac OS. It has no effect under Windows.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a variable reference instead of a string.

Pass **True** in the *invisible* parameter to hide the focus rectangle and **False** to keep it visible.

# OBJECT SET FONT

OBJECT SET FONT ( {* ;} object ; font )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| font | String | ⇒ | Font name |

## Description

**OBJECT SET FONT** displays the *object* using the font specified in the *font* parameter. The *font* parameter must contain a valid font name.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string.

## Example 1

The following example sets the font for a button named *bOK*:

```
OBJECT SET FONT(bOK;"Arial")
```

## Example 2

The following example sets the font for all the form objects whose name contains "info":

```
OBJECT SET FONT(*;"@info@";"Times")
```

## Example 3

The following example uses the special *%password* option, designed for entry and display of “password” type fields. When you pass "%password" in the *font* parameter:

- every character entered in the object is displayed with the same symbol,
- "copy" and "cut" actions are disabled in the object.

**Note:** You can use the *%password* option with field, variable and combo box type objects.

```
OBJECT SET FONT([Users]Password;"%password")
```

# OBJECT SET FONT SIZE

OBJECT SET FONT SIZE ( {* ;} object ; size )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| size | Longint | ⇒ | Font size in points |

## Description

**OBJECT SET FONT SIZE** sets the form objects specified by *object* to be displayed using the font size you pass in *size*.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

The *size* is any integer between 1 and 255. If the exact font size does not exist, characters are scaled.

The area for the object, as defined in the form, must be large enough to display the data in the new size. Otherwise, the text may be truncated or not displayed at all.

## Example 1

The following example sets the font size for a variable named *vtInfo*:

```
OBJECT SET FONT SIZE(vtInfo;14)
```

## Example 2

The following example sets the font size for all the form objects whose name starts with "hl":

```
OBJECT SET FONT SIZE(*;"hl@";14)
```

# OBJECT SET FONT STYLE

OBJECT SET FONT STYLE ( {* ;} object ; styles )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| styles | Longint | ⇒ | Font style |

## Description

**OBJECT SET FONT STYLE** sets the form objects specified by *object* to be displayed using the font style you pass in *styles*.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

You pass in *styles* a sum of the constants describing your font style selection. The following are the predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Bold | Longint | 1 |
| Italic | Longint | 2 |
| Plain | Longint | 0 |
| Underline | Longint | 4 |

## Example 1

This example sets the font style for a button named *bAddNew*. The font style is set to bold italic:

```
OBJECT SET FONT STYLE(bAddNew;Bold+Italic)
```

## Example 2

This example sets the font style to Plain for all form objects with names starting with “vt”:

```
OBJECT SET FONT STYLE(*;"vt@";Plain)
```

# OBJECT SET FORMAT

OBJECT SET FORMAT ( {* ;} object ; displayFormat )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| displayFormat | String | ⇒ | New display format for the object |

## Description

**OBJECT SET FORMAT** sets the display format for the objects specified by *object* to the format you pass in *displayFormat*. The new format is only used for the current display; it is not stored with the form.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

**OBJECT SET FORMAT** can be used for both input forms and output forms (displayed or printed) and can be applied to fields or variables (enterable/non-enterable).

Naturally, you must use a display format compatible with the type of data found in the object or with the object itself.

### Boolean

To format Boolean fields, there are two possibilities:

- You can pass a single value in *displayFormat*. In this case, the field will be displayed as a checkbox and its label will be the value specified.
- You can pass two values, separated by a semicolon (*;*), in *displayFormat*. In this case, the field will be displayed as two radio buttons.

### Date

To format Date fields or variables, pass **Char(n)** in *displayFormat*, where *n* is one of the following predefined constants provided by 4D:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null date | Longint | 100 | "" instead of 0 |
| Date RFC 1123 | Longint | 10 | |
| Internal date abbreviated | Longint | 6 | Dec 29, 2006 |
| Internal date long | Longint | 5 | December 29, 2006 |
| Internal date short | Longint | 7 | 12/29/2006 |
| Internal date short special | Longint | 4 | 12/29/06 (but 12/29/1896 or 12/29/2096) |
| ISO Date | Longint | 8 | 2006-12-29T00:00:00 (deprecated) |
| ISO Date GMT | Longint | 9 | 2010-09-13T16:11:53Z |
| System date abbreviated | Longint | 2 | Sun, Dec 29, 2006 |
| System date long | Longint | 3 | Sunday, December 29, 2006 |
| System date short | Longint | 1 | 12/29/2006 |

**Note:** The Blank if null date constant must be added to the format; it indicates that in the case of a null value, 4D must display an empty area instead of zeros.

### Time

To format Time fields or variables, pass **Char(n)** in *displayFormat*, where *n* is one of the following predefined constants provided by 4D:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null time | Longint | 100 | "" instead of 0 |
| HH MM | Longint | 2 | 01:02 |
| HH MM AM PM | Longint | 5 | 1:02 AM |
| HH MM SS | Longint | 1 | 01:02:03 |
| Hour min | Longint | 4 | 1 hour 2 minutes |
| Hour min sec | Longint | 3 | 1 hour 2 minutes 3 seconds |
| ISO time | Longint | 8 | 0000-00-00T01:02:03 |
| Min sec | Longint | 7 | 62 minutes 3 seconds |
| MM SS | Longint | 6 | 62:03 |
| System time long | Longint | 11 | 1:02:03 AM HNEC (Mac only) |
| System time long abbreviated | Longint | 10 | 1•02•03 AM (Mac only) |
| System time short | Longint | 9 | 01:02:03 |

**Note:** The Blank if null time constant must be added to the format; it indicates that in the case of a null value, 4D must display an empty area instead of zeros.

### Picture

To format Picture fields or variables, pass **Char(n)** in *displayFormat*, where *n* is one of the following predefined constants provided by 4D:

| Constant | Type | Value |
|---|---|---|
| On background | Longint | 3 |
| Replicated | Longint | 7 |
| Scaled to fit | Longint | 2 |
| Scaled to fit prop centered | Longint | 6 |
| Scaled to fit proportional | Longint | 5 |
| Truncated centered | Longint | 1 |
| Truncated non centered | Longint | 4 |

### Alpha and number

To format fields or variables of the Alpha or Number type, pass the label of the format directly in the *displayFormat* parameter.

For more information about display formats, see the **Number formats** and **Alpha formats** sections of the 4D *Design Reference* manual.

**Note:** In *displayFormat*, to use custom display formats that you may have created in the tool box, prefix the name of the format with a vertical bar (|).

### Picture buttons

To format picture buttons, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*cols;lines;picture;flags{;ticks}*

- *cols* = number of columns in the picture.
- *lines* = number of lines in the picture.
- *picture* = picture used, coming from the picture library or a picture variable:
  - If the picture comes from the picture library, enter its number, preceded by a question mark (e.g.: "?250").
  - If the picture comes from a picture variable, enter the variable name.
- *flags* = display mode and operation of a picture button. This parameter can take any of the following values: 0, 1, 2, 16, 32, 64 and 128. Each of these values represents a display mode or an operation mode. These values are cumulative; for instance, if you want to enable the modes 1 and 64, pass 65 in the *flags* parameter. Here are the details for each value:
  - *flags* = 0 (no option)
    Displays the next picture in the series when the user clicks the picture. Displays the previous picture in the series when the user holds down the Shift key and clicks on the picture. When the user reaches the last picture in the series, the picture does not change when the user clicks it again. That is, it does not cycle back to the first picture in the series.

    - *flags* = 1 (Switch Continuously)
      Similar to the previous option except that the user can hold down the mouse button to display the pictures continuously (i.e., as an animation). When the user reaches the last picture, the object does not cycle back to the first picture.
    - *flags* = 2 (Loop Back to First Frame)
      Similar to the previous option except that the pictures are displayed in a continuous loop. When the user reaches the last picture and clicks again, the first picture appears, and so forth.
    - *flags* = 16 (Switch when Roll Over)
      The contents of the picture button are modified when the mouse cursor passes over it. The initial picture is re-established when the cursor leaves the button's area. This mode is frequently used in multimedia applications or in HTML documents. The picture that is then displayed is the last picture of the thumbnail table, unless the Use Last Frame as Disabled option is selected (128). If that option is selected, it is the next-to-last thumbnail that is displayed.
    - *flags* = 32 (Switch Back when Released)
      This mode operates with two pictures. It displays the first picture all the time except when the user clicks the button. In that case, the second picture is displayed until the mouse button is released, whereupon it switches back to the first picture. This mode allows you to create an action button that displays its status (idle or clicked). You can use this mode to create a 3D effect or display any picture that depicts the action.
    - *flags* = 64 (Transparent)
      Used to make the background picture transparent.
    - *flags* = 128 (Use Last Frame as Disabled)
      This mode allows you to set the last thumbnail as the thumbnail to display when the button is disabled. When this mode is selected, 4D displays the last thumbnail when the button is disabled. When this mode is used in addition to the modes 0, 1 and 2, the last thumbnail is not taken into account in the sequence of the other modes. It will appear only when the button is disabled.
- *ticks* = activates the “Switch every n Ticks” mode and sets the time interval between the display of each picture. When this optional parameter is passed, it allows you to cycle through the contents of the picture button at the specified speed. For example, if you enter "2;3;?16807;0;10", the picture button will display a different picture every 10 ticks. When this mode is active, only the Transparent mode can be used (64).

### Picture pop-up menus

To format picture pop-up menus, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*cols;lines;picture;hMargin;vMargin;flags*

- *cols* = number of columns in the picture.
- *lines* = number of lines in the picture.
- *picture* = picture used, coming from the picture library or a picture variable:
    - If the picture comes from the picture library, enter its number, preceded by a question mark (e.g.: "?250").
    - If the picture comes from a picture variable, enter the variable name.
- *hMargin* = margin in pixels between the horizontal limits of the menu and the picture.
- *vMargin* = margin in pixels between the vertical limits of the menu and the picture.
- *flags* = transparency mode of picture pop-up menu. Accepts the values 0 and 64:
    - *flags* = 0: the picture pop-up menu is not transparent,
    - *flags* = 64: the picture pop-up menu is transparent.

### Thermometers and rulers

To format objects of the thermometer or ruler type, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*min;max;unit;step;flags{;format{;display}}*

- *min* = value of the first graduation of the indicator.
- *max* = value of the last graduation of the indicator.
- *unit* = interval between the indicator graduations.
- *step* = minimum interval of cursor movement in the indicator.
- *flags* = display mode and operation of indicators. This parameter accepts the values 0, 2, 3, 16, 32 and 128. These values can be accumulated in order to set several options (except for 128). Here are the details for each value:
    - *flags* = 0: does not display the units.
    - *flags* = 2: displays the units on the right or below the indicator.
    - *flags* = 3: displays the units on the left or above the indicator.
    - *flags* = 16: displays graduations adjacent to the units.
    - *flags* = 32: On Data Change is executed while the user is adjusting the indicator. If this value is not used, On Data Change occurs only after the user is finished adjusting the indicator.

    - *flags* = 128: activates the "Barber shop" (continuous animation) mode. This value cannot be combined with others. In this mode, the other parameters are ignored (except for the *display* parameter if passed). For more information about this mode, please refer to the *Design Reference* manual.
- *format* = display format of the indicator graduations.
  Keep in mind that the units and graduations are automatically hidden if the size of the indicator object does not permit them to be displayed correctly.
- *display* = specific display options. In the case of thermometers, this parameter is only taken into account when the *flags* subparameter is 128.
    - *display* = 0 (or is omitted): displays a standard ruler / displays a thermometer in continuous animation of the "barber shop" type.
    - *display* = 1 : activates "Stepper" mode for a ruler / activates the "Asynchronous progress" mode for a thermometer. For more information about these options, please refer to the *Design Reference* manual.

### Dials

To format objects of the dial type, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*min;max;unit;step{;flags}*

- *min* = value of the first graduation of the indicator.
- *max* = value of the last graduation of the indicator.
- *unit* = interval between the indicator graduations.
- *step* = minimum interval of cursor movement in the indicator.
- *flags* = operation mode of the dial (optional). This parameter only accepts the value 32: On Data Change is executed while the user is adjusting the indicator. If this value is not used, On Data Change occurs only after the user is finished adjusting the indicator.

### Button grids

To format button grids, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*cols;lines*

- *cols* = number of columns of the grid.
- *lines* = number of lines of the grid.

**Note:** For more information about the display formats for form objects, refer to the 4D Design Reference manual.

### 3D buttons

To format 3D buttons, in the *displayFormat* parameter, pass a character string respecting the following syntax:
*title;picture;background;titlePos;titleVisible;iconVisible;style;horMargin;vertMargin;iconOffset;popupMenu;hyperlink;numStates*

- *title* = Button title. This value can be expressed as text or a resource number (ex.: “:16800,1”)
- *picture* = Picture linked to a button that comes from a picture library or a picture variable:
    - If the picture comes from a picture library, enter its number, preceded with a question mark (ex.: “?250”).
    - If the picture comes from a picture variable, enter the variable name.
    - If the picture comes from a file stored in the Resources folder of the database, enter a URL of the type "#{folder/}picturename" or "file:{folder/}picturename".
- *background* = Background picture linked to a button (Custom style), that comes from a picture library, a picture variable, a PICT resource or a file stored in the Resources folder (see above).
- *titlePos* = position of the button title. Five values are possible:
    - *titlePos* = 1: Left
    - *titlePos* = 2: Top
    - *titlePos* = 3: Right
    - *titlePos* = 4: Bottom
    - *titlePos* = 5: Middle
- *titleVisible* = Defines whether or not the title is visible. Two values are possible:
    - *titleVisible* = 0: the title is hidden
    - *titleVisible* = 1: the title is displayed
- *iconVisible* = Defines whether or not the icon is visible. Two values are possible:
    - *iconVisible* = 0 : the icon is hidden
    - *iconVisible* = 1 : the icon is displayed
- *style* = Button style. The value of this option determines whether various other options are taken into consideration (for example, background). The following values are possible:
    - *style* = 0: None
    - *style* = 1: Background offset

    - *style* = 2: Push button
    - *style* = 3: Toolbar button
    - *style* = 4: Custom
    - *style* = 5: Circle
    - *style* = 6: Small system square
    - *style* = 7: Office XP
    - *style* = 8: Bevel
    - *style* = 9: Rounded bevel
    - *style* = 10: Collapse/Expand
    - *style* = 11: Help
    - *style* = 12: OS X Textured
    - *style* = 13: OS X Gradient
- *horMargin* = Horizontal margin. Number of pixels delimiting the inside left and right margins of the button (areas that the icon and the text must not encroach upon).
- *vertMargin* = Vertical margin. Number of pixels delimiting the inside top and bottom margins of the button (areas that the icon and the text must not encroach upon).
- *iconOffset* = Shifting of the icon to the right and down. This value, expressed in pixels, indicates the shifting of the button icon to the right and down when the button is clicked (the same value is used for both directions).
- *popupMenu* = Association of a pop-up menu with the button. Three values are possible:
    - *popupMenu* = 0: No pop-up menu
    - *popupMenu* = 1: With linked pop-up menu
    - *popupMenu* = 2: With separate pop-up menu
- *hyperlink* = TItle is underlined on mouseover to resemble a hyperlink (legacy mechanism). Two values are possible:
    - *hyperlink* = 0: title is not underlined on mouseover
    - *hyperlink* = 1: title is underlined on mouseover
- *numStates* = Number of states present in picture used as icon for the 3D button, and which will be used by 4D to represent the standard button states (from 0 to 4).

Certain options are not taken into account for all 3D button styles.  Also, in certain cases, you may wish to not change all the options. To not pass an option, simply omit the corresponding value. For example, if you do not want to pass the *titleVisible*, *vertMargin* and *hyperlink* options, you can write:

```
OBJECT SET FORMAT(myVar;"NiceButton:?256::562:1:;1:4:5:;5:0:;2")
```

### List box headers

To format the icon in a list box header, pass a character string in the *displayFormat* parameter, which respects the following syntax:
*picture;iconPos*

- *picture* = header picture, coming from the picture library, a picture variable, or a picture file:
    - If the picture comes from the picture library, enter its number, preceded by a question mark (e.g.: "?250").
    - If it comes from a picture variable, enter the variable name.
    - If it comes from a file stored in the Resources folder of the database, enter a URL of the type "# {folder/}picturename" or "file:{folder/}picturename".
- *iconPos* = position of icon in header. Two values are supported:
    - *iconPos* = 1: Left
    - *iconPos* = 2: Right

This feature is useful, for example, when you want to work with a customized sort icon.

## Example 1

The following line of code formats the *[Employee]Date Hired* field to the fifth format (Internal date long).

```
OBJECT SET FORMAT([Employee]Date Hired;Char(Internal date long))
```

## Example 2

The following example changes the format for a *[Company]ZIP Code* field according to the length of the value stored in the field:

```
If(Length([Company]ZIP Code)=9)
   OBJECT SET FORMAT([Company]ZIP Code;"#####-####")
Else
   OBJECT SET FORMAT([Company]ZIP Code;"#####")
End if
```

## Example 3

The following example formats the value of the [Stats]Results field depending on whether it is a positive, negative, or null number:

```
OBJECT SET FORMAT([Stats]Results;"### ##0.00;(### ##0.00);")
```

## Example 4

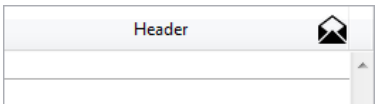
The following example sets the format of a Boolean field to display Married and Unmarried, instead of the default Yes and No:

```
OBJECT SET FORMAT([Employee]Marital Status;"Married;Unmarried")
```

## Example 5

Provided that you have stored a picture file named "envelope_open.png" in the Resources folder of the database, you can write:

```
vIcon:="#envelope_open.png"
vPos:="2" // Right
OBJECT SET FORMAT(*;"Header1";vIcon+";"+vPos)
```



## Example 6

The following example sets the format of a Boolean field to display a checkbox labelled “Classified”:

```
OBJECT SET FORMAT([Folder]Classification;"Classified")
```

## Example 7

You have a table of thumbnails containing 1 row and 4 columns, intended to display a picture button (“default”, “clicked”, “roll over” and “disabled”). You want to associate the Switch when Roll Over, Switch back when Released and Use Last Frame as Disabled options with it:

```
OBJECT SET FORMAT(*;"PictureButton";"4;1;?15000;176")
```

## Example 8

Switching a thermometer to "Barber shop" mode:

```
OBJECT SET FORMAT($Mythermo;";;;;128")
$Mythermo:=1 `Start animation
```

# OBJECT SET HELP TIP

OBJECT SET HELP TIP ( {* ;} object ; helpTip )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| helpTip | Text | ⇒ | Contents of help message |

## Description

The **OBJECT SET HELP TIP** command sets or dynamically modifies the help tip associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

When the form is executed, help messages appear as help tips when the cursor moves over the field or object. Help tips can also be set using the Form editor and the Structure editor in Design mode.

Pass the contents of the message in the *helpTip* parameter. You can pass either:

- a character string, for example "Use a / as separator",
- an empty string "" to remove the help tip.

# OBJECT SET HORIZONTAL ALIGNMENT

OBJECT SET HORIZONTAL ALIGNMENT ( {* ;} object ; alignment )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object name (String) If omitted, object is a field or a variable |
| object | Form object | ⇒ | Object name (if * specified), or Field or variable (if * omitted) |
| alignment | Longint | ⇒ | Alignment code |

## Description

The **OBJECT SET HORIZONTAL ALIGNMENT** command allows you to set the type of horizontal alignment applied to the object(s) designated by the *object* and * parameters.

If you specify the optional * parameter, you indicate an object name (a string) in the *object* parameter. If you omit the * parameter, you indicate a field or variable in the *object* parameter. In this case, you specify a field or variable reference (field or variable objects only) instead of a string.

Pass one of the constants of the **Form Objects (Properties)** theme in the *alignment* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Align center | Longint | 3 | |
| Align default | Longint | 1 | |
| Align left | Longint | 2 | |
| Align right | Longint | 4 | |
| wk justify | Longint | 5 | Available for 4D Write Pro areas only |

The form objects to which alignment can be applied are as follows:

- Scrollable areas
- Combo boxes
- Static text
- Group areas
- Pop up menu/Drop-down lists
- Fields
- Variables
- List boxes
- List box columns
- List box headers
- List box footers
- **4D Write Pro Reference** areas

# OBJECT SET INDICATOR TYPE

OBJECT SET INDICATOR TYPE ( {* ;} object ; indicator )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| indicator | Longint | ⇒ | Indicator type |

## Description

The **OBJECT SET INDICATOR TYPE** command modifies the type of progress indicator for the thermometer(s) designated by the *object* and * parameters in the current process.

The indicator type defines the display variant of the thermometer. For more information, refer to **Indicators** in the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *indicator* parameter, pass the type of indicator you want to display. You can use one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Asynchronous progress bar | Longint | 3 | Circular indicator displaying continuous animation |
| Barber shop | Longint | 2 | Bar displaying continuous animation |
| Progress bar | Longint | 1 | Standard progress bar |

# OBJECT SET KEYBOARD LAYOUT

OBJECT SET KEYBOARD LAYOUT ( {* ;} object ; languageCode )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| languageCode | String | ⇒ | RFC3066 ISO639 and ISO3166 language code,<br>"" = no change |

## Description

The **OBJECT SET KEYBOARD LAYOUT** command sets or dynamically modifies the keyboard layout associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or field. In this case, you pass a reference instead of a name.

In *languageCode*, you pass a string indicating the code of the language to use, based on RFC3066, ISO639 and ISO3166. For more information, refer to the description of the **SET DATABASE LOCALIZATION** command.

# OBJECT SET LIST BY NAME

OBJECT SET LIST BY NAME ( {* ;} object {; listType}; list )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object Name (String) If omitted, object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| listType | Longint | ⇒ | Type of list: Choice list, Required list or Excluded list |
| list | String | ⇒ | Name of the list to use as Choice list or "" to disassociate the list |

## Description

The **OBJECT SET LIST BY NAME** command sets, replaces or disassociates the *list* associated with the object or group of objects specified by *object*. The list whose name is passed in the *list* parameter must have been created using the List Editor in the Design environment.

This command can be applied in an input or dialog form, to fields and enterable variables whose value can be entered as text.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string.

**Note:** This command cannot be used with fields located in a subform's list form.

The **OBJECT SET LIST BY NAME** command now allows you to set or replace all the types of lists associated with the object(s) designated by the *object* and * parameters: choice lists, list of required values, and lists of excluded values. To do this, in the *listType* parameter you pass one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Choice list | Longint | 0 | Simple list of values to choose from ("Choice List" option in the Property List) (default) |
| Excluded list | Longint | 2 | Lists values not accepted for entry ("Excluded List" option in the Property List) |
| Required list | Longint | 1 | Lists only values accepted for entry ("Required List" option in the Property List) |

If you omit this parameter, value 0 (Choice list) is used by default.

In the current process, to disassociate a list that was associated with the *object*, pass an empty string ("") in the *list* parameter for the type of list concerned.

## Example 1

The following example sets a choice list for a shipping field. If the shipping is overnight, then the choice list is set to shippers who can ship overnight. Otherwise, it is set to the standard shippers:

```
If([Shipments]Overnight)
   OBJECT SET LIST BY NAME([Shipments]Shipper;"Fast Shippers")
Else
   OBJECT SET LIST BY NAME([Shipments]Shipper;"Normal Shippers")
End if
```

## Example 2

Associate the "color_choice" list as a simple pop-up/drop-down list named "DoorColor":

```
OBJECT SET LIST BY NAME(*;"DoorColor";Choice list;"color_choice")
 // in this case, the 3rd parameter (constant) can be omitted
```

## Example 3

You want to associate the "color_choice" list with the "WallColor" combo box. Since this combo box is enterable, you want for it not to be possible to use certain colors such as "black", "purple" etc. These colors are placed in the "excl_colors" list:

```
OBJECT SET LIST BY NAME(*;"WallColor";Choice list;"color_choice")
OBJECT SET LIST BY NAME(*;"WallColor";Excluded list;"excl_colors")
```

## Example 4

You want to remove the list associations:

```
 // removal of a choice list
OBJECT SET LIST BY NAME(*;"DoorColor";Choice list;"")
 // removal of list of values that are not allowed
OBJECT SET LIST BY NAME(*;"WallColor";Excluded list;"")
```

# OBJECT SET LIST BY REFERENCE

OBJECT SET LIST BY REFERENCE ( {* ;} object {; listType}; list )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| listType | Longint | ⇒ | Type of list: Choice list, Required list or Excluded list |
| list | ListRef | ⇒ | List reference number |

## Description

The **OBJECT SET LIST BY REFERENCE** command defines or replaces the list associated with the object(s) designated by the *object* and * parameters, with the hierarchical list referenced in the *list* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

By default, if you omit the *listType* parameter, the command defines a source choice list (choice of values) for the object. You can designate any type of list in the *listType* parameter. To do this, you just need to pass one of the following constants found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Choice list | Longint | 0 | Simple list of values to choose from ("Choice List" option in the Property List) (default) |
| Excluded list | Longint | 2 | Lists values not accepted for entry ("Excluded List" option in the Property List) |
| Required list | Longint | 1 | Lists only values accepted for entry ("Required List" option in the Property List) |

In *list*, pass the reference number of the hierarchical list that you want to associated with the object. This list must have been generated using the **Copy list**, **Load list** or **New list** command.

To end the association of a *list* with an *object*, you can just pass 0 in the *list* parameter for the type of list concerned.

Removing a list association does not delete the list reference from memory. Remember to call the **CLEAR LIST** command when you no longer need the list.

This command is particularly interesting in the context of a pop-up or combo box associated with a variable or a field (see the *Design Reference* manual). In this case, the association is dynamic and any change in the list is copied to the form. When the object is associated with an array, the list is copied into the array and any changes to the list are not available automatically (see example 5).

## Example 1

Associating a simple choice list (default list type) to a text field:

```
vCountriesList:=New list
APPEND TO LIST(vCountriesList;"Spain";1)
APPEND TO LIST(vCountriesList;"Portugal";2)
APPEND TO LIST(vCountriesList;"Greece";3)
OBJECT SET LIST BY REFERENCE([Contact]Country;vCountriesList)
```

## Example 2

Associating the "vColor" list as a simple choice list with the "DoorColor" pop-up/drop-down list:

```
vColor:=New list
APPEND TO LIST(vColor;"Blue";1)
APPEND TO LIST(vColor;"Green";2)
APPEND TO LIST(vColor;"Red";3)
APPEND TO LIST(vColor;"Yellow";4)
OBJECT SET LIST BY REFERENCE(*;"DoorColor";Choice list;vColor)
```

## Example 3

Now you want to associate the "vColor" list with a combo box named "WallColor". Since this combo box is enterable, you want to make sure certain colors, such as "black," "purple," etc., cannot be used. These colors are placed in the "vReject" list:

```
OBJECT SET LIST BY REFERENCE(*;"WallColor";Choice list;vColor)
vReject:=New list
APPEND TO LIST(vReject;"Black";1)
APPEND TO LIST(vReject;"Gray";2)
APPEND TO LIST(vReject;"Purple";3)
OBJECT SET LIST BY REFERENCE(*;"WallColor";Excluded list;vReject)
```

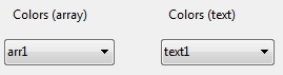
## Example 4

You want to remove the list associations:

```
OBJECT SET LIST BY REFERENCE(*;"WallColor";Choice list;0)
OBJECT SET LIST BY REFERENCE(*;"WallColor";Required list;0)
OBJECT SET LIST BY REFERENCE(*;"WallColor";Excluded list;0)
```

## Example 5

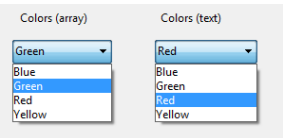
This example illustrates the difference in how the command works when applied to a pop-up menu associated with a text array or one associated with a text variable. There are two pop-up menus in a form:



The contents of these pop-up menus is set using the *<>vColor* list (containing color values). The following code is executed when the form is loaded:

```
ARRAY TEXT(arr1;0) //arr1 pop up
C_TEXT(text1) //text1 pop up
OBJECT SET LIST BY REFERENCE(*;"arr1";<>vColor)
OBJECT SET LIST BY REFERENCE(*;"text1";<>vColor)
```

During execution, both menus propose the same values:

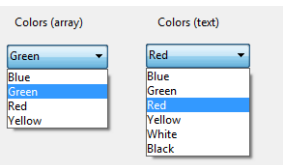


(*Montage showing contents of menus simultaneously*)

Then you run the following code, for example by means of a button:

```
APPEND TO LIST(<>vColor;"White";5)
APPEND TO LIST(<>vColor;"Black";6)
```

Only the menu associated with the Text field is updated (by means of the dynamic reference):



In order to update the list associated with the pop-up managed by array, you need to call the **OBJECT SET LIST BY REFERENCE** command again to copy the contents of the list.

# OBJECT SET MAXIMUM VALUE

OBJECT SET MAXIMUM VALUE ( {* ;} object ; maxValue )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| maxValue | Date, Time, Number | ⇒ | Maximum value for object |

## Description

The **OBJECT SET MAXIMUM VALUE** command modifies the maximum value of the object(s) designated by the *object* and * parameters for the current process.

The "Maximum Value" property can be applied to number, date or time type data. For more information, refer to **Maximum and minimum values** in the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In *maxValue*, pass the new maximum value you want to assign to the object for the current process. This value must correspond to the object type, otherwise error 18 "Field types are incompatible" is returned.

# OBJECT SET MINIMUM VALUE

OBJECT SET MINIMUM VALUE ( {* ;} object ; minValue )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| minValue | Date, Time, Number | ⇒ | Minimum value for object |

## Description

The **OBJECT SET MINIMUM VALUE** command modifies the minimum value of the object(s) designated by the *object* and * parameters for the current process.

The "Minimum Value" property can be applied to number, date or time type data. For more information, refer to **Maximum and minimum values** in the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In *minValue*, pass the new minimum value you want to assign to the object for the current process. This value must correspond to the object type, otherwise error 18 "Field types are incompatible" is returned.

# OBJECT SET MULTILINE

OBJECT SET MULTILINE ( {* ;} object ; multiline )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| multiline | Longint | ⇒ | Status of multiline property |

## Description

The **OBJECT SET MULTILINE** command modifies the "Multiline" property of the object(s) designated by the *object* and * parameters.

The "Multiline" property controls two parameters related to the display and printing of text areas: display of words located at the end of the line in single-line areas and the automatic insertion of line returns. For more information, refer to **Multiline** in the *Design Reference* manual. If you apply this command to an object that does not support this property, the command does nothing.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *multiline* parameter, pass the new value of the option that you want to set. You can use the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Multiline Auto | Longint | 0 | In single-line areas, words located at the end of lines are truncated and there are no line returns.<br>In multiline areas, 4D carries out automatic line returns. |
| Multiline No | Longint | 2 | There are never line returns: the text is always displayed on a single row. If the Alpha or Text field or variable contains carriage returns, the text located after the first carriage return is removed as soon as the area is modified. |
| Multiline Yes | Longint | 1 | In single-line areas, the text is displayed up to the first carriage return or until the last word that can be displayed entirely. 4D inserts line returns; it is possible to scroll the contents of the area by pressing the down arrow key.<br>In multiline areas, 4D carries out automatic line returns. |

## Example

You want to prohibit multiple lines in an entry area:

```
OBJECT SET MULTILINE(*;"vEntry";Multiline No)
```

# OBJECT SET PLACEHOLDER

OBJECT SET PLACEHOLDER ( {* ;} object ; placeholderText )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| placeholderText | Text | ⇒ | Placeholder text associated with object |

## Description

The **OBJECT SET PLACEHOLDER** command associates placeholder text with the object(s) designated by the *object* and * parameters.

For more information about placeholder text, refer to the *Design Reference* manual.

If placeholder text is already associated with the object through the Property List, this text is replaced in the current process by the contents of the *placeholderText* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In *placeholderText*, pass the help text or indication that must appear when the object is empty.

**Note:** The **OBJECT SET PLACEHOLDER** command does not support the insertion of xliff references into the placeholder text. This is only possible for placeholder text that is defined using the Property List.

This command can only be used with form objects of the variable, field or combo box type. You can associate placeholder text with Alpha and Text type values. You can also associate it with Date or Time type data if the form object is given the "Blank if null" property.

## Example

You want to display "Search" as placeholder text in a combo box:

```
OBJECT SET PLACEHOLDER(*;"search_combo";"Search")
```

# OBJECT SET PRINT VARIABLE FRAME

OBJECT SET PRINT VARIABLE FRAME ( {* ;} object ; variableFrame {; fixedSubform} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ➡ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| variableFrame | Boolean | ➡ | True = Variable frame printing, False = Fixed frame printing |
| fixedSubform | Longint | ➡ | Options for printing subforms in fixed size |

## Description

The **OBJECT SET PRINT VARIABLE FRAME** command modifies the Print Variable Frame property of the object(s) designated by the *object* and * parameters.

This property is available for the following objects:

- Text or Picture type variables and fields (see **Print Variable Frame** in the *Design Reference* manual)
- 4D Write Pro areas (see **Using a 4D Write Pro area** in the 4D Write Pro reference manual).
- Subforms. Subforms have an additional option for fixed size printing (see **Subform Printing** in the *Design Reference* manual); the command can be used to configure this option using the *fixedSubform* parameter.

If you apply this command to an object that does not support this property, the command does nothing.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

Pass a Boolean in the *variableFrame* parameter: if you pass **True**, the object is printed with a variable frame. If you pass **False**, it is printed with a fixed frame.

The optional *fixedSubform* parameter lets you set an additional option when you pass **False** in the *variableFrame* parameter and the *object* is a subform (it is ignored in all other cases). In this case, you can define the fixed frame printing mode for the subform. You can pass one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Print Frame fixed with multiple records | Longint | 2 | The frame remains the same size, but 4D prints the form several times to include all the records. |
| Print Frame fixed with truncation | Longint | 1 | 4D prints only the records that fit into the area of the subform. The form is printed only once and those records that are not printed are ignored. |

# OBJECT SET RESIZING OPTIONS

OBJECT SET RESIZING OPTIONS ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| horizontal | Longint | ⇒ | Horizontal resizing option |
| vertical | Longint | ⇒ | Vertical resizing option |

## Description

The **OBJECT SET RESIZING OPTIONS** command sets or dynamically modifies the resizing options for the object(s) designated by the *object* and * parameters for the current process. These options specify how the object is displayed when the form window is resized.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In the *horizontal* parameter, you pass a value indicating the horizontal resizing option that you want to specify for the *object*. You can pass one of the following constants, found in the **Form Objects (Properties)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Resize horizontal grow | Longint | 1 | If the window grows by 50% in width, the object is expanded by 50% to the right. |
| Resize horizontal move | Longint | 2 | If the window grows by 100 pixels in width, the object is moved 100 pixels to the right. |
| Resize horizontal none | Longint | 0 | If the window is expanded in width, neither the width nor the position of the object changes. |

In the *vertical* parameter, you pass a value indicating the vertical resizing option that you want to specify for the *object*. You can pass one of the following constants, found in the **Form Objects (Properties)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Resize vertical grow | Longint | 1 | If the window grows by 50% in height, the object is lengthened by 50% towards the bottom. |
| Resize vertical move | Longint | 2 | If the window grows by 100 pixels in height, the object is moved 100 pixels towards the bottom. |
| Resize vertical none | Longint | 0 | If the window is expanded in height, neither the height nor the position of the object changes. |

# OBJECT SET RGB COLORS

OBJECT SET RGB COLORS ( {* ;} object ; foregroundColor ; backgroundColor {; altBackgrndColor} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| foregroundColor | Longint | ⇒ | RGB color value for Foreground color |
| backgroundColor | Longint | ⇒ | RGB color value for Background color |
| altBackgrndColor | Longint | ⇒ | RGB color value for Alternating background color |

## Description

The **OBJECT SET RGB COLORS** command changes the foreground and background colors of the objects specified by the *object* parameter and the optional * parameter. When the command is applied to a List box object, an additional parameter lets you modify the alternating color of the rows.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the **Object Properties** section.

The optional *altBackgrndColor* parameter lets you set an alternate background color for even-numbered rows. This parameter is only used when the object specified is a List box or a column of the List box. When this parameter is used, the *backgroundColor* parameter is only used for odd-numbered rows. Using alternating colors makes lists easier to read.

If *object* specifies a List box object, alternating colors are used for the entire List box. If *object* specifies a column of the List box, only the column will use the colors set.

You indicate RGB color values in *foregroundColor*, *backgroundColor* and *altBackgrndColor*. An RGB value is a 4-byte Long Integer whose format (*0x00RRGGBB*) is described in the following table (bytes are numbered from 0 to 3, from right to left):

| Byte | Description |
|---|---|
| 3 | Must be zero if absolute RGB color |
| 2 | Red component of the color (0..255) |
| 1 | Green component of the color (0..255) |
| 0 | Blue component of the color (0..255) |

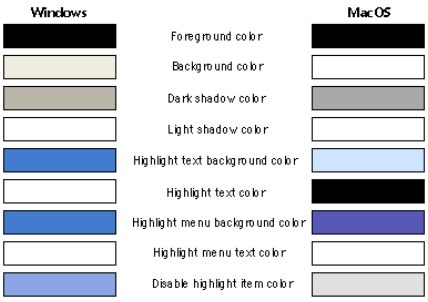
The following table shows some examples of RGB color values:

| Value | Description |
|---|---|
| *0x00000000* | Black |
| *0x00FF0000* | Bright Red |
| *0x0000FF00* | Bright Green |
| *0x000000FF* | Bright Blue |
| *0x007F7F7F* | Gray |
| *0x00FFFF00* | Bright Yellow |
| *0x00FF7F7F* | Red Pastel |
| *0x00FFFFFF* | White |

Alternatively, you can specify one of the “system” colors used by 4D for drawing objects whose colors are set automatically. The following predefined constants are provided by 4D:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Background color | Longint | -2 | This constant can only be used with the *backgroundColor* and *altBackgrndColor* parameters. |
| Background color none | Longint | -16 | |
| Dark shadow color | Longint | -3 | |
| Disable highlight item color | Longint | -11 | |
| Foreground color | Longint | -1 | |
| Highlight menu background color | Longint | -9 | |
| Highlight menu text color | Longint | -10 | |
| Highlight text background color | Longint | -7 | |
| Highlight text color | Longint | -8 | |
| Light shadow color | Longint | -4 | |

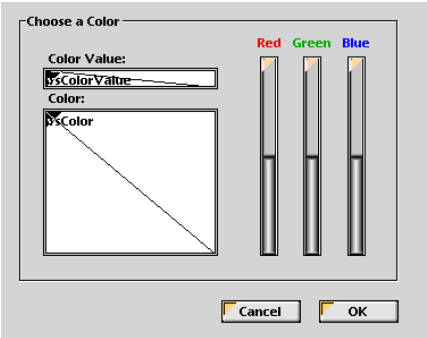
For example, you can get the following colors for enterable field or variable type objects on a standard system:



**WARNING:** These automatic colors depend on the system as well as the type of object to which they are assigned. Depending on the OS version or whether you customize your system colors, 4D will adjust its automatic colors accordingly. Use the automatic color values for setting objects to the system colors, not for setting them to the example colors shown above.

## Example 1

This form contains the two non-enterable variables *vsColorValue* and *vsColor* as well as the three thermometers: *thRed*, *thGreen*, and *thBlue*.



Here are the methods for these objects:

```
  ` vsColorValue non-enterable Object Method
Case of
   :(Form event=On Load)
      vsColorValue:="0x00000000"
End case
  ` vsColor non-enterable variable Object Method
Case of
   :(Form event=On Load)
      vsColor:=""
      OBJECT SET RGB COLORS(vsColor;0x00FFFFFF;0x0000)
End case

  ` thRed Thermometer Object Method
```

```
CLICK IN COLOR THERMOMETER

` thGreen Thermometer Object Method
CLICK IN COLOR THERMOMETER

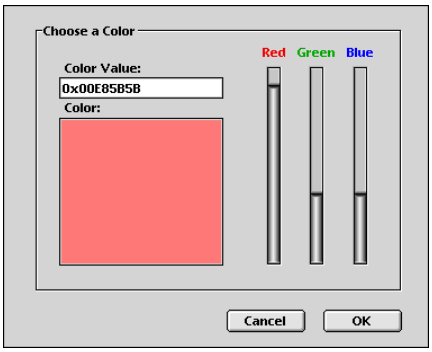
` thBlue Thermometer Object Method
CLICK IN COLOR THERMOMETER
```

The project method called by the three thermometers is:

```
` CLICK IN COLOR THERMOMETER Project Method
OBJECT SET RGB COLORS(vsColor;0x00FFFFFF;(thRed<<16)+(thGreen<<8)+thBlue)
vsColorValue:=String((thRed<<16)+(thGreen<<8)+thBlue;"&x")
If(thRed=0)
   vsColorValue:=Substring(vsColorValue;1;2)+"0000"+Substring(vsColorValue;3)
End if
```

Note the use of the **Bitwise Operators** for calculating the color value from the thermometer values.

When executed, the form looks like this:



## Example 2

Changing to transparent background with a light font color:

```
OBJECT SET RGB COLORS(*;"myVar";Light shadow color;Background color none)
```

# OBJECT SET SCROLL POSITION

OBJECT SET SCROLL POSITION ( * ; object {; vPosition {; hPosition}}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a table, a field or a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Table or field or variable (if * is omitted) |
| vPosition | Longint | ⇒ | Line number to display or Vertical scrolling in pixels (pictures) |
| hPosition | Longint | ⇒ | Column number to display (list box) or Horizontal scrolling in pixels (pictures) |
| * | Operator | ⇒ | Display of line (and column if the hPosition parameter is passed) in first position after scroll |

## Description

The **OBJECT SET SCROLL POSITION** command allows scrolling the contents of several types of objects: the lines of a subform, of a list form (displayed using the **MODIFY SELECTION** or **DISPLAY SELECTION** commands), or of a hierarchical list, the rows and columns of a list box or even the pixels of a picture.

**Note:** Scrolling via programming remains possible even if scrollbars have been hidden in the form.

If you pass the first optional * parameter, you indicate that the *object* parameter is the name of a subform, a hierarchical list, a list box object or a picture field/variable (in this case, pass a string in *object*). If you do not pass anything in this parameter, you indicate that the *object* parameter is a table (list form table or subform table), a variable (*ListRef* of a hierarchical list or list box or picture) or a field.

The *vPosition* parameter can be used to specify the number of the row to display or, in the case of a picture, the vertical coordinate of the pixel to display.
If you do not pass this parameter, the command provokes the vertical scroll of lines of the list so that the first highlighted line in the list is visible. In this case, if no line is selected or if at least one selected line is already visible, no vertical scrolling is applied.
If you pass this parameter, the command provokes the vertical scroll of lines of the list so that the set line is visible (highlighted or not). If the line is already visible, the command does nothing, unless the second * parameter is passed (see below).

- For list forms and subforms, this number is the number of the line among the current selection (its position).
- In the case of hierarchical lists, the command takes the expanded/collapsed state of the items into account.
- For list boxes, this number is the number of the row among all the object rows (including hidden rows). If the number passed in *vPosition* corresponds to a hidden row in the list box, the command displays the first visible row that follows.

  **Note:** Keep in mind that this command goes by the "standard" representation (non-hierarchical) of a list box, even if it is displayed in hierarchical mode. Therefore, the result may be different depending on whether the list box is displayed in standard or hierarchical mode (see example).
- For pictures displayed in the form, *vPosition* indicates the vertical coordinate point of the picture to display in the object. Pass 0 in *vPosition* if you do not want to scroll the picture vertically. The value must be expressed in pixels in relation to the origin of the picture. If the vertical coordinate point is already shown in the object, the command does nothing (except when you pass the second * parameter. see below). The picture must be displayed in the "Truncated (non-centered)" format.

The *hPosition* parameter can be used in the context of a list box or a picture.

- For list boxes, you can pass a column number in *hPosition*. Executing the command causes horizontal scrolling of the list box so that this column will be shown. If the column is already visible, the command does nothing. As with vertical scrolling, if you pass the second optional * parameter, the column made visible by the command (if the list box is actually scrolled) will be placed in the first position (see below).
- For a picture displayed in a form, *hPosition* indicates the horizontal coordinate point to display in the object. The value must be expressed in pixels in relation to the origin of the picture. If the horizontal coordinate point is already shown in the object, the command does nothing (except when you pass the second * parameter. see below).

If you pass the second optional * parameter:

- the line made visible using the command (if the list was scrolled) will be placed in the first position of the list. If the line is situated at the end of the list, this option has no effect.

- in the context of a picture, the coordinates requested will be placed at the origin of the picture variable (0,0), even if these coordinates were already shown in the object.

**Note:** The **HIGHLIGHT RECORDS** command features an optional * parameter that allows delegating scroll management to the **OBJECT SET SCROLL POSITION** command.

## Example 1

This example illustrates the difference in the way the command functions depending on whether the list box is displayed in standard or hierarchical mode:

```
OBJECT SET SCROLL POSITION(*;"mylistbox";4;2;*) // displays 4th row of 2nd column of list box in the first position
```

If this statement is applied to a list box displayed in standard mode:

| | | | | |
|---|---|---|---|---|
| France | Brittany | Brest | 120000 | ... |
| France | Brittany | Quimper | 80000 | ... |
| France | Brittany | Rennes | 200000 | ... |
| France | **Normandy** | Caen | 220000 | ... |
| France | Normandy | Deauville | 4000 | ... |
| France | Normandy | Cherbourg | 41000 | ... |
| ... | ... | ... | ... | ... |

... the rows and columns of the list box actually scroll:

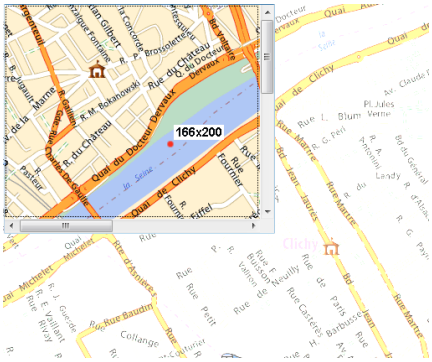
| | | | | |
|---|---|---|---|---|
| Normandy | Caen | 220000 | ... | ... |
| Normandy | Deauville | 4000 | ... | ... |
| **Normandy** | Cherbourg | 41000 | ... | ... |
| ... | ... | ... | ... | ... |
| ... | ... | ... | ... | ... |
| ... | ... | ... | ... | ... |
| ... | ... | ... | ... | ... |

On the other hand, if the same statement is applied to a list box displayed in hierarchical mode, the rows scroll but not the columns because the 2nd column is part of the hierarchy:

| V **Normandy** | |
|---|---|
| Caen | 220000 |
| Deauville | 4000 |
| Cherbourg | 41000 |
| ... | |

## Example 2

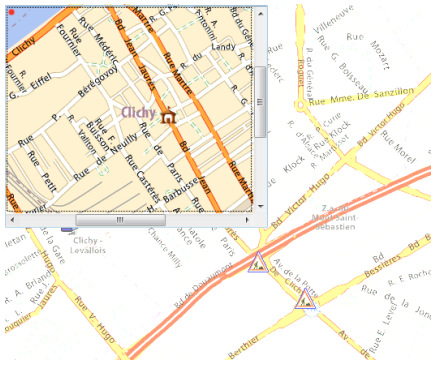
You want to scoll a picture that is included in a form variable. This montage shows the visible part of the picture as well as the point to be displayed (166 pixels vertically and 200 pixels horizontally):



To scroll the visible part and display the red point at the origin of the picture variable, you can just write:

```
OBJECT SET SCROLL POSITION(*;"myVar";166;200;*)
```

You then get the following result:



Make sure that you do not omit the second * parameter in this case, otherwise the picture will not scroll because the point defined is already displayed.

# OBJECT SET SCROLLBAR

OBJECT SET SCROLLBAR ( {* ;} object ; horizontal ; vertical )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| horizontal | Boolean, Longint | ⇒ | Visibility of horizontal scrollbar |
| vertical | Boolean, Longint | ⇒ | Visibility of vertical scrollbar |

## Description

The **OBJECT SET SCROLLBAR** command allows you to display or hide the horizontal and/or vertical scrollbars in the object set using the *object* and * parameters.

If you pass the optional * parameter, you indicate that the *object* parameter is an object name (string). If you do not pass this parameter, you indicate that the *object* parameter is a variable. In this case, you do not pass a string, but a variable reference. For more information about object names, refer to the **Object Properties** section.

In the *horizontal* and *vertical* parameters, you pass values indicating whether the corresponding scrollbars should be displayed. You can pass either Boolean values (True=displayed, False=hidden), or numeric values (0=hidden, 1=displayed, 2=automatic mode). Using numeric values gives you access to the automatic mode, where scrollbars are only displayed when necessary.

The following table indicates the values you can pass in the *horizontal* and *vertical* parameters for objects that accept scrollbars (automatic mode is not available for all objects):

| Objects with scrollbars | Hide scrollbar | Show scrollbar | Automatic mode |
|---|---|---|---|
| Text object fields and variables | False or 0 | True or 1 | *not available* |
| Picture object fields and variables | False or 0 | True or 1 | 2 |
| List boxes | False or 0 | True or 1 | 2 |
| Hierarchical lists | False or 0 | True or 1 | 2 |
| Subforms | False or 0 | True or 1 | *not available* |

By default, scrollbars are displayed.

**Note:** For more information about the automatic mode, refer to **Scroll bars**.

# OBJECT SET SHORTCUT

OBJECT SET SHORTCUT ( {* ;} object ; key {; modifiers} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable or field |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable or field (if * is omitted) |
| key | String | ⇒ | Key to associate with object |
| modifiers | Longint | ⇒ | Modifier key mask or combination of masks |

## Description

The **OBJECT SET SHORTCUT** command sets or dynamically modifies the keyboard shortcut associated with the object(s) designated by the *object* and * parameters for the current process.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable or a field. In this case, you pass a reference instead of a name.

In the *key* parameter, pass a string indicating the key to associate with the object. You can either pass:

- a standard key name, for example "B"
- or a constant (or its value) from the **Shortcut and Associated Keys** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Shortcut with Backspace | String | [backspace] | |
| Shortcut with Carriage Return | String | [return] | |
| Shortcut with Delete | String | [del] | |
| Shortcut with Down arrow | String | [down arrow] | |
| Shortcut with End | String | [end] | |
| Shortcut with Enter | String | [enter] | |
| Shortcut with Escape | String | [esc] | |
| Shortcut with F1 | String | [F1] | |
| Shortcut with F10 | String | [F10] | |
| Shortcut with F11 | String | [F11] | |
| Shortcut with F12 | String | [F12] | |
| Shortcut with F13 | String | [F13] | |
| Shortcut with F14 | String | [F14] | |
| Shortcut with F15 | String | [F15] | |
| Shortcut with F2 | String | [F2] | |
| Shortcut with F3 | String | [F3] | |
| Shortcut with F4 | String | [F4] | |
| Shortcut with F5 | String | [F5] | |
| Shortcut with F6 | String | [F6] | |
| Shortcut with F7 | String | [F7] | |
| Shortcut with F8 | String | [F8] | |
| Shortcut with F9 | String | [F9] | |
| Shortcut with Help | String | [help] | |
| Shortcut with Home | String | [home] | |
| Shortcut with Left arrow | String | [left arrow] | |
| Shortcut with Page down | String | [page down] | |
| Shortcut with Page up | String | [page up] | |
| Shortcut with Right arrow | String | [right arrow] | |
| Shortcut with Tabulation | String | [tab] | |
| Shortcut with Up arrow | String | [up arrow] | |

In the *modifiers* parameter, you can pass one or more modifier keys to associate with the shortcut. To set the *modifiers* parameter, pass one or more of the following "Mask" type constants found in the **Events (Modifiers)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Command key mask | Longint | 256 | Ctrl key under Windows, Command key under OS X |
| Control key mask | Longint | 4096 | Ctrl key under OS X, or right click under Windows and OS X |
| Option key mask | Longint | 2048 | Alt key (also called Option under OS X) |
| Shift key mask | Longint | 512 | Windows and OS X |

**Note:** When you omit the *modifiers* parameter, the object is enabled as soon as you press the key that was set. For example, if you associate the "H" key with a button, this button is enabled whenever you press the H key. This kind of functioning is to be reserved for specific interfaces.

## Example

You want to associate a different shortcut depending on the current language of the application. In the On Load form event, you can write:

```
Case of
      vLang="FR"
      OBJECT SET SHORTCUT(*;"SortButton";"T";Command key mask+Shift key mask) // Ctrl+Shift+T in French
      vLang="US"
      OBJECT SET SHORTCUT(*;"SortButton";"O";Command key mask+Shift key mask) // Ctrl+Shift+O in English
End case
```

# OBJECT SET STYLE SHEET

OBJECT SET STYLE SHEET ( {* ;} object ; styleSheetName )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| styleSheetName | Text | ⇒ | Name of style sheet |

## Description

The **OBJECT SET STYLE SHEET** command modifies, for the current process, the style sheet associated with the object(s) designated by the *object* and * parameters. A style sheet modifies the font, font size and (except for automatic style sheets) font style.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *styleSheetName* parameter, you pass the name of the style sheet to be applied to the *object*. You can also pass either:

- the name of an existing style sheet (if the style sheet does not exist, an error is returned, that you can intercept using a method installed by the **ON ERR CALL** command),
- an empty string ("") so as to not apply the style sheet to the *object*, or
- one of the following constants found in the "**Font Styles**" theme in order to apply an automatic style sheet:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Automatic style sheet | String | __automatic__ | Used by default for all objects |
| Automatic style sheet_additional | String | __automatic_additional_text__ | Supported by static text, fields and variables only. Used for additional text in dialog boxes. |
| Automatic style sheet_main | String | __automatic_main_text__ | Supported by static text, fields and variables only. Used for main text in dialog boxes. |

If a style sheet was already associated with the object in Design mode, calling this command replaces it for the current process.

During the session, if you use the **ST SET ATTRIBUTES**, **ST SET TEXT** or **OBJECT SET FONT** commands on the *object* in order to modify its font or font size, the reference to the style sheet is automatically deleted from the object -- even if you assign the same attributes as those of the style sheet. However, if you modify the style (bold, italic, etc.), for example using the **ST SET ATTRIBUTES** or **OBJECT SET FONT STYLE** commands, these new properties are added to the style sheet for the duration of the session.

# OBJECT SET SUBFORM

OBJECT SET SUBFORM ( {* ;} object {; aTable}; detailSubform {; listSubform} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| aTable | Table | ⇒ | Table of form (if table form) |
| detailSubform | Text | ⇒ | Name of detail form of subform |
| listSubform | Text | ⇒ | Name of list form of subform (table form) |

## Description

The **OBJECT SET SUBFORM** command dynamically modifies the detail form as well as, optionally, the screen list form associated with the subform object designated by the *object* and * parameters.

**Note:** This command cannot change the type of the subform itself (list or page). This property can only be set in Design mode.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In the *aTable* parameter, pass the table of the forms to be used. This parameter is optional; you can omit it when you specify a project form as detail subform.

In the *detailSubform* parameter, pass the name of the form to use as detail subform.

In the *listSubform* parameter, pass the name of the form to use as list subform. This parameter can only be passed when you modify a list type subform.

When you modify a page subform, the command can be executed at any time; current selections are not modified. However, when you modify a list subform, it can only be modified when it displays the list. If the command is executed when the detail form is displayed following a double-click in the list, an error is generated.

# OBJECT SET TEXT ORIENTATION

OBJECT SET TEXT ORIENTATION ( {* ;} object ; orientation )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| orientation | Longint | ⇒ | Value of object orientation |

## Description

The **OBJECT SET TEXT ORIENTATION** command modifies the orientation of the object(s) designated by the *object* and * parameters for the current process.

The "Orientation" property, available in the Form editor, performs permanent rotations of text areas in your forms. Unlike this property, the **OBJECT SET TEXT ORIENTATION** command applies the rotation to the contents of the object, but not to the object itself. For more information, refer to the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).
Only static text as well as non-enterable variables and fields can be rotated. If you apply this command to an object that does not support text orientation, the command does nothing.

In the *orientation* parameter, you pass the absolute orientation that you want to assign to the object. You must use one of the following constants, found in the "**Form Objects (Properties)**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Orientation 0° | Longint | 0 | No rotation (default value) |
| Orientation 180° | Longint | 180 | Orientation of text to 180° clockwise |
| Orientation 90° left | Longint | 270 | Orientation of text to 90° counter-clockwise |
| Orientation 90° right | Longint | 90 | Orientation of text to 90° clockwise |

**Note:** Only angles corresponding to these values are supported. If you pass any other value, it will be ignored.

## Example

You want to apply an orientation of 270° to a variable in your form:

```
OBJECT SET ENTERABLE(*;"myVar";False)
 // mandatory if variable is enterable
OBJECT SET TEXT ORIENTATION(*;"myVar";Orientation 90°  left)
```

# OBJECT SET THREE STATES CHECKBOX

OBJECT SET THREE STATES CHECKBOX ( {* ;} object ; threeStates )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| threeStates | Boolean | ⇒ | True = three-states checkbox, False = standard checkbox |

## Description

The **OBJECT SET THREE STATES CHECKBOX** command modifies, for the current process, the "Three-States" property of the checkbox(es) designated by the *object* and * parameters.

The "Three-states" option allows the additional "semi-checked" state to be used for checkboxes. For more information, refer to **Three-States check box** in the *Design Reference* manual.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

This command only applies to checkboxes associated with variables, and not to Boolean fields that are represented as checkboxes.

In the *threeStates* parameter, pass **True** to enable the "three states" mode, or **False** to disable it.

# OBJECT SET TITLE

OBJECT SET TITLE ( {* ;} object ; title )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object Name (String) If omitted, object is a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Variable (if * is omitted) |
| title | String | ⇒ | New title for the object |

## Description

The **OBJECT SET TITLE** command changes the title of the object(s) specified by *object* to the value you pass in *title*.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the section **Object Properties**.

**OBJECT SET TITLE** can be applied to any simple objects that display a title:

- buttons and 3D buttons,
- check boxes and 3D check boxes,
- radio buttons and 3D radio buttons,
- listbox headers,
- static text areas,
- group boxes.

Usually, you will apply this command to one object at a time. The object title area must be big enough to hold the text; otherwise, the text is truncated.

Do not use carriage returns in *title*.

If you want to set a title on more than one line, use the "¥" character ("¥¥" in the code editor) as a line return. This is permitted for 3D buttons, 3D check boxes, 3D radio buttons and list box headers.

**Note:** Pass "¥¥¥" when you want to use the "¥" character in the title.

## Example 1

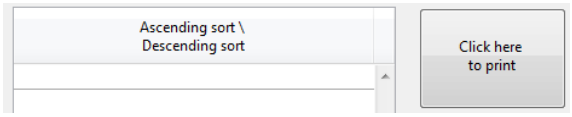
The following example is the object method of a search button located in the footer area of an output form displayed using **MODIFY SELECTION**. The method searches a table; depending on the search results, it enables or disables a button labeled *bDelete* and changes its title:

```
QUERY([People];[People]Name=vName)
Case of
   :(Records in selection([People])=0) // No people found
      OBJECT SET TITLE(bDelete;" Delete")
      OBJECT SET ENABLED(bDelete;False)
   :(Records in selection([People])=1) // One person found
      OBJECT SET TITLE(bDelete;"Delete Person")
      OBJECT SET ENABLED(bDelete;True)
   :(Records in selection([People])>1) // Many people found
      OBJECT SET TITLE(bDelete;"Delete People")
      OBJECT SET ENABLED(bDelete;True)
End case
```

## Example 2

You want to insert titles on two lines:

```
OBJECT SET TITLE(*;"header1";"Ascending sort ¥¥¥ ¥¥Descending sort")
OBJECT SET TITLE(*;"button1";"Click here ¥¥to print")
```



Ascending sort \
Descending sort
Click here
to print

# OBJECT SET VERTICAL ALIGNMENT

OBJECT SET VERTICAL ALIGNMENT ( {* ;} object ; alignment )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string)<br>If omitted, object is a variable |
| object | Form object | ⇒ | Object Name (if * is specified) or<br>Variable (if * is omitted) |
| alignment | Longint | ⇒ | Alignment code |

## Description

The **OBJECT SET VERTICAL ALIGNMENT** command modifies the type of vertical alignment applied to the object(s) designated by the *object* and * parameters.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (a string). If you do not pass this parameter, this indicates that the *object* is a variable. In this case, you pass a variable reference instead of a string.

In *alignment*, you pass one of the following constants found in the **Form Objects (Properties)** theme:

| Constant | Type | Value |
|---|---|---|
| Align bottom | Longint | 4 |
| Align center | Longint | 3 |
| Align default | Longint | 1 |
| Align top | Longint | 2 |

Vertical alignment can be applied to the following form objects:

- list boxes,
- list box columns,
- list box headers and footers.

# OBJECT SET VISIBLE

OBJECT SET VISIBLE ( {* ;} object ; visible )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, Object is an Object Name (String) If omitted, Object parameter is a Field or a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Field or Variable (if * is omitted) |
| visible | Boolean | ⇒ | True for visible, False for invisible |

## Description

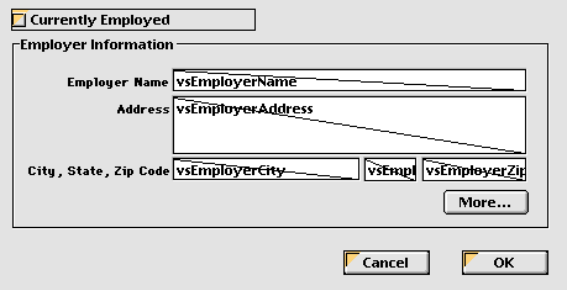
The **OBJECT SET VISIBLE** command shows or hides the objects specified by *object*.

If you specify the optional * parameter, you indicate an object name (a string) in *object*. If you omit the optional * parameter, you indicate a field or a variable in *object*. In this case, you specify a field or variable reference (field or variable objects only) instead of a string. For more information about object names, see the section **Object Properties**.

If you pass *visible* equal to **TRUE**, the objects are shown. If you pass *visible* equal to **FALSE**, the objects are hidden.

## Example

Here is a typical form in the Design environment:

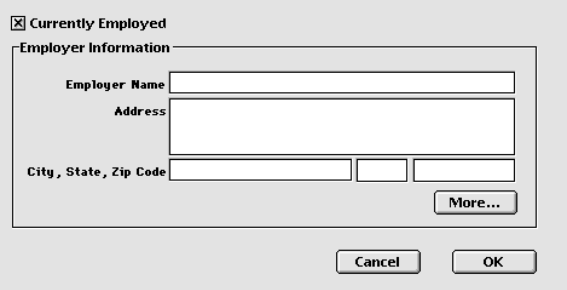


The objects in the **Employer Information** group box each have an object name that contains the expression “employer” (including the group box). When the **Currently Employed** check box is checked, the objects must be visible; when the check box is unchecked, the objects must be invisible.
Here is the object method of the check box:

```
  ` cbCurrentlyEmployed Check Box Object Method
Case of
   :(Form event=On Load)
      cbCurrentlyEmployed:=1

   :(Form event=On Clicked)
  ` Hide or Show all the objects whose name contains "emp"
      OBJECT SET VISIBLE(*;"@emp@";cbCurrentlyEmployed#0)
  ` But always keep the check box itself visible
      OBJECT SET VISIBLE(cbCurrentlyEmployed;True)
End case
```

Therefore, when executed, the form looks like:



or:

Currently Employed
Cancel
OK

# _o_DISABLE BUTTON

_o_DISABLE BUTTON ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object Name (String) If omitted, object is a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Variable (if * is omitted) |

## Compatibility note

The **_o_DISABLE BUTTON** command was declared obsolete in 4D since version 12 and is kept only for compatibility reasons. Its overall scope, which includes all instances of the designated variable and not only those of the current form, does not correspond to those of the "Objects (Forms)" command theme.
**_o_DISABLE BUTTON** can be replaced favorably by the **OBJECT SET ENABLED** command.

# _o_ENABLE BUTTON

_o_ENABLE BUTTON ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an Object Name (String) If omitted, object is a Variable |
| object | Form object | ⇒ | Object Name (if * is specified), or Variable (if * is omitted) |

## Compatibility note

The **_o_ENABLE BUTTON** command is declared obsolete in 4D beginning with version 12 and is kept only for compatibility reasons. Its overall scope, which includes all instances of the designated variable and not only those of the current form, does not correspond to those of the "Object (Forms)" command theme.
**_o_ENABLE BUTTON** and **_o_DISABLE BUTTON** can be replaced favorably by the **OBJECT SET ENABLED** and **OBJECT Get enabled** commands.

# Objects (Language)

- Structure of 4D language objects
- OB Copy
- OB Get
- OB GET ARRAY
- OB GET PROPERTY NAMES
- OB Get type
- OB Is defined
- OB Is empty
- OB REMOVE
- OB SET
- OB SET ARRAY
- OB SET NULL

## Structure of 4D language objects

---

The commands of the **Objects (Language)** theme create and work with data in object form. This extends the exchange opportunities between 4D and any application that supports structured data.

All the commands in this theme support the following 4D objects:

- Object variables or object arrays created and initialized using the **C_OBJECT** ("**Compiler**" theme) or **ARRAY OBJECT** ("**Arrays**" theme) commands.
- Object fields from the 4D database (see **4D field types**).

The structure of "native" 4D objects is based on the classic principle of "property/value" pairs. The syntax of these objects is based on JSON notation, but does not follow it completely.

**Note:** To work with JSON objects, you must use the commands found in the "**JSON**" theme.

- An attribute **name** is always a text, for example "Name".
- An attribute **value** can be one of the following types:
  - number (Real, Integer, etc.)
  - text
  - array (text, real, longint, integer, Boolean, object, pointer)
  - null
  - Boolean
  - date (format "YYYY-MM-DDTHH:mm:ss.SSSZ")
  - object (objects can be nested on several levels)
  - object variables and arrays also support pointers (stored as such, evaluated using the **JSON Stringify** command or when copying).

**Warning:** Keep in mind that attribute names differentiate between upper and lower case.

# OB Copy

OB Copy ( object {; resolvePtrs} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| resolvePtrs | Boolean | ➡ | True = resolve pointers, False or omitted = do not resolve pointers |
| Function result | Object | ⮌ | Copy of object |

## Description

The **OB Copy** command returns an object containing a complete copy of the properties, sub-objects and values for the *object*.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

If *object* contains pointer type values, by default the copy also contains the pointers. However, you can resolve pointers when copying by passing **True** in the *resolvePtrs* parameter. In this case, each pointer present as a value in object is evaluated when copying and its dereferenced value is used.

## Example 1

You want to duplicate an object containing simple values:

```
C_OBJECT($Object)
C_TEXT($JsonString)

ARRAY OBJECT($arraySel;0)
ALL RECORDS([Product])
While(Not(End selection([Product])))
   OB SET($Object;"id";[Product]ID_Product)
   OB SET($Object;"Product Name";[Product]Product_Name)
   OB SET($Object;"Price";[Product]Price)
   OB SET($Object;"Tax rate";[Product]Tax_rate)
   $ref_value:=OB Copy($Object) //direct copy
   APPEND TO ARRAY($arraySel;$ref_value)
 //the contents of $ref_value are identical to those of $Object
   NEXT RECORD([Product])
End while
 //the contents of $ref_value
$JsonString:=JSON Stringify array($arraySel)
```

## Example 2

You duplicate an object containing pointers:

```
C_OBJECT($ref)

OB SET($ref;"name";->[Company]name) //object with pointers
OB SET($ref;"country";->[Company]country)
ARRAY OBJECT($sel;0)
ARRAY OBJECT($sel2;0)

ALL RECORDS([Company])

While(Not(End selection([Company])))
   $ref_comp:=OB Copy($ref) // copy without evaluating pointers
 // $ref_comp={"name":"->[Company]name","country":"->[Company]Country"}
   $ref_comp2:=OB Copy($ref;True) //copy with evaluation of pointers
 // $ref_comp={"name":"4D SAS","country":"France"}
   APPEND TO ARRAY($sel;$ref_comp)
   APPEND TO ARRAY($sel2;$ref_comp2)
```

```
    NEXT RECORD([Company])
End while

$Object:=JSON Stringify array($sel)
$Object2:=JSON Stringify array($sel2)

 // $Object = [{"name":"","country":""},{"name":"","country":""},...]
 // $Object2 = [{"name":"4D SAS","country":"France"},{"name":"4D, Inc","country":"USA"},
{"name":"Catalan","country":"France"}...]
```

# OB Get

OB Get ( object ; property {; type} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| property | Text | ➡ | Name of property to read |
| type | Longint | ➡ | Type to which to convert the value |
| Function result | Boolean, Date, Object, Pointer, Real, Text | ↩ | Current value of property |

## Description

The **OB Get** command returns the current value of the *property* of the *object*, optionally converted into the *type* specified.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

**Note:** This command supports attribute definitions in 4D Write Pro *objects*, like the **WP GET ATTRIBUTES** command (see example 9). However, unlike **WP GET ATTRIBUTES**, **OB Get** does not allow you to handle a picture variable or field directly as an attribute value.

In the *property* parameter, pass the label of the property to be read. Note that the *property* parameter is case sensitive.

By default, 4D returns the value of the property in its original type. You can "force" the typing of the value returned using the optional *type* parameter. To do this, in *type* you pass one of the following constants found in the **Field and Variable Types** theme:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is longint | Longint | 9 |
| Is object | Longint | 38 |
| Is pointer | Longint | 23 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |

The command returns the value of the *property*. Several types of data are supported. Note that:

- a pointer is returned as such; it can be evaluated using the **JSON Stringify** command,
- dates are returned in the format "YYYY-MM-DDTHH:mm:ss.SSSZ"
- in real values, the decimal separator is always a period "."
- times are returned as a number. Note that **OB SET** stores times as milliseconds, in compliance with the JavaScript standard, while 4D expects a number of seconds. In order for **OB Get** to interpret a stored time correctly, you need to use the Is time constant.

## Example 1

Retrieving a text type value:

```
C_OBJECT($ref)
C_TEXT($FirstName)
OB SET($ref;"FirstName";"Harry")
$FirstName:=OB Get($ref;"FirstName") // $FirstName = "Harry" (text)
```

## Example 2

Retrieving a real number value converted into a longint:

```
OB SET($ref ;"age";42)
$age:=OB Get($ref ;"age") // $age is a real number (default)
$age:=OB Get($ref ;"age";Is longint) // $age is a longint
```

## Example 3

Retrieving the values of an object:

```
C_OBJECT($ref1;$ref2)
OB SET($ref1;"LastName";"Smith") // $ref1={"LastName":"Smith"}
OB SET($ref2;"son";$ref1) // $ref2={"son":{"LastName":"Smith"}}
$son:=OB Get($ref2;"son") // $son={"LastName":"john"} (object)
$sonsName:=OB Get($son ;"name") // $sonsName="john" (text)
```

## Example 4

Modifying the age of an employee twice:

```
C_OBJECT($ref_john;$ref_jim)
OB SET($ref_john;"name";"John";"age";35)
OB SET($ref_jim;"name";"Jim";"age";40)
APPEND TO ARRAY($myArray;$ref_john) // we create an object array
APPEND TO ARRAY($myArray;$ref_jim)
 // we change the age for John from 35 to 25
OB SET($myArray{1};"age";25)
 // We replace the age of "John" in the array
For($i;1;Size of array($myArray))
   If(OB Get($myArray{$i};"name")="John")
      OB SET($myArray{$i};"age";36) // instead of 25
 // $ref_john={"name":"John","age":36}
   End if
End for
```

## Example 5

Deserializing a data string formatted in ISO:

```
C_OBJECT($object)
C_DATE($birthday)
C_TEXT($birthdayString)
OB SET($object;"Birthday";"1990-12-25T12:00:00Z")
$birthdayString:=OB Get($object;"Birthday")
 // $birthdayString="1990-12-25T12:00:00Z"
$birthday:=OB Get($object;"Birthday";Is date)
 // $birthday=25/12/90
```

## Example 6

Using nested objects:

```
C_OBJECT($ref1;$child;$children)
C_TEXT($childName)
OB SET($ref1;"firstname";"John";"lastname";"Monroe")
 //{"firstname":"john","lastname":"Monroe"}
OB SET($children;"children";$ref1)
$child:=OB Get($children;"children")
 //$son = {"firstname":"John","lastname":"Monroe"} (object)
$childName:=OB Get($child;"lastname")
 //$childName = "Monroe" (text)
 //or
$childName:=OB Get(OB Get($children;"children");"lastname")
 // $childName = "Monroe" (text)
```

## Example 7

Recovery in 4D of a time stored in an object:

```
C_OBJECT($obj_o)
C_TIME($set_h;$get_h)

$set_h:=?01:00:00?+1
OB SET($obj_o;"myHour";$set_h)
 // $obj_o == {"myHour":3601000}
 // The time is stored in milliseconds
$get_h:=OB Get($obj_o;"myHour";Is time)
 // $get_h == ?01:00:01?
 // The time is read correctly
```

## Example 8

Examples of working with 4D object fields:

```
 // Define a value
OB SET([People]Identity_OB;"First name";$firstName)
OB SET([People]Identity_OB;"Last name";$lastName)

 // Get a value
$firstName:=OB Get([People]Identity_OB;"First name")
$lastName:=OB Get([People]Identity_OB;"Last name")
```

## Example 9

In the method of a form containing a 4D Write Pro area, you can write:

```
If(Form event=On Validate)
   OB SET([MyDocuments]My4DWP;"myatt_Last edition by";Current user)
   OB SET([MyDocuments]My4DWP;"myatt_Category";"Memo")
End if
```

You can also read custom attributes of the documents:

```
vAttrib:=OB Get([MyDocuments]My4DWP;"myatt_Last edition by")
```

# OB GET ARRAY

OB GET ARRAY ( object ; property ; array )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| property | Text | ➡ | Name of property to read |
| array | Text array, Real array, Boolean array, Object array, Pointer array, Longint variable | ⬅ | Value array of property |

## Description

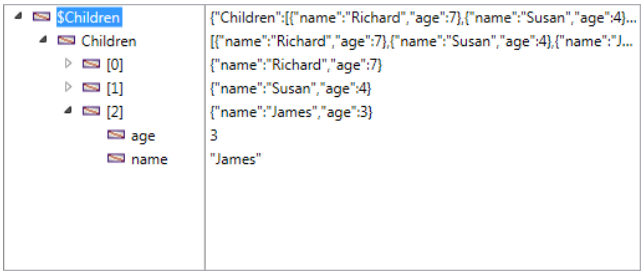
The **OB GET ARRAY** command retrieves, in *array*, the array of values stored in the *property* of the language object designated by the *object* parameter.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

In the *property* parameter, pass the label of the property to be read. Note that the *property* parameter is case sensitive.

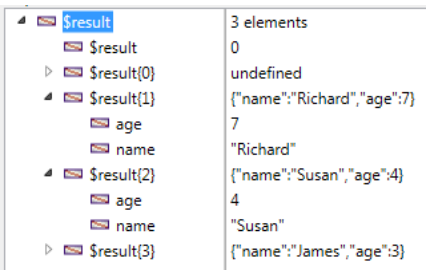
## Example 1

Given an object array defined in the example of the **OB SET ARRAY** command:



We want to retrieve these values:

```
ARRAY OBJECT($result;0)
OB GET ARRAY($Children;"Children";$result)
```



## Example 2

We want to change a value in the first element of the array:

```
 // Change the value of "age":
ARRAY OBJECT($refs)
OB GET ARRAY($refEmployees;"__ENTITIES";$refs)
OB SET($refs{1};"age";25)
```

# OB GET PROPERTY NAMES

OB GET PROPERTY NAMES ( object ; arrProperties {; arrTypes} )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ⇨ | Structured object |
| arrProperties | Text array | ⇦ | Property names |
| arrTypes | Longint array | ⇦ | Property types |

## Description

The **OB GET PROPERTY NAMES** command returns, in *arrProperties*, the names of the properties contained in the language object designated by the *object* parameter.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

Pass a text array in the *arrProperties* parameter. If the array does not exist, the command creates and sizes it automatically.

Optionally, you can also pass a longint array in *arrTypes*. For each element of *arrProperties*, the command returns, in *arrTypes*, the type of value stored in the property. You can compare the values received with the following constants, found in the "**Field and Variable Types**" theme:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is JSON null | Longint | 255 |
| Is object | Longint | 38 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |
| Object array | Longint | 39 |

## Example 1

You want to test that an object is not empty:

```
ARRAY TEXT(arrNames;0)
ARRAY LONGINT(arrTypes;0)
C_OBJECT($ref_richard)
OB SET($ref_richard;"name";"Richard";"age";7)
OB GET PROPERTY NAMES($ref_richard;arrNames;arrTypes)
 // arrNames{1}="name", arrNames{2}="age"
 // arrTypes{1}=2, arrTypes{2}=1
If(Size of array(arrNames)#0)
 // ...
End if
```

## Example 2

Using an object array element:

```
C_OBJECT($Children;$ref_richard;$ref_susan;$ref_james)
ARRAY OBJECT($arrayChildren;0)

OB SET($ref_richard;"name";"Richard";"age";7)
APPEND TO ARRAY($arrayChildren;$ref_richard)
OB SET($ref_susan;"name";"Susan";"age";4;"girl";True) //additional attribute
APPEND TO ARRAY($arrayChildren;$ref_susan)
OB SET($ref_james;"name";"James")
OB SET NULL($ref_james;"age") //null attribute
APPEND TO ARRAY($arrayChildren;$ref_james)

OB GET PROPERTY NAMES($arrayChildren{1};$arrNames;$arrTypes)
```

```
 // $arrayChildren{1} = {"name":"Richard","age":7}
 // $arrNames{1}="name"
 // $arrNames{2}="age"
 // $arrTypes{1}=2
 // $arrTypes{2}=1

OB GET PROPERTY NAMES($arrayChildren{2};$arrNames;$arrTypes)
 // $arrayChildren{3} = {"name":"Susan","age":4,"girl":true}
 // $arrNames{1}="name"
 // $arrNames{2}="age"
 // $arrNames{3}="girl"
 // $arrTypes{1}=2
 // $arrTypes{2}=1
 // $arrTypes{3}=6

OB GET PROPERTY NAMES($arrayChildren{3};$arrNames;$arrTypes)
 // $arrayChildren{3} = {"name":"James","age":null}
 // $arrNames{1}="name"
 // $arrNames{2}="age"
 // $arrTypes{1}=2
 // $arrTypes{2}=255
```

# OB Get type

OB Get type ( object ; property ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| property | Text | ➡ | Property name |
| Function result | Longint | ⮌ | Property value type |

## Description

The **OB Get type** command returns the type of value associated with the *property* of the language *object*.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

In the *property* parameter, pass the label of the property whose type you want to find out.
Note that the *property* parameter is case sensitive.

The command returns a longint indicating the type of value. You can compare this value with the following constants, found in the "**Field and Variable Types**" theme:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is JSON null | Longint | 255 |
| Is object | Longint | 38 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |
| Is undefined | Longint | 5 |
| Object array | Longint | 39 |

## Example

We want to get the type of standard values:

```
C_OBJECT($ref)
OB SET($ref;"name";"smith";"age";42)
$type:=OB Get type($ref;"name") //$type returns 2
$type2:=OB Get type($ref;"age") //$type2 returns 1
```

# OB Is defined

OB Is defined ( object {; property} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| property | Text | ➡ | If passed = property to check, if omitted = check object |
| Function result | Boolean | ⮌ | If property omitted: True if object is defined, otherwise False.<br>If property passed: True if property is defined, otherwise False |

## Description

The **OB Is defined** command returns True if *object* or *property* is defined, and False otherwise.

*object* must have been created using the **C_OBJECT** command or designate a 4D object field.

By default, if you omit the *property* parameter, the command checks whether the *object* is defined. An object is defined if its contents has been initialized.

**Note:** An object can be defined but empty. To find out if an object is undefined or empty, use the **OB Is empty** command.

If you pass the *property* parameter, the command checks whether this property exists in *object*. Note that the *property* parameter is case sensitive.

## Example 1

Syntax testing the initialization of an object:

```
C_OBJECT($object)
$def:=OB Is defined($object) // $def=false since $object is not initialized

OB SET($object;"Name";"Martin")
OB REMOVE($object;"Name")
$def2:=OB Is defined($object) // $def2=true since $object is empty {} but has been initialized
```

## Example 2

Test for existence of a property:

```
C_OBJECT($ref)
OB SET($ref;"name";"smith";"age";42)
 //...
If(OB Is defined($ref;"age"))
 //...
End if
```

This test is equivalent to:

```
If(OB Get type($Object;"name")#Is undefined)
```

# OB Is empty

OB Is empty ( object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ⇒ | Structured object |
| Function result | Boolean | ⇐ | True if object is empty or undefined, otherwise False |

## Description

The **OB Is empty** command returns True if *object* is undefined or empty, and False if *object* is defined (initialized) and contains at least one property.

*object* must have been created using the **C_OBJECT** command or designate a 4D object field.

## Example

Here are the different results of this command as well as the **OB Is defined** command, depending on the context:

```
C_OBJECT($ref)
$empty:=OB Is empty($ref) // True
$def:=OB Is defined($ref) // False

OB SET($ref;"name";"Susie";"age";4)
 // $ref="{"name":"Susie","age":4}"
$empty:=OB Is empty($ref) // False
$def:=OB Is defined($ref) // True

OB REMOVE($ref;"name")
OB REMOVE($ref;"age")
$empty:=OB Is empty($ref) // True
$def:=OB Is defined($ref) // True
```

# OB REMOVE

OB REMOVE ( object ; property )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ⇒ | Structured object |
| property | Text | ⇒ | Name of property to remove |

## Description

The **OB REMOVE** command removes the *property* of the language object designated by the *object* parameter. This command removes the *property* as well as its current value.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

In the *property* parameter, pass the label of the property to be read. Note that the *property* parameter is case sensitive.

## Example

You want to remove the "age" property of an object:

```
C_OBJECT($Object)
OB SET($Object;"name";"smith";"age";42;"client";True)
 // $Object={"name":"smith","age":42,"client":true}
OB REMOVE($Object;"age")
 // $Object={"name":"smith","client":true}
```

# OB SET

OB SET ( object ; property ; value {; property2 ; value2 ; ... ; propertyN ; valueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ⇒ | Structured object |
| property | Text | ⇒ | Name of property to set |
| value | Text, Date, Boolean, Pointer, Number, Object | ⇒ | New value of property |

## Description

The **OB SET** command creates or modifies one or more *property*/*value* pairs in the language object designated by the *object* parameter.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

**Note:** This command supports attribute definitions in 4D Write Pro *objects*, like the **WP SET ATTRIBUTES** command (see example 10). However, unlike **WP SET ATTRIBUTES**, **OB SET** does not allow you to handle a picture variable or field directly as an attribute value.

In the *property* parameter, pass the label of the property to be created or modified. If the property already exists in *object*, its value is updated. If it does not exist, it is created.
Note that the *property* parameter is case sensitive.

In the *value* parameter, pass the value you want to set for the property. Several data types are supported. Note that:

- if you pass a pointer, it is kept as is; it is evaluated using the **JSON Stringify** command,
- dates are stored in the format "YYYY-MM-DDTHH:mm:ss.SSSZ". When converting 4D dates into text prior to storing them in the object, by default the program takes the local time zone into account. You can modify this behavior using the JSON use local time selector of the **SET DATABASE PARAMETER** command.
- if you pass a time, it is stored as a number of milliseconds (Real) in *object*.
- if you pass a language object, the command uses the object reference and not a copy.

## Example 1

Creating an object and adding a text type property:

```
C_OBJECT($Object)
OB SET($Object ;"FirstName";"John";"LastName";"Smith")
 // $Object = {"FirstName":"John","LastName":"Smith"}
```

## Example 2

Creating an object and adding a Boolean type property:

```
C_OBJECT($Object)
OB SET($Object ;"LastName";"smith";"age";42;"client";True)
 // $Object = {"LastName":"smith","age":42,"client":true}
```

## Example 3

Modifying a property:

```
 // $Object = {"FirstName":"John","LastName":"Smith"}
OB SET($Object ;"FirstName";"Paul")
 // $Object = {"FirstName":"Paul","LastName":"Smith"}
```

## Example 4

Adding a property:

```
 // $Object = {"FirstName":"John","LastName":"Smith"}
OB SET($Object ;"department";"Accounting")
 // $Object = {"FirstName":"Paul","LastName":"Smith","department":"Accounting"}
```

## Example 5

Renaming a property:

```
C_OBJECT($Object)
OB SET($Object ;"LastName";"James";"age";35)
 // $Object = {"LastName":"James","age":35}
OB SET($Object ;"FirstName";OB Get($Object ;"LastName"))
 // $Object = {"FirstName":""James","nom":"James","age":35}
OB REMOVE($Object ;"LastName")
 // $Object = {"FirstName":""James","age":35}
```

## Example 6

Using a pointer:

```
 // $Object = {"FirstName":"Paul","LastName":"Smith"}
C_TEXT($LastName)
OB SET($Object ;"LastName";->$LastName)
 // $Object = {"FirstName":"Paul","LastName":"->$LastName"}
$JsonString:=JSON Stringify($Object)
 // $JsonString="{"FirstName":"Paul","LastName":""}
$LastName:="Wesson"
$JsonString:=JSON Stringify($Object)
 // $JsonString="{"FirstName":"Paul","LastName":"Wesson"}
```

## Example 7

Using an object:

```
C_OBJECT($ref_smith)
OB SET($ref_smith ;"name";"Smith")
C_OBJECT($ref_emp)
OB SET($ref_emp ;"employee";$ref_smith)
$Json_string :=JSON Stringify($ref_emp)
 // $ref_emp = {"employee":{"name":"Smith"}} (object)
 // $Json_string = "{"employee":{"name":"Smith"}}" (string)
```

You can also change a value on the fly:

```
OB SET($ref_smith ;"name";"Smyth")
 // $ref_smith = {"employee":{"name":"Smyth"}}
$string:=JSON Stringify($ref_emp)
 // $string = "{"employee":{"name":"Smyth"}}"
```

## Example 8

If you have defined the [Rect]Desc field as an object field, you can write:

```
CREATE RECORD([Rect])
[Rect]Name:="Blue square"
OB SET([Rect]Desc;"x";"50";"y";"50";"color";"blue")
SAVE RECORD([Rect])
```

## Example 9

You want to export data in JSON that contains a converted 4D date. Note that conversion occurs when the date is saved in the object, so you must call the **SET DATABASE PARAMETER** command before calling **OB SET**:

```
C_OBJECT($o)
SET DATABASE PARAMETER(JSON use local time;0)
OB SET($o ;"myDate";Current date) // JSON conversion
$json:=JSON Stringify($o)
SET DATABASE PARAMETER(JSON use local time;1)
```

## Example 10

In the method of a form containing a 4D Write Pro area, you can write:

```
If(Form event=On Validate)
   OB SET([MyDocuments]My4DWP;"myatt_Last edition by";Current user)
   OB SET([MyDocuments]My4DWP;"myatt_Category";"Memo")
End if
```

You can also read custom attributes of the documents:

```
vAttrib:=OB Get([MyDocuments]My4DWP;"myatt_Last edition by")
```

# OB SET ARRAY

OB SET ARRAY ( object ; property ; array )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ➡ | Structured object |
| property | Text | ➡ | Name of property to set |
| array | Text array, Real array, Boolean array, Object array, Pointer array, Longint array | ➡ | Array to store in property |

## Description

The **OB SET ARRAY** command defines the *array* to be associated with the *property* in the language object designated by the *object* parameter.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

In the *property* parameter, pass the label of the property to be created or modified. If the property already exists in *object*, its value is updated. If it does not exist, it is created.
Note that the *property* parameter is case sensitive.

In the *array* parameter, pass the array that must be passed as the property value. Several array types are supported.

**Note:** It is not possible to use two-dimensional arrays.

## Example 1

Using a text array:

```
C_OBJECT($Children)
ARRAY TEXT($arrChildren;3)
$arrChildren{1}:="Richard"
$arrChildren{2}:="Susan"
$arrChildren{3}:="James"

OB SET ARRAY($Children;"Children";$arrChildren)
 // Value of $Children = {"Children":["Richard","Susan","James"]}
```

## Example 2

Adding an element to an array:

```
ARRAY TEXT($arrText;2)
$arrText{1}:="Smith"
$arrText{2}:="White"
C_OBJECT($Employees)
OB SET ARRAY($Employees;"Employees";$arrText)
APPEND TO ARRAY($arrText;"Brown") // Add to the 4D array
 // $Employees = {"Employees":["Smith","White"]}

OB SET ARRAY($Employees;"Employees";$arrText)
 // $Employees = {"Employees":["Smith","White","Brown"]}
```

## Example 3

Using a text array with selection of an element:

```
 // $Employees = {"Employees":["Smith","White","Brown"]}
OB SET ARRAY($Employees ;"Manager";$arrText{1})
 // $Employees = {"Employees":["Smith","White","Brown"],"Manager":["Smith"]}
```

## Example 4

Using an object array:

```
C_OBJECT($Children;$ref_richard;$ref_susan;$ref_james)
ARRAY OBJECT($arrChildren;0)
OB SET($ref_richard;"nom";"Richard";"age";7)
APPEND TO ARRAY($arrChildren;$ref_richard)
OB SET($ref_susan;"name";"Susan";"age";4)
APPEND TO ARRAY($arrChildren;$ref_susan)
OB SET($ref_james;"name";"James";"age";3)

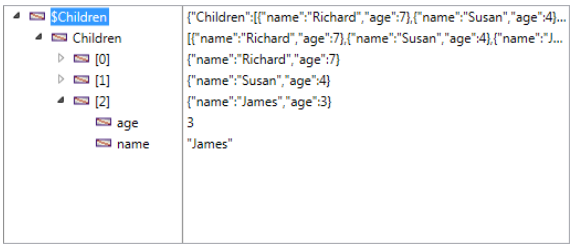
APPEND TO ARRAY($arrChildren;$ref_james)

 // $arrChildren {1} = {"name":"Richard","age":7}
 // $arrChildren {2} = {"name":"Susan","age":4}
 // $arrChildren {3} = {"name":"James","age":3}

OB SET ARRAY($Children;"Children";$arrChildren)

 // $Children = {"Children":[{"name":"Richard","age":7},{"name":"Susan",
 // "age":4},{"name":"James","age":3}]}
```

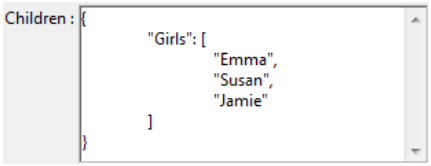
Here is how the object appears in the debugger:



## Example 5

Using an Object field:

```
ARRAY TEXT($arrGirls;3)
$arrGirls{1}:="Emma"
$arrGirls{2}:="Susan"
$arrGirls{3}:="Jamie"
OB SET ARRAY([People]Children;"Girls";$arrGirls)
```



# OB SET NULL

OB SET NULL ( object ; property )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Object, Object Field | ⇒ | Structured object |
| property | Text | ⇒ | Name of property where null value is to be applied |

## Description

The **OB SET NULL** command stores the **null** value in the language object designated by the *object* parameter.

*object* must have been defined using the **C_OBJECT** command or designate a 4D object field.

In the *property* parameter, pass the label of the property where you want to store the **null** value. If the property already exists in *object*, its value is updated. If it does not exist, it is created.
Note that the *property* parameter is case sensitive.

## Example

We want to put the null value in the "age" property for Lea:

```
C_OBJECT($ref)
OB SET($ref;"name";"Lea";"age";4)
 // $ref = {"name":"Lea","age":4}
...
OB SET NULL($ref ;"age")
 // $ref = {"name":"Lea","age":null}
```

# On a Series

- On a Series
- Average Updated 16.0
- Max Updated 16.0
- Min Updated 16.0
- Std deviation
- Sum Updated 16.0
- Sum squares
- Variance

## On a Series

The functions of this theme perform calculations on a series of values.

The **Average**, **Max**, **Min**, **Sum**, **Sum squares**, **Std deviation** and **Variance** functions are applied to fields or arrays:

- When applied to fields, they use the current selection of records,
- When applied to arrays, they use array elements.

Note that when they are applied to fields, the **Sum squares**, **Std deviation** et **Variance** functions can be used only during printing.

All these functions work on numeric data only and return numeric values.

### Using statistical functions apart from printing

When **Average**, **Max**, **Min** or **Sum** are used on a field outside a printing operation, they may have to load each record in the current selection to calculate the result. If there are many records, this process may take some time. To limit the processing time, you can index the field.

**Note**: When the operation is long, a progress thermometer appears. This thermometer has a Stop button that lets the user interrupt the operation. If the user clicks this button, the OK variable is set to 0. If the operation is completed correctly, the OK variable is set to 1.

### Using statistical functions in a printed report

When statistical functions are used in a report, they behave in a specific way because the report itself must load each record. Use these functions in a form or object method when printing with the **PRINT SELECTION** command or when printing by choosing **Print** from the **File** menu in the Design environment.

When you use these functions in a report, the values that are returned are reliable only at break level 0, and only when break processing is turned on. This means that they are useful only at the end of a report, after all the records have been processed.

You would use these functions only in an object method for a non-enterable area that is included in the B0 Break area.

Remember that the field passed as a parameter to the statistical function must be a numeric.

# Average

Average ( series {; attributePath} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ⇒ | Data for which to return the average |
| attributePath | Text | ⇒ | Path of attribute for which to return the average |
| Function result | Real | ⇐ | Arithmetic mean (average) of series |

## Description

**Average** returns the arithmetic mean (average) of *series*. If *series* is an indexed field, the index is used to find the average.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

This command accepts an optional *attributePath* parameter of the Text type, that you can use if *series* is an object field. It allows you to define the path of the attribute to compute. Use the standard dot notation to define paths to nested attributes, for example "company.address.number". Keep in mind that object attribute names are case-sensitive.
Only numeric attribute values are computed. If there are values in the attribute path which are not of a numeric type, they are ignored.

If the command is correctly executed, the OK system variable is set to 1. If it is interrupted (for example if the user clicks on the **Stop** button of the progress thermometer), the OK variable is set to 0.

## Example 1

The following example sets the variable *vAverage* that is in the B0 Break area of an output form. The line of code is the object method for *vAverage*. The object method is not executed until the level 0 break:

```
vAverage:=Average([Employees] Salary)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Employees])
ORDER BY([Employees];[Employees]LastNm;>)
BREAK LEVEL(1)
ACCUMULATE([Employees]Salary)
FORM SET OUTPUT([Employees];"PrintForm")
PRINT SELECTION([Employees])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the chapter **Printing**.

## Example 2

This example gets the average of the first 15 grades in the selection:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
ORDER BY([Exams];[Exams]Exam_Grade;<)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
ARRAY REAL($ArrGrades;15)
vAverage:=Average($ArrGrades)
```

## Example 3

Your [Customer] table contains a "full_Data" object field with the following data:
