

You can perform the following computations:

```
C_REAL($vAvg)
ALL RECORDS([Customer])
$vAvg:=Average([Customer]full_Data;"age")
 //$vAvg is 44.46

C_LONGINT($vTot)
$vTot:=Sum([Customer]full_Data;"Children[].age")
 //$vTot is 105
```

# Max

Max ( series {; attributePath} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ➡ | Data for which to return the maximum value |
| attributePath | Text | ➡ | Path of attribute for which to return the maximum value |
| Function result | Real | ⮌ | Maximum value in series |

## Description

**Max** returns the maximum value in *series*. If *series* is an indexed field, the index is used to find the maximum value.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

If the *series* selection is empty, **Max** returns 0.

This command accepts an optional *attributePath* parameter of the Text type, that you can use if *series* is an object field. It allows you to define the path of the attribute to compute. Use the standard dot notation to define paths to nested attributes, for example "company.address.number". Keep in mind that object attribute names are case-sensitive.
Only numeric attribute values are computed. If there are values in the attribute path which are not of a numeric type, they are ignored.

If the command is correctly executed, the OK system variable is set to 1. If it is interrupted (for example if the user clicks on the **Stop** button of the progress thermometer), the OK variable is set to 0.

## Example 1

The following example is an object method for the variable *vMax* placed in the break 0 portion of the form. The variable is printed at the end of the report. The object method assigns the maximum value of the field to the variable, which is then printed in the last break of the report.

```
vMax:=Max([Employees] Salary)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Employees])
ORDER BY([Employees];[Employees]LastNm;>)
BREAK LEVEL(1)
ACCUMULATE([Employees]Salary)
FORM SET OUTPUT([Employees];"PrintForm")
PRINT SELECTION([Employees])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the chapter **Printing**.

## Example 2

This example gets the highest value in the array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vMax:=Max($ArrGrades)
```

## Example 3

For an example of computing an object field attribute, please refer to the example 3 of the **Average** command description.

# Min

Min ( series {; attributePath} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ⇒ | Data for which to return the minimum value |
| attributePath | Text | ⇒ | Path of attribute for which to return the minimum value |
| Function result | Real | ⇐ | Minimum value in series |

## Description

**Min** returns the minimum value in *series*. If *series* is an indexed field, the index is used to find the minimum value.

If the *series* selection is empty, **Min** returns 0.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

This command accepts an optional *attributePath* parameter of the Text type, that you can use if *series* is an object field. It allows you to define the path of the attribute to compute. Use the standard dot notation to define paths to nested attributes, for example "company.address.number". Keep in mind that object attribute names are case-sensitive.
Only numeric attribute values are computed. If there are values in the attribute path which are not of a numeric type, they are ignored.

If the command is correctly executed, the OK system variable is set to 1. If it is interrupted (for example if the user clicks on the **Stop** button of the progress thermometer), the OK variable is set to 0.

## Example 1

The following example is an object method for the variable *vMin* placed in the break 0 portion of the form. The variable is printed at the end of the report. The object method assigns the minimum value of the field to the variable, which is then printed in the last break of the report:

```
vMin:=Min([Employees]Salary)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Employees])
ORDER BY([Employees];[Employees]LastNm;>)
BREAK LEVEL(1)
ACCUMULATE([Employees]Salary)
FORM SET OUTPUT([Employees];"PrintForm")
PRINT SELECTION([Employees])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the chapter **Printing**.

## Example 2

The following example finds the lowest sale amount of an employee and displays the result in an alert box:

```
ALERT("Minimum sale = "+String(Min([Employees]Sales)))
```

## Example 3

This example gets the lowest value in the array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vMin:=Min($ArrGrades)
```

## Example 4

For an example of computing an object field attribute, please refer to the example 3 of the **Average** command description.

# Std deviation

Std deviation ( series ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ⇒ | Data for which to return the standard deviation |
| Function result | Real | ⇐ | Standard deviation of series |

## Description

**Std deviation** returns the standard deviation of *series*. If *series* is an indexed field, the index is used to find the standard deviation.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

## Example 1

The following example is an object method for the variable *vDeviate*. The object method assigns the standard deviation for a data series to *vDeviate*:

```
vDeviate:=Std deviation([Table1]DataSeries)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Table1])
ORDER BY([Table1];[Table1]DataSeries;>)
BREAK LEVEL(1)
ACCUMULATE([Table1]DataSeries)
OUTPUT FORM([Table1];"PrintForm")
PRINT SELECTION([Table1])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the printing commands.

## Example 2

This example gets the standard deviation of a series of values placed in an array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vStdDev:=Std deviation($ArrGrades)
```

# Sum

Sum ( series {; attributePath} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ➡ | Data for which to return the sum |
| attributePath | Text | ➡ | Path of attribute for which to return the sum |
| Function result | Real | ⮌ | Sum for series |

## Description

The **Sum** command returns the sum (total of all values) for *series*. If *series* is an indexed field, the index is used to total the values.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

This command accepts an optional *attributePath* parameter of the Text type, that you can use if *series* is an object field. It allows you to define the path of the attribute to compute. Use the standard dot notation to define paths to nested attributes, for example "company.address.number". Keep in mind that object attribute names are case-sensitive.
Only numeric attribute values are computed. If there are values in the attribute path which are not of a numeric type, they are ignored.

If the command is correctly executed, the OK system variable is set to 1. If it is interrupted (for example if the user clicks on the **Stop** button of the progress thermometer), the OK variable is set to 0.

## Example 1

The following example is an object method for a *vTotal* variable placed in a form. The object method assigns the sum of all salaries to *vTotal*:

```
vTotal:=Sum([Employees]Salary)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Employees])
ORDER BY([Employees];[Employees]LastNm;>)
BREAK LEVEL(1)
ACCUMULATE([Employees]Salary)
OUTPUT FORM([Employees];"PrintForm")
PRINT SELECTION([Employees])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the printing commands.

## Example 2

This example gets the sum of all the values placed in an array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vSum:=Sum($ArrGrades)
```

## Example 3

For an example of computing an object field attribute, please refer to the example 3 of the **Average** command description.

# Sum squares

Sum squares ( series ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ➡ | Data for which to return the sum of squares |
| Function result | Real | ⮌ | Sum of squares of series |

## Description

**Sum squares** returns the sum of the squares of *series*. If *series* is an indexed field, the index is used to find the sum of the squares.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

## Example 1

The following example is an object method for the variable *vSquares*. The object method assigns the sum of squares for a data series to *vSquares*. The *vSquares* variable is printed in the last break of the report:

```
vSquares:=Sum squares([Table1]DataSeries)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Table1])
ORDER BY([Table1];[Table1]DataSeries;>)
BREAK LEVEL(1)
ACCUMULATE([Table1]DataSeries)
OUTPUT FORM([Table1];"PrintForm")
PRINT SELECTION([Table1])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the chapter **Printing**.

## Example 2

This example gets the sum of the squares of the values placed in an array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vSumSquares:=Sum squares($ArrGrades)
```

# Variance

Variance ( series ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| series | Field, Array | ⇒ | Data for which to return the variance |
| Function result | Real | ⇐ | Variance of series |

## Description

**Variance** returns the variance for *series*. If *series* is an indexed field, the index is used to find the variance.

You can pass an array (one or two dimensions) in *series*. In this case, the array must be of the Integer, Longint or Real type.

The variance of a set of values is their average squared deviation from the mean. Its measures the dispersion of values around the mean. 4D uses the following variance formula:

**Variance(x) = Sum (x-m)*(x-m)/(n-1)**
*m = Mean*
*n = Number of values*

If the values considered are not a sample, multiple the value returned by **Variance** by (n-1)/n.

## Example 1

The following example is an object method for the variable *var*. The object method assigns the sum of squares for a data series to *var*:

```
var:=Variance(Students]Grades)
```

The following method is called to print the records in the selection and to activate break processing:

```
ALL RECORDS([Students])
ORDER BY([Students];[Students]Class;>)
BREAK LEVEL(1)
ACCUMULATE([Students]Grades)
OUTPUT FORM([Students];"PrintForm")
PRINT SELECTION([Students])
```

**Note:** The parameter to the **BREAK LEVEL** command should be equal to the number of breaks in your report. For more information about break processing, refer to the chapter **Printing**.

## Example 2

This example gets the variance of the values placed in an array:

```
ARRAY REAL($ArrGrades;0)
QUERY([Exams];[Exams]Exam_Date=!01/07/11!)
SELECTION TO ARRAY([Exams]Exam_Grade;$ArrGrades)
vVariance:=Variance($ArrGrades)
```

# Operators

- Operators
- Bitwise Operators
- Comparison Operators
- Date Operators
- Logical Operators
- Numeric Operators
- Picture Operators
- String Operators
- Time Operators

# Operators

Operators are symbols used to specify operations performed between expressions. They:

- Perform calculations on numbers, dates, and times.
- Perform string operations, Boolean operations on logical expressions, and specialized operations on pictures.
- Combine simple expressions to generate new expressions.

## Precedence

The order in which an expression is evaluated is called precedence. 4D has a strict left-to-right precedence, in which algebraic order is not observed. For example:

```
3+4*5
```

returns 35, because the expression is evaluated as 3 + 4, yielding 7, which is then multiplied by 5, with the final result of 35.

To override the left-to-right precedence, you MUST use parentheses. For example:

```
3+(4*5)
```

returns 23 because the expression (4 * 5) is evaluated first, because of the parentheses. The result is 20, which is then added to 3 for the final result of 23.

Parentheses can be nested inside other sets of parentheses. Be sure that each left parenthesis has a matching right parenthesis to ensure proper evaluation of expressions. Lack of, or incorrect use of parentheses can cause unexpected results or invalid expressions. Furthermore, if you intend to compile your applications, you must have matching parentheses —the compiler detects a missing parenthesis as a syntax error.

## The Assignment Operator

You MUST distinguish the assignment operator *:=* from the other operators. Rather than combining expressions into a new one, the assignment operator copies the value of the expression to the right of the assignment operator into the variable or field to the left of the operator. For example, the following line places the value 4 (the number of characters in the word Acme) into the variable named **MyVar**. **MyVar** is then typed as a numeric value.

```
MyVar := Length ("Acme")
```

**Important:** Do NOT confuse the assignment operator *:=* with the equality comparison operator =.

The other operators provided by the 4D language are described in the following sections:

## String Operators

See the **String Operators** section.

## Numeric Operators

See the **Numeric Operators** section.

## Date Operators

See the **Date Operators** section.

## Time Operators

See the **Time Operators** section.

## Comparison Operators

See the **Comparison Operators** section.

## Logical Operators

See the **Logical Operators** section.

## Picture Operators

See the **Picture Operators** section.

## Bitwise Operators

See the **Bitwise Operators** section.

## Bitwise Operators

---

The bitwise operators operates on **Long Integer** expressions or values.

**Note:** If you pass an *Integer* or a *Real* value to a bitwise operator, 4D evaluates the value as a **Long Integer** value before calculating the expression that uses the bitwise operator.

While using the bitwise operators, you must think about a **Long Integer** value as an array of 32 bits. The bits are numbered from 0 to 31, from right to left.

Because each bit can equal 0 or 1, you can also think about a **Long Integer** value as a value where you can store 32 **Boolean** values. A bit equal to 1 means True and a bit equal to *0* means False.

An expression that uses a bitwise operator returns a **Long Integer** value, except for the **Bit Test** operator, where the expression returns a **Boolean** value. The following table lists the bitwise operators and their syntax:

| Operation | Operator | Syntax | Returns | |
|---|---|---|---|---|
| Bitwise AND | & | Long & Long | Long | |
| Bitwise OR (inclusive) | \| | Long \| Long | Long | |
| Bitwise OR (exclusive) | ^\| | Long ^\| Long | Long | |
| Left Bit Shift | << | Long << Long | Long | (see note 1) |
| Right Bit Shift | >> | Long >> Long | Long | (see note 1) |
| Bit Set | ?+ | Long ?+ Long | Long | (see note 2) |
| Bit Clear | ?- | Long ?- Long | Long | (see note 2) |
| Bit Test | ?? | Long ?? Long | Boolean | (see note 2) |

**Notes**

1. For the **Left Bit Shift** and **Right Bit Shift** operations, the second operand indicates the number of positions by which the bits of the first operand will be shifted in the resulting value. Therefore, this second operand should be between *0* and *31*. Note however, that shifting by *0* returns an unchanged value and shifting by more than *31* bits returns 0x00000000 because all the bits are lost. If you pass another value as second operand, the result is non-significant.
2. For the **Bit Set**, **Bit Clear** and **Bit Test** operations , the second operand indicates the number of the bit on which to act. Therefore, this second operand must be between *0* and *31*; otherwise, the result of the expression is non-significant.

The following table lists the bitwise operators and their effects:

| Operation | Description |
|---|---|
| Bitwise AND | Each resulting bit is the logical AND of the bits in the two operands.<br>Here is the logical AND table:<br>*1 & 1 --> 1*<br>*0 & 1 --> 0*<br>*1 & 0 --> 0*<br>*0 & 0 --> 0*<br>In other words, the resulting bit is *1* if the two operand bits are *1*;otherwise the resulting bit is *0*. |
| Bitwise OR (inclusive) | Each resulting bit is the logical OR of the bits in the two operands.<br>Here is the logical OR table:<br>*1 \| 1 --> 1*<br>*0 \| 1 --> 1*<br>*1 \| 0 --> 1*<br>*0 \| 0 --> 0*<br>In other words, the resulting bit is *1* if at least one of the two operand bits is *1*; otherwise the resulting bit is *0*. |
| Bitwise OR (exclusive) | Each resulting bit is the logical XOR of the bits in the two operands.<br>Here is the logical XOR table:<br>*1 ^\| 1 --> 0*<br>*0 ^\| 1 --> 1*<br>*1 ^\| 0 --> 1*<br>*0 ^\| 0 --> 0*<br>In other words, the resulting bit is *1* if only one of the two operand bits is *1*; otherwise the resulting bit is *0*. |
| Left Bit Shift | The resulting value is set to the first operand value, then the resulting bits are shifted to the left by the number of positions indicated by the second operand. The bits on the left are lost and the new bits on the right are set to 0.<br>**Note:** Taking into account only positive values, shifting to the left by N bits is the same as multiplying by *2^N*. |
| Right Bit Shift | The resulting value is set to the first operand value, then the resulting bits are shifted to the right by the number of position indicated by the second operand. The bits on the right are lost and the new bits on the left are set to 0.<br>**Note:** Taking into account only positive values, shifting to the right by N bits is the same as dividing by *2^N*. |
| Bit Set | The resulting value is set to the first operand value, then the resulting bit, whose number is indicated by the second operand, is set to *1*. The other bits are left unchanged. |
| Bit Clear | The resulting value is set to the first operand value, then the resulting bit, whose number is indicated by the second operand, is set to *0*. The other bits are left unchanged. |
| Bit Test | Returns True if, in the first operand, the bit whose number is indicated by the second operand is equal to *1.* Returns False if, in the first operand, the bit whose number is indicated by the second operand is equal to *0*. |

## Example

1) The following table gives an example of each bit operator:

| Operation | Example | Result |
|---|---|---|
| Bitwise AND | 0x0000FFFF & 0xFF00FF00 | 0x0000FF00 |
| Bitwise OR (inclusive) | 0x0000FFFF \| 0xFF00FF00 | 0xFF00FFFF |
| Bitwise OR (exclusive) | 0x0000FFFF ^\| 0xFF00FF00 | 0xFF0000FF |
| Left Bit Shift | 0x0000FFFF << 8 | 0x00FFFF00 |
| Right Bit Shift | 0x0000FFFF >> 8 | 0x000000FF |
| Bit Set | 0x00000000 ?+ 16 | 0x00010000 |
| Bit Clear | 0x00010000 ?- 16 | 0x00000000 |
| Bit Test | 0x00010000 ?? 16 | True |

2) 4D provides many predefined constants. The literals of some of these constants end with “bit” or “mask.” For example, this is the case of the constants provided in the **Resources Properties** theme:

| Constant | Type | Value |
|---|---|---|
| Changed resource bit | Longint | 1 |
| Changed resource mask | Longint | 2 |
| Locked resource bit | Longint | 4 |
| Locked resource mask | Longint | 16 |
| Preloaded resource bit | Longint | 2 |
| Preloaded resource mask | Longint | 4 |
| Protected resource bit | Longint | 3 |
| Protected resource mask | Longint | 8 |
| Purgeable resource bit | Longint | 5 |
| Purgeable resource mask | Longint | 32 |
| System heap resource bit | Longint | 6 |
| System heap resource mask | Longint | 64 |

These constants enable you to test the value returned by **Get resource properties** or to create the value passed to **_o_SET RESOURCE PROPERTIES**. Constants whose literal ends with “bit” give the position of the bit you want to test, clear, or set. Constants whose literal ends with “mask” gives a long integer value where only the bit (that you want to test, clear, or set) is equal to one.

For example, to test whether a resource (whose properties have been obtained in the variable *$vlResAttr*) is purgeable or not, you can write:

```
If($vlResAttr ?? Purgeable resource bit) ` Is the resource purgeable?
```

or:

```
If(($vlResAttr  & Purgeable resource mask)#0)Is the resource purgeable?
```

Conversely, you can use these constants to set the same bit. You can write:

```
$vlResAttr:=$vlResAttr ?+Purgeable resource bit
```

or:

```
$vlResAttr:=$vlResAttr |Purgeable resource bit
```

3) This example stores two *Integer* values into a *Long Integer* value. You can write:

```
$vlLong:=($viIntA<<16)|$viIntB  ` Store two Integers in a Long Integer
$vlIntA:=$vlLong>>16 ` Extract back the integer stored in the high-word
$viIntB:=$vlLong  & 0xFFFF ` Extract back the Integer stored in the low-word
```

**Tip:** Be careful when manipulating *Long Integer* or *Integer* values with expressions that combine numeric and bitwise operators. The high bit (bit 31 for Long Integer, bit 15 for Integer) sets the sign of the value — positive if it is cleared, negative if it is set. Numeric operators use this bit for detecting the sign of a value, bitwise operators do not care about the meaning of this bit.

## Comparison Operators

The tables in this section show the comparison operators as they apply to string, numeric, date, time, pointer and picture with metadata expressions (you cannot use them with array or BLOB type expressions). An expression that uses a comparison operator returns a Boolean value, either **TRUE** or **FALSE**.

**Note:** You can compare two pictures using the **Equal pictures** command.

### String Comparisons

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Equality | String = String | Boolean | "abc" = "abc" | True |
| | | | "abc" = "abd" | False |
| Inequality | String # String | Boolean | "abc" # "abd" | True |
| | | | "abc" # "abc" | False |
| Greater than | String > String | Boolean | "abd" > "abc" | True |
| | | | "abc" > "abc" | False |
| Less than | String < String | Boolean | "abc" < "abd" | True |
| | | | "abc" < "abc" | False |
| Greater than or equal to | String >= String | Boolean | "abd" >= "abc" | True |
| | | | "abc" >= "abd" | False |
| Less than or equal to | String <= String | Boolean | "abc" <= "abd" | True |
| | | | "abd" <= "abc" | False |
| Contains keyword | String % String | Boolean | "Alpha Bravo" % "Bravo" | True |
| | | | "Alpha Bravo" % "ravo" | False |
| | Picture % String | Boolean | *Picture_expr* % "Mer" | True (*) |

**(*)** If the keyword "Mer" is associated with the picture stored in the picture expression (field or variable).
**Important:** Additional information about string comparisons are provided at the end of this section.

### Numeric Comparisons

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Equality | Number = Number | Boolean | 10 = 10 | True |
| | | | 10 = 11 | False |
| Inequality | Number # Number | Boolean | 10 #11 | True |
| | | | 10 # 10 | False |
| Greater than | Number > Number | Boolean | 11 > 10 | True |
| | | | 10 > 11 | False |
| Less than | Number < Number | Boolean | 10 < 11 | True |
| | | | 11 < 10 | False |
| Greater than or equal to | Number >= Number | Boolean | 11 >= 10 | True |
| | | | 10 >= 11 | False |
| Less than or equal to | Number <= Number | Boolean | 10 <= 11 | True |
| | | | 11 <= 10 | False |

### Date Comparisons

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Equality | Date = Date | Boolean | !1/1/97! =!1/1/97! | True |
| | | | !1/20/97! =!1/1/97! | False |
| Inequality | Date # Date | Boolean | !1/20/97! # !1/1/97! | True |
| | | | !1/1/97! # !1/1/97! | False |
| Greater than | Date > Date | Boolean | !1/20/97! > !1/1/97! | True |
| | | | !1/1/97! > !1/1/97! | False |
| Less than | Date < Date | Boolean | !1/1/97! < !1/20/97! | True |
| | | | !1/1/97! < !1/1/97! | False |
| Greater than or equal to | Date >= Date | Boolean | !1/20/97! >=!1/1/97! | True |
| | | | !1/1/97!>=!1/20/97! | False |
| Less than or equal to | Date <= Date | Boolean | !1/1/97!<=!1/20/97! | True |
| | | | !1/20/97!<=!1/1/97! | False |

## Time Comparisons

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Equality | Time = Time | Boolean | ?01:02:03? = ?01:02:03? | True |
| | | | ?01:02:03? = ?01:02:04? | False |
| Inequality | Time # Time | Boolean | ?01:02:03? # ?01:02:04? | True |
| | | | ?01:02:03? # ?01:02:03? | False |
| Greater than | Time > Time | Boolean | ?01:02:04? > ?01:02:03? | True |
| | | | ?01:02:03? > ?01:02:03? | False |
| Less than | Time < Time | Boolean | ?01:02:03? < ?01:02:04? | True |
| | | | ?01:02:03? < ?01:02:03? | False |
| Greater than or equal to | Time >= Time | Boolean | ?01:02:03? >=?01:02:03? | True |
| | | | ?01:02:03? >=?01:02:04? | False |
| Less than or equal to | Time <= Time | Boolean | ?01:02:03? <=?01:02:03? | True |
| | | | ?01:02:04? <=?01:02:03? | False |

## Pointer comparisons

With:

```
  ` vPtrA and vPtrB point to the same object
vPtrA:=->anObject
vPtrB:=->anObject
  ` vPtrC points to another object
vPtrC:=->anotherObject
```

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Equality | Pointer = Pointer | Boolean | vPtrA = vPtrB | True |
| | | | vPtrA = vPtrC | False |
| Inequality | Pointer # Pointer | Boolean | vPtrA # vPtrC | True |
| | | | vPtrA # vPtrB | False |

## More about string comparisons

- Strings are compared on a character-by-character basis (except in the case of searching by keywords, see below).
- When strings are compared, the case of the characters is ignored; thus, "a"="A" returns TRUE. To test if the case of two characters is different, compare their character codes. For example, the following expression returns FALSE:

```
Character code("A")=Character code("a") // because 65 is not equal to 97
```

- When strings are compared, diacritical characters are compared using the system character comparison table of your computer. For example, the following expressions return TRUE:

```
"n"="ñ"
"n"="Ñ"
"A"="å"
 // and so on
```

- Unlike other string comparisons, searching by keywords looks for “words” in “texts”: words are considered both individually and as a whole. The % operator always returns False if the query concerns several words or only part of a word (for example, a syllable). The “words” are character strings surrounded by “separators,” which are spaces and punctuation characters and dashes. An apostrophe, like in “Today's”, is usually considered as part of the word, but will be ignored in certain cases (see the rules below). Numbers can be searched for because they are evaluated as a whole (including decimal symbols). Other symbols (currency, temperature, and so on) will be ignored.

```
"Alpha Bravo Charlie"%"Bravo" // Returns True
"Alpha Bravo Charlie"%"vo" ` Returns False
"Alpha Bravo Charlie"%"Alpha Bravo" // Returns False
"Alpha,Bravo,Charlie"%"Alpha" // Returns True
"Software and Computers"%"comput@" // Returns True
```

**Notes**:
- 4D uses the ICU library for detecting keywords. For more information about the rules implemented, please refer to the following address:http://www.unicode.org/unicode/reports/tr29/#Word_Boundaries.
- In the Japanese version, instead of ICU, 4D uses *Mecab* by default for detecting keywords. For more information, please refer to **Support of Mecab (Japanese version)**.

- The wildcard character (@) can be used in any string comparison to match any number of characters. For example, the following expression is TRUE:

```
"abcdefghij"="abc@"
```

The wildcard character must be used within the second operand (the string on the right side) in order to match any number of characters. The following expression is FALSE, because the @ is considered only as a one character in the first operand:

```
"abc@"="abcdefghij"
```

The wildcard means “one or more characters or nothing”. The following expressions are TRUE:

```
"abcdefghij"="abcdefghij@"
"abcdefghij"="@abcdefghij"
"abcdefghij"="abcd@efghij"
"abcdefghij"="@abcdefghij@"
"abcdefghij"="@abcde@fghij@"
```

On the other hand, whatever the case, a string comparison with two consecutive wildcards will always return FALSE. The following expression is FALSE:

```
"abcdefghij"="abc@@fg"
```

When the comparison operator is or contains a < or > symbol, only comparison with a single wildcard located at the end of the operand is supported:

```
"abcd"<="abc@" // Valid comparison
"abcd"<="abc@ef" //Not a valid comparison
```

**Tip:**If you want to execute comparisons or queries using @ as a character (and not as a wildcard), you have two options:

- Use the **Character code (**At sign**)** instruction.
Imagine, for example, that you want to know if a string ends with the @ character.
- the following expression (if *$vsValue* is not empty) is always TRUE:

```
($vsValue≤Length($vsValue)≥="@")
```

- the following expression will be evaluated correctly:

```
(Character code($vsValue≤Length($vsValue)≥)#64)
```

- Use the "Consider @ as a wildcard only when at the beginning or end of text patterns" option which can be accessed using the Database Settings dialog box.
  This option lets you define how the @ character is interpreted when it is included in a character string. As such, it can influence how comparison operators are used in Query or Order By. For more information, refer to the 4D *Design Reference* manual.

## Date Operators

---

An expression that uses a date operator returns a date or a number, depending on the operation. All date operations will result in an accurate date, taking into account the change between years and leap years. The following table shows the date operators:

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Date difference | Date – Date | Number | !1997-01-20! - !1997-01-01! | 19 |
| Day addition | Date + Number | Date | !1997-01-20! + 9 | !1997-01-29! |
| Day subtraction | Date – Number | Date | !1997-01-20! - 9 | !1997-01-11! |

## Logical Operators

---

4D supports two logical operators that work on Boolean expressions: conjunction (AND) and inclusive disjunction (OR). A logical AND returns TRUE if both expressions are TRUE. A logical OR returns TRUE if at least one of the expressions is TRUE.

4D also provides the Boolean functions *True*, *False*, and *Not*. For more information, see the descriptions of these commands.

The following table shows the logical operators:

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| AND | Boolean & Boolean | Boolean | ("A" = "A") & (15 # 3) | True |
| | | | ("A" = "B") & (15 # 3) | False |
| | | | ("A" = "B") & (15 = 3) | False |
| OR | Boolean \| Boolean | Boolean | ("A" = "A") \| (15 # 3) | True |
| | | | ("A" = "B") \| (15 # 3) | True |
| | | | ("A" = "B") \| (15 = 3) | False |

The following is the truth table for the AND logical operator:

| **Expr1** | **Expr2** | **Expr1** & **Expr2** |
|---|---|---|
| True | True | True |
| True | False | False |
| False | True | False |
| False | False | False |

The following is the truth table for the OR logical operator:

| **Expr1** | **Expr2** | **Expr1 \| Expr2** |
|---|---|---|
| True | True | True |
| True | False | True |
| False | True | True |
| False | False | False |

**Tip**: If you need to calculate the exclusive disjunction between Expr1 and Expr2, evaluate:

```
(Expr1|Expr2) & Not(Expr1 & Expr2)
```

## Numeric Operators

---

An expression that uses a numeric operator returns a number. The following table shows the numeric operators:

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Addition | Number + Number | Number | 2 + 3 | 5 |
| Subtraction | Number – Number | Number | 3 – 2 | 1 |
| Multiplication | Number * Number | Number | 5 * 2 | 10 |
| Division | Number /Number | Number | 5 / 2 | 2.5 |
| Longint division | Number ¥ Number | Number | 5 ¥ 2 | 2 |
| Modulo | Number % Number | Number | 5 % 2 | 1 |
| Exponentiation | Number ^ Number | Number | 2 ^ 3 | 8 |

The modulo operator % divides the first number by the second number and returns a whole number remainder. Here are some examples:

- 10 % 2 returns 0 because 10 is evenly divided by 2.
- 10 % 3 returns 1 because the remainder is 1.
- 10.5 % 2 returns 0 because the remainder is not a whole number.

**WARNING**:

- The modulo operator % returns significant values with numbers that are in the Long Integer range (from minus 2^31 to 2^31 minus one). To calculate the modulo with numbers outside of this range, use the **Mod** command.
- The longint division operator ¥ returns significant values with integer numbers only.

## Picture Operators

An expression that uses a picture operator returns a picture. The following table shows the picture operators.

| Operation | Syntax | Action |
|---|---|---|
| Horizontal concatenation | Pict1 + Pict2 | Add Pict2 to the right of Pict1 |
| Vertical concatenation | Pict1 / Pict2 | Add Pict2 to the bottom of Pict1 |
| Exclusive superimposition(*) | Pict1 & Pict2 | Superimposes Pict2 on top of Pict1 (Pict2 in foreground) |
| Inclusive superimposition(*) | Pict1 \| Pict2 | Superimposes Pict2 on Pict1 and returns resulting mask if both pictures are the same size |
| Horizontal move | Picture + Number | Move Picture horizontally Number pixels |
| Vertical move | Picture / Number | Move Picture vertically Number pixels |
| Resizing | Picture * Number | Resize Picture by Number ratio |
| Horizontal scaling | Picture *+ Number | Resize Picture horizontally by Number ratio |
| Vertical scaling | Picture */ Number | Resize Picture vertically by Number ratio |

**(*)** The functioning of the exclusive superimposition (&) and inclusive superimposition (|) operators is modified starting with 4Dv14 following the update of the display management libraries used by the program.
**Pict3 := Pict1 & Pict2** produces the same result as:

```
COMBINE PICTURES(pict3;pict1;Superimposition;pict2)
```

**Pict3 := Pict1 | Pict2** produces the same result as:

```
$equal:=Equal pictures(Pict1;Pict2;Pict3)
```

Note that in order to use the **|** operator, Pict1 and Pict2 must have exactly the same dimension. If both pictures are a different size, the operation Pict1 | Pict2 produces a blank picture.

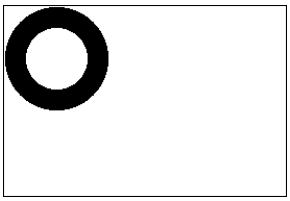
**Note:** The **COMBINE PICTURES** command can be used to superimpose pictures while keeping the characteristics of each source picture in the resulting picture.

The picture operators return vectorial pictures if the two source pictures are vectorial. Remember, however, that pictures printed by the display format On Background are printed bitmapped.

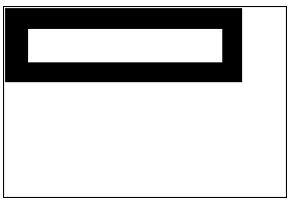
## Example

In the following examples, all of the pictures are shown using the display format On Background.

Here is the picture *circle*:



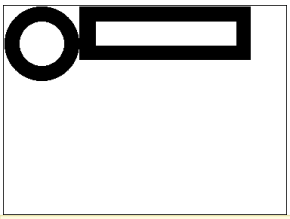
Here is the picture *rectangle*:



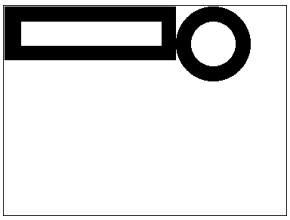
In the following examples, each expression is followed by its graphical representation.

- Horizontal concatenation

```
circle+rectangle ` Place the rectangle to the right of the circle
```

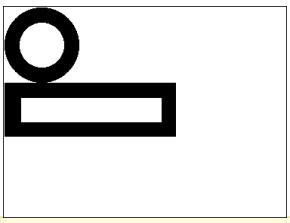


```
rectangle+circle ` Place the circle to the right of the rectangle
```

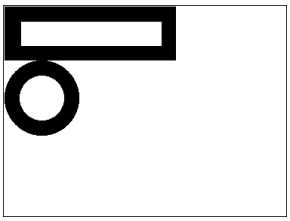


- Vertical concatenation

```
circle/rectangle ` Place the rectangle under the circle
```

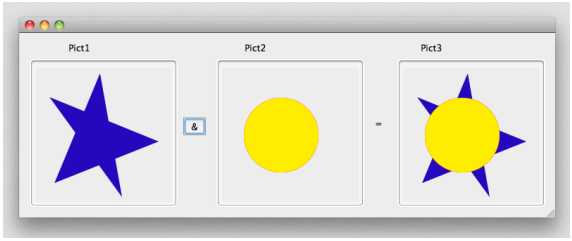


```
rectangle/circle ` Place the circle under the rectangle
```



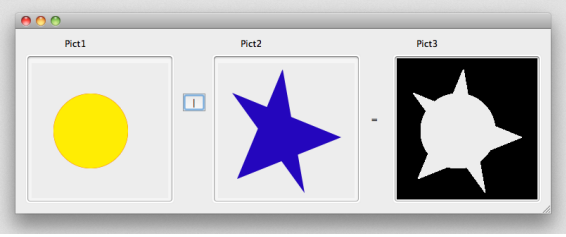
- Exclusive superimposition

```
Pict3:=Pict1 & Pict2 // Superimposes Pict2 on top of  Pict1
```



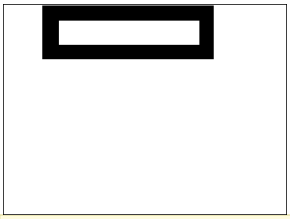
- Inclusive superimposition

```
Pict3:=Pict1|Pict2 // Recovers resulting mask from superimposing two pictures of the same size
```

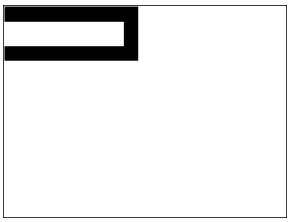


- Horizontal move

```
rectangle+50 ` Move the rectangle 50 pixels to the right
```

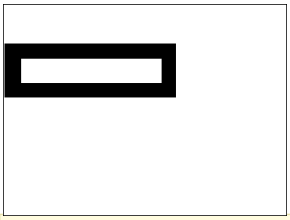


```
rectangle-50 ` Move the rectangle 50 pixels to the left
```

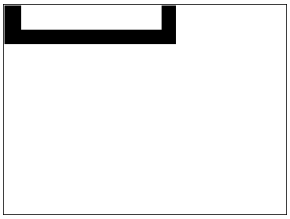


- Vertical move

```
rectangle/50 ` Move the rectangle down by 50 pixels
```

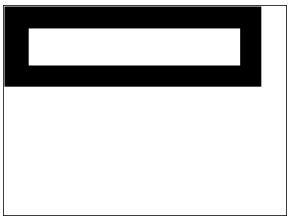


```
rectangle/-20 ` Move the rectangle up by 20 pixels
```

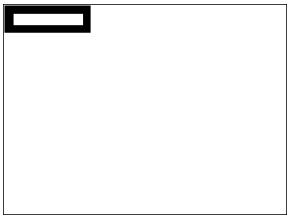


- Resize

```
rectangle*1.5 ` The rectangle becomes 50% bigger
```

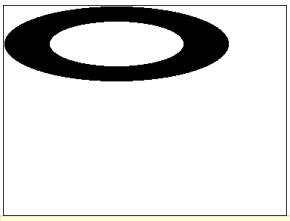


```
rectangle*0.5 ` The rectangle becomes 50% smaller
```

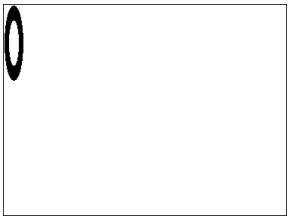


- Horizontal scaling

```
circle*+3 ` The circle becomes 3 times wider
```

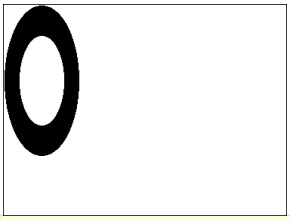


```
circle*+0.25 ` The circle's width becomes a quarter of what it was
```

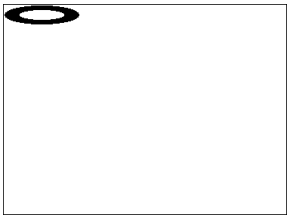


- Vertical scaling

```
circle*/2 ` The circle becomes twice as tall
```



```
circle*/0.25 ` The circle's height becomes a quarter of what it was
```



## String Operators

---

An expression that uses a string operator returns a string. The following table shows the string operators:

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Concatenation | String + String | String | "abc" + "def" | "abcdef" |
| Repetition | String * Number | String | "ab" * 3 | "ababab" |

## Time Operators

An expression that uses a time operator returns a time or a number, depending on the operation. The following table shows the time operators:

| Operation | Syntax | Returns | Expression | Value |
|---|---|---|---|---|
| Addition | Time + Time | Time | ?02:03:04? + ?01:02:03? | ?03:05:07? |
| Subtraction | Time – Time | Time | ?02:03:04? – ?01:02:03? | ?01:01:01? |
| Addition | Time + Number | Number | ?02:03:04? + 65 | 7449 |
| Subtraction | Time – Number | Number | ?02:03:04? – 65 | 7319 |
| Multiplication | Time * Number | Number | ?02:03:04? * 2 | 14768 |
| Division | Time / Number | Number | ?02:03:04? / 2 | 3692 |
| Longint division | Time ¥ Number | Number | ?02:03:04? ¥ 2 | 3692 |
| Modulo | Time % Time | Time | ?20:10:00? % ?04:20:00? | ?02:50:00? |
| Modulo | Time % Number | Number | ?02:03:04? % 2 | 0 |

### Example 1

To obtain a time expression from an expression that combines a time expression with a number, use the commands **Time** and **Time string**.

You can combine expressions of the time and number types using the **Time** or **Current time** functions. For example:

Example:

```
 //The following line assigns to $vlSeconds the number of seconds that will be elapsed between midnight and one hour from now
$vlSeconds:=Current time+3600
 //The following line assigns to $vHSoon the time it will be in one hour
$vhSoon:=Time(Current time+3600)
```

The second line could be written in a simpler way:

```
 // The following line assigns to $vHSoon the time it will be in one hour
$vhSoon:=Current time+?01:00:00?
```

### Example 2

Some situations may require you to convert a time expression into a numeric expression.
For example, you open a document using **Open document**, which returns a Document Reference (*DocRef*) that is formally a time expression. Later, you want to pass that *DocRef* to a 4D Extension routine that expects a numeric value as document reference. In such a case, use the addition with 0 (zero) to get a numeric value from the time value, but without changing its value.

Example:

```
  ` Select and open a document
$vhDocRef:=Open document("")
If(OK=1)
  ` Pass the DocRef time expression as a numeric expresssion to a 4D Extension routine
   DO SOMETHING SPECIAL(0+$vhDocRef)
End if
```

### Example 3

The Modulo operator can be used, more specifically, to add times that take the 24-hour format into account:

```
$t1:=?23:00:00? // It is 23:00 p.m.
 // We want to add 2 and a half hours
$t2:=$t1 +?02:30:00? // With a simple addition, $t2 is ?25:30:00?
$t2:=($t1 +?02:30:00?)%?24:00:00? // $t2 is ?01:30:00? and it is 1:30 a.m. the next morning
```

# Pasteboard

- Managing Pasteboards
- APPEND DATA TO PASTEBOARD
- CLEAR PASTEBOARD
- Get file from pasteboard
- GET PASTEBOARD DATA
- GET PASTEBOARD DATA TYPE
- GET PICTURE FROM PASTEBOARD
- Get text from pasteboard
- Pasteboard data size
- SET FILE TO PASTEBOARD
- SET PICTURE TO PASTEBOARD
- SET TEXT TO PASTEBOARD

# Managing Pasteboards

The commands of the “Pasteboard” theme can be used both for managing copy/paste actions (Clipboard management), as well as inter-application drag and drop actions.

4D uses two data pasteboards: one for copied (or cut) data, which is the actual clipboard that was already present in previous versions, and the other for data being dragged and dropped.
These two pasteboards are managed using the same commands. You access one or the other depending on the context:

- The drag and drop pasteboard can only be accessed within the On Begin Drag Over, On Drag over or On Drop form events and in the **On Drop database method**. Outside of these contexts, the drag and drop pasteboard is not available.
- The copy/paste pasteboard can be accessed in all other cases. Unlike the drag and drop pasteboard, it keeps the data that are placed in it during the entire session. so long as they are not cleared or reused.

## Types of Data

During drag and drop actions, different types of data can be placed on and read from the pasteboard. You can access a data type in several ways:

- Via its 4D signature: The 4D signature is a character string indicating a data type referenced by the 4D application. The use of 4D signatures facilitates the development of multi-platform applications since these signatures are identical under Mac OS and Windows. You will find the list of 4D signatures below.
- Via a UTI (Uniform Type Identifier, Mac OS only): The UTI standard, specified by Apple, associates a character string with each type of native object. For example, GIF pictures have the UTI type “com.apple.gif”. UTI types are published in Apple documentations as well as by the editors concerned.
- Via its number or its format name (Windows only): Under Windows, each native data type is referenced by its number (“3”, “12”, and so on) and a name (“Rich Text Edit”). By default, Microsoft specifies several native types called standard data formats. In addition, third-party editors can “save” format names in the system, which then attributes them a number in return. For more information about this and about native types, please refer to the Microsoft developer documentation (more particularly at http://msdn2.microsoft.com/en-us/library/ms649013.aspx).

**Note:** In 4D commands, the Windows format numbers are handled as text.

All the commands of the “Pasteboard” theme can work with each one of these data types. You can find out which data types are present in the pasteboard in each of these formats using the **GET PASTEBOARD DATA TYPE** command.

**Note:** The 4-character types (TEXT, PICT or custom types) are kept for compatibility with prior versions of 4D.

## 4D Signatures

Here is the list of standard 4D signatures as well as their description:

| Signature | Description |
|---|---|
| "com.4d.private.text.native" | Text in native character set |
| "com.4d.private.text.utf16" | Text in Unicode character set |
| "com.4d.private.text.rtf" | Enriched text |
| "com.4d.private.picture.pict" | PICT picture format |
| "com.4d.private.picture.png" | PNG picture format |
| "com.4d.private.picture.gif" | GIF picture format |
| "com.4d.private.picture.jfif" | JPEG picture format |
| "com.4d.private.picture.emf" | EMF picture format |
| "com.4d.private.picture.bitmap" | BITMAP picture format |
| "com.4d.private.picture.tiff" | TIFF picture format |
| "com.4d.private.picture.pdf" | PDF document |
| "com.4d.private.file.url" | File pathname |

# APPEND DATA TO PASTEBOARD

APPEND DATA TO PASTEBOARD ( dataType ; data )

| Parameter | Type | | Description |
|---|---|---|---|
| dataType | String | ⇒ | Type of data to be added |
| data | BLOB | ⇒ | Data to append to the pasteboard |

## Description

The **APPEND DATA TO PASTEBOARD** command appends to the pasteboard the data contained in the BLOB *data* under the data type specified in *dataType*.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard.

In *dataType*, pass a value specifying the type of data to be added. You can pass a 4D signature, a UTI type (Mac OS), a format name/number (Windows), or a 4-character type (compatibility). For more information about these types, please refer to the **Managing Pasteboards** section.

**Note for Windows users:** When the command is used with Text type data (*dataType* is "TEXT", com.4d.private.text.native or com.4d.private.text.utf16), the string contained in the BLOB parameter *data* must end with the NULL character under Windows.

Usually, you will use the **APPEND DATA TO PASTEBOARD** command to append multiple instances of the same data to the pasteboard or to append data that is not text or a picture. To append new data to the pasteboard, you must first clear the pasteboard using the **CLEAR PASTEBOARD** command.

If you want to clear and append:

- text to the pasteboard, use the **SET TEXT TO PASTEBOARD** command,
- a picture to the pasteboard, use the **SET PICTURE TO PASTEBOARD** command.
- a file pathname (drag and drop), use the **SET FILE TO PASTEBOARD** command.

However, note that if a BLOB actually contains some text or a picture, you can use the **APPEND DATA TO PASTEBOARD** command to append a text or a picture to the pasteboard.

## Example

Using Pasteboard commands and BLOBs, you can build sophisticated Cut/Copy/Paste schemes that deal with structured data rather than a unique piece of data. In the following example, the two project methods ***SET RECORD TO PASTEBOARD*** and ***GET RECORD FROM PASTEBOARD*** enable you to treat a whole record as one piece of data to be copied to or from the pasteboard.

```
 // SET RECORD TO PASTEBOARD project method
 // SET RECORD TO PASTEBOARD ( Number )
 // SET RECORD TO PASTEBOARD ( Table number )

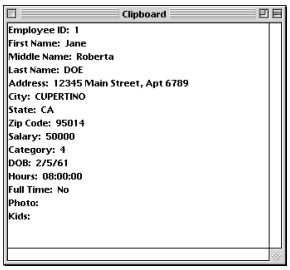
C_LONGINT($1;$vlField;$vlFieldType)
C_POINTER($vpTable;$vpField)
C_STRING(255;$vsDocName)
C_TEXT($vtRecordData;$vtFieldData)
C_BLOB($vxRecordData)

 // Clear the pasteboard (it will stay empty if there is no current record)
CLEAR PASTEBOARD
 // Get a pointer to the table whose number is passed as parameter
$vpTable:=Table($1)
 // If there is a current record for that table
If((Record number($vpTable->)>=0)|(Is new record($vpTable->)))
 //Initialize the text variable that will hold the text image of the record
   $vtRecordData:=""
 // For each field of the record:
   For($vlField;1;Get last field number($1))
 //Get the type of the field
      GET FIELD PROPERTIES($1;$vlField;$vlFieldType)
```

```
    // Get a pointer to the field
        $vpField:=Field($1;$vlField)
    // Depending on the type of the field, copy (or not) its data in the appropriate manner
        Case of
           :(($vlFieldType=Is alpha field)|($vlFieldType=Is text))
              $vtFieldData:=$vpField->
           :(($vlFieldType=Is real)|($vlFieldType=Is integer)|($vlFieldType=Is longint)|($vlFieldType=Is date)|($vlFieldType=Is
time))
              $vtFieldData:=String($vpField->)
           :($vlFieldType=Is Boolean)
              $vtFieldData:=String(Num($vpField->);"Yes;;No")
           Else
    // Skip and ignore other field data types
              $vtFieldData:=""
        End case
    // Accumulate the field data into the text variable holding the text image of the record
        $vtRecordData:=$vtRecordData+Field name($1;$vlField)+":"+Char(9)+$vtFieldData+CR
    // Note: The method CR returns Char(13) on Macintosh and Char(13)+Char(10) on Windows
      End for
    // Put the text image of the record into the pasteboard
      SET TEXT TO PASTEBOARD($vtRecordData)
    // Name for scrap file in Temporary folder
      $vsDocName:=Temporary folder+"Scrap"+String(1+(Random%99))
    // Delete the scrap file if it exists (error should be tested here)
      DELETE DOCUMENT($vsDocName)
    // Create scrap file
      SET CHANNEL(10;$vsDocName)
    // Send the whole record into the scrap file
      SEND RECORD($vpTable->)
    // Close the scrap file
      SET CHANNEL(11)
    // Load the scrap file into a BLOB
      DOCUMENT TO BLOB($vsDocName;$vxRecordData)
    // We longer need the scrap file
      DELETE DOCUMENT($vsDocName)
    // Append the full image of the record into the pasteboard
    // Note: We use arbitrarily "4Drc" as data type
      APPEND DATA TO PASTEBOARD("4Drc";$vxRecordData)
    // At this point, the pasteboardcontains:
    // (1) A text image of the record (as shown in the screen shots below)
    // (2) A whole image of the record (Picture, Subfile and BLOB fields included)
   End if
```

While entering the following record:

If you apply the method ***SET RECORD TO PASTEBOARD*** to the [Employees] table, the pasteboard will contain the text image of the record, as shown, and also the whole image of the record.



You can paste this image of the record to another record, using the method ***GET RECORD FROM PASTEBOARD***, as follows:

```
 // GET RECORD FROM PASTEBOARD method
 // GET RECORD FROM PASTEBOARD( Number )
 // GET RECORD FROM PASTEBOARD( Table number )
C_LONGINT($1;$vlField;$vlFieldType;$vlPosCR;$vlPosColon)
C_POINTER($vpTable;$vpField)
C_STRING(255;$vsDocName)
C_BLOB($vxPasteboardData)
C_TEXT($vtPasteboardData;$vtFieldData)

 // Get a pointer to the table whose number is passed as parameter
$vpTable:=Table($1)
 // If there is a current record
If((Record number($vpTable->)>=0)|(Is new record($vpTable->)))
   Case of
 // Does the pasteboard contain a full image record?
      :(Pasteboard data size("4Drc")>0)
 //  If so, extract the pasteboard contents
         GET PASTEBOARD DATA("4Drc";$vxPasteboardData)
 // Name for scrap file in Temporary folder
         $vsDocName:=Temporary folder+"Scrap"+String(1+(Random%99))  
 // Delete the scrap file if it exists (error should be tested here)
         DELETE DOCUMENT($vsDocName)
 // Save the BLOB into the scrap file
         BLOB TO DOCUMENT($vsDocName;$vxPasteboardData)
 // Open the scrap file
         SET CHANNEL(10;$vsDocName)
 // Receive the whole record from the scrap file
         RECEIVE RECORD($vpTable->)
 // Close the scrap file
         SET CHANNEL(11)
 // We longer need the scrap file
         DELETE DOCUMENT($vsDocName)
 // Does the pasteboard contain TEXT?
      :(Pasteboard data size("TEXT")>0)
 // Extract the text from the pasteboard
         $vtPasteboardData:=Get text from pasteboard
 // Initialize field number to be increment
         $vlField:=0
         Repeat
 // Look for the next field line in the text
            $vlPosCR:=Position(CR;$vtPasteboardData)
            If($vlPosCR>0)
 // Extract the field line
               $vtFieldData:=Substring($vtPasteboardData;1;$vlPosCR-1)
 // If there is a colon ":"
               $vlPosColon:=Position(":";$vtFieldData)
               If($vlPosColon>0)
 // Take only the field data (eliminate field name)
                  $vtFieldData:=Substring($vtFieldData;$vlPosColon+2)
               End if
 // Increment field number
               $vlField:=$vlField+1
 // Pasteboard may contain more data than we need...
               If($vlField<=Get last field number($vpTable))
 // Get the type of the field
                  GET FIELD PROPERTIES($1;$vlField;$vlFieldType)
 // Get a pointer to the field
                  $vpField:=Field($1;$vlField)
 // Depending on the type of the field, copy (or not) the text in the appropriate manner
                  Case of
                     :(($vlFieldType=Is alpha field)|($vlFieldType=Is text))
                        $vpField->:=$vtFieldData
                     :(($vlFieldType=Is real)|($vlFieldType=Is integer)|($vlFieldType=Is longint))
                        $vpField->:=Num($vtFieldData)
                     :($vlFieldType=Is date)
                        $vpField->:=Date($vtFieldData)
                     :($vlFieldType=Is time)
                        $vpField->:=Time($vtFieldData)
```

```
                    :($vlFieldType=Is Boolean)
                       $vpField->:=($vtFieldData="Yes")
                    Else
   // Skip and ignore other field data types
                 End case
              Else
   // All fields have been assigned, get out of the loop
                 $vtPasteboardData:=""
              End if
   // Eliminate text that has just been extracted
              $vtPasteboardData:=Substring($vtPasteboardData;$vlPosCR+Length(CR))
           Else
   // No delimiter found, get out of the loop
              $vtPasteboardData:=""
           End if
   // Repeat as long as we have data
        Until(Length($vtPasteboardData)=0)
     Else
        ALERT("The pasteboard does not any data that can be pasted as a record.")
  End case
End if
```

## System variables and sets

If the BLOB data is correctly appended to the pasteboard, OK is set to 1; otherwise OK is set to 0 and an error may be generated.

# CLEAR PASTEBOARD

CLEAR PASTEBOARD
Does not require any parameters

## Description

The **CLEAR PASTEBOARD** command clears the pasteboard of all its contents. If the pasteboard contains multiple instances of the same data, all instances are cleared. After a call to **CLEAR PASTEBOARD**, the pasteboard is empty.

You must call **CLEAR PASTEBOARD** once before appending new data to the pasteboard using the command **APPEND DATA TO PASTEBOARD**, because this latter command does not clear the pasteboard before appending the new data.

Calling **CLEAR PASTEBOARD** once and then calling **APPEND DATA TO PASTEBOARD** several times enables you to Cut or Copy the same data under different formats.

On the other hand, the **SET TEXT TO PASTEBOARD** and **SET PICTURE TO PASTEBOARD** commands automatically clear the pasteboard before appending the data to it.

## Example 1

The following code clears and then appends data to the pasteboard:

```
CLEAR PASTEBOARD ` Make sure the pasteboard is emptied
APPEND DATA TO PASTEBOARD("com.4d.private.picture.gif";$vxSomeData) ` Add some gif pictures
APPEND DATA TO PASTEBOARD("com.4d.private.text.rtf";$vxSylkData) ` Add some RTF text
```

## Example 2

See example for the **APPEND DATA TO PASTEBOARD** command.

# Get file from pasteboard

Get file from pasteboard ( xIndex ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| xIndex | Longint | ➡ | Xth file included in drag action |
| Function result | String | ⮌ | Pathname of file extracted from pasteboard |

## Description

The **Get file from pasteboard** command returns the absolute pathname of a file included in a drag and drop operation. Several files can be selected and moved simultaneously. The *xIndex* parameter is used to designate a file from among the set of files selected.

If there is no Xth file in the pasteboard, the command returns an empty string.

## Example

The following example can be used to retrieve in an array all the pathnames of the files included in a drag and drop operation:

```
ARRAY TEXT($filesArray;0)
C_TEXT($vfileArray)
C_INTEGER($n)
$n:=1
Repeat
   $vfileArray:=Get file from pasteboard($n)
   If($vfileArray#"")
      APPEND TO ARRAY($filesArray;$vfileArray)
      $n:=$n+1
   End if
Until($vfileArray="")
```

# GET PASTEBOARD DATA

GET PASTEBOARD DATA ( dataType ; data )

| Parameter | Type | | Description |
|---|---|---|---|
| dataType | String | ⇒ | Type of data to be extracted from pasteboard |
| data | BLOB | ⇐ | Requested data extracted from the pasteboard |

## Description

The **GET PASTEBOARD DATA** command returns, in the BLOB field or in the *data* variable, the data present in the pasteboard and whose type you pass in *dataType*. (If the pasteboard contains text copied within 4D, then the BLOB's character set is likely to be UTF-16.)

**Note:** In the context of copy/paste operations, the pasteboard corresponds to the clipboard.

In *dataType*, pass a value specifying the type of data to be retrieved. You can pass a 4D signature, a UTI type (Mac OS), a format name/number (Windows), or a 4-character type (compatibility). For more information about these types, please refer to the **Managing Pasteboards** section.

**Note:** You cannot read file type data with this command; in order to do this, you have to use the **Get file from pasteboard** command.

## Example

The following object methods for two buttons copy from and paste data to the array *asOptions* (pop-up menu, drop-downlist,...) located in a form:

```
 ` bCopyasOptions object method
If(Size of array(asOptions)>0) ` Is there something to copy?
   VARIABLE TO BLOB(asOptions;$vxClipData) ` Accumulate the array elements in a BLOB
   CLEAR PASTEBOARD ` Empty the pasteboard
   APPEND DATA TO PASTEBOARD("artx";asOptions) ` Note the data type arbitrarily chosen
End if

 ` bPasteasOptions object method
If(Pasteboard data size("artx")>0) ` Is there some "artx" data in the pasteboard?
   GET PASTEBOARD DATA("artx";$vxClipData) ` Extract the data from the pasteboard
   BLOB TO VARIABLE($vxClipData;asOptions) ` Populate the array with the BLOB data
   asOptions:=0 ` Reset the selected element for the array
End if
```

## System variables and sets

If the data is correctly extracted, OK is set to 1; otherwise OK is set to 0 and an error is generated.

# GET PASTEBOARD DATA TYPE

GET PASTEBOARD DATA TYPE ( 4Dsignatures ; nativeTypes {; formatNames} )

| Parameter | Type | | Description |
|---|---|---|---|
| 4Dsignatures | Text array | ⇦ | 4D signatures of data types |
| nativeTypes | Text array | ⇦ | Native data types |
| formatNames | Text array | ⇦ | Format names (Windows only), empty strings under Mac OS |

## Description

The **GET PASTEBOARD DATA TYPE** command gets the list of data types present in the pasteboard. This command should generally be used in the context of a drag and drop operation, within the On Drop or On Drag Over form events of the destination object. More particularly, it allows the pasteboard to be checked for the presence of a specific type of data.

This command returns the data types in several different forms via two (or three) arrays:

- The *4Dsignatures* array contains the data types expressed using the internal 4D signature (for example, “com.4d.private.picture.gif”). If a data type found is not recognized by 4D, an empty string (“”) is returned in the array.
- The *nativeTypes* array contains the data types expressed using their native types. The format of native types differs between Mac OS and Windows.
  - Under Mac OS, native types are expressed as UTIs (Uniform Type Identifier).
  - Under Windows, native types are expressed as numbers, with each number being associated with a format name. The *nativeTypes* array contains these numbers in the form of strings (“3”, “12”, and so on). If you want to use more explicit labels, it is recommended to use the optional *formatNames* array, which contains the format names of the native types under Windows.

  The *nativeTypes* array lets any type of data found in the pasteboard to be supported, including data whose type is not referenced by 4D.
- Under Windows, you can also pass the *formatNames* array, which receives the names of the data types found in the pasteboard. The values returned in this array can be used, for example, to build a format selection pop-up menu. Under Mac OS, the *formatNames* array returns empty strings.

For more information about the data types supported, please refer to the **Managing Pasteboards** section.

# GET PICTURE FROM PASTEBOARD

GET PICTURE FROM PASTEBOARD ( picture )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇦ | Picture extracted from pasteboard |

## Description

**GET PICTURE FROM PASTEBOARD** returns the picture present in the pasteboard in the *picture* field or variable.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard.

## Example

The following button's object method assigns the picture (jpeg or gif format) present in the pasteboard (if any) to the field [Employees]Photo:

```
If((Pasteboard data size("com.4d.private.picture.jpeg")>0)|(Pasteboard data size("com.4d.private.picture.gif")>0))
   GET PICTURE FROM PASTEBOARD([Employees]Photo)
Else
   ALERT("The pasteboard does not contain any pictures.")
End if
```

## System variables and sets

If the picture is correctly extracted, OK is set to 1; otherwise OK is set to 0.

# Get text from pasteboard

Get text from pasteboard -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String |  | Returns the text (if any) present in the pasteboard |

## Description

**Get text from pasteboard** returns the text present in the pasteboard.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard

If the pasteboard contains enriched text (for example in RTF format), the text will keep its attributes when it is dropped or pasted, if the destination area is compatible.

Note that 4D text fields and variables can contain up to 2 GB of text.

## System variables and sets

If the text is correctly extracted, OK is set to 1; otherwise OK is set to 0.

# Pasteboard data size

Pasteboard data size ( dataType ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| dataType | String | ➡ | Data type |
| Function result | Longint | ⮌ | Size (in bytes) of data located in the pasteboard or error code |

## Description

The **Pasteboard data size** command checks whether there is any data of the type you passed in *dataType* present in the pasteboard.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard.

If the pasteboard is empty or does not contain any data of the specified type, the command returns an error -102. If the pasteboard contains data of the specified type, the command returns the size of this data, expressed in bytes.

In *dataType*, pass a value specifying the type of data to be checked for. You can pass a 4D signature, a UTI type (Mac OS), a format name/number (Windows), or a 4-character type (compatibility). For more information about these types, please refer to the **Managing Pasteboards** section.

After you have detected that the pasteboard contains data of the type in which you are interested, you can extract that data from the pasteboard using one the following commands:

- If the pasteboard contains text type data, you can obtain that data using the **Get text from pasteboard** command, which returns a text value, or the **GET PASTEBOARD DATA** command, which returns the text in a BLOB.
- If the pasteboard contains picture type data, you can obtain that data using the **GET PICTURE FROM PASTEBOARD** command, which returns the picture in a picture field or variable, or the **GET PASTEBOARD DATA** command, which returns the picture in a BLOB.
- If the pasteboard contains a file pathname, you can extract it using the **Get file from pasteboard** command, which will return the file pathname.
- For any other data type, use the **GET PASTEBOARD DATA** command, which returns the data in a BLOB.

## Example 1

The following code tests whether the pasteboard contains a picture and, if so, copies that picture into a 4D variable:

```
If(Pasteboard data size(Picture data)=1) //Is there a picture in the pasteboard?
   GET PICTURE FROM PASTEBOARD($vPicVariable) //If so, extract the picture from the pasteboard
Else
   ALERT("There is no picture in the pasteboard.")
End if
```

## Example 2

Usually, applications cut and copy Text or Picture type data into the pasteboard, because most applications recognize these two standard data types. However, an application can append to the pasteboard several instances of the same data in different formats. For example, each time you cut or copy a part of a spreadsheet, the spreadsheet application could append the data under the hypothetical 'SPSH' format, as well as in SYLK and TEXT formats. The 'SPSH' instance would contain the data formatted using the application's data structure. The SYLK form would contain the same data, but using the SYLK format recognized by most of the other spreadsheet programs. Finally, the TEXT format would contain the same data, without the extra information included in the SYLK or the hypothetical 'SPSH' format. At this point, while writing Cut/Copy/Paste routines between 4D and that hypothetical spreadsheet application, assuming you know the description of the 'SPSH' format and that you are ready to parse SYLK data, you could write something like:

```
Case of
   ` First, check whether the pasteboard contains data from the hypothetical spreadsheet application
   :(Pasteboard data size('SPSH')>0)
   ` ...
   ` Second, check whether the pasteboard contains Sylk data
```

```
    :(Pasteboard data size('SYLK')>0)
  ` ...
  ` Finally check whether the pasteboard contains Text data
    :(Pasteboard data size('TEXT')>0)
  ` ...
End case
```

In other words, you try to extract from the pasteboard the instance of the data that carries most of the original information.

## Example 3

You want to drag some private data from different objects in your form. You can write:

```
 //source object
If(Form event=On Begin Drag Over)
   APPEND DATA TO PASTEBOARD("some.private.data";$data)
End if
```

```
 //target object
If(Form event=On Drag Over)
   $0:=Choose(Pasteboard data size("some.private.data")>0;0;-1)
End if
```

## Example 4

See the example for the **APPEND DATA TO PASTEBOARD** command.

# SET FILE TO PASTEBOARD

SET FILE TO PASTEBOARD ( file {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| file | String | ⇒ | File name or complete pathname of file |
| * | Operator | ⇒ | If passed = add; If omitted = replace |

## Description

The **SET FILE TO PASTEBOARD** command adds the complete pathname of the file passed in the *file* parameter. This command can be used to set up interfaces allowing the drag and drop of 4D objects to files on the desktop for example.

In the *file* parameter, you can pass either a complete pathname or a simple file name (without a pathname). In the latter case, the file must be located next to the database structure file.

The command accepts the star * as an optional parameter. By default, when this parameter is omitted, the command replaces the contents of the pasteboard by the last pathname specified by *file*. If you pass this parameter, the command adds the *file* to the pasteboard. This way it can contain a "stack" of file pathnames. In both cases, if data other than pathnames was present in the pasteboard, it is erased.

**Note:** The pasteboard is in read-only mode during the On Drag Over form event. It is therefore not possible to use this command in that context.

# SET PICTURE TO PASTEBOARD

SET PICTURE TO PASTEBOARD ( picture )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture to be placed in pasteboard |

## Description

**SET PICTURE TO PASTEBOARD** clears the pasteboard and puts a copy of the picture passed in *picture* into it.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard

The picture is transported in its native format (jpeg, tif, png, etc.).

After you have put a picture into the pasteboard, you can retrieve it using the **GET PICTURE FROM PASTEBOARD** command or for example **GET PASTEBOARD DATA**("com.4d.private.picture.gif";...).

## Example

Using a floating window, you display a form that contains the array *asEmployeeName*, which lists the names of the employees from an [Employees] table. Each time you click on a name, you want to copy the employee's picture to the pasteboard. In the object method for the array, you write:

```
If(asEmployeeName#0)
   QUERY([Employees];[Employees]Last name=asEmployeeName{asEmployeeName})
   If(Picture size([Employees]Photo)>0)
      SET PICTURE TO PASTEBOARD([Employees]Photo) ` Copy the employee's photo
   Else
      CLEAR PASTEBOARD ` No photo or no record found
   End if
End if
```

## System variables and sets

If a copy of the picture is correctly put into the pasteboard, the OK variable is set to 1.
If there is not enough memory to paste the picture into the pasteboard, the OK variable is set to 0, but no error is generated.

# SET TEXT TO PASTEBOARD

SET TEXT TO PASTEBOARD ( text )

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ⇨ | Text to be put into the pasteboard |

## Description

**SET TEXT TO PASTEBOARD** clears the pasteboard and then puts a copy of the text you passed in *text* into the pasteboard.

**Note:** In the case of copy/paste operations, the pasteboard is equivalent to the Clipboard

After you have put some text into the pasteboard, you can retrieve it using the **Get text from pasteboard** command or by calling for example **GET PASTEBOARD DATA** ("com.4d.private.text.native";...).

4D text expressions can contain up to 2 GB of text.

**Note:** The pasteboard is read only during the On Drag Over form event. It is not possible to use this command in this context.

## Example

See the example for the **APPEND DATA TO PASTEBOARD** command.

## System variables and sets

If a copy of the text is correctly placed in the pasteboard, the OK variable is set to 1. If there is not enough memory to place a copy of the text in the pasteboard, the OK variable is set to 0, but no error is generated.

# PHP

- Executing PHP scripts in 4D
- PHP Execute
- PHP GET FULL RESPONSE
- PHP GET OPTION
- PHP SET OPTION
- PHP modules support

# Executing PHP scripts in 4D

4D lets you directly execute PHP scripts. This new possibility gives you access to the wealth of utility libraries available via PHP. More particularly, these libraries provide the following functions:

- ciphering (MD5) and hashing,
- handling of ZIP files,
- handling of pictures,
- LDAP access,
- COM access (control of MS Office documents), etc.

This list is not exhaustive. For a complete list of the PHP modules available by default with 4D, please refer to the **PHP modules support** section. Also, please note that it is possible to install additional custom modules.

To execute a PHP script or function, you must use the **PHP Execute** command. By default, 4D includes version 5.4.11 of PHP. Executed scripts must be compatible with this version and with the modules installed.

For a complete description of PHP commands and syntax, please refer to the abundant PHP documentation available on the Internet. As an example, here are the addresses for a few reference sites:
http://us.php.net/manual/en/
http://phpdeveloper.org/
http://php.start4all.com/
http://php.resourceindex.com/Documentation/

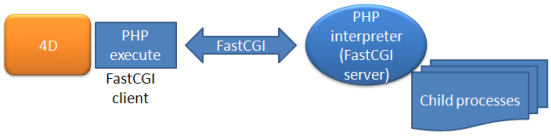
## Architecture

4D provides a PHP interpreter compiled in FastCGI, client-server type communication protocol between an application and a PHP interpreter.

The PHP interpreter pilots a set of system execution processes called "child processes". These processes are dedicated to the processing of requests sent by 4D. The execution of the requests is synchronous. For optimization reasons, by default up to five child processes can be run simultaneously (this number can be modified via the Database Settings or via the **SET DATABASE PARAMETER** command). Under Mac OS, these processes launched on the first request and are kept permanently by the PHP interpreter. Under Windows, 4D creates the processes according to its needs and recycles them if necessary. 4D automatically supports the handling of the processes of the PHP interpreter provided by default (launching and closing).

**Note:** If the 4D program quits unexpectedly while child PHP processes are still active, you must delete them manually via the system process management window.

The following diagram illustrates the 4D/PHP architecture of 4D:



This architecture works with a system of internal requests sent by 4D to a predefined TCP address (IP address and port number). If necessary, for example if several PHP interpreters are executed on the same machine, this address can be modified via the Database Settings or via the **SET DATABASE PARAMETER** command.

**Warning:** If you launch two 4D applications on the same machine and execute PHP statements on each of them (via the **PHP Execute** command), it is imperative to modify the listening ports of the FastCGI PHP interpreter so that you use a different one for each application. Otherwise, PHP statements may fail to execute correctly in an unpredictable manner and even freeze your 4D application.

## Using another PHP interpreter or another php.ini file

You can choose to use another PHP interpreter than the one provided by 4D. This allows you to keep the same PHP interpreter even if 4D is updated. In addition, it allows you to install all the custom modules you want -- in fact, you cannot

use a custom PHP file with the interpreter included in 4D. To use PHP configuration options other than the ones provided by default, you need to manage an external interpreter.

A custom PHP interpreter must respect two conditions:

- It must be compiled in FastCGI,
- It must be located on the same machine as 4D.

To use a custom PHP interpreter, you simply need to configure it so that it listens to a specific address and TCP port and to indicate to 4D to not activate the internal interpreter. These parameters can be specified either via database settings, or for the session via the **SET DATABASE PARAMETER** command. Of course, in this case, you must manage the starting and functioning of the interpreter yourself.

The *php.ini* initialization file is placed in the **Resources** folder of the database. The php.ini file can be used, more particularly, to declare the location of the PHP extensions.
If this file is not present during the first call, 4D will create it with the appropriate configuration options.

The php.ini file of the external interpreter must contain the following entries:

- **auto_prepend_file** which provides the complete pathname to the *4D_Execute_PHP.php* utility script. This script is found in [4D application]Resources/php/Windows or /Mac. Without this entry, only complete scripts can be executed: calls to a routine inside a script will not work.
- **display_errors** sets a "stderr" so that 4D can be informed when an error occurs during the execution of PHP code. Example:

```
; stderr - Display the errors to STDERR (only affects the CGI/CLI)
; To direct the errors to STDERR for the CGI/CLI:
display_errors = "stderr"
```

For more information about the configuration of custom php.ini files, please consult the comments found in the php.ini file provided by 4D.

# PHP Execute

PHP Execute ( scriptPath {; functionName {; phpResult {; param} {; param2 ; ... ; paramN}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| scriptPath | Text | ⇒ | Pathname to PHP script or "" to execute a PHP function |
| functionName | Text | ⇒ | PHP function to be executed |
| phpResult | Operator, Variable, Field | ⇐ | Result of PHP function execution or * to not receive any result |
| param | Text, Boolean, Real, Longint, Date, Time | ⇒ | Parameter(s) of PHP function |
| Function result | Boolean | ⇒ | True = execution correct False = execution error |

## Description

The **PHP Execute** command can be used to execute a PHP script or function.

Pass the pathname of the PHP script to be executed in the *scriptPath* parameter. This can be a relative pathname if the file is located next to the database structure or an absolute path. The pathname can be expressed in either the system syntax or POSIX syntax.
If you want to execute a standard PHP function directly, pass an empty string ("") in *scriptPath*. The function name must be passed in the second parameter

Pass a PHP function name in the *functionName* parameter if you want to execute a specific function in the *scriptPath* script. If you pass an empty string or omit the *functionName* parameter, the script is entirely executed.

**Note:** PHP is case sensitive for function names. Do not use parentheses, just enter the function name only.

The *phpResult* parameter receives the result of the execution of the PHP function. You can pass either:

- a variable, an array or a field in order to receive the result,
- the * character if the function does not return any result or if you do not want to retrieve it.

The *phpResult* parameter can be of the Text, Longint, Real, Boolean, or Date type as well as (except for arrays) a field of the BLOB or Time type. 4D will carry out the conversion of the data and any adjustments needed according to the principles described in the **Conversion of data returned** section below.

- If you passed a function name in the *functionName* parameter, *phpResult* will receive what the PHP developer returned with the **return** command from the body of the function.
- If you use the command without passing a function name in the *functionName* parameter, *phpResult* will receive what the PHP developer returned with the **echo** command (or a similar command).

If you call a PHP function that expects arguments, use the *param1...N* parameters to pass one or more values. The values must be separated by semi-colons. You can pass values of the Alpha, Text, Boolean, Real, Integer, Longint, Date or Time type. Pictures, BLOBs and Objects are not accepted. You can send an array; in this case, you must pass a pointer to the array to the **PHP Execute** command, otherwise the current index of the array will be sent as an integer (see the example). The command accepts all types of arrays except for pointer, picture and 2D arrays.
The *param1...N* parameters are sent in PHP in the JSON format in UTF-8. They are automatically decoded with the PHP **json_decode** command before being sent to the PHP *functionName* function.

**Note:** For technical reasons, the size of parameters passed via the FastCGI protocol must not exceed 64 KB. You need to take this limitation into account if you use parameters of the Text type.

The command returns True if the execution has been carried out correctly on the 4D side, in other words, if the launching of the execution environment, the opening of the script and the establishing of the communication with the PHP interpreter were successful. Otherwise, an error is generated, which you can intercept with the **ON ERR CALL** command and analyze with **GET LAST ERROR STACK**.
In addition, the script itself may generate PHP errors. In this case, you must use the **PHP GET FULL RESPONSE** command in order to analyze the source of the error (see example 4).

**Note:** PHP can be used to configure error management. For more information, please refer, for example, to the following page: http://www.php.net/manual/en/errorfunc.configuration.php#ini.error-reporting.

### Conversion of data returned

The following table specifies how 4D interprets and converts data that is returned according to the type of the *phpResult* parameter.

| Type of *phpResult parameter* | Processing by 4D | Example |
|---|---|---|
| BLOB | 4D recovers the data received without any modifications(*). | |
| Text | 4D expects data encoded in UTF-8 (*). The PHP developer may need to use the PHP **utf8_encode** command. | Example of PHP script:<br>`echo utf8_encode(myText)` |
| Date | 4D expects a date sent as a string in the RFC 3339 format (sometimes called DATE_ATOM in PHP). This format is of the type "YYYY-MM-DDTHH:MM:SS", for example: 2005-08-15T15:52:01+00:00. 4D ignores the time part and returns the date in UTC. | |
| Time | 4D expects a time sent as a string in the RFC 3339 format (see the Date type). 4D ignores the date part and returns the number of seconds elapsed since midnight while considering the date in the local time zone. | Example of PHP script for sending 2h30'45":<br>`echo date( DATE_ATOM, mktime( 2,30,45))` |
| Integer or Real | 4D interprets the numerical value expressed with numbers, the + or - sign and/or the exponent prefixed by 'e'. Any '.' or ',' character is interpreted as a decimal separator. | Example of PHP script:<br>`echo -1.4e-16;` |
| Boolean | 4D returns True if it receives the string "true" from PHP or if the numerical evaluation gives a value that is not Null. | Example of PHP script:<br>`echo (a==b);` |
| Array | 4D considers that the PHP array was returned in the JSON format. | Example of PHP script for returning an array of two texts:<br>`echo json_encode( array( "hello", "world"));` |

(*) By default, HTTP headers are not returned:
- If you use **PHP Execute** by passing a function in the *functionName* parameter, HTTP headers are never returned in *phpResult*. They are only available through the **PHP GET FULL RESPONSE** command.
- If you use **PHP Execute** without a function name (the *functionName* parameter is omitted or contains an empty string), you can return HTTP headers by setting the PHP raw result option to True using the **PHP SET OPTION** command.

**Note:** If you need to recover large volumes of data using PHP, it is usually more efficient to pass by the *stdOut* buffer (**echo** command or similar) rather than by the function return. For more information, refer to the description of the **PHP GET FULL RESPONSE** command.

### Using environment variables

You can use the **SET ENVIRONMENT VARIABLE** command to specify the environment variables used by the script. Warning: after calling **LAUNCH EXTERNAL PROCESS** or **PHP Execute**, the set of environment variables is erased.

### Special functions

4D provides the following special functions:

- **quit_4d_php**: used to quit the PHP interpreter and all its child processes. If at least one child process is executing a script, the interpreter does not quit and the **PHP Execute** command returns False.
- **relaunch_4d_php**: used to relaunch the PHP interpreter.

Note that the interpreter is relaunched automatically when the first request is sent by **PHP Execute**.

## Example 1

Calling the "myPhpFile.php" script without any function. Here are the contents of the script:

```
<?php
echo 'Current PHP version: ' . phpversion();
?>
```

The following 4D code:

```
C_TEXT($result)
C_BOOLEAN($isOK)
$isOK:=PHP Execute("C:¥¥php¥¥myPhpFile.php";"";$result)
ALERT($Result)
```

... will display "Current PHP version: 5.3"

## Example 2

Calling the *myPhpFunction* function in the "myNewScript.php" script with parameters. Here are the contents of the script:

```
<?php
// . . . PHP code. . .
function myPhpFunction($p1, $p2) {
    return $p1 . ' '. $p2;
}
// . . . PHP code.. . .
?>
```

Calling with function:

```
C_TEXT($result)
C_TEXT($param1)
C_TEXT($param2)
C_BOOLEAN($isOk)
$param1 :="Hello"
$param2 :="4D world!"
$isOk:=PHP Execute("C:¥¥MyFolder¥¥myNewScript.php";"myPhpFunction";$result;$param1;$param2)
ALERT($result) // Displays "Hello 4D world!"
```

## Example 3

Quitting the PHP interpreter:

```
$ifOk:=PHP Execute("";"quit_4d_php")
```

## Example 4

Error management:

```
 // Installation of the error-management method
phpCommError:="" // Modified by PHPErrorHandler
$T_saveErrorHandler :=Method called on error
ON ERR CALL("PHPErrorHandler")</p><p> // Execution of script
C_TEXT($T_result)
If(PHP Execute("C:¥¥MyScripts¥¥MiscInfos.php";"";$T_result))
 // No error, $T_Result contains the result
Else
 // An error is detected, managed by PHPErrorHandler
   If(phpCommError="")
      ... // PHP error, use PHP GET FULL RESPONSE
   Else
      ALERT(phpCommError)
   End if
End if
```

```
 // Uninstalling method
ON ERR CALL($T_saveErrorHandler)
```

The ***PHP_errHandler*** method is as follows:

```
phpCommError:=""
GET LAST ERROR STACK(arrCodes;arrComps;arrLabels)
For($i;1;Size of array(arrCodes))
   phpCommError:=phpCommError+String(arrCodes{$i})+" "+arrComps{$i}+" "+
   arrLabels{$i}+Char(Carriage return)
End for
```

## Example 5

Dynamic creation by 4D of a script before its execution:

```
DOCUMENT TO BLOB("C:¥¥Scripts¥¥MyScript.php";$blobDoc)
If(OK=1)
   $strDoc:=BLOB to text($blobDoc;UTF8 text without length)

   $strPosition:=Position("function2Rename";$strDoc)

   $strDoc:=Insert string($strDoc;"_v2";Length("function2Rename")+$strPosition)

   TEXT TO BLOB($strDoc;$blobDoc;UTF8 text without length)
   BLOB TO DOCUMENT("C:¥¥Scripts¥¥MyScript.php";$blobDoc)
   If(OK#1)
      ALERT("Error on script creation")
   End if
End if
```

The script is then executed:

```
$err:=PHP Execute("C:¥¥Scripts¥¥MyScript.php";"function2Rename_v2";*)
```

## Example 6

Direct retrieval of a Date and Time type value. Here are the contents of the script:

```
<?php
// . . . code php. . .
echo date(DATE_ATOM, mktime(1, 2, 3, 4, 5, 2009));
// . . . code php. . .
?>
```

Receiving the date on the 4D side:

```
C_DATE($phpResult_date)
$result :=PHP Execute("C:¥php_scripts¥ReturnDate.php";"";$phpResult_date)
 //$phpResult_date is !05/04/2009 !

C_TIME($phpResult_time)
$result :=PHP Execute("C:¥php_scripts¥ReturnDate.php";"";$phpResult_time)
 //$phpResult_time is ?01 :02 :03 ?
```

## Example 7

Distribution of data in arrays:

```
ARRAY TEXT($arText ;0)
ARRAY LONGINT($arLong ;0)
$p1 :=","
```

```
$p2 :="11,22,33,44,55"
$phpok :=PHP Execute("";"explode";$arText;$p1;$p2)
$phpok :=PHP Execute("";"explode";$arLong;$p1;$p2)

 // $arText contains the Alpha values "11", "22", "33", etc.
 // $arLong contains the numbers, 11, 22, 33, etc.
```

## Example 8

Initialization of an array:

```
ARRAY TEXT($arText ;0)
$phpok :=PHP Execute("";"array_pad";$arText;->$arText;50;"undefined")
 // Execute in PHP: $arrTest = array_pad($arrTest, 50, ' undefined' );
 // Fills the $arText array with 50 "undefined" elements
```

## Example 9

Passing of parameters via an array:

```
ARRAY INTEGER($arInt;0)
$phpok :=PHP Execute("";"json_decode";$arInt;"[13,51,69,42,7]")
 // Execute in PHP: $arInt = json_decode(' [13,51,69,42,7]' );
 // Fills the array with the initial values
```

## Example 10

Here is an example of the basic use of the trim function, to remove extra spaces and/or invisible characters from the beginning and end of a string:

```
C_TEXT($T_String)
$T_String:="   Hello  "
C_BOOLEAN($B)
$B:=PHP Execute("";"trim";$T_String;$T_String)
```

For more information concerning the trim function, please refer to the PHP documentation.

# PHP GET FULL RESPONSE

PHP GET FULL RESPONSE ( stdOut {; errLabels ; errValues} {; httpHeaderFields {; httpHeaderValues}} )

| Parameter | Type | | Description |
|---|---|---|---|
| stdOut | Text variable, BLOB variable | ⇦ | Contents of stdOut buffer |
| errLabels | Text array | ⇦ | Labels of errors |
| errValues | Text array | ⇦ | Values of errors |
| httpHeaderFields | Text array | ⇦ | Names of HTTP headers |
| httpHeaderValues | Text array | ⇦ | Values of HTTP headers |

## Description

The **PHP GET FULL RESPONSE** command lets you obtain additional information about the response returned by the PHP interpreter. This command is particularly useful in the case of an error occurring during execution of the script.

The PHP script can write data in the stdOut buffer (echo, print, etc.). The command returns the data directly in the *stdOut* variable and applies the same conversion principles as described in the **PHP Execute** command.

The synchronized *errLabels* and *errValues* text arrays are filled when the execution of the PHP scripts causes errors. These arrays provide information in particular on the error origin, script and line. These two arrays are inseparable: if *errLabels* is passed, *errValues* must be passed as well.

Since exchanges between 4D and the PHP interpreter are carried out via FastCGI, the PHP interpreter functions as if it were called by an HTTP server and therefore sends HTTP headers. You can recover these headers and their values in the *httpHeaderFields* and *httpHeaderValues* arrays.

# PHP GET OPTION

PHP GET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇨ | Option to get |
| value | Text, Boolean | ⇦ | Current value of option |

## Description

The **PHP GET OPTION** command can be used to find out the current value of an option relating to the execution of PHP scripts.

Pass a constant from the "**PHP**" theme in the *option* parameter to designate the option to be gotten. The command returns the current value of the option in the *value* parameter. You can pass one of the following constants:

| Constant | Type | Value | Comment |
|---|---|---|---|
| PHP privileges | Longint | 1 | Definition of specific user privileges relating to the execution of the script.<br>**Possible value(s)**: String in the form "User:Password". For example: "root:jd51254d" |
| PHP raw result | Longint | 2 | Definition of processing mode for HTTP headers returned by PHP in the execution result when this result is of the Text type (when the result is of the BLOB type, headers are always kept).<br>**Possible value(s)**: Boolean. False (default value = remove HTTP headers from result. True = keep HTTP headers. |

**Note:** Only the user account is returned when you use the PHP privileges option with the **PHP GET OPTION** command (the password is not returned).

## Example

We want to find out the current user account:

```
C_TEXT($userAccount)
PHP GET OPTION(PHP privileges;$userAccount)
ALERT($userAccount)
```

# PHP SET OPTION

PHP SET OPTION ( option ; value {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ➡ | Option to be set |
| value | Text, Boolean | ➡ | New value of option |
| * | Operator | ➡ | If passed: modification only applied to next call |

## Description

The **PHP SET OPTION** command is used to set specific options before calling the **PHP Execute** command. The scope of this command is the current process.

Pass a constant from the "**PHP**" theme in the *option* parameter to designate the option to be modified and pass the new value for the option in the *value* parameter. Here is a description of the options:

| Constant | Type | Value | Comment |
|---|---|---|---|
| PHP privileges | Longint | 1 | Definition of specific user privileges relating to the execution of the script.<br>**Possible value(s)**: String in the form "User:Password". For example: "root:jd51254d" |
| PHP raw result | Longint | 2 | Definition of processing mode for HTTP headers returned by PHP in the execution result when this result is of the Text type (when the result is of the BLOB type, headers are always kept).<br>**Possible value(s)**: Boolean. False (default value = remove HTTP headers from result. True = keep HTTP headers. |

By default, **PHP SET OPTION** sets the option for all subsequent calls to **PHP Execute** of the process. If you want to set it for the next call only, pass the star (*) parameter.

## Example

Execute the "myAdminScript.php" script with Admin access rights:

```
PHP SET OPTION(PHP privileges;"admin:mypwd";*)
 `Since we pass the *, the admin privileges will only be used once
C_TEXT($result)
C_BOOLEAN($isOK)
$isOK:=PHP Execute("myAdminScript.php";$result)
If($isOK)
   ALERT($result)
End if
```

# PHP modules support

This appendix details the implementation of PHP modules in 4D. The following subjects are covered:

- List of standard PHP modules provided by default with the PHP interpreter of 4D
- List of standard PHP modules not retained by 4D
- Modifications of the php.ini file.

**Note:** If you want to install additional modules, you must use an external FastCGI-php interpreter (see **Using another PHP interpreter or another php.ini file**).

## Modules provided by default

The following table details the PHP modules provided by default with 4D.

### Generic modules

| Name | Web Site | Description |
| --- | --- | --- |
| BCMath | http://php.net/bc | Binary calculator handling numbers of any size and precision represented as strings.<br>Example:<br>`C_LONGINT($value;$result)`<br>`$value:=4`<br>`$ok:=PHP Execute("";"bcpow";$result;$value;3)` |
| Calendar | http://php.net/calendar | Set of functions simplifying conversion between different calendar formats. Based on Julian Day Count.<br>Example:<br>`C_LONGINT($NumberOfDays)`<br>`$ok:=PHP Execute("";"cal_days_in_month";$NumberOfDays;1;2;2010)` |
| Ctype | http://php.net/ctype | Functions that check whether a character or a string belongs to a certain character class, depending on the current local configuration<br>Example:<br>`// Check that all the characters of a string are punctuation marks`<br>`C_TEXT($myString)`<br>`$myString:=",.;/"`<br>`$ok:=PHP Execute("";"ctype_punct";$isPunct;$myString)` |
| Date and Time | http://php.net/datetime | Recovery of the date and time from the server where the PHP script is executed<br>Example:<br>`//Calculation of time of sunrise in Lisbon, Portugal`<br>`//Latitude: 38.4 North`<br>`//Longitude: 9 West`<br>`//Zenith ~= 90`<br>`//Time-lag: +1 GMT`<br>`C_TIME($SunriseTime)`<br>`$ok:=PHP Execute("";"date_sunrise";$SunriseTime;0;1;38,41;-9;90;1)` |
| DOM (Document Object Model) | http://php.net/dom | Use of XML documents via the DOM API in PHP 5 |
| Exif | http://php.net/exif | Work with image metadata. |
| Fileinfo(*) | http://php.net/fileinfo | Detection of type of contents and encoding of a file. |
| Filter | http://php.net/filter | Validate and filter data from a non-secure source, like user entries.<br>Example:<br>`C_LONGINT($filterId)`<br>`C_TEXT($result)`<br>`$ok:=PHP Execute("";"filter_id";$filterId;"validate_email")`<br>`$ok:=PHP Execute("";"filter_var";$result;"hop@123.com";$filterId)` |
| FTP (File Transfert Protocol) | http://php.net/ftp | Detailed access to a FTP server |
| Hash | http://php.net/hash | Message Digest engine. Allows direct or incremental processing of arbitrary length messages using a variety of hashing algorithms<br>Example:<br>`C_TEXT($md5Result)`<br>`$ok:=PHP Execute("";"md5";$md5Result;"this is my string to hash")` |
| GD | http://php.net/gd | Working with images |

| | | |
|---|---|---|
| (Graphics Draw) Library | | |
| Iconv | http://php.net/iconv | Conversion of files between various character sets |
| JSON (JavaScript Object Notation) | http://php.net/json | Implementation of JSON data exchange format |
| LDAP | http://php.net/ldap | LDAP is an access protocol to "folder servers" that store information in the form of a tree diagram |
| LibXML | http://php.net/libxml | Library of XML functions and constants |
| LibXSLT | http://php.net/xsl | Library of XSL transformation functions |
| Multibyte String | http://php.net/mbstring | Set of functions for working with strings that can be used to handle multi-byte character encodings or to convert character strings. |
| OpenSSL | http://php.net/openssl | Use of OpenSSL functions to generate and verify signatures, to seal (encode) and open (decode) data. |
| PCRE (Perl Compatible Regular Expressions) | http://php.net/pcre | Set of functions that implement rational expressions using the same syntax and semantics Perl 5<br><br>Example:<br>`// This example removes unnecessary spaces from a string`<br>`C_TEXT($myString)`<br>`$myString:="foo o bar"`<br>`PHP Execute("";"preg_replace";$myString;"/¥¥s¥¥s+/";" ";$myString)`<br>`ALERT($myString)`<br>`//The string is now 'foo o bar' without repeated spaces` |
| PDO (PHP Data Objects) | http://php.net/pdo | Interface for accessing a database. Requires a database-specific PDO driver. |
| PDO_SQLITE | http://php.net/pdo_sqlite | Driver that implements the PHP Data Objects (PDO) interface to allow PHP access to SQLite 3 databases. |
| Reflection | http://php.net/reflection | Complete reflection API that lets you reverse-engineer classes, interfaces, functions and methods as well as extensions |
| Phar (PHP Archive) | http://php.net/phar | Allows a complete PHP application to be included in a unique file named "phar" (PHP Archive) to facilitate its installation and configuration |
| Session | http://php.net/session | Support of PHP sessions<br>Example:<br>Sessions are used in Web applications to preserve the context between each request. When you call **PHP Execute** in 4D, the PHP script can start a session and store anything that is useful to be kept as context in the associated $_SESSION array. If a PHP script uses sessions, you must obtain the session ID returned by PHP using the **PHP GET FULL RESPONSE** command and specify it before each call to **PHP Execute** using the **SET ENVIRONMENT VARIABLE** command.<br>`// "PHP Execute with context" method`<br>`If(<>PHP_Session#"")`<br>`SET ENVIRONMENT VARIABLE("HTTP_COOKIE";<>PHP_Session)`<br>`End if`<br>`If(PHP Execute($1))`<br>`PHP GET FULL RESPONSE($0;$errorInfos;$errorValues;$headerFields;$headerValues)`<br>`$idx:=Find in array($headerFields;"Set-Cookie")`<br>`If($idx>0)`<br>`<>PHP_Session:=$headerValues{$idx}`<br>`End if`<br>`End if` |

| | | |
|---|---|---|
| SimpleXML | http://php.net/simpleXML | Very simple and easy-to-use tools to be used to convert XML to an object that can be processed with its properties and array iterators |
| Sockets | http://php.net/sockets | Implementation of a low-level interface to the socket communication functions based on BSD sockets and providing the possibility to act as both a socket server as well as a client. |
| SPL (Standard PHP Library) | http://php.net/spl | Collection of interfaces and classes that are meant to solve standard problems. |
| SQLite | http://php.net/sqlite | Extension for the SQLite database engine. This engine is embeddable. |
| SQLite3 | http://php.net/sqlite3 | Support for SQLite version 3 databases |
| Tokenizer | http://php.net/tokenizer | Functions that let you write your own PHP analysis tools or modification tools without having to deal with the language specification at the lexical level |
| XML (eXtensible Markup Language) | http://php.net/xml | Parsing of XML documents |
| XMLreader | http://php.net/xmlreader | XML Pull parser |
| XMLwriter | http://php.net/xmlwriter | Generation of XML format streams or files |
| Zlib | http://php.net/zlib | Reading and writing of gzip (.gz) compressed files<br>Example:<br>`WEB GET HTTP HEADER($names;$values)`<br>`$pos:=Find in array($names;"Accept-Encoding")`<br>`If($pos>0)`<br>`  Case of`<br>`  :(Position($values{$pos};"gzip")>0)`<br>`  WEB SET HTTP HEADER("Content-Encoding: gzip")`<br>`  PHP Execute("";"gzencode";$html;$html)`<br>`  :(Position($values{$pos};"deflate")>0)`<br>`  WEB SET HTTP HEADER("Content-Encoding: deflate")`<br>`  PHP Execute("";"gzdeflate";$html;$html)`<br>`  End case`<br>`End if`<br>`WEB SEND TEXT($html)` |
| Zip | http://php.net/zip | Reading and writing of ZIP compressed archives and the files inside them |

(*) In the current version of 4D, these modules are not available under Windows

### Modules only available under Windows

For structural reasons, the following PHP modules are only available on the Windows platform.

| Name | Web Site | Description |
|---|---|---|
| COM & .NET | http://php.net/com | COM (Component Object Model) is one of the main ways for applications and components to communicate on Windows platforms. In addition, 4D supports the instantiation and creation of .Net assemblies via the COM layer. |
| ODBC (Open DataBase Connectivity) | http://php.net/odbc | In addition to standard ODBC support, the Unified ODBC functions in PHP gives you access to several databases that have borrowed the semantics of the ODBC API to implement their own API. |
| WDDX (Web Distributed Data eXchange) | http://php.net/wddx | Facilitates data exchanges between Web applications over the Web, regardless of the platform |

## Disabled modules

The following PHP modules have not been implemented in 4D. The rightmost column gives the reason they were not implemented:

| Name | Web Site | Cause - Alternative solution |
| --- | --- | --- |
| Mimetype | http://php.net/mime-magic | Obsolete (Deprecated) - Use Fileinfo |
| POSIX (Portable Operating System Interface) | http://php.net/posix | Obsolete (Deprecated) |
| Regular Expression (POSIX Extended) | http://php.net/regex | Obsolete (Deprecated) - Use PCRE |
| Crack | http://php.net/crack | Restrictive license |
| ffmpeg | http://ffmpeg-php.sourceforge.net/ | Restrictive license - Use ffmpeg in command line with LAUNCH EXTERNAL PROCESS |
| Image Magick | http://php.net/manual/book.imagick.php | Restrictive license - Use GD 2 |
| IMAP (Internet Message Access Protocol) | http://php.net/imap | Restrictive license - Use the 4D Internet Commands integrated plugin |
| PDF (Portable Document Format) | http://php.net/pdf | Restrictive license - Use Haru PDF |
| Mysqlnd (MySQL Native Driver) | http://dev.mysql.com/downloads/connector/php-mysqlnd/ | Not pertinent in the 4D environment |

## Customizing the php.ini file

The "php.ini" file to modify (see below) can be located either in the **Resources¥php** folder of the 4D application (default file) or in the **Resources** folder of the database (custom file). For more on this subject, refer to **Executing PHP scripts in 4D**.

**Warning:** Modifying the "php.ini" file must be done with caution and requires a good knowledge of PHP. For more information about the configuration of custom php.ini files, you can consult the comments found in the php.ini file provided by 4D.

**Note:** If the duration of PHP processing is relatively long (beyond 30 seconds), by default a 'timeout' error will be returned in 4D and the processing will fail. In this case, you can set the default *timeout* in order to allocate more time to PHP execution. There are two ways to do this:

- by setting the **max_execution_time** variable in the "php.ini" file (pass a value in seconds). Warning: this setting affects all the scripts.
- by calling the **set_time_limit(nbSec)** command in the PHP execution script that is performing the long processing. Pass the maximum duration allocated to the execution of the PHP script in *nbSec*. We recommend using this setting since it only affects this script. Usually, for security reasons, it is preferable to keep a lower *timeout* value for PHP scripts.

# Pictures

- Pictures
- BLOB TO PICTURE
- COMBINE PICTURES
- CONVERT PICTURE
- CREATE THUMBNAIL
- Equal pictures

# Pictures

## Native Formats Supported

4D integrates native management of picture formats. This means that pictures will be displayed and stored in their original format, without any interpretation in 4D. The specific features of the different formats (shading, transparent areas, etc.) will be retained when they are copied and pasted, and will be displayed without alteration. This native support is valid for all pictures stored in 4D: library pictures, pictures pasted into forms in Design mode, pictures pasted into fields or variables in Application mode, etc.

4D uses native APIs to encode and decode pictures (fields and variables) under both Windows and Mac OS. These implementations provide access to numerous native forms, including the RAW format, currently used by digital cameras.

- **Under Windows**, 4D uses WIC (Windows Imaging Component). WIC natively supports the following formats: BMP, PNG, ICO (decoding only), JPEG, GIF, TIFF and WDP (Microsoft Windows Digital Photo).
  It is possible to use additional formats such as JPEG-2000 by installing third-party WIC codecs.
- **Under Mac OS**, 4D uses ImageIO. All the available ImageIO codecs are therefore natively supported for decoding (reading) as well as encoding (writing):

| Decoding | Encoding |
|---|---|
| public.jpeg | public.jpeg |
| com.compuserve.gif | com.compuserve.gif |
| public.png | public.png |
| public.jpeg-2000 | public.jpeg-2000 |
| com.nikon.raw-image | public.tiff |
| com.pentax.raw-image | com.adobe.photoshop.image |
| com.sony.arw-raw-image | com.adobe.pdf |
| com.adobe.raw-image | com.microsoft.bmp |
| public.tiff com.canon.crw-raw-image | com.truevision.tga-image |
| com.canon.cr2-raw-image | com.sgi.sgi-image |
| com.canon.tif-raw-image | com.apple.pict *(deprecated)* |
| com.sony.raw.image | com.ilm.openexr-image |
| com.olympus.raw-image | |
| com.konicaminolta.raw-image | |
| com.panasonic.raw-image | |
| com.fuji.raw-image | |
| com.adobe.photoshop-image | |
| com.adobe.illustrator.ai-image | |
| com.adobe.pdf | |
| com.microsoft.ico | |
| com.microsoft.bmp | |
| com.truevision.tga-image | |
| com.sgi.sgi-image | |
| com.apple.quicktime-image *(deprecated)* | |
| com.apple.icns | |
| com.apple.pict *(deprecated)* | |
| com.apple.macpaint-image | |
| com.kodak.flashpix-image | |
| public.xbitmap-image | |
| com.ilm.openexr-image | |
| public.radiance | |

Under Windows as under Mac OS, the formats supported vary according to the operating system and the custom codecs that are installed on the machines. To find out which codecs are available, you must use the **PICTURE CODEC LIST** command.

**Note:** WIC and ImageIO permit the use of metadata in pictures. Two commands, **SET PICTURE METADATA** and **GET PICTURE METADATA**, let you benefit from metadata in your developments.

### Picture Codec IDs

Picture formats recognized by 4D are returned by the **PICTURE CODEC LIST** command as picture Codec IDs. They can be returned in the following forms:

- As an extension (for example ".gif")
- As a Mime type (for example "image/jpeg")

The form returned for each format will depend on the way the Codec is recorded at the operating system level.
Most of the 4D picture management commands can receive a Codec ID as a parameter. It is therefore imperative to use the system ID returned by the **PICTURE CODEC LIST** command.

### Unavailable picture format

A specific icon is displayed for pictures saved in a format that is not available on the machine. The extension of the missing format is shown at the bottom of the icon:

The icon is automatically used wherever the picture is meant to be displayed:

This icon indicates that the picture cannot be displayed or manipulated locally -- but it can be saved without alteration so that it can be displayed on other machines. This is the case, for instance, for PDF pictures on Windows, or for pictures based on PICT displayed on a 64-bit 4D Server under OS X.

### Activation of QuickTime (compatibility)

By default, the picture codecs related to QuickTime are no longer supported in 4D beginning with v14.

For compatibility reasons, you can reactivate QuickTime in your application by means of the QuickTime support option of the **SET DATABASE PARAMETER** command. However, we no longer recommend using QuickTime codecs.

**Note:** The QuickTime reactivation option is ignored in 64-bit versions of 4D Developer Edition (no QuickTime support).

## Mouse Coordinates in a Picture

4D lets you retrieve the local coordinates of the mouse in a picture field or variable in case of a click or a hovering, even if a scroll or zoom has been applied to the picture. This mechanism, similar to that of a picture map, can be used, for example, to handle scrollable button bars or the interface of cartography software.

The coordinates are returned in the *MouseX* and *MouseY* **System Variables**. The coordinates are expressed in pixels with respect to the top left corner of the picture (0,0). If the mouse is outside of the picture coordinates system, -1 is returned in *MouseX* and *MouseY*.

You can get the value of these variables as part of the On Clicked, On Double Clicked, On Mouse up, On Mouse Enter, or On Mouse Move form events.

## Picture Operators

4D allows you to carry out **operations** on 4D pictures, such as concatenation, superimposing, etc. This point is covered in the **Picture Operators** section.

# BLOB TO PICTURE

BLOB TO PICTURE ( pictureBlob ; picture {; codec} )

| Parameter | Type | | Description |
|---|---|---|---|
| pictureBlob | BLOB | ⇒ | BLOB containing a picture |
| picture | Picture | ⇐ | Picture from BLOB |
| codec | String | ⇒ | Picture codec ID |

## Description

The **BLOB TO PICTURE** command inserts a picture stored in a BLOB into a 4D picture variable or field, regardless its original format.

This command is similar to the command **READ PICTURE FILE**, it just applies to a BLOB instead of a file. It allows you to display pictures stored in native format into BLOBs. You can load a picture into a BLOB using, for example, the command **DOCUMENT TO BLOB** or **PICTURE TO BLOB**.

A BLOB variable or field containing a picture is passed in the *pictureBlob* parameter. The picture can be in any format supported natively by 4D. You can obtain the list of available formats using the **PICTURE CODEC LIST** command. If you pass the optional *codec* parameter, 4D will use the value provided in this parameter to decode the BLOB (see the specific functioning of the command with this third parameter below).

Pass in the *picture* parameter the 4D picture field or variable which should display the picture.

**Note:** The internal picture format will be stored within the 4D variable or field.

Once the command has been executed, if the BLOB was correctly decoded, the *picture* parameter contains the picture to display.

The optional *codec* parameter lets you specify the codec to be used for decoding the BLOB.

If you pass a codec recognized by 4D in *codec* (returned by the **PICTURE CODEC LIST** command), it is applied to the BLOB and the picture is returned in the *picture* field or variable.

If you pass a codec that is not recognized by 4D in *codec*, a new codec is recorded dynamically with the ID passed in the parameter. 4D then returns a picture that encapsulates the BLOB and the OK variable is set to 1. In this case, to retrieve the BLOB, you will need to use the **PICTURE TO BLOB** command with the same custom ID. This particular mechanism can be used to meet two specific needs:

- encapsulation of a BLOB (that is not a picture) into a picture,
- loading a picture without using a codec.

The implementation of these mechanisms allows, more specifically, the creation of "BLOB arrays" via picture arrays. This technique must be used with caution because, since the arrays are loaded entirely into memory, working with large sized BLOBs can affect the functioning of the application.

**Note:** A BLOB created by the **VARIABLE TO BLOB** command is managed automatically; it is not necessary to pass a codec to encapsulate it since the BLOB is "signed." In this case, for the opposite operation, you will need to pass ".4DVarBlob" to the **PICTURE TO BLOB** command as the codec ID.

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. If the conversion has failed (QuickTime is not installed, the BLOB does not contain a readable picture, the codec parameter recognized but BLOB not validated, etc.), OK is set to 0 and the 4D picture variable or field is returned empty.

# COMBINE PICTURES

COMBINE PICTURES ( resultingPict ; pict1 ; operator ; pict2 {; horOffset ; vertOffset} )

| Parameter | Type | | Description |
|---|---|---|---|
| resultingPict | Picture | ⇐ | Picture resulting from combination |
| pict1 | Picture | ⇒ | First picture to combine |
| operator | Longint | ⇒ | Type of combination to be done |
| pict2 | Picture | ⇒ | Second picture to combine |
| horOffset | Longint | ⇒ | Horizontal offset for superimposition |
| vertOffset | Longint | ⇒ | Vertical offset for superimposition |

## Description

The **COMBINE PICTURES** command combines the *pict1* and *pict2* pictures in *operator* mode in order to produce a third, *resultingPict*. The resulting picture is of the compound type and keeps all the characteristics of the source pictures.

**Note:** This command extends the functionalities offered by the conventional picture combination operators (+/, etc., see the **Picture Operators** section). These operators remain entirely usable in 4D v11.

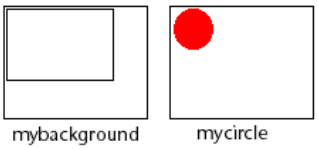
In *operator*, pass the type of combination to be applied. Three types of combinations, which can be accessed via the constants of the "**Picture Transformation**" theme, are proposed:

- Horizontal concatenation (1): *pict2* is attached to *pict1*, the top left corner of *pict2* coincides with the top right corner of *pict1*.
- Vertical concatenation (2): *pict2* attached to *pict1*, the top left corner of *pict2* coincides with the lower left corner of *pict1*.
- Superimposition (3): *pict2* is placed over *pict1*, the top left corner of *pict2* coincides with the top left corner of *pict1*. If the optional *horOffset* and *vertOffset* parameters are used, a translation is applied to *pict2* before superimposition. The values passed in *horOffset* and *vertOffset* must correspond to pixels. Pass positive values for an offset to the right or towards the bottom and a negative value for an offset to the left or towards the top.

**Note:** Superimposition carried out by the **COMBINE PICTURES** command differs from the superimposition provided by the conventional & and |operators (exclusive and inclusive superimposition). While the **COMBINE PICTURES** command preserves the characteristics of each source picture in the resulting picture, the & and | operators process each pixel and generate a bitmap picture in all cases. These operators, originally intended for black and white pictures, are now obsolete.

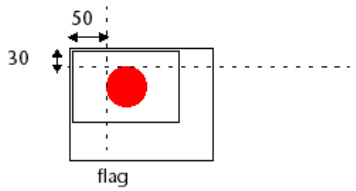
## Example

Given the following pictures:



```
COMBINE PICTURES(flag;mybackground;Superimposition;mycircle;50;30)
```

Result:



# CONVERT PICTURE

CONVERT PICTURE ( picture ; codec {; compression} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇨ | Picture to be converted |
| | | ⇦ | Converted picture |
| codec | String | ⇨ | Picture Codec ID |
| compression | Real | ⇨ | Quality of compression |

## Description

The **CONVERT PICTURE** command converts *picture* into a new type.

The *codec* parameter indicates the type of picture to be generated. A Codec can be an extension (for example, ".gif") or a Mime type (for example, "image/jpeg"). You can get a list of Codecs that are available using the **PICTURE CODEC LIST** command.

If the *picture* field or variable is a compound type (if, for example, it is the result of a copy-paste action), only the information corresponding to the codec type are preserved in the resulting picture.

**Note:** If the type of *codec* requested is the same as the original type of the *picture*, no conversion is carried out and the picture is returned "as is" (except when the *compression* parameter is used, see below).

The optional *compression* parameter, if passed, can be used to specify the compression quality to be applied to the resulting picture when a compatible Codec is used. In *compression*, pass a value between 0 and 1 to specify the quality of the compression, where 0 is the most mediocre quality (high compression) and 1 the best quality (low compression). This parameter is only taken into account when the Codec supports compression (for example JPEG or HDPhoto) and is supported by the WIC and ImageIO APIs. For more information about picture management APIs in 4D, please refer to the **Pictures** section. By default, if you omit the *compression* parameter, the best quality is applied (compression =1).

## Example 1

Conversion of the vpPhoto picture to the jpeg format:

```
CONVERT PICTURE(vpPhoto;".jpg")
```

## Example 2

Conversion of a picture with 60% quality:

```
CONVERT PICTURE(vPicture;".JPG";0.6)
```

# CREATE THUMBNAIL

CREATE THUMBNAIL ( source ; dest {; width {; height {; mode {; depth}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| source | Picture | ⇒ | 4D picture field or variable to convert as a thumbnail |
| dest | Picture | ⇐ | Resulting thumbnail |
| width | Integer | ⇒ | Thumbnail width in pixels, Default value = 48 |
| height | Integer | ⇒ | Thumbnail height in pixels, Default value = 48 |
| mode | Integer | ⇒ | Thumbnail creation mode Default value = Scaled to fit prop centered (6) |
| depth | Integer | ⇒ | Obsolete, do not use |

## Description

The **CREATE THUMBNAIL** command returns a thumbnail from a given source picture. Thumbnails are usually used for picture preview within multimedia software or Web sites.

You pass in the *source* parameter the 4D variable or field containing the picture to reduce to a thumbnail. You pass in the *dest* parameter the 4D picture field or variable which should host the resulting thumbnail.

The optional parameters *width* and *height* define the required thumbnail size (in pixels). If you omit these parameters, the thumbnail default size will be 48 x 48 pixels.

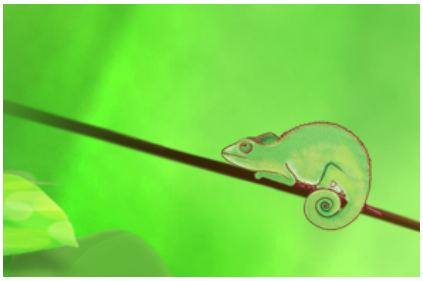
The optional parameter *mode* defines the thumbnail creation mode, i.e. the resizing mode. Three modes are available. The following predefined constants are provided by 4D in the "**Picture Display Formats**" constant theme:

| Constant | Type | Value |
|---|---|---|
| Scaled to fit | Longint | 2 |
| Scaled to fit prop centered | Longint | 6 |
| Scaled to fit proportional | Longint | 5 |

**Note:** Only these constants can be used with **CREATE THUMBNAIL**. The other constants in this theme cannot be applied to this command.

If you do not enter any parameter, the "Scaled to fit prop centered" mode (6) is applied by default. Below is an illustration of the various modes:

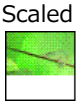
Source picture



Resulting thumbnails (48x48)

- Scaled to fit = 2

- Scaled to fit proportional = 5



- Scaled to fit prop centered = 6 (default mode)

**Note:** With the "Scaled to fit proportional" and the "Scaled to fit prop centered", the free space will be displayed in white. When these modes are applied to picture field or variable in 4D forms, the free space is transparent.

The *depth* parameter is ignored and must be omitted. The command always uses the current screen depth (number of colors).

# Equal pictures

Equal pictures ( picture1 ; picture2 ; mask ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| picture1 | Picture field, Picture variable | ⇒ | Original source picture |
| picture2 | Picture field, Picture variable | ⇒ | Picture to compare |
| mask | Picture field, Picture variable | ⇐ | Resulting mask |
| Function result | Boolean | ⇒ | True if both pictures are identical; otherwise, False |

## Description

The **Equal pictures** command precisely compares both the dimensions and the contents of two pictures.

Pass the source picture in *picture1* and the picture you want to compare with it in *picture2*.

- If the pictures are not the same dimension, the command returns **False** and the *mask* parameter contains a blank picture.
- If the pictures are of the same dimension but with different contents, the command returns **False** and the *mask* parameter contains the resulting picture mask based on a comparison of the two pictures. This comparison is performed pixel by pixel, and each pixel that does not match appears white on a black background.
- If both pictures are exactly the same, the command returns **True** and the *mask* parameter contains a picture that is completely black.

## System variables and sets

If the command is executed successfully (the two pictures are compared), the system variable OK is set to 1. In the case of an anomaly, particularly if one of the pictures is not initialized (blank picture), the OK variable is set to 0.

## Example

In the following example, we compare two pictures (pict1 and pict2) and display the resulting mask:

Here is the code for the **Compare** button:

```
$equal :=Equal pictures($pict1;$pict2;$mask)
```

# Get picture file name

Get picture file name ( picture ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture field, Picture variable | ⇒ | Picture for which to get default name |
| Function result | Text | ⇐ | Default name of picture file |

## Description

The **Get picture file name** command returns the current default name of the picture passed as parameter.

The default name is used when exporting the picture to a disk file. It can be set automatically based on the original name of the picture file imported into the picture field or variable, or using the **SET PICTURE FILE NAME** command. For more information, refer to the *Design Reference* manual.

If the picture does not have a default name, the command returns an empty string.

# GET PICTURE FORMATS

GET PICTURE FORMATS ( picture ; codecIDs )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇨ | Picture field or variable to analyze |
| codecIDs | Text array | ⇦ | Picture codec IDs |

## Description

The **GET PICTURE FORMATS** command returns an array of all the codec IDs (picture formats) contained in the *picture* passed as parameter. A 4D picture (field or variable) can contain the same picture encoded in different formats, such as PNG, BMP, GIF, etc.

In the *picture* parameter, you pass a picture field or a picture variable whose included formats you want to be returned in the *codecIDs* array.

The codec IDs returned are established by 4D in exactly the same way as for the **PICTURE CODEC LIST** command. They can be returned in the following forms:

- As extensions (for example, ".gif")
- As Mime types (for example, "image/jpeg")
- As 4-character QuickTime codes

**Notes:**

- The following codecs, handled internally by 4D, are always returned as extensions: JPEG, PNG, TIFF, GIF, BMP, SVG, PDF, EMF.
- 4-character QuickTime codes may be returned in databases where the QuickTime support compatibility option has been set (using the **SET DATABASE PARAMETER** command). However, QuickTime is no longer supported in 4D and we do not recommend using QuickTime codecs.

For more information about picture codec IDs, refer to the **Pictures** section.

## Example

You want to know the picture formats stored in a field for the current record:

```
ARRAY TEXT($aTPictureFormats;0)
 //Get all the formats saved
GET PICTURE FORMATS([Employees]Photo;$aTPictureFormats)
```

# GET PICTURE FROM LIBRARY

GET PICTURE FROM LIBRARY ( picRef | picName ; picture )

| Parameter | Type | | Description |
|---|---|---|---|
| picRef \| picName | Longint, String | ⇨ | Reference number of Picture Library graphic or Name of Picture Library graphic |
| picture | Picture variable | ⇦ | Picture from the Picture Library |

## Description

The **GET PICTURE FROM LIBRARY** command returns in the *picture* parameter the Picture Library graphic whose reference number is passed in *picRef* or whose name is passed in *picName*.

If there is no picture with that reference number or name, **GET PICTURE FROM LIBRARY** leaves *picture* unchanged.

## Example 1

The following example returns in *vgMyPicture* the picture whose reference number is stored in the local variable *$vlPicRef*:

```
GET PICTURE FROM LIBRARY($vlPicRef;vgMyPicture)
```

## Example 2

The following example returns in *$DDcom_Prot_MyPicture* the picture with the name "DDcom_Prot_Button1" stored in the Picture Library:

```
GET PICTURE FROM LIBRARY("DDcom_Prot_Button1";$DDcom_Prot_MyPicture)
```

## Example 3

See the third example for the **PICTURE LIBRARY LIST** command.

## System variables and sets

If the Picture Library exists, the **OK** variable is set to 1. Otherwise, **OK** is set to zero.

## Error management

If there is not enough memory to return the picture, an error -108 is generated. You can catch this error using an error-handling method.

# GET PICTURE KEYWORDS

GET PICTURE KEYWORDS ( picture ; arrKeywords {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture field, Picture variable | ⇒ | Picture for which to get associated keywords |
| arrKeywords | Text array | ⇐ | Array containing extracted keywords |
| * | Operator | ⇒ | If passed = use distinct values |

## Description

The **GET PICTURE KEYWORDS** command returns, in the *arrKeywords* array, the list of keywords associated with the picture passed as parameter.

Only keywords set using **IPTC/Keywords** metadata are taken into account. Other types of metadata are ignored by the command. The command only works with picture types that support this type of metadata (JPEG, TIFF, etc.).

**Note:** Metadata of the IPTC/Keywords type are now indexable in 4D (see the *Design Reference* manual).

If you pass the * parameter, the method only returns "distinct values" of keywords, in other words, a list with no duplicates.

If the picture does not contain keywords or IPTC/Keywords metadata, the command returns an empty array and no error is generated.

**Note:** Results returned by this command can differ according to the current value of the "Consider only non-alphanumeric chars for keywords" database setting (see the **Database/Data storage page**).

# GET PICTURE METADATA

GET PICTURE METADATA ( picture ; metaName ; metaContents {; metaName2 ; metaContents2 ; ... ; metaNameN ; metaContentsN} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ➡ | Picture whose metadata you want to get |
| metaName | Text | ➡ | Name or path of block to get |
| metaContents | Variable | ⬅ | Metadata contents |

## Description

The **GET PICTURE METADATA** command can be used to read the contents of the metadata (or meta-tags) found in *picture* (4D picture field or variable). For more information about metadata, please refer to the description of the **SET PICTURE METADATA** command.

In the *metaName* parameter, pass a string specifying the type of metadata to retrieve. You can pass:

- a constant from the **Picture Metadata Names** theme containing a tag path,
- the name of a complete block of metadata ("TIFF", "EXIF", "GPS" or "IPTC"),
- an empty string ("").

Pass the variable intended to receive the metadata in the *metaContents* parameter.

- If you passed a tag path in *metaName*, the *metaContents* parameter will directly contain the value to get. The value will be converted to the type of the variable. Variables of the Text type will be formatted in XML (XMP standard). You can pass an array when the metadata contains more than one value (this is the case, more particularly, for the IPTC Keywords tags).
- If you passed a block name or an empty string in *metaName*, the *metaContents* parameter must be a valid XML DOM element reference. In this case, the contents of the designated block (or all the blocks if you passed an empty string in *metaName*) is recopied into the element referenced.

## Example 1

Use of DOM tree structures

```
$xml:=DOM Create XML Ref("Root") //Creation of an XML DOM tree

 //Reception of TIFF metadata
$_Xml_TIFF:=DOM Create XML element($xml;"/Root/TIFF")
GET PICTURE METADATA(vPicture;"TIFF";$_Xml_TIFF)

 //Reception of GPS metadata
$_Xml_GPS:=DOM Create XML element($xml;"/Root/GPS")
GET PICTURE METADATA(vPicture;"GPS";$_Xml_GPS)
```

## Example 2

Use of variables

```
C_DATE($dateAsDate)
GET PICTURE METADATA(vPicture;TIFF date time;$dateAsDate)
 //only returns the date since $dateAsDate is of the Date type

C_TEXT($dateAsText)
GET PICTURE METADATA(vPicture;TIFF date time;$dateAsText)
 //only returns the date but in XML format

C_INTEGER($urgency)
GET PICTURE METADATA(vPicture;IPTC urgency;$urgency)
```

## Example 3

Reception of tags with multiple values in arrays

```
ARRAY TEXT($tTkeywords;0)
GET PICTURE METADATA(vPicture;IPTC keywords;$tTkeywords)
```

After execution of the command, arrTkeywords contains for example:

```
$arrTkeywords{1}="France"
$arrTkeywords{2}="Europe"
```

## Example 4

Reception of tags with multiple values in a Text variable

```
C_TEXT($vTwords;0)
GET PICTURE METADATA(vPicture;IPTC keywords;$vTwords)
```

After execution of the command, *vTwords* contains for example "France;Europe".

## System variables and sets

The *OK* system variable returns 1 if the retrieval of the metadata has proceeded correctly and 0 if an error occurs or if at least one of the tags is not found. In all cases, the any values that can be read are returned.

# Is picture file

Is picture file ( filePath {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| filePath | Text | ⇒ | File pathname |
| * | Operator | ⇒ | Validate data |
| Function result | Boolean | ⇐ | True = filePath designates a picture file; otherwise, False |

## Description

The **Is picture file** command tests the file designated by the *filePath* parameter and returns True if it is a valid picture file. The command returns False if the file is not of the picture type or if it is not found.

Pass the pathname of the picture file to be tested in the *filePath* parameter. The path must be expressed with the system syntax. You can pass an absolute pathname or a pathname relative to the database structure file. If you pass an empty string (""), the command returns False.

If you do not pass the * parameter, the command tests the file by looking for its extension among the list of available codecs. If you want to be able to test files without extensions or to carry out a more thorough verification, pass the * parameter. In this case, the command makes additional tests: it loads and inspects the file header and queries the codecs in order to validate the picture. This syntax slows command execution.

**Note:** The command returns True for PDF files under Windows and EMF files under Mac OS.

# PICTURE CODEC LIST

PICTURE CODEC LIST ( codecArray {; namesArray}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| codecArray | String array | ⇦ | IDs of available picture Codecs |
| namesArray | String array | ⇦ | Names of picture Codecs |
| * | Operator | ⇨ | Return list of reading (decoding) Codecs |

## Description

The **PICTURE CODEC LIST** command fills the *codecArray* array with the list of picture Codec IDs that are available on the machine where it is executed. This list includes the Codec IDs of picture formats that are managed natively by 4D.

The Codec IDs can be returned in the *codecArray* array in the following forms:

- As an extension (for example, ".gif")
- As a Mime type (for example, "image/jpeg")

**Compatibility note:** If QuickTime has been enabled in the database (see the **Pictures** section), 4-character QuickTime codes can also be returned (for example "PNTG").

The form returned by the command will depend on the way the Codec is recorded at the operating system level. The optional *namesArray* array can be used to retrieve the name of each Codec. These names are more explicit than the IDs. This array can be used, for example, to build and display a menu listing the available Codecs.

By default, if you do not pass the * parameter, the command returns only the Codecs that can be used to encode (write) pictures. These IDs can be used in the *format* parameter of the picture export commands **WRITE PICTURE FILE** and **PICTURE TO BLOB**.

If you pass the * parameter, the command also returns the list of codecs used for decoding (reading) the pictures. The two lists are not exclusive, certain reading and writing Codecs are identical. Codecs intended for encoding pictures may usually be used for decoding. On the other hand, decoding Codecs cannot necessarily be used for encoding. For example, the ".jpg" Codec will be found in both lists, whereas the ".xbmp" Codec will only be found in the list of reading (decoding) Codecs.

# PICTURE LIBRARY LIST

PICTURE LIBRARY LIST ( picRefs ; picNames )

| Parameter | Type | | Description |
|---|---|---|---|
| picRefs | Longint array | ⇦ | Reference numbers of the Picture Library graphics |
| picNames | String array | ⇦ | Names of the Picture Library graphics |

## Description

The **PICTURE LIBRARY LIST** command returns the reference numbers and names of the pictures currently stored in the Picture Library of the database.

After the call, you retrieve the reference numbers in the array *picRefs* and the names in the array *picNames*. The two arrays are synchronized: the nth element of *picRefs* is the reference number of the Picture Library graphic whose name is returned in the nth element of *picNames*.

If necessary, the command automatically creates and sizes the *picRefs* and *picNames* arrays.

The maximum length of a Picture Library graphic name is 255 characters.

If there are no pictures in the Picture Library, both arrays are returned empty.

To obtain the number of pictures currently stored in the Picture Library, use the **Size of array** command to get the size of one of the two arrays.

## Example 1

The following code returns the catalog of the Picture Library in the arrays *alPicRef* and *asPicName*:

```
PICTURE LIBRARY LIST(alPicRef;asPicName)
```

## Example 2

The following example tests whether or not the Picture Library is empty:

```
PICTURE LIBRARY LIST(alPicRef;asPicName)
If(Size of array(alPicRef)=0)
   ALERT("The Picture Library is empty.")
Else
   ALERT("The Picture Library contains "+String(Size of array(alPicRef))+" pictures.")
End if
```

## Example 3

The following example exports the Picture Library to a document on disk:

```
PICTURE LIBRARY LIST($alPicRef;$asPicName)
$vlNbPictures:=Size of array($alPicRef)
If($vlNbPictures>0)
   SET CHANNEL(12;"")
   If(OK=1)
      $vsTag:="4DV6PICTURELIBRARYEXPORT"
      SEND VARIABLE($vsTag)
      SEND VARIABLE($vlNbPictures)
      gError:=0
      For($vlPicture;1;$vlNbPictures)
         $vlPicRef:=$alPicRef{$vlPicture}
         $vsPicName:=$asPicName{$vlPicture}
         GET PICTURE FROM LIBRARY($alPicRef{$vlPicture};$vgPicture)
         If(OK=1)
            SEND VARIABLE($vlPicRef)
```

```
            SEND VARIABLE($vsPicName)
            SEND VARIABLE($vgPicture)
         Else
            $vlPicture:=$vlPicture+1
            gError:=-108
         End if
      End for
      SET CHANNEL(11)
      If(gError#0)
         ALERT("The Picture Library could not be exported, retry with more memory.")
         DELETE DOCUMENT(Document)
      End if
   End if
Else
   ALERT("The Picture Library is empty.")
End if
```

# PICTURE PROPERTIES

PICTURE PROPERTIES ( picture ; width ; height {; hOffset {; vOffset {; mode}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture for which to get information |
| width | Longint | ⇐ | Width of the picture expressed in pixels |
| height | Longint | ⇐ | Height of the picture expressed in pixels |
| hOffset | Longint | ⇐ | Horizontal offset when displayed on background |
| vOffset | Longint | ⇐ | Vertical offset when displayed on background |
| mode | Longint | ⇐ | Transfer mode when displayed on background |

## Description

The **PICTURE PROPERTIES** command returns information about the picture you pass in *picture*.

The *width* and *height* parameters return the width and height of the picture.

The *hOffset*, *vOffset*, and *mode* parameters return the horizontal and vertical positions and the transfer mode of the picture when displayed on the background in a form (“On Background”).

# Picture size

Picture size ( picture ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture for which to return the size in bytes |
| Function result | Longint | ⇐ | Size in bytes of the picture |

## Description

**Picture size** returns the size of *picture* in bytes.

# PICTURE TO BLOB

PICTURE TO BLOB ( picture ; pictureBlob ; codec )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture field or variable |
| pictureBlob | BLOB | ⇐ | BLOB to receive the converted picture |
| codec | String | ⇒ | Picture Codec ID |

## Description

The **PICTURE TO BLOB** command converts a picture stored in a 4D variable or field to another format and places the resulting picture in a BLOB.

A picture 4D field or variable is passed in the *picture* parameter. In the *pictureBlob* parameter is passed a BLOB variable or field which should contain the converted picture.

Pass in the *codec* parameter a string setting the conversion format.

A Codec can be an extension (for example, ".gif") or a Mime type (for example "image/jpeg"). You can get a list of available Codecs via the **PICTURE CODEC LIST** command.

Once the command has been executed, the *pictureBlob* contains the picture in the specified format.

If the conversion was successful, the system variable OK is set to 1. If the conversion has failed (converter not available), OK is set to 0 and the generated BLOB is empty (0 byte).

# PICTURE TO GIF

PICTURE TO GIF ( pict ; blobGIF )

| Parameter | Type | | Description |
|---|---|---|---|
| pict | Picture | ⇒ | Picture field or picture variable |
| blobGIF | BLOB | ⇐ | BLOB containing the GIF picture |

## Description

The **PICTURE TO GIF** command converts a PICT picture stored in a variable or in a 4D field into a GIF picture.

You pass a picture variable or a picture field in *pict* and a BLOB variable or a BLOB field in *blobGIF*. After executing the command, *blobGIF* contains the image in GIF format.

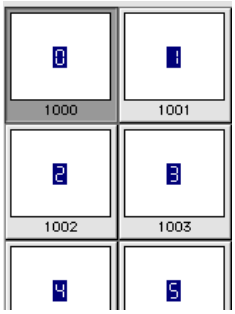
**Note:** The GIF picture format cannot contain more than 256 colors. If the original PICT picture contains more colors, some may be lost. The command reduces the number of colors according to the system palette. The GIF generated is of type 87a (opaque) and normal (not interlaced).

You can then save the picture located in *blobGIF* in a file using the **Windows Ctrl down** command or you can even publish it on the Web.

If the conversion was successful, the *OK* system variable is set to 1. Otherwise, it will be equal to 0.

## Example

Let us assume that you want to generate a GIF picture on the fly by displaying a connection counter. In the database's picture library, place all the numbers as pictures:



In the **On Web Connection Database Method**, you write the following code:

```
If(Web Context)
   ...
Else
   C_BLOB($blob)
   Case of
         ...
      :($1="/4dcgi/counter") `Generating a GIF counter
 `When 4D detects this URL while sending the static page
         $blob:=gifcounter(◊nbHits) `Calculates the GIF picture
 `The ◊nbHits variable contains the number of connections
         WEB SEND BLOB($blob;"image/gif")
 `Insert the picture and send it to the browser
         ...
   End case
End if
```

Here is the gifcounter method:

```
C_LONGINT($1)
C_PICTURE($img)
C_BLOB($0)
If($1=0)
   $ndigits:=1
Else
```

```
   $ndigits:=1+Length(String($1))
End if
If($ndigits<5)
   $ndigits:=5
End if

$div:=10^($ndigits-1)
For($i;1;$ndigits)
   $ref:=Int($1/$div)%10
   GET PICTURE FROM LIBRARY($ref+1000;picture)
   $img:=$img+picture
   $div:=$div/10
End for

PICTURE TO GIF($img;$0)
```

When sending a page to the Web browser, 4D displays a GIF picture that looks like the following picture:

## System variables and sets

If the conversion was successful, the *OK* system variable is set to 1. Otherwise, it will be equal to 0.

# READ PICTURE FILE

READ PICTURE FILE ( fileName ; picture {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ⇒ | Name or full pathname of the file to read, or empty string |
| picture | Picture | ⇐ | Field or variable receiving picture |
| * | Operator | ⇒ | If passed = accept any type of file |

## Description

The **READ PICTURE FILE** command opens the picture saved in the *fileName* disk file and loads it in the *picture* 4D field or variable.

You can pass in *fileName* the full pathname of the file to read, or a file name only. If you pass only the file name, it should be located next to the database structure file. Under Windows, the file extension must be indicated.
If an empty string ("") is passed in *fileName*, the standard Open file dialog box appears and the user selects the file to be read, as well as the available formats.

You can get the list of available formats using the **PICTURE CODEC LIST** command.

You pass in *picture* the picture variable or field which will receive the picture read.

**Note:** The internal picture format is stored within the 4D variable or field.

If you pass the optional * parameter, the command will accept any type of file. This means that you can work with pictures without necessarily having the suitable codecs (see the description of the **BLOB TO PICTURE** command).

## System variables and sets

If the command is executed successfully, the system variable Document contains the full pathname to the open file and the system variable OK is set to 1. Otherwise, OK is set to 0.

# REMOVE PICTURE FROM LIBRARY

REMOVE PICTURE FROM LIBRARY ( picRef | picName )

| Parameter | Type | | Description |
|---|---|---|---|
| picRef \| picName | Longint, String | ⇒ | Reference number of Picture Library graphic or Name of Picture Library graphic |

## Description

The **REMOVE PICTURE FROM LIBRARY** command removes from the Picture Library the picture whose reference number is passed in *picRef* or whose name is passed in *picName*.

If there is no picture with that reference number or name, the command does nothing.

**4D Server: REMOVE PICTURE FROM LIBRARY** cannot be used from within a method executed on the server machine (stored procedure or trigger). If you call **REMOVE PICTURE FROM LIBRARY** on a server machine, nothing happens—the call is ignored.

**Warning:** Design objects (hierarchical list items, menu items, etc.) may refer to Picture Library graphics. Use caution when deleting a Picture Library graphic programmatically.

## Example 1

The following example deletes the picture #4444 from the Picture Library.

```
REMOVE PICTURE FROM LIBRARY(4444)
```

## Example 2

The following example deletes from the Picture Library any pictures whose names begin with a dollar sign (*$*):

```
PICTURE LIBRARY LIST($alPicRef;$asPicName)
For($vlPicture;1;Size of array($alPicRef))
   If($asPicName{$vlPicture}="$@")
      REMOVE PICTURE FROM LIBRARY($alPicRef{$vlPicture})
   End if
End for
```

# SET PICTURE FILE NAME

SET PICTURE FILE NAME ( picture ; fileName )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture field, Picture variable | ⇒ | Picture for which to set the default name |
| fileName | Text | ⇒ | Default picture name |

## Description

The **SET PICTURE FILE NAME** command sets or changes the default file name for the picture passed as parameter.

This name may have been set automatically based on the original name of the picture file imported into the picture field or variable or during a prior call to **SET PICTURE FILE NAME**.

The default name is used as the file name when the picture is exported in a disk file. If the contents of the field are copied into a varaible or into another field, the default name is also copied. For more information, refer to the *Design Reference* manual.

# SET PICTURE METADATA

SET PICTURE METADATA ( picture ; metaName ; metaContents {; metaName2 ; metaContents2 ; ... ; metaNameN ; metaContentsN} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture whose metadata you want to set |
| metaName | Text | ⇒ | Name or path of block to set |
| metaContents | Variable | ⇒ | Metadata contents |

## Description

The **SET PICTURE METADATA** command lets you set or modify the contents of the metadata (or meta-tags) found in the *picture* (4D picture field or variable), when they are modifiable.

Metadata are additional information inserted into pictures. 4D lets you handled four types of standard metadata: EXIF, GPS, IPTC and TIFF.

**Note:** For a detailed description of these metadata types, you can consult the following documents: http://www.iptc.org/std/IIM/4.1/specification/IIMV4.1.pdf (IPTC) and http://exif.org/Exif2-2.PDF (TIFF, EXIF and GPS).

In the *metaName* parameter, pass a string specifying the type of metadata to set or modify. You can pass:

- one of the constants from the **Picture Metadata Names** theme. This theme groups together all the tags supported by 4D. Each constant contains a tag path (for example, "TIFF/DateTime"),
- the name of a complete block of metadata ("TIFF", "EXIF", "GPS" or "IPTC"),
- an empty string ("").

Pass the new values of the metadata in the *metaContents* parameter:

- If you passed a tag path constant in *metaName*, in the contents parameter you can pass the value to set directly or one of the appropriate constants from the **Picture Metadata Values** theme. The value can be of the Text, Longint, Real, Date or Time type, according to the metadata specified. You can use an array if the metadata contains more than one value. If you pass a string, it must be formated in XML (XMP standard). You can pass an empty string ("") in order to erase any existing metadata.
- If you passed a block name or an empty string in *metaName*, in the *metaContents* parameter you can pass the XML DOM reference of the element containing the metadata to set. In the case of an empty string, all the metadata will be modified.

**Warning:** Certain metadata are read only and therefore cannot be modified by the **SET PICTURE METADATA** command, for example TIFF XResolution/TIFF YResolution, EXIF Color Space or EXIF Pixel X Dimension/EXIF Pixel Y Dimension.

Under Windows, if an error occurs during execution of the command, the *OK* variable is set to 0. Note that under Mac OS, for technical reasons, metadata writing errors are not detected. Therefore this command does not modify the *OK* variable under Mac OS.

**Notes:**

- Only certain picture formats (more specifically, JPEG and TIFF) support metadata. Conversely, formats such as GIF or BMP do not accept metadata. When you convert a picture with metadata to a format that does not support it, then information is lost.
- Under OS X version 10.7 (Lion), a bug in the native framework used for encoding and decoding picture metadata may cause inaccuracies in GPS coordinates. In this case, updating to OS X 10.8 (Mountain Lion) or 10.9 (Maverick) is strongly recommended.

## Example 1

Setting several values of the "Keywords" metadata via arrays:

```
ARRAY TEXT($arrTkeywords;2)
$arrTkeywords{1}:="France"
$arrTkeywords{2}:="Europe"
SET PICTURE METADATA(vPicture;IPTC keywords;$arrTkeywords)
```

## Example 2

Setting of GPS block via a DOM reference:

```
C_TEXT($domMetas)
$domMetas:=DOM Parse XML source("metas.xml")
C_TEXT($gpsRef)
$gpsRef:=DOM Find XML element($domMetas;"Metadatas/GPS")
If(OK=1)
   SET PICTURE METADATA(vImage;"GPS";$refGPS)
 //here $gpsRef actually points to the GPS element
   ...
End if
DOM CLOSE XML($domMetas)
```

## Note

When all the metadata are handled via a DOM element reference, the tags are stored as attributes attached to an element (a child of the referenced element) whose name is the block name (TIFF, IPTC, etc.). When a specific metadata block is manipulated, the block tags are stored as attributes that are directly attached to the element referenced by the command.

# SET PICTURE TO LIBRARY

SET PICTURE TO LIBRARY ( picture ; picRef ; picName )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ➡ | New picture |
| picRef | Longint | ➡ | Reference number of Picture Library graphic |
| picName | String | ➡ | New name of the picture |

## Description

The **SET PICTURE TO LIBRARY** command creates a new picture or replaces a picture in the Picture Library.

Before the call, you pass:

- the picture reference number in *picRef* (range 1...32767 )
- the picture itself in *picture*.
- the name of the picture in *picName* (maximum length: 255 characters).

If there is an existing Picture Library graphic with the same reference number, the picture contents are replaced and the picture is renamed according to the values passed in *picture* and *picName.*

If there is no Picture Library graphic with the reference number passed in *picRef*, a new picture is added to the Picture Library.

**4D Server: SET PICTURE TO LIBRARY** cannot be used from within a method executed on the server machine (stored procedure or trigger). If you call **SET PICTURE TO LIBRARY** on a server machine, nothing happens—the call is ignored.

**Warning:** Design objects (hierarchical list items, menu items, etc.) may refer to Picture Library graphics. Use caution when modifying a Picture Library graphic programmatically.

**Note:** If you pass an empty picture in *picture* or a negative or null value in *picRef*, the command does nothing.

## Example 1

No matter what the current contents of the Picture Library, the following example adds a new picture to the Picture Library by first looking for a unique picture reference number:

```
PICTURE LIBRARY LIST($alPicRef;$asPicNames)
Repeat
   $vlPicRef:=1+Abs(Random)
Until(Find in array($alPicRef;$vlPicRef)<0)
SET PICTURE TO LIBRARY(vgPicture;$vlPicRef;"New Picture")
```

## Example 2

The following example imports into the Picture Library the pictures (stored in a document on disk) created by the third example for the command **PICTURE LIBRARY LIST**:

```
SET CHANNEL(10;"")
If(OK=1)
   RECEIVE VARIABLE($vsTag)
   If($vsTag="4DV6PICTURELIBRARYEXPORT")
      RECEIVE VARIABLE($vlNbPictures)
      If($vlNbPictures>0)
         For($vlPicture;1;$vlNbPictures)
            RECEIVE VARIABLE($vlPicRef)
            If(OK=1)
               RECEIVE VARIABLE($vsPicName)
            End if
            If(OK=1)
               RECEIVE VARIABLE($vgPicture)
            End if
```

```
            If(OK=1)
               SET PICTURE TO LIBRARY($vgPicture;$vlPicRef;$vsPicName)
            Else
               $vlPicture:=$vlNbPictures+1
               ALERT("This file looks like being damaged.")
            End if
         End for
      Else
         ALERT("This file looks like being damaged.")
      End if
   Else
      ALERT("The file  ""+Document+""  is not a Picture Library export file.")
   End if
   SET CHANNEL(11)
   End
```

## Error management

If there is not enough memory to add the picture to the Picture Library, an error -108 is generated. Note that I/O errors may also be returned (i.e., the structure file is locked). You can catch these errors using an error-handling method.

# TRANSFORM PICTURE

TRANSFORM PICTURE ( picture ; operator {; param1 {; param2 {; param3 {; param4}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Source picture to be transformed |
| | | ⇐ | Resulting picture after transformation |
| operator | Longint | ⇒ | Type of transformation to be done |
| param1 | Real | ⇒ | Transformation parameter |
| param2 | Real | ⇒ | Transformation parameter |
| param3 | Real | ⇒ | Transformation parameter |
| param4 | Real | ⇒ | Transformation parameter |

## Description

The **TRANSFORM PICTURE** command applies a transformation of the *operator* type to the picture passed in the *picture* parameter.

**Note:** This command extends the functionalities offered by conventional picture transformation operators (+/, etc., see the **Picture Operators** section*)*. These operators remain entirely usable in 4D.

The source *picture* is modified directly after execution of the command. Note that certain operations are not destructive and can be reversed by performing the opposite operation or by means of the “Reset” operation. For example, a picture reduced to 1% will regain its original size with no alteration if it is enlarged by a factor of 100 subsequently. Transformations do not modify the original picture type: for example, a vectorial picture will remain vectorial after its transformation.

In *operator*, pass the number of the operation to be carried out and in *param*, the parameter(s) needed for this operation (the number of parameters depends on the operation). You can use one of the constants of the "**Picture Transformation**" theme in *operator*. These operators and their parameters are described in the following table:

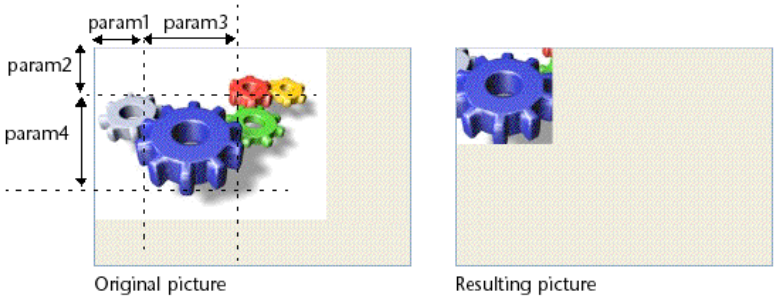
| operator (value) | param1 | param2 | param3 | param4 | Values | Cancellable |
|---|---|---|---|---|---|---|
| Reset (0) | - | - | - | - | - | - |
| Scale (1) | Width | Height | - | - | Factors | Yes |
| Translate (2) | X axis | Y axis | - | - | Pixels | Yes |
| Flip horizontally (3) | - | - | - | - | | Yes |
| Flip vertically (4) | - | - | - | - | | Yes |
| Crop (100) | X Orig. | Y Orig. | Width | Height | Pixels | No |
| Fade to grey scale (101) | - | - | - | - | | No |
| Transparency (102) | RGB color | - | - | - | Hexadecimal | No |

- Reset: All matrix operations carried out on the picture (scale, flip, and so on) are undone.
- Scale: The picture is resized horizontally and vertically according to the values passed respectively in *param1* and *param2*. These values are factors: for example, to enlarge the width by 50%, pass 1.5 in *param1* and to reduce the height by 50%, pass 0.5 in *param2*.
- Translate: The picture is moved by *param1* pixels horizontally and by *param2* pixels vertically. Pass a positive value to move to the right or towards the bottom and a negative value to move to the left or towards the top.
- Flip horizontally and Flip vertically: The original picture is flipped. Any movement that was carried out beforehand will not be taken into account.
- Crop: The picture is cropped starting from the point of the *param1* and *param2* coordinates (expressed in pixels). The width and height of the new picture is determined by the *param3* and *param4* parameters. This transformation cannot be undone.
- Fade to grey scale: The picture is switched to gray scale (no parameter is required). This transformation cannot be undone.
- Transparency: A transparency mask is applied to the picture based on the color passed in *param1*. For example, if you pass 0x00FFFFFF (white color) in *param1*, all the white pixels in the original picture will be transparent in the transformed picture. This operation can be applied to bitmap or vector pictures. By default, if the *param1* parameter is omitted, the color white (0x00FFFFFF) is set as the target color. This function is specially designed to handle transparency in pictures converted from the deprecated PICT format pictures, but can be used with pictures of any type. This transformation cannot be undone.

## Example 1

Here is an example of cropping a picture (the picture is displayed in the form with the “Truncated (non-centered)” format):

```
TRANSFORM PICTURE($vpGears;Crop;50;50;100;100)
```

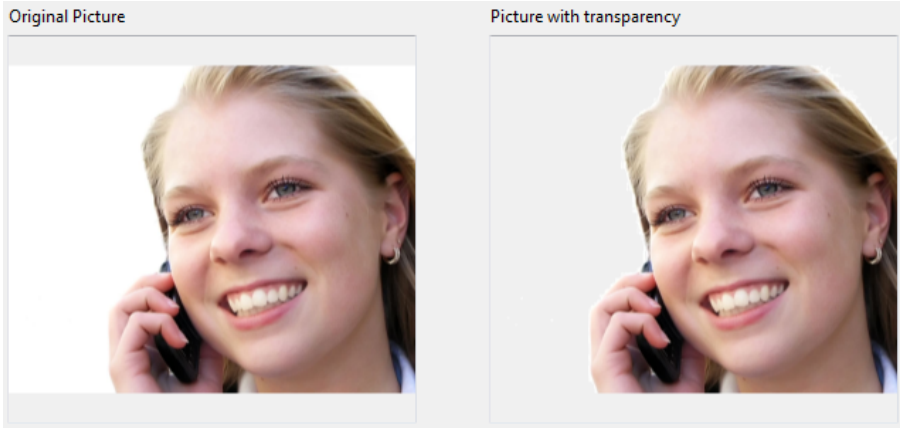


## Example 2

You want to set the white parts of a picture to transparent. To do this, you can use the following code:

```
TRANSFORM PICTURE(Pict1;Transparency;0x00FFFFFF) //0x00FFFFFF is white
```

You will get the following result:



# WRITE PICTURE FILE

WRITE PICTURE FILE ( fileName ; picture {; codec} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | Alpha | ⇒ | Name or full pathname of the file to write, or empty string |
| picture | Picture | ⇒ | Picture field or variable to write |
| codec | String | ⇒ | Picture Codec ID |

## Description

The **WRITE PICTURE FILE** command saves the picture passed in the *picture* parameter in the defined *codec* to disk.

You can pass in *fileName* the full pathname to the file to create, or a file name only. If you just pass the file name, the file will be located next to the database structure file. The file extension has to be indicated.

If an empty string ("") is passed in *fileName*, the standard Save file dialog box is displayed and the user can indicate the name, location and format of the file to create. If a default name is associated with the Picture field, it is provided in the dialog box (see the **SET PICTURE FILE NAME** command).

You will pass in *picture* the picture variable or field which contains the picture to save on disk.

The optional *codec* parameter can be used to define the format in which the picture will be saved. A Codec can be an extension (for example, ".gif") or a Mime type (for example "image/jpeg"). You can get a list of available Codecs via the **PICTURE CODEC LIST** command.

If you omit the *codec* parameter, the command will attempt to determine the codec based on the extension of the file name passed in the *fileName* parameter. For example, if you pass the statement:

```
WRITE PICTURE FILE("c:¥folder¥photo.jpg";myphoto)
```

... the command will use the JPEG codec to store the picture.
If the extension used does not correspond to any available codec, the file is not saved and the OK system variable is set to 0. If you do not pass a *codec* or a file extension, the picture file is saved in PICT format.

**Note:** If the write format of the *picture* (indicated via the extension of *fileName* or the *codec* parameter) is the same the as its original type and if no transformation operation has been applied to it, the picture is written "as is", without any modification.

If the command is executed successfully, the system variable Document contains the full pathname to the file created and the system variable OK is set to 1. Otherwise, OK is set to 0.

# _o_PICTURE TYPE LIST

_o_PICTURE TYPE LIST ( formatArray {; nameArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| formatArray | String array | ⇦ | QuickTime codes for the available import/export formats |
| nameArray | String array | ⇦ | Format names |

## Compatibility Note:

This command requires QuickTime and does not provide access to formats managed natively by 4D since version 11. It is thus of limited interest and can be replaced favorably by the **PICTURE CODEC LIST** command.

# _o_QT COMPRESS PICTURE

_o_QT COMPRESS PICTURE ( picture ; method ; quality )

| Parameter | Type | | Description |
|---|---|---|---|
| picture | Picture | ⇒ | Picture to be compressed |
| | | ⇐ | Compressed picture |
| method | String | ⇒ | 4-character string compression method |
| quality | Longint | ⇒ | Compression quality (1..1000) |

## Compatibility note

This command calls for obsolete mechanisms and must be replaced by the **CONVERT PICTURE** command.

# _o_QT COMPRESS PICTURE FILE

_o_QT COMPRESS PICTURE FILE ( document ; method ; quality )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Document reference number |
| method | String | ⇒ | 4-character string compression method |
| quality | Longint | ⇒ | Compression quality (1..1000) |

## Compatibility note

This command calls for obsolete mechanisms and must now be replaced by the **WRITE PICTURE FILE** or **PICTURE TO BLOB** commands.

# _o_QT LOAD COMPRESS PICTURE FROM FILE

_o_QT LOAD COMPRESS PICTURE FROM FILE ( document ; method ; quality ; picture )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Document reference number |
| method | String | ⇒ | 4-character string compression method |
| quality | Longint | ⇒ | Compression quality (1..1000) |
| picture | Picture | ⇐ | Compressed picture |

## Compatibility note

This command calls for obsolete mechanisms and must now be replaced by the **READ PICTURE FILE** and **CONVERT PICTURE** commands.

# _o_SAVE PICTURE TO FILE

_o_SAVE PICTURE TO FILE ( document ; picture )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Document reference number |
| picture | Picture | ⇒ | Picture to be saved |

## Compatibility note

This command calls for obsolete mechanisms and is only kept for compatibility reasons. It has been favorably replaced by the **WRITE PICTURE FILE** command.

# Printing

- Integration of PDFCreator driver under Windows
- ACCUMULATE
- BLOB to print settings New 16.0
- BREAK LEVEL
- CLOSE PRINTING JOB

- Print settings to BLOB New 16.0
- PRINTERS LIST Updated 16.0
- Printing page
- SET CURRENT PRINTER
- SET PRINT MARKER
- SET PRINT OPTION Updated 16.0
- SET PRINT PREVIEW
- SET PRINTABLE MARGIN
- Subtotal

# Integration of PDFCreator driver under Windows

Support for PDF printing differs depending on the version of Windows:

- for Windows 8 and previous versions, you need to use the PDFCreator driver.
- starting with Windows 10, a native Microsoft driver is integrated.

**Note:** Under Mac OS, PDF printing is supported natively by the system.

## Windows 8 and previous versions

The support of PDF printing under Windows relies on the PDFCreator driver to offer simple and functional PDF printing functions. The **GET PRINT OPTION** and **SET PRINT OPTION** commands both make use of this driver.

PDFCreator is a free driver (OpenSource) governed by the AFPL (Aladdin Free Public License). To use the PDFCreator driver, you must download the appropriate version and install it in your environment. (It is not installed by default by 4D.) You must have Administrator access rights in order to install the driver. You can download PDFCreator here:
http://sourceforge.net/projects/pdfcreator/files/PDFCreator/

**Warning:** you must use a PDFCreator version that is **compatible with 4D**. To find out the compatible and certified versions of PDFCreator, please consult the certification matrices of 4D products, found on the **Resources page** (**Compatibility section**) of the 4D Web site.

During installation, a new virtual printer named "PDFCreator" by default is installed in your system. You can change this name if desired.

## Starting with Windows 10

Windows 10 includes a native PDF driver which allows 4D to create PDFs directly without needing to use a third-party driver like PDFCreator.

The driver name is "Microsoft Print to PDF".

Here is an example of creating a PDF document under Windows 10 using 4D print commands:

```
$pdfpath:=System folder(Desktop)+"test.pdf"

$pdfprintername:="Microsoft Print to PDF"
ARRAY TEXT($name1;0)
PRINTERS LIST($name1)
If(Find in array($name1;$pdfprintername)>0)
   SET CURRENT PRINTER($pdfprintername)
   SET PRINT OPTION(Destination option;2;$pdfpath)
   ALL RECORDS([Table_1])
   PRINT SELECTION([Table_1];*)
   SET CURRENT PRINTER("")
End if
```

# ACCUMULATE

ACCUMULATE ( data {; data2 ; ... ; dataN} )

| Parameter | Type | | Description |
|---|---|---|---|
| data | Field, Variable | ⇨ | Numeric field or variable on which to accumulate |

## Description

**ACCUMULATE** specifies the fields or variables to be accumulated during a form report performed using **PRINT SELECTION**.

You **must** execute **BREAK LEVEL** and **ACCUMULATE** before every report for which you want to do break processing. These commands activate break processing for a report. See the explanation for the **Subtotal** command.

Use **ACCUMULATE** when you want to include subtotals for numeric fields or variables in a form report. **ACCUMULATE** tells 4D to store subtotals for each of the Data arguments. The subtotals are accumulated for each break level specified with the **Subtotal** command.

Execute **ACCUMULATE** before printing the report with **PRINT SELECTION**.

Use the **Subtotal** function in the form method or an object method to return the subtotal of one of the *data* arguments.

## Example

See the example for the **BREAK LEVEL** command.

# BLOB to print settings

BLOB to print settings ( printSettings {; params} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| printSettings | BLOB | ⇒ | BLOB containing print settings |
| params | Longint | ⇒ | 0=Restore saved values for number of copies and page range, 1=Reset to default values |
| Function result | Longint | ⇐ | Status code: 1=Operation successful, 0=No current printer, -1=Incorrect parameters, 2=Printer changed |

## Description

The **BLOB to print settings** command replaces the current 4D print settings with the parameters stored in the *printSettings* BLOB. This BLOB must have been generated by the **Print settings to BLOB** command or the **_o_AP Print settings to BLOB** 4D Pack command (see below).

The *params* parameter allows you to define how to handle the basic "number of copies" and "page range" settings:

- If you pass 0 or omit this parameter, the values stored in the BLOB are restored,
- If you pass 1, the values are reset to default: the number of copies is set to 1 and the page range is set to "all pages".

The print settings are applied to the current printer and for the whole session, as long as no command such as **PAGE SETUP**, **SET PRINT OPTION** or **PRINT SELECTION** without the > parameter modifies them. The parameters set are used more particularly by the **PRINT SELECTION**, **PRINT LABEL**, **PRINT RECORD**, **Print form** and **QR REPORT** commands, as well as by the menu commands of 4D, including those of the Design environment.

The **PRINT SELECTION**, **PRINT LABEL**, and **PRINT RECORD** commands must be called with the > parameter (if applicable) in order for the settings defined by **BLOB to print settings** to be kept.

The command returns one of the following status codes:

- -1: the BLOB is incorrect,
- 0: no current printer is selected (in this case the command does nothing),
- 1: the BLOB has been correctly loaded,
- 2: the BLOB has been correctly loaded but the current printer name has changed(*).
  **Note:** Code (2) is always returned if the BLOB was created by the **_o_AP Print settings to BLOB** 4D Pack command, even if the printer name did not actually change, since this information was not included in the 4D Pack BLOBs.

(*) Settings depend on the currently selected printer at the moment the BLOB was saved. Applying these settings to a another printer is supported if both printers are of the same model. If the printers are different, only common parameters will be restored.

### Windows / OS X

The *printSettings* BLOB can be saved and read on both platforms. However, even if some print settings are common, some others are platform-specific and depend on the drivers and system versions. If the same *printSettings* BLOB is shared between both platforms, you may lose parts of the information.
When used in a heterogeneous environment, in order to restore the maximum settings available for each platform (and not only the common part), it is recommended that you work with two *printSettings* BLOBs, one for each platform.

### Compatibility with 4D Pack commands

The print settings BLOBs generated by the legacy **_o_AP Print settings to BLOB** command from 4D Pack can be loaded and used by the **BLOB to print settings** command. Note however that if they are saved using **Print settings to BLOB**, they are converted and can no longer be opened using **_o_AP BLOB to print settings**. The **BLOB to print settings** command stores much more printing information than **_o_AP Print settings to BLOB**.

## Example

You want to apply print settings previously saved to disk to the current 4D printing context:

```
C_BLOB(curSettings)
DOCUMENT TO BLOB(Get 4D folder(Active 4D Folder)+"current4Dsettings.blob";curSettings)
 //current4Dsettings has been created by Print settings to BLOB
$err:=BLOB to print settings(curSettings;0)
```

```
Case of
   :($err=1)
 //everything is OK
   :($err=2)
      CONFIRM("Printer has changed!¥n¥nCheck the print settings?")
      If(OK=1)
         PRINT SETTINGS
      End if
   :($err=0)
      ALERT("There is no current printer.")
   :($err=-1)
      ALERT("Invalid settings file.")
End case
```

# BREAK LEVEL

BREAK LEVEL ( level {; pageBreak} )

| Parameter | Type | | Description |
|---|---|---|---|
| level | Longint | ⇒ | Number of break levels |
| pageBreak | Longint | ⇒ | Break level for which to do a page break |

## Description

**BREAK LEVEL** specifies the number of break levels in a report performed using **PRINT SELECTION**.

You **must** execute **BREAK LEVEL** and **ACCUMULATE** before every report for which you want to do break processing. These commands activate break processing for a report. See the explanation for the **Subtotal** command.

The *level* parameter indicates the deepest level for which you want to perform break processing. You must have sorted the records with at least that many levels. If you have sorted more levels, those levels will be printed as sorted, but will not be processed for breaks.

Each break level that is generated will print the corresponding Break areas and Header areas in the form. There should be at least as many Break areas in the form as the number you pass in *level*. If there are more Break areas, they will be ignored and will not be printed.

The second, optional, argument, *pageBreak*, is used to cause page breaks during printing.

## Example

The following example prints a report with two break levels. The selection is sorted on four levels, but the **BREAK LEVEL** command specifies to break on only two levels. One field is accumulated with the **ACCUMULATE** command:

```
ORDER BY([Emp]Dept;>;[Emp]Title;>;[Emp]Last;>;[Emp]First;>) ` Sort on four levels
BREAK LEVEL(2) ` Turn on break processing to 2 levels (Dept and Title)
ACCUMULATE([Emp]Salary) ` Accumulate the salaries
FORM SET OUTPUT([Emp];"Dept salary") ` Select the report form
PRINT SELECTION([Emp]) ` Print the report
```

# CLOSE PRINTING JOB

CLOSE PRINTING JOB
Does not require any parameters

## Description

The **CLOSE PRINTING JOB** command closes the print job previously opened by the **OPEN PRINTING JOB** command and sends any printing document that has been assembled to the current printer.

Once this command is executed, the printer again becomes available for other print jobs.

# Get current printer

Get current printer -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String |  | Name of the current printer |

## Description

The **Get current printer** command returns the name of the current printer defined in the 4D application. By default, on start-up of 4D, the current printer is the printer defined in the system.

If the current printer is managed using a print server (spooler), the complete access path (under Windows) or the name of the spooler (under Mac OS) is returned.

To obtain the list of available printers as well as additional information, use the **PRINTERS LIST** command. To modify the current printer, use the **SET CURRENT PRINTER** command.

**Note:** When the Generic PDF driver constant is used with **SET CURRENT PRINTER**, **Get current printer** returns "_4d_pdf_printer" or the actual name of the PDF driver, if applicable (option not available with 4D 32-bit).

## System variables and sets

If no printer is installed, the system variable OK is set to 0. Otherwise, it is set to 1.

# Get print marker

Get print marker ( markNum ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| markNum | Longint | ⇒ | Marker number |
| Function result | Longint | ⇐ | Position of the marker |

## Description

The **Get print marker** command enables you to get the current position of a marker during printing.

This command can be used in two contexts:

- During the On Header form event, in the context of **PRINT SELECTION** and **PRINT RECORD** commands.
- During the On Printing Detail form event, in the context of the **Print form** command.

The coordinates are returned in pixels (1 pixel = 1/72 inch).

Pass one of the constants of the **Form Area** theme in the *markNum* parameter:

| Constant | Type | Value |
|---|---|---|
| Form break0 | Longint | 300 |
| Form break1 | Longint | 301 |
| Form break2 | Longint | 302 |
| Form break3 | Longint | 303 |
| Form break4 | Longint | 304 |
| Form break5 | Longint | 305 |
| Form break6 | Longint | 306 |
| Form break7 | Longint | 307 |
| Form break8 | Longint | 308 |
| Form break9 | Longint | 309 |
| Form detail | Longint | 0 |
| Form footer | Longint | 100 |
| Form header | Longint | 200 |
| Form header1 | Longint | 201 |
| Form header10 | Longint | 210 |
| Form header2 | Longint | 202 |
| Form header3 | Longint | 203 |
| Form header4 | Longint | 204 |
| Form header5 | Longint | 205 |
| Form header6 | Longint | 206 |
| Form header7 | Longint | 207 |
| Form header8 | Longint | 208 |
| Form header9 | Longint | 209 |

## Example

Refer to the example of the **SET PRINT MARKER** command.

# GET PRINT OPTION

GET PRINT OPTION ( option ; value1 {; value2} )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇨ | Option number or PDF option code |
| value1 | Longint, Text | ⇦ | Value 1 of the option |
| value2 | Longint, Text | ⇦ | Value 2 of the option |

## Description

The **GET PRINT OPTION** command returns the current value(s) of a print option.

The *option* parameter enables you to specify the option to get. You can either get a standard option (longint), or a PDF option code (string). The command returns, in the *value1* and (optionally) *value2* parameters, the current value(s) of the specified *option*.

To specify a standard printing option, you can use of the following predefined constants, located in the "**Print Options**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Paper option | Longint | 1 | If you use only *value1*, it contains the name of the paper. If you use both parameters, *value1* contains the paper width and *value2* contains the paper height. The width and height are expressed in screen pixels. Use the **PRINT OPTION VALUES** command to get the name, height and width of all the paper formats offered by the printer. |
| Orientation option | Longint | 2 | *value1* only: 1=Portrait, 2=Landscape. If a different orientation option is used, **GET PRINT OPTION** returns 0 in *value1*.<br>**64-bit versions**: This option can be called within a print job, which means that you can switch from portrait to landscape, or vice versa, during the same print job. |
| Scale option | Longint | 3 | *value1* only: scale value in percentage. Be careful, some printers do not allow you to modify the scale. If you pass an invalid value, the property is reset to 100% at the time of printing. |
| Number of copies option | Longint | 4 | *value1* only: number of copies to be printed. |
| Paper source option | Longint | 5 | (Windows only) *value1* only: number corresponding to the index, in the array of trays returned by the **PRINT OPTION VALUES** command, of the paper tray to be used. This option can only be used under Windows. |
| Color option | Longint | 8 | (Windows only) *value1* only: code specifying the mode for handling color: 1=Black and white (monochrome), 2=Color.<br>**64-bit versions**: This option is not supported in 4D 64-bit versions (obsolete) |
| Destination option | Longint | 9 | *value1*: code specifying the type of print destination: 1=Printer, 2=(PC)/PS File (Mac), 3=PDF file, 5=Screen (OS X driver option).<br>If *value1* is different from 1 or 5, *value2* contains pathname for resulting document. This path will be used until another path is specified. If a file with the same name already exists at the destination location, it will be replaced. With **GET PRINT OPTION**, if the current value is not in the predefined list, *value1* contains -1 and the system variable OK is set to 1. If an error occurs, *value1* and the system variable OK are set to 0.<br>**Note**: Under Windows, you can set the printing destination to 3 (PDF File) when the PDF Creator driver has been installed. When the *(9;3;path)* values are passed, 4D automatically starts a "silent" PDF printing which takes into account any option codes that are passed (note that if you pass an empty string in *value2* or omit this parameter, a file saving dialog appears at the time of printing.) After printing, the current settings are restored. This simplifies control of printing PDFs for 4D and lets you write multi-platform code. When the *(9;3;path)* values are not passed, printing is not controlled by 4D and any PDF Creator option codes that were passed are ignored. |
| Double sided option | Longint | 11 | (Windows only) *value1*: 0=Single-sided or standard, 1=Double-sided. If *value1*=1, *value2* contains the binding: 0=Left binding (default value), 1=Top binding.<br>**Note:** This option can only be used under Windows. |
| Spooler document name option | Longint | 12 | *value1* only: name of the current print document, which appears in the list of spooler documents. The name defined by this statement will be used for all the print documents of the session for as long as a new name or an empty string is not passed. To use or restore standard operation (using the method name in the case of a method, the table name for a record, etc.), pass an empty string in *value1*. |
| Mac spool file format option | Longint | 13 | (Mac only) *value1* only: 0=print job in PDF mode (default value) 1=print job in PostScript mode.<br>**Notes:**<br>- This option has no effect under Windows.<br>- Under OS X, printing is done as a PDF by default. However, the PDF print driver does not support PICT pictures with encapsulated PostScript information — these pictures are generated, more particularly, by vectorial drawing software. To avoid this problem, this option lets you modify the print mode to use under OS X for the current session. Keep in mind that printing in PostScript mode can lead to undesired side effects.<br>**64-bit versions:** This option is not supported; it is replaced by the Generic PDF driver option of the **SET CURRENT PRINTER** command. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Hide printing progress option | Longint | 14 | *value1* only: 1=hide progress windows, 0=display progress windows (default). This option is particularly useful in the case of PDF printing under OS X.<br>**Note:** There is already a Printing progress option found in the Database Settings dialog box (Interface page). However, it is applied globally to the application and does not hide all the windows under OS X. |
| Page range option | Longint | 15 | *value1*=first page to print (default value is 1) and (optional) *value2*=number of the last page to print (default value -1 = end of document). |
| Legacy printing layer option | Longint | 16 | (4D 64-bit versions for Windows only) *value1* only: 1=select the GDI-based legacy printing layer for the subsequent printing jobs. 0=select the D2D printing layer (default).<br>**64-bit versions:** This selector is only supported on 4D 64-bit single-user applications on Windows; it is ignored on other platforms. It is mainly intended to allow legacy plug-ins to print inside 4D jobs in 4D 64-bit applications. |

A PDF option code consists of two parts, *OptionType* and *OptionName*, combined together as "*OptionType:OptionName*". For more information on PDF option codes and possible values, refer to the description of the **SET PRINT OPTION** command.

**Note:** The **GET PRINT OPTION** command mainly supports PostScript printers. You can use this command with other types of printers, such as PCL or Ink, but in this case, it is possible that some options may not be available.

## System variables and sets

The system variable OK is set to 1 if the command has been executed correctly; otherwise, it is set to 0.

# Get print preview

Get print preview -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean |  | True = Print preview,<br>False = No print preview |

## Description

The **Get print preview** command returns True if the **SET PRINT PREVIEW** command was called with the **True** value in the current process.

Note that the user can modify this option before validating the dialog box. To get the final printing mode, you must use the **Is in print preview** command.

# GET PRINTABLE AREA

GET PRINTABLE AREA ( height {; width} )

| Parameter | Type | | Description |
|---|---|---|---|
| height | Longint | ⇐ | Height of printable area |
| width | Longint | ⇐ | Width of printable area |

## Description

The **GET PRINTABLE AREA** command returns the size, in pixels, of the *height* and *width* parameters of the printable area. This size depends on the current printing parameters, the paper orientation, etc.

The sizes returned do not vary from one page to another (after a page break, for instance).

Associated with the **Get printed height** command, this command is useful for knowing the number of pixels available for printing or for centering an object on the page.

**Note:** For more information regarding Printing management and terminology in 4D, refer to the **GET PRINTABLE MARGIN** command description.

To know the total size of the page, you can:

- either add the margins supplied by the **GET PRINTABLE MARGIN** command to the values returned by this command.
- or use the following syntax:

```
SET PRINTABLE MARGIN(0;0;0;0) ` Set the paper margin
GET PRINTABLE AREA(hPaper;wPaper) ` Paper size
```

# GET PRINTABLE MARGIN

GET PRINTABLE MARGIN ( left ; top ; right ; bottom )

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇦ | Left margin |
| top | Longint | ⇦ | Top margin |
| right | Longint | ⇦ | Right margin |
| bottom | Longint | ⇦ | Bottom margin |

## Description

The **GET PRINTABLE MARGIN** command returns the current values of the different margins defined using the **Print form**, **PRINT SELECTION** and **PRINT RECORD** commands.

The values are returned in pixels with respect to the paper edges.

It is possible to obtain the paper size as well as to calculate the printable area using the **GET PRINTABLE AREA** function.

### About Printable Margin Management

By default, the printing calculation in 4D is based on “printable margins”. The advantage of this system is that the forms adapt themselves automatically to the new printers (since they are positioned in the printable area). On the other hand, in the case of pre-printed forms, it was not possible to position the elements to be printed precisely because changing the printer can modify the printable margins.

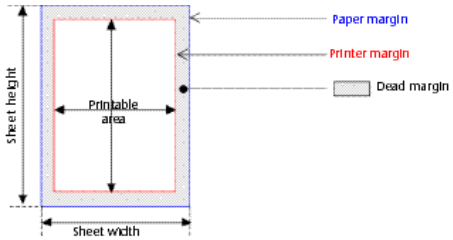
It is possible to base the form printing carried out using the **Print form**, **PRINT SELECTION** and **PRINT RECORD** commands on a fixed margin which is identical on each printer: the paper margins, i.e. the physical limits of the sheet. To do this, simply use the **GET PRINTABLE MARGIN**, **SET PRINTABLE MARGIN** and **GET PRINTABLE AREA** commands.

## About Printing Terminology

**Paper margin**: the paper margin corresponds to the physical limits of the sheet.

**Printer margin**: the printer margin is the margin beyond which the printer is incapable of printing (for material reasons: print rollers, printer head end-of-travel...). It varies from one printer to another and from one format to another.

**Dead margin**:this refers to the area located between the paper margin and the printer margin.



# Get printed height

Get printed height -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint |  | Position of the marker |

## Description

The **Get printed height** command returns the overall height (in pixels) of the section printed using the **Print form** command.

The value returned will be included between 0 (the top edge of the page) and the overall height returned by the **GET PRINTABLE AREA** command (the maximum size of the printable area).

If you print a new section using the **Print form** command, the height of the new section is added to this value. If the printable area available is insufficient to contain this section, a new page is generated and the value returned is 0.

The right and left printable margins, unlike the top and bottom margins (which may be defined using the **SET PRINTABLE MARGIN** command), do not influence the value returned.

**Note:** For more information regarding Printing management and terminology in 4D, refer to the **GET PRINTABLE MARGIN** command description.

# Is in print preview

Is in print preview -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True = Print preview,<br>False = No print preview |

## Description

The **Is in print preview** command returns True if the **Preview on Screen** option is checked in the printing dialog box and False otherwise. This setting is local to the process.

Unlike the **Get print preview** command, **Is in print preview** returns the final value of the option, after the dialog box is validated by the user. So this command lets you determine with certainty whether printing actually takes place in "preview" mode.

## Example

This example takes all types of printing into account:

```
SET PRINT PREVIEW(True) //Print preview by default
PRINT SETTINGS
If(OK=1)
 //The user may have changed the print destination
   If(Is in print preview) // True if preview
      FORM SET OUTPUT([Invoices];"toScreen")
   Else
      FORM SET OUTPUT([Invoices];"toPrinter"
   End if
   OPEN PRINTING JOB
   ALL RECORDS([Invoices])
   PRINT SELECTION([Invoices];>)
   CLOSE PRINTING JOB
End if
```

# Level

Level -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Longint | Current break or header level |

## Description

**Level** is used to determine the current header or break level. It returns the level number during the On Header and On Printing Break events.

Level 0 is the last level to be printed and is appropriate for printing a grand total. **Level** returns 1 when 4D prints a break on the first sorted field, 2 when 4D prints a break on the second sorted field, and so on.

## Example

This example is a template for a form method. It shows each of the possible events that can occur while a summary report uses a form as an output form. **Level** is called when a header or a break is printed:

```
  ` Method of a form being used as output form for a summary report
$vpFormTable:=Current form table
Case of
  ` ...
  :(Form event=On Header)
  ` A header area is about to be printed
     Case of
        :(Before selection($vpFormTable->))
  ` Code for the first break header goes here
        :(Level=1)
  ` Code for a break header level 1 goes here
        :(Level=2)
  ` Code for a break header level 2 goes here
  ` ...
     End case
  :(Form event=On Printing Detail)
  ` A record is about to be printed
  ` Code for each record goes here
  :(Form event=On Printing Break)
  ` A break area is about to be printed
     Case of
        :(Level=0)
  ` Code for a break level 0 goes here
        :(Level=1)
  ` Code for a break level 1 goes here
  ` ...
     End case
  :(Form event=On Printing Footer)
     If(End selection($vpFormTable->))
  ` Code for the last footer goes here
     Else
  ` Code for a footer goes here
     End if
End case
```

# OPEN PRINTING JOB

OPEN PRINTING JOB
Does not require any parameters

## Description

The **OPEN PRINTING JOB** command opens a print job and stacks all the subsequent printing orders there until the **CLOSE PRINTING JOB** command is called. This command lets you control the print jobs and, more particularly, ensure that no other unexpected print job can be inserted into a printing sequence.

The **OPEN PRINTING JOB** command can be used with all the 4D printing commands, the quick report commands, and the printing commands of the 4D Write and 4D View plug-ins. On the other hand, this command is not compatible with the 4D Chart plug-in, as well as most third-party plug-ins.

When a print job is opened with this command, the printer is placed in “busy” mode until the printing is actually launched. If a noncompatible plug-in launches a print job in this context, the “printer busy” error is returned.

You must call the **CLOSE PRINTING JOB** command to terminate the print job and send the print document to the printer. If you omit this command, the print document will remain in the stack and the printer will not be available until you quit the 4D application.

The print job is local to the process but printing is performed at the global level. Only one print job can be open at a time in 4D, all processes taken together.

**OPEN PRINTING JOB** uses the current print settings (default settings or set using the **PAGE SETUP** and/or **SET PRINT OPTION** commands). The commands that modify the print settings must be called before **OPEN PRINTING JOB**. Otherwise, an error is generated.

# PAGE BREAK

PAGE BREAK {( * | > )}

| Parameter | Type | | Description |
|---|---|---|---|
| * \| > | | ⇨ | * Cancel printing job started with Print form, or > Force one printing job |

## Description

**PAGE BREAK** triggers the printing of the data that has been sent to the printer and ejects the page. **PAGE BREAK** is used with **Print form** (in the context of the On Printing Detail form event) to force page breaks and to print the last page created in memory. Do not use **PAGE BREAK** with the **PRINT SELECTION** command. Instead, use **Subtotal** or **BREAK LEVEL** with the optional parameter to generate page breaks.

The * and > parameters are both optional.

The * parameter allows you to cancel a print job started with the **Print form** command. Executing this command immediately stops the print job in progress.

**Note:** Under Windows, this mechanism can be disrupted by the spooling properties of the print server. If the printer is configured to start printing immediately, cancelling will not be effective. For the **PAGE BREAK**(*) command to operate correctly, it is preferable to choose the "Start printing after last page is spooled" property for the printer.

The > parameter modifies the way in which the **PAGE BREAK** command behaves. This syntax has two effects:

- It holds the print job open until the **PAGE BREAK** command is executed again without a parameter.
- It gives priority to the print job. No other printing can take place until the print job is finished.
  The second option is particularly useful when used with a spooled print job. The > parameter guarantees that the print job will be spooled to one file. This will reduce printing time.

**Note:** When screen printing, if the user clicks on Cancel in the print preview dialog box, the **PAGE BREAK** command sets the system variable OK to 0.

## Example 1

See example for the **Print form** command.

## Example 2

Refer to the example of the **SET PRINT MARKER** command.

# PAGE SETUP

PAGE SETUP ( {aTable ;} form )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table owning form, or Default table, if omitted |
| form | String | ⇒ | Form to use for page setup |

## Description

**PAGE SETUP** sets the page setup for the printer to that stored with *form*. The page setup is stored with the form when the form is saved in the Design environment.

In the following three cases, the printing dialog boxes are not displayed and the printing is performed with the default print settings:

- Calling **PRINT SELECTION** to which you pass the optional * parameter
- Calling **PRINT RECORD** to which you pass the optional * parameter
- Issuing a series of calls to **Print form** not preceeded by a call to **PRINT SETTINGS**.

Calling **PAGE SETUP** enables you, in this case, to skip the printing dialog boxes AND to use print settings other than the default ones.

## Example

Several (empty) forms are created for a table named [Design Stuff]. The form “PS100” is assigned a page setup with a scaling of 100%, the form “PS90” is assigned a page setup with a scaling of 90%, and so on. The following project method enables you to print the selection of a table using various scalings without having to specify the scaling in the printing dialog boxes (which are not displayed), each time:

```
  ` AUTOMATIC SCALED PRINTING project method
  ` AUTOMATIC SCALED PRINTING ( Pointer ; String {; Long } )
  ` AUTOMATIC SCALED PRINTING ( ->[Table]; "Output form" {; Scaling } )
If(Count parameters>=3)
   PAGE SETUP([Design Stuff];"PS"+String($3))
   If(Count parameters>=2)
      OUTPUT FORM($1->;$2)
   End if
End if
If(Count parameters>=1)
   PRINT SELECTION($1->;*)
Else
   PRINT SELECTION(*)
End if
```

Once this project method is written, you call it in this way:

```
  ` Look for current invoices
QUERY([Invoices];[Invoices]Paid=False)
  ` Print Summary Report in 90% reduction
AUTOMATIC SCALED PRINTING(->[Invoices];"Summary Report";90)
  ` Print Detailed Report in 50% reduction
AUTOMATIC SCALED PRINTING(->[Invoices];"Detailed Report";50)
```

# Print form

Print form ( {aTable ;} form {; area1 {; area2}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table owning the form, or Default table, if omitted |
| form | String | ⇒ | Form to print |
| area1 | Longint | ⇒ | Print marker, or Beginning area (if area2 is specified) |
| area2 | Longint | ⇒ | Ending area (if area1 specified) |
| Function result | Longint | ⇐ | Height of printed section |

## Description

**Print form** simply prints *form* with the current values of fields and variables of *aTable*. It is usually used to print very complex reports that require complete control over the printing process. **Print form** does not do any record processing, break processing or page breaks. These operations are your responsibility. **Print form** prints fields and variables in a fixed size frame only.

Since **Print form** does not issue a page break after printing the form, it is easy to combine different forms on the same page. Thus, **Print form** is perfect for complex printing tasks that involve different tables and different forms. To force a page break between forms, use the **PAGE BREAK** command. In order to carry printing over to the next page for a form whose height is greater than the available space, call the **CANCEL** command before the **PAGE BREAK** command.

Three different syntaxes may be used:

- **Detail area printing**

Syntax:

```
height:=Print form(myTable;myForm)
```

In this case, **Print form** only prints the Detail area (the area between the Header line and the Detail line) of the form.

- **Form area printing**

Syntax:

```
height:=Print form(myTable;myForm;marker)
```

In this case, the command will print the section designated by the *marker*. Pass one of the constants of the **Form Area** theme in the marker parameter:

| Constant | Type | Value |
|---|---|---|
| Form break0 | Longint | 300 |
| Form break1 | Longint | 301 |
| Form break2 | Longint | 302 |
| Form break3 | Longint | 303 |
| Form break4 | Longint | 304 |
| Form break5 | Longint | 305 |
| Form break6 | Longint | 306 |
| Form break7 | Longint | 307 |
| Form break8 | Longint | 308 |
| Form break9 | Longint | 309 |
| Form detail | Longint | 0 |
| Form footer | Longint | 100 |
| Form header | Longint | 200 |
| Form header1 | Longint | 201 |
| Form header10 | Longint | 210 |
| Form header2 | Longint | 202 |
| Form header3 | Longint | 203 |
| Form header4 | Longint | 204 |
| Form header5 | Longint | 205 |
| Form header6 | Longint | 206 |
| Form header7 | Longint | 207 |
| Form header8 | Longint | 208 |
| Form header9 | Longint | 209 |

- **Section printing**

Syntax:

```
height:=Print form(myTable;myForm;areaStart;areaEnd)
```

In this case, the command will print the section included between the *areaStart* and *areaEnd* parameters. The values entered must be expressed in pixels.

The value returned by **Print form** indicates the height of the printable area. This value will be automatically taken into account by the **Get printed height** command.

The printer dialog boxes do not appear when you use **Print form**. The report does not use the print settings that were assigned to the form in the Design environment. There are two ways to specify the print settings before issuing a series of calls to **Print form**:

- Call **PRINT SETTINGS**. In this case, you let the user choose the settings.
- Call **PAGE SETUP**. In this case, print settings are specified programmatically.

**Print form** builds each printed page in memory. Each page is printed when the page in memory is full or when you call **PAGE BREAK**. To ensure the printing of the last page after any use of **Print form**, you must conclude with the **PAGE BREAK** command (except in the context of an **OPEN PRINTING JOB**, see note). Otherwise, if the last page is not full, it stays in memory and is not printed.

**Warning:** If the command is called in the context of a printing job opened with **OPEN PRINTING JOB**, you must NOT call **PAGE BREAK** for the last page because it is automatically printed by the **CLOSE PRINTING JOB** command. If you call **PAGE BREAK** in this case, a blank page is printed.

This command prints external areas and objects (for example, 4D Write or 4D View areas). The area is reset for each execution of the command.

**Warning:** Subforms are not printed with **Print form**. To print only one form with such objects, use **PRINT RECORD** instead.

**Print form** generates only one On Printing Detail event for the form method.

**4D Server:** This command can be executed on 4D Server within the framework of a stored procedure. In this context:

- Make sure that no dialog box appears on the server machine (except for a specific requirement).

- In the case of a problem concerning the printer (out of paper, printer disconnected, etc.), no error message is generated.

## Example 1

The following example performs as a **PRINT SELECTION** command would. However, the report uses one of two different forms, depending on whether the record is for a check or a deposit:

```
QUERY([Register]) ` Select the records
If(OK=1)
   ORDER BY([Register]) ` Sort the records
   If(OK=1)
      PRINT SETTINGS ` Display Printing dialog boxes
      If(OK=1)
         For($vlRecord;1;Records in selection([Register]))
            If([Register]Type ="Check")
               Print form([Register];"Check Out") ` Use one form for checks
            Else
               Print form([Register];"Deposit Out") ` Use another form for deposits
            End if
            NEXT RECORD([Register])
         End for
         PAGE BREAK ` Make sure the last page is printed
      End if
   End if
End if
```

## Example 2

Refer to the example of the **SET PRINT MARKER** command.

# PRINT LABEL

PRINT LABEL ( {aTable }{;}{ document {; * | >}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to print, or Default table, if omitted |
| document | String | ⇒ | Name of disk label document |
| * \| > | | ⇒ | * to suppress the printing dialog boxes, or > to not reinitialize print settings |

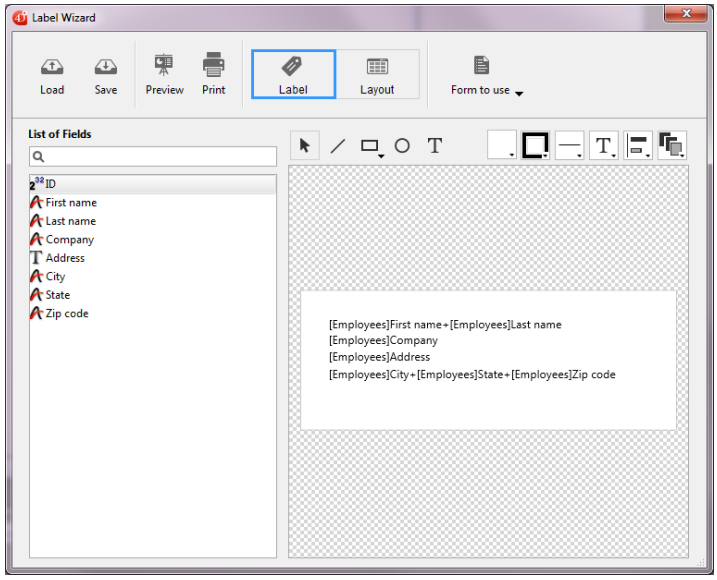
## Description

**PRINT LABEL** enables you to print labels with the data from the selection of *aTable*.

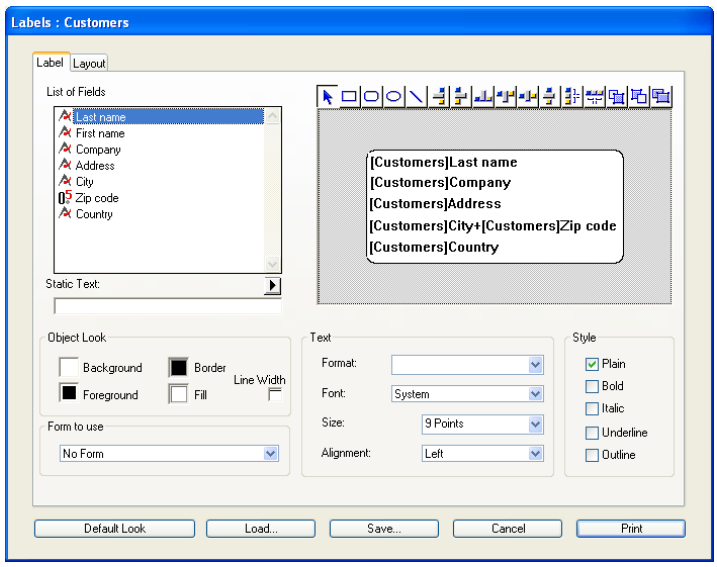
If do not specify the *document* parameter, **PRINT LABEL** prints the current selection of *aTable* as labels, using the current output form. You cannot use this command to print subforms. For details about creating forms for labels, refer to the 4D Design Reference manual.

If you specify the *document* parameter, **PRINT LABEL** enables you to access the Label Wizard (shown below) or to print an existing Label document stored on disk. See the following discussion.

64-bit version:



32-bit version:



**Compatibility note:** The 32-bit version of the label editor only supports ASCII characters. If you need to use a more extended character set, you have to print labels using the current output form.

By default, **PRINT LABEL** displays the printer dialog boxes (in 4D 32-bit versions) or the Print job dialog box (in 4D 64-bit versions) before printing. If the user cancels either of the printer dialog boxes, the command is canceled and the labels are

not printed.

You can suppress these dialog boxes by using either the optional asterisk (*) parameter or the optional “greater than” (>) parameter:

- The * parameter causes a print job using the current print parameters.
- Furthermore, the > parameter causes a print job without reinitializing the current print parameters. This setting is useful for executing several successive calls to **PRINT LABEL** (ex. inside a loop) while maintaining previously set customized print parameters. For an example of use of this parameter, refer to the **PRINT RECORD** command description.

Note that this parameter has no effect if the Label Wizard is involved.

If the Label Wizard is not involved, the OK variable is set to 1 if all labels are printed; otherwise, it is set to 0 (zero) (i.e., if user clicked **Cancel** in the printing dialog boxes).

If you specify the *document* parameter, the labels are printed with the label setup defined in *document*. If *document* is an empty string (""), **PRINT LABEL** will present an Open File dialog box so the user can specify the file to use for the label setup. If *document* is the name of a document that does not exist (for example, pass *char(1)* in *document)*, the Label Wizard is displayed and the user can define the label setup.

**Note:** If the *table* has been declared “invisible” in Design mode, the Label Wizard will not be displayed.

**4D Server:** This command can be executed on 4D Server within the framework of a stored procedure. In this context:

- Make sure that no dialog box appears on the server machine (except for a specific requirement). To do this, it is necessary to call the command with the * or > parameter.
- The syntax which makes the label editor appear does not work with 4D Server; in this case, the system variable OK is set to 0.
- In the case of a problem concerning the printer (out of paper, printer disconnected, etc.), no error message is generated.

## Example 1

The following example prints labels using the output form of a table. The example uses two methods. The first is a project method that sets the correct output form and then prints labels:

```
ALL RECORDS([Addresses]) ` Select all records
FORM SET OUTPUT([Addresses];"Label Out") ` Select the output form
PRINT LABEL([Addresses]) ` Print the labels
FORM SET OUTPUT([Addresses];"Output") ` Restore default output form
```

The second method is the form method for the form *"Label Out"*. The form contains one variable named *vLabel*, which is used to hold the concatenated fields. If the second address field (Addr2) is blank, it is removed by the method. Note that this task is performed automatically with the Label Wizard. The form method creates the label for each record:

```
  ` [Addresses]; "Label Out" form method
Case of
   :(Form event=On Load)
      vLabel:=[Addresses]Name1+" "+[Addresses]Name2+Char(13)+[Addresses]Addr1+Char(13)
      If([Addresses]Addr2 #"")
         vLabel:=vLabel+[Addresses]Addr2+Char(13)
      End if
      vLabel:=vLabel+[Addresses]City+", "+[Addresses]State+" "+[Addresses]ZipCode
End case
```

## Example 2

The following example lets the user query the [People] table, and then automatically prints the labels “My Labels”:

```
QUERY([People])
If(OK=1)
   PRINT LABEL([People];"My Labels";*)
End if
```

## Example 3

The following example lets the user query the [People] table, and then lets the user choose the labels to be printed:

```
QUERY([People])
If(OK=1)
   PRINT LABEL([People];"")
End if
```

## Example 4

The following example lets the user query the [People] table, and then displays the Label Wizard so the user can design, save, load and print any labels:

```
QUERY([People])
If(OK=1)
   PRINT LABEL([People];Char(1))
End if
```

# Print object

Print object ( {* ;} object {; posX {; posY {; width {; height}}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| posX | Longint | ⇒ | Horizontal location of object |
| posY | Longint | ⇒ | Vertical location of object |
| width | Longint | ⇒ | Width of object (pixels) |
| height | Longint | ⇒ | Height of object (pixels) |
| Function result | Boolean | ⇐ | True = object entirely printed; otherwise False |

## Description

The **Print object** command lets you print the form object(s) designated by the *object* and * parameters, at the location set by the *posX* and *posY* parameters.

Before calling the **Print object** command, you must designate the table or project form containing the objects to be printed, using the **FORM LOAD** command.

If you pass the optional * parameter, you indicate that the object parameter is an object name (character string). If you do not pass the * parameter, you indicate that object is a variable. In this case, you pass a variable reference (object type only) instead of a string.

The *posX* and *posY* parameters specify the starting point for printing the object(s). These values must be expressed in pixels. If these parameters are omitted, the object will be printed according to its location in the form.

The *width* and *height* parameters are used to specify the width and height of the form object. The **Print object** command does not manage objects of variable size. You must use the **OBJECT GET BEST SIZE** command to manage the size of objects. You can also use the **OBJECT GET BEST SIZE** command to find out the most appropriate size for objects containing text. Similarly, **Print object** will not cause automatic page breaks. You must manage them according to your needs.

You can use 4D commands to modify object properties (color, size, etc.) on the fly.

The command returns True if the object has been completely printed and False if this is not the case; in other words, if it was not able to print all the data associated with the object within the set framework. Typically, the command returns False when printing a list box if all the rows of the list box could not be printed. In this case, you can simply call the **Print object** command repeatedly until it returns True: a specific mechanism automatically causes the contents of the object to scroll after each call.

**Notes:**

- In the current version of 4D, only list box type objects have this mechanism (the command always returns True for any other type of object). In forthcoming versions of 4D, this functioning will be extended to other objects with variable contents.
- The **LISTBOX GET PRINT INFORMATION** command lets you check the status of the printing during the operation.

The **Print object** command can only be used in the context of a print job opened beforehand with the **OPEN PRINTING JOB** command. If it is not called in this context, the command does nothing. Several **Print object** commands can be called in the same print job.

**Note:** Hierarchical lists, subforms and Web areas cannot be printed.

## Example 1

Example for printing ten objects in a form:

```
PRINT SETTINGS
If(OK=1)
   OPEN PRINTING JOB
   If(OK=1)
      FORM LOAD("PrintForm")
      x:=100
      y:=50
      GET PRINTABLE AREA(hpaper;wpaper)
```

```
      For($i;1;10)
         OBJECT GET BEST SIZE(*;"Obj"+String($i);bestwidth;bestheight)
         $end:=Print object(*;"Obj"+String($i))
         y:=y+bestheight+15
         If(y>hpaper)
            PAGE BREAK(>)
            y:=50
         End if
      End for
   End if
   CLOSE PRINTING JOB
End if
```

## Example 2

Example of printing a complete list box:

```
Repeat
   $end:=Print object(*;"mylistbox")
Until($end)
```

# PRINT OPTION VALUES

PRINT OPTION VALUES ( option ; namesArray {; info1Array {; info2Array}} )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇒ | Option number |
| namesArray | Text array | ⇐ | Names of values |
| info1Array | Longint array | ⇐ | Values (1) of the option |
| info2Array | Longint array | ⇐ | Values (2) of the option |

## Description

In *namesArray*, the **PRINT OPTION VALUES** command returns a list of value names available for the print *option* defined. Optionally, you can retrieve information for each value in *info1Array* and *info2Array*.

The *option* parameter allows you to specify the option to get. You must pass one of the following constants of the "**Print Options**" theme (options able to return lists of value names):

| Constant | Type | Value | Comment |
|---|---|---|---|
| Paper option | Longint | 1 | If you use only *value1*, it contains the name of the paper. If you use both parameters, *value1* contains the paper width and *value2* contains the paper height. The width and height are expressed in screen pixels. Use the **PRINT OPTION VALUES** command to get the name, height and width of all the paper formats offered by the printer. |
| Paper source option | Longint | 5 | (Windows only) *value1* only: number corresponding to the index, in the array of trays returned by the **PRINT OPTION VALUES** command, of the paper tray to be used. This option can only be used under Windows. |

After command execution, the *namesArray* array as well as, where applicable, the *info1Array* and *info2Array* arrays will be filled in by the command with the names and information of the available values.

If you pass value 1 (Paper option) in the *option* parameter, the command will return the following information:

- in *namesArray*, the names of the available paper formats;
- in *info1Array*, the heights of each paper format;
- in *info2Array*, the widths of each paper format.

**Note:** In order to obtain this information, the print driver must have access to a valid PPD (PostScript Printer Description) file for the printer.

In order to apply a specific paper format using the **SET PRINT OPTION** command, you can either pass one of the values of *namesArray*, the corresponding values of *info1Array* and *info2Array*.

If you pass value 5 (Paper source option) in the *option* parameter, the command returns the names of the different trays available in *namesArray*, and their internal Windows ID numbers in *info1Array* (*info2Array* remains empty).

The order of the values in the arrays is defined by the print driver. To indicate a tray using the **SET PRINT OPTION** command, you must pass the index, as found in the *namesArray* or *info1Array* arrays, of the element desired.

**Note:** This option can only be used under Windows.

For more information on the different print options, refer to the description of the **SET PRINT OPTION** and **GET PRINT OPTION** commands.

All the information returned by these commands is supplied by the operating system. Refer to the documentation of your system for more details about specific options.

**Note:** The **PRINT OPTION VALUES** command only operates with PostScript printers.

# PRINT RECORD

PRINT RECORD ( {aTable}{;}{* | >} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to print the current record or Default table if omitted |
| * \| > | Operator | ⇒ | * to suppress the printer dialog boxes, or > to not reinitialize print settings |

## Description

**PRINT RECORD** prints the current record of *aTable*, without modifying the current selection. The current output form is used for printing. If there is no current record for *aTable*, **PRINT RECORD** does nothing.

You can print subforms with the **PRINT RECORD** command. This is not possible with **Print form**.

**Note:** If there are modifications to the record that have not been saved, this command prints the modified field values, not the field values located on disk.

By default, **PRINT RECORD** displays the printer dialog boxes (in 4D 32-bit versions) or the Print job dialog box (in 4D 64-bit versions) before printing. If the user cancels either of the printer dialog boxes, the command is canceled and the record is not printed.

You can suppress these dialog boxes by using either the optional asterisk (*) parameter or the optional “greater than” (>) parameter:

- The * parameter causes a print job using the current print parameters (default parameters or those defined by the **PAGE SETUP** and/or **SET PRINT OPTION** commands).
- Furthermore, the > parameter causes a print job without reinitializing the current print parameters. This setting is useful for executing several successive calls to **PRINT RECORD** (e.g. inside a loop) while maintaining previously set customized print parameters.

**4D Server:** This command can be executed on 4D Server within the framework of a stored procedure. In this context:

- Make sure that no dialog box appears on the server machine (except for a specific requirement). To do this, it is necessary to call the command with the * or > parameter.
- In the case of a problem concerning the printer (out of paper, printer disconnected, etc.), no error message is generated.

**Warning:** Do not use the **PAGE BREAK** command with **PRINT RECORD**. **PAGE BREAK** is exclusively reserved for use in combination with the **Print form** command.

## Example 1

The following example prints the current record of the [Invoices] table. The code is contained in the object method of a **Print** button on the input form. When the user clicks the button, the record is printed using an output form designed for this purpose.

```
FORM SET OUTPUT([Invoices];"Print One From Data Entry") ` Select the right output form for printing
PRINT RECORD([Invoices];*) ` Print Invoices as it is (without showing the printing dialog boxes)
FORM SET OUTPUT([Invoices];"Standard Output") ` Restore the previous output form
```

## Example 2

The following example prints the same current record in two different forms. The code is contained in the object method of a **Print** button on the input form. You want to set customized print parameters and then use them in the two forms.

```
PRINT SETTINGS `User defines print parameters
If(OK=1)
   FORM SET OUTPUT([Employees];"Detailed") `Use the first print form
   PRINT RECORD([Employees];>) `Print using user-defined parameters
   FORM SET OUTPUT([Employees];"Simple") `Use the second print form
   PRINT RECORD([Employees];>) `Print using user-defined parameters
```

```
      FORM SET OUTPUT([Employees];"Output") `Restore default output form
   End if
```

# PRINT SELECTION

PRINT SELECTION ( {aTable}{;}{* | >} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to print the selection, or Default table, if omitted |
| * \| > | Operator | ⇒ | * to delete the printing dialog boxes, or > to not reinitialize print settings |

## Description

**PRINT SELECTION** prints the current selection of *aTable*. The records are printed with the current output form of the table in the current process. **PRINT SELECTION** performs the same action as the Print menu command in the Design environment. If the selection is empty, **PRINT SELECTION** does nothing.

By default, **PRINT SELECTION** displays the printer dialog boxes (in 4D 32-bit versions) or the Print job dialog box (in 4D 64-bit versions) before printing. If the user cancels either of the printer dialog boxes, the command is canceled and the report is not printed.

You can delete these dialog boxes by using either the optional asterisk (*) parameter or the optional “greater than” (>) parameter:

- The * parameter causes a print job using the current print parameters (default parameters or those defined by the **PAGE SETUP** and/or **SET PRINT OPTION** commands).
- Furthermore, the > parameter causes a print job without reinitializing the current print parameters. This setting is useful for executing several successive calls to **PRINT SELECTION** (e.g., inside a loop) while maintaining previously set customized print parameters. For an example of the use of this parameter, refer to the **PRINT RECORD** command description.

During printing, the output form method and/or the form’s object methods are executed depending on the events that are enabled for the form and objects using the Property List window in the Design environment, as well as on the events actually occurring:

- An On Header event is generated just before a header area is printed.
- An On Printing Detail event is generated just before a record is printed.
- An On Printing Break event is generated just before a break area is printed.
- An On Printing Footer event is generated just before a footer is printed.

You can check whether **PRINT SELECTION** is printing the first header by testing **Before selection** during an On Header event. You can also check for the last footer, by testing **End selection** during an On Printing Footer event. For more information, see the description of these commands, as well as those of **Form event** and **Level**.

To print a sorted selection with subtotals or breaks using **PRINT SELECTION**, you must first sort the selection. Then, in each Break area of the report, include a variable with an object method that assigns the subtotal to the variable. You can also use statistical and arithmetical functions like **Sum** and **Average** to assign values to variables. For more information, see the descriptions of **Subtotal**, **BREAK LEVEL** and **ACCUMULATE**.

**Warning:** Do not use the **PAGE BREAK** command with the **PRINT SELECTION** command. **PAGE BREAK** is to be used with the **Print form** command.

After a call to **PRINT SELECTION**, the OK variable is set to 1 if the printing has been completed. If the printing was interrupted, the OK variable is set to 0 (zero) (i.e., the user clicked Cancel in the printing dialog boxes).

**4D Server:** This command can be executed on 4D Server within the framework of a stored procedure. In this context:

- Make sure that no dialog box appears on the server machine (except for a specific requirement). To do this, it is necessary to call the command with the * or > parameter.
- In the case of a problem concerning the printer (out of paper, printer disconnected, etc.), no error message is generated.

## Example

The following example selects all the records in the [People] table. It then uses the **DISPLAY SELECTION** command to display the records and allows the user to highlight the records to print. Finally, it uses the selected records with the **USE SET** command, and prints them with **PRINT SELECTION**:

```
ALL RECORDS([People]) ` Select all records
DISPLAY SELECTION([People];*) ` Display the records
USE SET("UserSet") ` Use only records picked by user
PRINT SELECTION([People]) ` Print the records that the user picked
```

# PRINT SETTINGS

PRINT SETTINGS {( dialType )}

| Parameter | Type | | Description |
|---|---|---|---|
| dialType | Longint | ⇨ | Dialog box(es) to be displayed |

## Description

**PRINT SETTINGS** displays either one or two print settings dialog boxes. This command must be called before a series of **Print form** commands or the **OPEN PRINTING JOB** command.

The optional *dialType* parameter can be used to configure the display of the printing dialog boxes. You can use one of the following constants from the **Print Options** theme. The displayed dialog box(es) will actually depend on your 4D version, as shown in the following table:

| dialType value (constant) | 4D 64-bit | 4D 32-bit |
|---|---|---|
| 0 or omitted | Print job | Page setup+Print job |
| 1 (Page setup dialog) | Page setup | Page setup |
| 2 (Print dialog) | Print job (= 0 or omitted) | Print job |

**Note:** The Print Job dialog box contains a **Preview on Screen** check box that allows the user to preview their print job. You can preset or reset this option by calling **SET PRINT PREVIEW** before calling **PRINT SETTINGS**.

## Example

See example for the command **Print form**.

## System variables and sets

If the user clicks OK in both dialog boxes, the OK system variable is set to 1. Otherwise, the OK system variable is set to 0.

# Print settings to BLOB

Print settings to BLOB ( printSettings ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| printSettings | BLOB | ⇦ | Current print settings |
| Function result | Longint | ⇨ | Status code: 1=Operation successful, 0=No current printer |

## Description

The **Print settings to BLOB** command saves the current 4D print settings in the *printSettings* BLOB. The *printSettings* parameter stores all the settings used for printing:

- Layout parameters such as paper, orientation, scale, etc.
- Print parameters such as number of copies, paper source, etc.

This command must be used in conjunction with the **BLOB to print settings** command. These commands allow you to save a user's current print settings and reload them subsequently so that users will not need to specify their parameters each time they start a print job. In addition, it allows you to save "private" printer settings (specific to the printer driver) that are not available as standard printing parameters.

The BLOB generated must not be modified by programming; it can only be used by the **BLOB to print settings** command.

The command returns 1 if the BLOB has been generated correctly, and 0 if no current printer is selected.

### Windows / OS X

The *printSettings* BLOB can be saved and read on both platforms. However, even if some print settings are common, some others are platform-specific and depend on the drivers and system versions. If the same *printSettings* BLOB is shared between both platforms, you may lost information parts.
When used in an heterogeneous environment, in order to restore the maximum settings available for each platform (and not only the common part), it is recommended that you handle two *printSettings* BLOBs, one for each platform.

## Example

You want to store the current print settings to disk:

```
C_BLOB(curSettings)
PRINT SETTINGS //displays print settings dialog to the user
If(OK=1)
   $err:=Print settings to BLOB(curSettings)
   If($err=1)
      BLOB TO DOCUMENT(Get 4D folder+"current4Dsettings.blob":curSettings)
   Else
      ALERT("No selected printer")
   End if
End if
```

# PRINTERS LIST

PRINTERS LIST ( namesArray {; altNamesArray {; modelsArray}} )

| Parameter | Type | | Description |
|---|---|---|---|
| namesArray | Text array | ⇦ | Printer names |
| altNamesArray | Text array | ⇦ | Windows: Printer locations Mac OS: Custom printer names |
| modelsArray | Text array | ⇦ | Printer models |

## Description

The **PRINTERS LIST** command fills in the array(s) passed as parameter(s) with the names as well as, optionally, the locations or custom names and models of the available printers for the machine.

**Note:** If the printers are managed using a print server (spooler), the complete access path (under Windows) or the name of the spooler (under Mac OS) is returned.

Pass the name of a text array in the *namesArray* parameter. After command execution, this array will contain the names of available printers. Under Mac OS, this will be the fixed “system” names.

You can pass a second optional array, *altNamesArray*. The contents of this array will depend on the platform:

- Under Windows, for each printer, you get its network location (or local port).
- Under Mac OS, for each printer, you get its custom name, which can be modified by the user. This name can be used, for example, in dialog boxes.

The optional *modelsArray* parameter is used to get the model of each printer. (**Note:** This parameter is not supported on 32-bit versions of 4D for Mac).

Use the **SET CURRENT PRINTER** and **Get current printer** commands to modify or get the selected printer in 4D. You must pass them the names returned in the first array (*namesArray*)

Under Windows, the name of a printer can be modified manually at the operating system level. On the other hand, its location and model type are linked to its physical characteristics. Therefore, you can use the optional array values to check the characteristics of the selected printer — typically, you can check that all the client machines use the same printer.

Under Mac OS, this check can be carried out using the name of the printer (name of the print server), which is the same for each machine that is connected.

## System variables and sets

The system variable OK is set to 1 if the command has been executed correctly; otherwise, it is set to 0 and the arrays are returned empty.

# Printing page

Printing page -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Page number of page currently being printed |

## Description

**Printing page** returns the printing page number. It can be used only when you are printing with **PRINT SELECTION** or the Print menu in the Design environment.

## Example

The following example changes the position of the page numbers on a report so that the report can be reproduced in a double-sided format. The form for the report has two variables that display page numbers. A variable in the lower-left corner (*vLeftPageNum*) will print the even page numbers. A variable in the lower-right corner (*vRightPageNum*) will print the odd page numbers. The example tests for even pages, then clears and sets the appropriate variables:

```
Case of
   :(Form event=On Printing Footer)
      If((Printing page% 2)=0) ` Modulo is 0, it is an even page
         vLeftPageNum:=String(Printing page) ` Set the left page number
         vRightPageNum:="" ` Clear the right page number
      Else ` Otherwise it is an odd page
         vLeftPageNum:="" ` Clear the left page number
         vRightPageNum:=String(Printing page) ` Set the right page number
      End if
End case
```

# SET CURRENT PRINTER

SET CURRENT PRINTER ( printerName )

| Parameter | Type | | Description |
|---|---|---|---|
| printerName | String | ⇒ | Name of printer to be used |

## Description

The **SET CURRENT PRINTER** command is designates the printer to be used for printing with the current 4D application.

Pass the name of the printer to be selected in the *printerName* parameter. To get a list of available printers, use the **PRINTERS LIST** command beforehand.
If you pass an empty string in *printerName*, the current printer defined in the system will be used.

**SET CURRENT PRINTER** allows you to designate the generic PDF printer of the system in order to print PDFs. The value to use depends on the version of the OS as well as that of 4D.

- **Windows 8 and previous versions:**
  4D relies on the PDFCreator driver to facilitate the printing of PDF documents under Windows (see the **Integration of PDFCreator driver under Windows** section). To print a PDF document, in the *printerName* parameter, pass the name of the virtual printer that was installed by the PDFCreator driver. By default, the name of the virtual printer is "PDFCreator". However, this name may have been modified when the driver was installed. In order for 4D to automatically look for and use the name of the virtual printer, even if it has been customized, in the *printerName* parameter you must pass the following constant (**Print Options** theme):

| Constant | Type | Value |
|---|---|---|
| PDFCreator Printer name | String | PDFCreator |

- **Starting with Windows 10:**
  Windows 10 includes a native PDF printer driver, which allows 4D to create PDFs directly without it being necessary to use a third-party driver such as PDFCreator.
  The name of the driver is "Microsoft Print to PDF" (see the example found in the **Integration of PDFCreator driver under Windows** section).

- **Under OS X and starting with Windows 10 (4D Developer Edition v15 R5 64-bit and higher):**
  A constant found in the **Print Options** theme allows you to designate the generic PDF printer automatically, regardless of the platform. This facilitates the writing of generic code.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Generic PDF driver | String | _4d_pdf_printer | **Note:** This function is not available in 32-bit versions of 4D.<br>○ On OS X, sets the current printer to the default driver. This driver is invisible; it is not found in the list returned by **PRINTERS LIST**. Note that a PDF document path must have been set using **SET PRINT OPTION**, otherwise error 3107 is returned.<br>○ On Windows, sets the current printer to the Windows PDF driver (named "Microsoft Print to PDF"). This constant is only available in Windows 10 with the PDF option installed. In other Windows versions, or if no PDF driver is available, the command does nothing and the *OK* variable is set to 0. |

The **SET CURRENT PRINTER** command must be called before **SET PRINT OPTION**, so that the options available correspond to the selected printer. On the other hand, **SET CURRENT PRINTER** must be called after **PAGE SETUP**, otherwise the print settings are lost.

This command can be used with the **PRINT SELECTION**, **PRINT RECORD**, **Print form**, and **QR REPORT** commands, and is applied to all 4D printing, including that in Design mode.
It is imperative for print commands to be called with the > parameter (where applicable) so that the specified settings are not lost.

## System variables and sets

If printer selection is carried out correctly, the system variable OK is set to 1. Should the opposite occur (for instance if the designated printer is not found), the system variable OK is set to 0 and the current printer remains unchanged.

## Example

Creation of a PDF document under Windows 10 with 4D Developer Edition 64-bit:

```
C_TEXT($pdfpath)
$pdfpath:=System folder(Desktop)+"test.pdf"
SET CURRENT PRINTER(Generic PDF driver)
SET PRINT OPTION(Destination option;2;$pdfpath)
ALL RECORDS([Table_1])
PRINT SELECTION([Table_1];*)
SET CURRENT PRINTER("")
```

# SET PRINT MARKER

SET PRINT MARKER ( markNum ; position {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| markNum | Longint | ⇒ | Marker number |
| position | Longint | ⇒ | New position for the marker |
| * | Operator | ⇒ | If passed = move subsequent markers If omitted = do not move subsequent markers |

## Description

The **SET PRINT MARKER** command enables the definition of the marker position during printing. Combined with the **Get print marker**, **OBJECT MOVE** or **Print form** commands, this command allows you to adjust the size of the print areas.

**SET PRINT MARKER** can be used in two contexts:

- during the On Header form event, in the context of **PRINT SELECTION** and **PRINT RECORD** commands.
- during the On Printing Detail form event, in the context of the **Print form** command. This operation facilitates the printing of customized reports (see example).

The effect of the command is limited to printing; no modification appears on the screen. The modifications made to the forms are not saved.

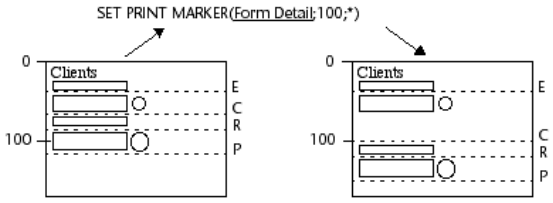
Pass one of the constants of the **Form Area** theme in the *markNum* parameter:

| Constant | Type | Value |
|---|---|---|
| Form break0 | Longint | 300 |
| Form break1 | Longint | 301 |
| Form break2 | Longint | 302 |
| Form break3 | Longint | 303 |
| Form break4 | Longint | 304 |
| Form break5 | Longint | 305 |
| Form break6 | Longint | 306 |
| Form break7 | Longint | 307 |
| Form break8 | Longint | 308 |
| Form break9 | Longint | 309 |
| Form detail | Longint | 0 |
| Form footer | Longint | 100 |
| Form header | Longint | 200 |
| Form header1 | Longint | 201 |
| Form header10 | Longint | 210 |
| Form header2 | Longint | 202 |
| Form header3 | Longint | 203 |
| Form header4 | Longint | 204 |
| Form header5 | Longint | 205 |
| Form header6 | Longint | 206 |
| Form header7 | Longint | 207 |
| Form header8 | Longint | 208 |
| Form header9 | Longint | 209 |

In *position*, pass the new position desired, expressed in pixels.

If you pass the optional * parameter, all the markers located below the marker specified in *markNum* will be moved the same number of pixels and in the same direction as this marker when the command is executed. **Warning:** in this case, any objects present in the areas located below the marker are also moved.

When the * parameter is used, it is possible to position the *markNum* marker beyond the initial position of the markers that follow it — these latter markers will be moved simultaneously.

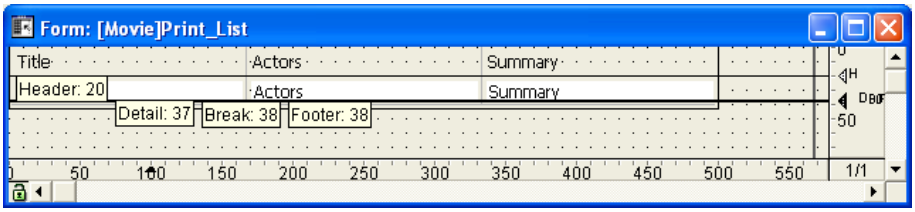


**Notes:**

- This command modifies only the existing marker position. It does not allow the addition of markers. If you designate a marker that does not exist in the form, the command will not do anything.
- The print marker mechanism in the Design mode is retained: a marker cannot go any higher than the one that precedes it, nor any lower than the one that follows it (when the * parameter is not used).

## Example

This complete example enables you to generate the printing of a three-column report, the height of each row being calculated on the fly according to the contents of the fields.
The output form used for printing is as follows:



The On Printing Detail form event was selected for the form (keep in mind that no matter what area is printed, the **Print form** command only generates this type of form event).
For each record, the row height must be adapted according to the contents of the "Actors" or "Summary" column (column having the most content). Here is the desired result:

| Title | Actors | Summary |
|---|---|---|
| The Avengers | Ralph Fiennes, Uma Thurman, Sean Connery, Jim Broadbent, Patrick Macnee, Fiona Shaw, Eddie Izzard, Eileen Atkins | "The Avengers", the popular TV series from the sixties, is brought to the big screen with a mix of humour, retro fashion and action. Ralph Fiennes plays the role of well dressed John Steed and Uma Thurman is the beautiful Emma Peel dressed in a jumpsuit. Our two special agents fight crime in style. Sean Connery plays Sir August De Wynter, an evil genious that wants to take over the world with his high-tech weather machine. Unleashing snow storms or heatwaves, and armed with remote-controlled killer bees, this nut is a real menance to society. But all these climate changes won't stop our two heroes. A cup of tea, anyone? |
| 20,000 Leagues Under The Sea | | "The year is 1868, when New England's fishing harbors are the scene for a creature of unknown origin destroying ships at sea. It is the job of Professor Pierre Aronnax, a marine expert, and Ned Land, the iron-willed sailor, to learn the truth of the monster roaming the seas. The great novelist, Jules Verne, described this perilous journey to the darkest depths of the sea with Captain Nemo aboard the Nautilus." |
| The Adventures Of Ichabod And Mr. Toad (Walt Disney C | Bing Crosby, Basil Rathbone, Eric Blore, Pat O'Malley, John McLeish, Colin Campbell, Campbell Grant, Claud Allister | Hang on for the wild motorcar ride of J. Thaddeus Toad as he drives his friends Mole, Rat and Angus MacBadger into a worried frenzy! Then meet the spindly Ichabod Crane, who dreams of sweeping beautiful Katrina Van Tassel off her feet, despite opposition from town bully Brom Bones, who also has his eye on Katrina. The comic rivalry introduces Ichabod to the legend of the Headless Horseman resulting in a heart-thumping climax. Wonderfully narrated by Basil Rathbone and Bing Crosby, The Adventures Of Ichabod And Mr. Toad brims with high-spirited adventure, brilliant animation and captivating music you'll want to share with your family time and again. |
| Mission To Mars | Gary Sinise, Tim Robbins, Don Cheadle, Jerry O'Connell, Connie Nielsen | From the director of Mission Impossible comes the thrilling, eye-popping science-fiction adventure Mission To Mars - starring Gary Sinise (Snake Eyes) and Tim Robbins (Austin Powers: The Spy Who Shagged Me). The year is 2020, and the first manned mission to Mars, commanded by Luke Graham (Don Cheadle - Out Of Sight), lands safely on the red planet. But the Martian landscape harbors a bizarre and shocking secret that leads to a mysterious disaster so catastrophic, it decimates the crew. Haunted by a cryptic last message from Graham, NASA launches the Mars Recovery Mission to investigate and bring back survivors - if there are any. Confronted with nearly insurmountable dangers, but propelled by deep friendship, the team finally lands on Mars and makes a discovery so amazing, it takes your breath away. Mission To Mars is an action-packed rocket ride that will enthrall you with its stunning special effects and keep you on the edge of your seat. |
| The Abyss: Special Edition | Ed Harris, Mary Elizabeth Mastrantonio, Michael Biehn, Leo Burmeister, Todd Graff, John Bedford Lloyd, Kimberly Scott | In this thrilling, underwater action-adventure from writer-director James Cameron (Titanic, Terminator 2: Judgment Day, Aliens), a civilian oil-rig crew is recruited to conduct a search-and-rescue effort when a nuclear submarine mysteriously sinks. One diver (Ed Harris) soon finds himself on a spectacular odyssey over 25,000 feet below the ocean's surface, where he confronts a mysterious force that has the power to change the world or destroy it. Includes both the Special Edition, with 28 minutes of additional footage, and the original theatrical version, along with the 80-minute documentary Under Pressure: Making The Abyss, and much more. |
| Absence Of The Good | Stephen Baldwin, Rob Knepper, Shawn Hurt, Allen Garfield, Silas Weir Mitchell, Tyne Daly | One cop. One killer. No clues. No time. After his son is shot to death at school, Detective Caleb Barnes (Stephen Baldwin) loses touch with his soul. When a series of seemingly unrelated murders plagues Salt Lake City, the detective hides his grief in search for the killer. Hampered by a lack of clues and his commander's unrelenting pressure, Caleb painstakingly unravels a tangled web, exposing a malignant family history of abuse and murder. |

The print project method is as follows:

```
C_LONGINT(vLprint_height;$vLheight;vLprinted_height)
C_STRING(31;vSprint_area)
PAGE SETUP([Film];"Print_List3")
GET PRINTABLE AREA(vLprint_height)
vLprinted_height:=0
ALL RECORDS([Film])

vSprint_area:="Header" //Printing of header area
$vLheight:=Print form([Film];"Print_List3";Form header)
$vLheight:=21 //Fixed height
vLprinted_height:=vLprinted_height+$vLheight

While(Not(End selection([Film])))
   vSprint_area:="Detail" `Printing of detail area
   $vLheight:=Print form([Film];"Print_List3";Form detail)
 `Detail calculation is carried out in the form method
   vLprinted_height:=vLprinted_height+$vLheight
   If(OK=0) `CANCEL has been carried out in the form method
      PAGE BREAK
      vLprinted_height:=0
      vSprint_area:="Header" `Reprinting of the header area
      $vLheight:=Print form([Film];"Print_List3";Form header)
      $vLheight:=21
      vLprinted_height:=vLprinted_height+$vLheight
      vSprint_area:="Detail"
      $vLheight:=Print form([Film];"Print_List3";Form detail)
      vLprinted_height:=vLprinted_height+$vLheight
   End if
   NEXT RECORD([Film])
End while
PAGE BREAK `Make sure that the last page is printed
```

The Print_List3 form method is as follows:

```
C_LONGINT($l;$t;$r;$b;$fixed_wdth;$exact_hght;$l1;$t1;$r1;$b1)
C_LONGINT($final_pos;$i)
C_LONGINT($detail_pos;$header_pos;$hght_to_print;$hght_remaining)

Case of
   :(vSprint_area="Detail") `Printing of detail underway
      OBJECT GET COORDINATES([Film]Actors;$l;$t;$r;$b)
      $fixed_wdth:=$r-$l  `Calculation of the Actors text field size
      $exact_hght:=$b-$t
      OBJECT GET BEST SIZE([Film]Actors;$wdth;$hght;$fixed_wdth)
 `Optimal size of the field according to its contents
      $movement:=$hght-$exact_hght

      OBJECT GET COORDINATES([Film]Summary;$l1;$t1;$r1;$b1)
      $fixed_wdth1:=$r1-$l1  `Calculation of the Summary text field size
      $exact_hght1:=$b1-$t1
      OBJECT GET BEST SIZE([Film]Summary;$wdth1;$hght1;$fixed_wdth1)
 `Optimal size of the field according to its contents
      $movement1:=$hght1-$exact_hght1
      If($movement1>$movement)
 `We determine the highest field
         $movement:=$movement1
      End if

      If($movement>0)
         $position:=Get print marker(Form detail)
         $final_pos:=$position+$movement
 `We move the Detail marker and those that follow it
         SET PRINT MARKER(Form detail;$final_pos;*)
 `Resizing of text areas
         OBJECT MOVE([Film]Actors;$l;$t;$r;$hght+$t;*)
         OBJECT MOVE([Film]Summary;$l1;$t1;$r1;$hght1+$t1;*)

 `Resizing of dividing lines
```

```
            OBJECT GET COORDINATES(*;"H1Line";$l;$t;$r;$b)
            OBJECT MOVE(*;"H1Line";$l;$final_pos-1;$r;$final_pos;*)
            For($i;1;4;1)
               OBJECT GET COORDINATES(*;"VLine"+String($i);$l;$t;$r;$b)
               OBJECT MOVE(*;"VLine"+String($i);$l;$t;$r;$final_pos;*)
            End for
         End if

   `Calculation of available space
         $detail_pos:=Get print marker(Form detail)
         $header_pos:=Get print marker(Form header)
         $hght_to_print:=$detail_pos-$header_pos
         $hght_remaining:=printing_height-vLprinted_height
         If($hght_remaining<$hght_to_print) `Insufficient height
            CANCEL `Move form to the next page
         End if
   End case
```

# SET PRINT OPTION

SET PRINT OPTION ( option ; value1 {; value2} )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇒ | Option number or PDF option code |
| value1 | Longint, Text | ⇒ | Value 1 of the option |
| value2 | Longint, Text | ⇒ | Value 2 of the option |

## Description

The **SET PRINT OPTION** command is used to modify, by programming, the value of a print option. Each option defined using this command is applied to the entire database and for the duration of the session as long as no other command that modifies print parameters (**PRINT SETTINGS**, **PRINT SELECTION** without the > parameter, etc.) is called. If a print job has been opened, the option is set for the job and cannot be modified as long as the job has not terminated.

The *option* parameter allows you to indicate the option to be modified. You can pass either one of the predefined constants of the "**Print Options**" theme, or a PDF option code (usable with the PDFCreator driver under Windows only).

Pass the new value(s) of the specified *option* in the *value1* and (optionally) *value2* parameters. The number and nature of the values to be passed depend on the type of option specified.

### Using an option number (constant)

The following table lists the options and their possible values:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Paper option | Longint | 1 | If you use only *value1*, it contains the name of the paper. If you use both parameters, *value1* contains the paper width and *value2* contains the paper height. The width and height are expressed in screen pixels. Use the **PRINT OPTION VALUES** command to get the name, height and width of all the paper formats offered by the printer. |
| Orientation option | Longint | 2 | *value1* only: 1=Portrait, 2=Landscape. If a different orientation option is used, **GET PRINT OPTION** returns 0 in *value1*.<br>**64-bit versions**: This option can be called within a print job, which means that you can switch from portrait to landscape, or vice versa, during the same print job. |
| Scale option | Longint | 3 | *value1* only: scale value in percentage. Be careful, some printers do not allow you to modify the scale. If you pass an invalid value, the property is reset to 100% at the time of printing. |
| Number of copies option | Longint | 4 | *value1* only: number of copies to be printed. |
| Paper source option | Longint | 5 | (Windows only) *value1* only: number corresponding to the index, in the array of trays returned by the **PRINT OPTION VALUES** command, of the paper tray to be used. This option can only be used under Windows. |
| Color option | Longint | 8 | (Windows only) *value1* only: code specifying the mode for handling color: 1=Black and white (monochrome), 2=Color.<br>**64-bit versions**: This option is not supported in 4D 64-bit versions (obsolete) |
| Destination option | Longint | 9 | *value1*: code specifying the type of print destination: 1=Printer, 2=(PC)/PS File (Mac), 3=PDF file, 5=Screen (OS X driver option).<br>If *value1* is different from 1 or 5, *value2* contains pathname for resulting document. This path will be used until another path is specified. If a file with the same name already exists at the destination location, it will be replaced. With **GET PRINT OPTION**, if the current value is not in the predefined list, *value1* contains -1 and the system variable OK is set to 1. If an error occurs, *value1* and the system variable OK are set to 0.<br>**Note**: Under Windows, you can set the printing destination to 3 (PDF File) when the PDF Creator driver has been installed. When the *(9;3;path)* values are passed, 4D automatically starts a "silent" PDF printing which takes into account any option codes that are passed (note that if you pass an empty string in *value2* or omit this parameter, a file saving dialog appears at the time of printing.) After printing, the current settings are restored. This simplifies control of printing PDFs for 4D and lets you write multi-platform code. When the *(9;3;path)* values are not passed, printing is not controlled by 4D and any PDF Creator option codes that were passed are ignored. |
| Double sided option | Longint | 11 | (Windows only) *value1*: 0=Single-sided or standard, 1=Double-sided. If *value1*=1, *value2* contains the binding: 0=Left binding (default value), 1=Top binding.<br>**Note:** This option can only be used under Windows. |
| Spooler document name option | Longint | 12 | *value1* only: name of the current print document, which appears in the list of spooler documents. The name defined by this statement will be used for all the print documents of the session for as long as a new name or an empty string is not passed. To use or restore standard operation (using the method name in the case of a method, the table name for a record, etc.), pass an empty string in *value1*. |
| Mac spool file format option | Longint | 13 | (Mac only) *value1* only: 0=print job in PDF mode (default value) 1=print job in PostScript mode.<br>**Notes:**<br>- This option has no effect under Windows.<br>- Under OS X, printing is done as a PDF by default. However, the PDF print driver does not support PICT pictures with encapsulated PostScript information — these pictures are generated, more particularly, by vectorial drawing software. To avoid this problem, this option lets you modify the print mode to use under OS X for the current session. Keep in mind that printing in PostScript mode can lead to undesired side effects.<br>**64-bit versions:** This option is not supported; it is replaced by the Generic PDF driver option of the **SET CURRENT PRINTER** command. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Hide printing progress option | Longint | 14 | *value1* only: 1=hide progress windows, 0=display progress windows (default). This option is particularly useful in the case of PDF printing under OS X.<br>**Note:** There is already a Printing progress option found in the Database Settings dialog box (Interface page). However, it is applied globally to the application and does not hide all the windows under OS X. |
| Page range option | Longint | 15 | *value1*=first page to print (default value is 1) and (optional) *value2*=number of the last page to print (default value -1 = end of document). |
| Legacy printing layer option | Longint | 16 | (4D 64-bit versions for Windows only) *value1* only: 1=select the GDI-based legacy printing layer for the subsequent printing jobs. 0=select the D2D printing layer (default).<br>**64-bit versions:** This selector is only supported on 4D 64-bit single-user applications on Windows; it is ignored on other platforms. It is mainly intended to allow legacy plug-ins to print inside 4D jobs in 4D 64-bit applications. |

Once set using this command, a print option is kept throughout the duration of the session for the entire 4D application. It will be used by the **PRINT SELECTION**, **PRINT RECORD**, **Print form**, **QR REPORT** and **WP PRINT** commands, as well as for all 4D printing, including that in Design mode.

**Notes:**

- It is indispensable to use the optional > parameter with the **PRINT SELECTION**, **PRINT RECORD** and **PAGE BREAK** commands in order to avoid resetting the print options that were set using the **SET PRINT OPTION** command.
- The **SET PRINT OPTION** command mainly supports PostScript printers. You can use this command with other types of printers, such as PCL or Ink, but in this case, it is possible that some options may not be available.

### Using a PDF option code (Windows)

In order to be able to use a PDF option code in the *option* parameter, you must have installed the PDFCreator driver in your 4D environment (for more information, refer to the **Integration of PDFCreator driver under Windows** section). Moreover, in order for option codes to be taken into account, you need to have enabled control of PDF printing for 4D using the following statement:

```
SET PRINT OPTION(Destination option;3;fileName)
```

Otherwise, option codes are ignored.

A PDFoption code is a Text type value consisting of two parts, *OptionType* and *OptionName*, combined together as "*OptionType:OptionName*". Here is the description of this code:

- *OptionType* Indicates whether you are specifying a native PDFCreator option or a 4D PDF administration option. Two values are accepted:
  - **PDFOptions** = native option
  - **PDFInfo** = internal option.
- *OptionName* Specifies the option to be set (depending on the *OptionType* value).
  - If *OptionType* = **PDFOptions**, you can pass one of several PDFCreator native options in *OptionName*. For example, the UseAutosave option affects the automatic backup. In order to be able to modify this option, pass "PDFOptions:UseAutosave" in the *option* parameter and the value to be used in the *value1* parameter. For a complete description of the PDFCreator native options, please refer to the documentation provided with the PDFCreator driver.
  - If *OptionType* = **PDFInfo**, you can pass one of the following specific selectors in *OptionName*:
    - **Reset print**: used to reset the internal waiting status in order, more particularly, to exit from an infinite loop. In this case, *value1* is not used.
    - **Reset standard options**: used to reset all the PDFCreator options to their default values. If printing is in progress, the default settings are applied after its completion. In this case, *value1* is not used.
    - **Start**: used to start or stop the PDFCreator spooler. Pass 0 in *value1* to stop it and 1 to start it.
    - **Reset options**: used to reset all the options modified since the beginning of the session using the **SET PRINT OPTION** command and the **PDFOptions** selector.
    - **Version**: used to read the current version number of the PDFCreator driver. This selector can only be used with the **GET PRINT OPTION** command. The number is returned in the *value1* parameter.
    - **Last error**: used to read the last error returned by the PDFCreator driver. This selector can only be used with the **GET PRINT OPTION** command. The error number is returned in the *value1* parameter.
    - **Print in progress**: used to find out if 4D is waiting for printing by PDFCreator. This selector can only be used with the **GET PRINT OPTION** command. The *value1* parameter returns 1 if 4D is waiting for PDFCreator and 0 otherwise.

- **Job count**: used to find out the number of jobs waiting in the printing queue. This selector can only be used with the **GET PRINT OPTION** command. The number of jobs is returned in the *value1* parameter.
- **Synchronous Mode**: used to set the synchronization mode betwen printing requests sent by 4D and the PDFCreator driver. Since 4D cannot get information about the current status of a print job that is in the printing queue, this option can be used to better control the execution of the jobs by only sending them when the status of the PDFCreator driver is "free". In this case, 4D is synchronized with the driver. Pass 0 in *value1* for 4D to send print requests immediately (default value) and 1 in order for 4D to be synchronized and to wait for the driver to have finished the job in progress before sending another one.

**Note:** After each printing, 4D automatically re-establishes the previous settings of the PDFCreator driver in order to avoid any interference with other programs using PDFCreator.

## Example 1

The following method enables the PDF driver so as to print all the records of the table at the C:¥Test¥Test_PDF_X location where X is the sequence number of the record:

```
SET CURRENT PRINTER(PDFCreator Printer Name)
 // Under Windows, select the virtual printer installed by PDFCreator
If(OK=1) // If PDFCreator is actually installed

   ALL RECORDS([Table_1])
   For($i;1;Records in selection([Table_1]))
      SET PRINT OPTION(Destination option;3;"C:¥¥Test¥¥Test_PDF_"+String($i))
 // Destination option 3 launches a PDFCreator print job
      PRINT RECORD([Table_1];*)
      NEXT RECORD([Table_1])
   End for
 // Resetting of the PDFCreator driver options
   SET PRINT OPTION("PDFInfo:Reset standard options";0)
End if
```

## Example 2

In 64-bit versions, the value of Orientation option can be modified within the same print job (special case). Note that the option must have been set before the **PAGE BREAK** command:

```
ALL RECORDS([People])
PRINT SETTINGS
If(OK=1)
   OPEN PRINTING JOB
   SET PRINT OPTION(Orientation option;1) //portrait
   Print form([People];"Vertical_Form")

   SET PRINT OPTION(Orientation option;2) //landscape
   PAGE BREAK //must be called imperatively AFTER the option
   Print form([People];"Horiz_Form")
   CLOSE PRINTING JOB
End if
```

## System variables and sets

The system variable OK is set to 1 if the command has been executed correctly; otherwise, it is set to 0.

If you pass an invalid option code (option not recognized by PDFCreator for example), OK is set to 0.

## Error management

If the value passed for an *option* is invalid or if it is not available on the printer, the command returns an error (that you can intercept using an error-handling method installed by the **ON ERR CALL** command) and the current value of the option remains unchanged.

# SET PRINT PREVIEW

SET PRINT PREVIEW ( preview )

| Parameter | Type | | Description |
|---|---|---|---|
| preview | Boolean | ⇒ | Preview on screen (TRUE), or No preview (FALSE) |

## Description

**SET PRINT PREVIEW** allows you to programmatically check or uncheck the Preview on Screen option of the Print dialog box. If you pass TRUE in *preview*, Preview on Screen will be checked, if you pass FALSE in *preview*, Preview on Screen will be unchecked. This setting is local to a process and does not affect the printing of other processes or users.

## Example

The following example turns on the Preview on Screen option to display the results of a query on screen, and then turns it off.

```
QUERY([Customers])
If(OK=1)
   SET PRINT PREVIEW(True)
   PRINT SELECTION([Customers] ;*)
   SET PRINT PREVIEW(False)
End if
```

# SET PRINTABLE MARGIN

SET PRINTABLE MARGIN ( left ; top ; right ; bottom )

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ➡ | Left margin |
| top | Longint | ➡ | Top margin |
| right | Longint | ➡ | Right margin |
| bottom | Longint | ➡ | Bottom margin |

## Description

The **SET PRINTABLE MARGIN** command sets the values of various printing margins by using the **Print form**, **PRINT SELECTION** and **PRINT RECORD** commands.

You can pass one of the following values in the *left*, *top*, *right* and *bottom* parameters:

- 0 = use paper margins
- -1 = use printer margins
- value > 0 = margin in pixels (remember that 1 pixel in 72 dpi represents approximately 0.4 mm)

The values of the *right* and *bottom* parameters relate to the right and bottom edges of the paper respectively.

**Note:** For more information regarding Printing management and terminology in 4D, refer to the **GET PRINTABLE MARGIN** command description.

By default, 4D bases its printouts on the printer margins. Once the **SET PRINTABLE MARGIN** command is executed, the modified parameters are retained in the same process for the entire session.

## Example 1

The following example gets the size of the dead margin:

```
SET PRINTABLE MARGIN(-1;-1;-1;-1) `Sets the printer margin
GET PRINTABLE MARGIN($l;$t;$r;$b)
 `$l, $t, $r and $b correspond to the dead margins of the sheet
```

## Example 2

The following example gets the paper size:

```
SET PRINTABLE MARGIN(0:0:0:0) `Sets the paper margin
GET PRINTABLE AREA($height;$width)
 `For size A4: $height=842 ; $width=595 pixels
```

# Subtotal

Subtotal ( data {; pageBreak} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| data | Field | ⇒ | Numeric field or variable to return subtotal |
| pageBreak | Longint | ⇒ | Break level for which to cause a page break |
| Function result | Real | ⇐ | Subtotal of data |

## Description

**Subtotal** returns the subtotal for *data* for the current or last break level. **Subtotal** works only when a sorted selection is being printed with **PRINT SELECTION** or when printing using Print in the Design environment. The *data* parameter must be of type real, integer, or long integer. Assign the result of the **Subtotal** function to a variable placed in the Break area of the form.

**Warning:** You **must** execute **BREAK LEVEL** and **ACCUMULATE** before every form report for which you want to do break processing and calculate subtotals. See discussion at the end of the description of this command.

The second, optional, argument to **Subtotal** is used to cause page breaks during printing. If *pageBreak* is 0, **Subtotal** does not issue a page break. If *pageBreak* equals 1, **Subtotal** issues a page break for each level 1 break. If *pageBreak* equals 2, **Subtotal** issues a page break for each level 1 and level 2 break, and so on.

**Tip:** If you execute **Subtotal** from within an output form displayed at the screen, an error will be generated, triggering an infinite loop of updates between the form and the error window. To get out of this loop, press Alt+Shift (Windows) or Option-Shift (Macintosh) when you click on the Abort button in the Error window (you may have to do so several times). This temporarily stops the updates for the form's window. Select another form as the output form so the error will occur again. Go back to the Design Environment and isolate the call to **Subtotal** into a test **Form event**= On Printing Break if you use the form both for display and printing.

## Example

The following example is a one-line object method in a Break area of a form (B0, the area above the B0 marker). The *vSalary* variable is placed in the Break area. The variable is assigned the subtotal of the Salary field for this break level. Break processing must have been activated beforehand using the **BREAK LEVEL** and **ACCUMULATE** commands.

```
Case of
   :(Form event=On Printing Break)
      vSalary:=Subtotal([Employees]Salary)
End case
```

For more information about designing forms with header and break areas, see the 4D Design Reference manual.

## Activating Break Processing in Form Reports

In order to generate reports with breaks, break processing in form reports can be activated by calling the **BREAK LEVEL** and **ACCUMULATE** commands.

You must execute both of these commands before printing a form report. The **Subtotal** function is still required in order to display values on a form. You must sort on at least as many levels as you need to break on.

When using **BREAK LEVEL** and **ACCUMULATE**, the process to print a report is typically like this:

1. Select the records to be printed.
2. Sort the records using **ORDER BY**. Sort on at least the same number of levels as breaks.
3. Execute **BREAK LEVEL** and **ACCUMULATE**.
4. Print the report using **PRINT SELECTION**.

The **Subtotal** function is necessary in order to display values on a form.

# Process (Communications)

- About semaphores
- About workers
- CALL PROCESS

- VARIABLE TO VARIABLE

# About semaphores

## What is a semaphore?

In a computer program, a semaphore is a tool used to protect actions that need to be performed by only one process or user at a time.

In 4D, the conventional need for using semaphores is for modifying an interprocess array: if one process is modifying the values of the array, another process must not be able to do the same thing at the same time. The developer uses a semaphore to indicate to a process that it can only perform its sequence of operations if no other process is already performing the same tasks. When a process encounters a semaphore, there are three possibilities:

- It immediately gets the right to pass
- It waits for its turn until it gets the right to pass
- It continues on its way, abandoning the idea of performing the tasks.

The semaphore therefore protects parts of the code. It allows only one process through at a time and blocks access until the process currently holding the right of use relinquishes this right by releasing the semaphore.

## Commands for working with semaphores

In 4D, you set a semaphore by calling the **Semaphore** function. To release a semaphore, you call the **CLEAR SEMAPHORE** command.

The **Semaphore** function has a very special behavior since it potentially performs two actions simultaneously:

- If the semaphore is already assigned, the function returns **True**
- If the semaphore is not assigned, the function assigns it to the process and returns **False** at the same time.

This double action performed by the same command ensures that no external operation can be inserted between the semaphore test and its assignment.

You can use the **Test semaphore** command to find out whether a semaphore is already assigned or not. This command is mainly used as part of long operations, such as the annual closing of accounts, where **Test semaphore** lets you control the interface to prevent access to certain operations such as the addition of accounting data.

## How to use semaphores

Semaphores should be used according to the following principles:

- A semaphore must be set and released in the same method,
- The execution of code protected by the semaphore must be as short as possible,
- The code must be timed by means of the *tickCount* parameter of the **Semaphore** function to wait for the release of the semaphore.

Here is typical code for using a semaphore:

```
While(Semaphore("MySemaphore";300))
   IDLE
End while
 // place code protected by semaphore here
CLEAR SEMAPHORE("MySemaphore")
```

A semaphore that is not released can block part of the database. Setting and releasing semaphores in the same method helps to eliminate this risk.

Minimizing the code protected by the semaphore increases the fluidity of the application and avoids the semaphore acting as a bottleneck.

Finally, using the optional *tickCount* parameter of the **Semaphore** command is essential for optimizing the wait for the semaphore to be released. Using this parameter, the commands works as follows:

- The process waits a maximum of the specified number of ticks (300 in the example) for the semaphore to be available, without the code execution moving on to the next line,
- If the semaphore is released before the end of this limit, it is immediately assigned to the process (**Semaphore** returns False) and code execution resumes,
- If the semaphore is not released before the end of this limit, then code execution resumes.

The command also prioritizes requests by establishing a queue. This way, the first process requesting a semaphore will be the first to get one.

Note that the wait time is set depending on the specifics of the application.

## Local or global semaphores

There are two types of semaphores in 4D: local semaphores and global semaphores.

- A local semaphore is accessible by all processes on the same workstation and only on the workstation. A local semaphore can be created by prefixing the name of the semaphore with a dollar sign ($). You use local semaphores to monitor operations among processes executing on the same workstation. For example, a local semaphore can be used to monitor access to an interprocess array shared by all the processes in your single-user database or on the workstation.

- A global semaphore is accessible to all users and all their processes. You use global semaphores to monitor operations among users of a multi-user database.

Global and local semaphores are identical in their logic. The difference resides in their scope.

In client-server mode, global semaphores are shared among all the processes running on all clients and servers. A local semaphore is only shared among the processes running on the machine where it has been created.

In 4D, global or local semaphores have the same scope because you are the only user. However, if your database is being used in both setups, make sure to use global or local semaphores depending on what you want to do.

**Note:** We recommend using local semaphores when you need a semaphore to manage a local aspect for a client of the application, such as the interface or an array of interprocess variables. If you use a global semaphores in this case, it would not only cause unnecessary network exchanges but could also affect other client machines unnecessarily. Using a local semaphore would avoid these undesirable side effects.

# About workers

## Overview

A **Worker process** is a simple and powerful way to exchange information between processes.  This feature is based upon an asynchronous messaging system that allows processes and forms to be called and asked to execute methods with parameters in their own context.

**Note:** A project method can also be executed with parameters in the context of any form using the **CALL FORM** command.

A worker can be "hired" by any process (using the **CALL WORKER** command) to execute project methods with parameters in their own context, thus allowing access to shared information.

This functionality addresses the following needs regarding 4D interprocess communication:

- Since they are supported by both cooperative and preemptive processes, they are the perfect solution for interprocess communication in preemptive processes (interprocess variables are not allowed in preemptive processes).
- They provide a simple alternative to semaphores, which can be cumbersome to set and complex to use (see **About semaphores**).

**Note:** Although they have been designed mainly for interprocess communication in the context of preemptive processes (64-bit versions only), **CALL WORKER** and **CALL FORM** are available in 32-bit versions and can be used with cooperative processes.

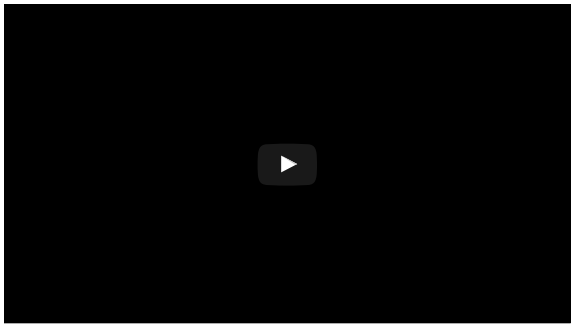
## Using workers

A **worker** is used to ask a process to execute project methods. A worker consists of:

- a unique name, also used to name its associated process
- an associated process, that may or may not exist at a given moment
- a message box
- a startup method (optional)

You ask a worker to execute a project method by calling the **CALL WORKER** command. The worker and its message box are created at first use; its associated process is also automatically launched at first use. If the worker process dies thereafter, the message box remains open and any new message in the box will start a new worker process.

The following animation illustrates this sequence:



Unlike the **New process** command, a worker process remains alive after the execution of the process method ends. This means that all method executions for the same worker will be run in the same process, which maintains all process state information (process variables, current record and current selection, etc.). Consequently, methods executed successively will access and thus share the same information, allowing communication between processes. The worker's message box handles successive calls asynchronously.

**CALL WORKER** encapsulates both the method name and command arguments in a message that is posted in the worker's message box. The worker process is then started, if it does not already exist, and asked to execute the message. This means that **CALL WORKER** will usually return before the method is actually executed (processing is asynchronous). For this reason, **CALL WORKER** does not return any value. If you need a worker to send information back to the process which called it (callback), you need to use **CALL WORKER** again to pass the information needed to the caller. Of course, in this case, the caller itself must be a worker.

It is not possible to use **CALL WORKER** to execute a method in a process created by the **New process** command. Only worker processes have a message box and can thus be called by **CALL WORKER**. Note that a process created by **New**

**process** can call a worker, but cannot be called back.

Worker processes can be created on 4D Server through stored procedures: for example, you can use the **Execute on server** command to execute a method that calls the **CALL WORKER** command.

A worker process is closed by a call to the **KILL WORKER** command, which empties the worker's message box and asks the associated process to stop processing messages and to terminate its current execution as soon as the current task is finished.

The startup method of a worker is the method used to create the worker (at first use). If **CALL WORKER** is called with an empty *method* parameter, then the startup method is automatically reused as method to execute.

The main process created by 4D when opening a database for user and application modes is a worker process and can be called using **CALL WORKER**. Note that the name of the main process may vary depending on the 4D localization language, but it always has the process number 1; as a result, it's more convenient to designate it by process number instead of process name when calling **CALL WORKER**.

### Identifying Worker processes

All worker processes, except the main process, have the process type Worker process (5) returned by the **PROCESS PROPERTIES** command.

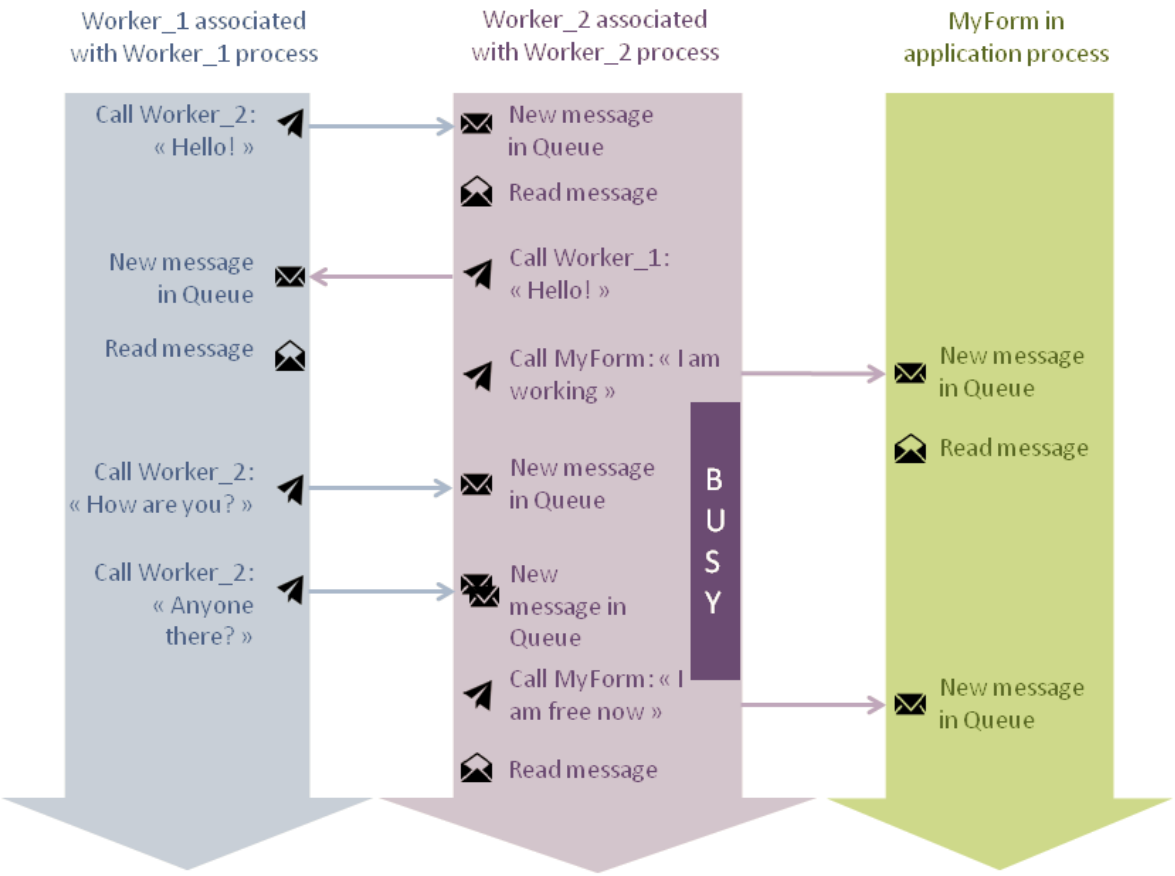
New icons identify worker processes in the Runtime Explorer and the 4D Server administration window:

| Process type | Icon |
|---|---|
| Preemptive worker process |  |
| Cooperative worker process |  |

**Note:** Other existing process icons have been updated in 4D v15 R5.

## Principles of use

The following graphic shows a communication sequence between two workers and a form. Information is exchanged by means of strings:



1. Worker_1 calls Worker_2 and passes "Hello!" as parameter.

2. Worker_2 gets the message and reads it. It calls Worker_1 back and passes "Hello!" as parameter.
3. Worker_2 then calls the MyForm form and passes "I am working" as parameter. It begins a time-consuming operation and its status becomes 'busy'.
4. Worker_1 calls Worker_2 twice but, thanks to the asynchronous messaging system, messages are simply queued. They are processed once Worker_2 is available - after Worker_2 has called MyForm.

# CALL PROCESS

CALL PROCESS ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇒ | Process number |

## Description

**CALL PROCESS** calls the form displayed in the frontmost window of *process*.

**Important: CALL PROCESS** only works between processes running on the same machine.

If you call a process that does not exist, nothing happens.

If *process* (the target process) is not currently displaying a form, nothing happens. The form displayed in the target process receives an On Outside Call event. This event must be enabled for that form in the Design environment **Form Properties** window, and you must manage the event in the form method. If the event is not enabled or if it is not managed in the form method, nothing happens.

**Note:** The On Outside Call event modifies the entry context of the receiving input form. In particular, if a field was being edited, the On Data Change event is generated.

The caller process (the process from which **CALL PROCESS** is executed) does not "wait"— **CALL PROCESS** has an immediate effect. If necessary, you must write a waiting loop for a reply from the called process, using interprocess variables or using process variables (reserved for this purpose) that you can read and write between the two processes (using **GET PROCESS VARIABLE** and **SET PROCESS VARIABLE**).

To communicate between processes that do not display forms, use the **GET PROCESS VARIABLE** and **SET PROCESS VARIABLE** commands.

**CALL PROCESS** has the alternate syntax **CALL PROCESS**(-1).

In order not to slow down the execution of methods, 4D does not redraw interprocess variables each time they are modified. If you pass -1 instead of a process reference number in the *process* parameter, 4D does not call any process. Instead, it redraws all the interprocess variables currently displayed in all windows of any process running on the same machine.

## Example

See example for **On Exit database method**.

# CALL WORKER

CALL WORKER ( process ; method {; param}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Text, Longint | ⇒ | Name or number of worker process |
| method | Text | ⇒ | Name of project method to call |
| param | Expression | ⇒ | Parameter(s) passed to method |

## Description

The **CALL WORKER** command creates or calls the worker process whose name or ID you passed in *process*, and requests the execution of the *method* in its context with the optional *param* parameter(s).

The **CALL WORKER** command encapsulates the *param* parameters into a message and posts it in the worker's message box. For more information on worker processes, please refer to the **About workers** section.

In the *process* parameter, you can specify the worker using its process name or its process number:

- If you pass the number of a process that does not exist, or if the process specified was not created by **CALL WORKER** nor by 4D itself (such as the main application process), **CALL WORKER** does nothing.
- If you pass the name of a process that does not exist, a new worker process is created.

**Note:** The **main process**, created by 4D when a database is opened for the user interface and the application mode, is a worker process and can be called by **CALL WORKER**. However, since its name can vary depending on the 4D language, it is preferable to designate this process using its number (always 1) when you use **CALL WORKER**.

The worker process appears in the list of processes of the Runtime Explorer and is returned by the **PROCESS PROPERTIES** command when applied to this process.

In *method*, you pass the name of the project method to execute in the context of the worker process. You can pass an empty string; in this case, the worker executes the method that was originally used to start its process, if any (i.e., the startup method of the worker).

**Note:** It is not possible to pass an empty string in *method* when the command calls the main process (process number 1) since it was not started using a project method. As a result, ***CALL WORKER*** *(1;"")* does nothing.

You can also pass parameters to the *method* using one or more optional *param* parameters. You pass parameters the same way you would pass them to a subroutine (see the **Passing Parameters to Methods** section). Upon starting execution in the context of the process, the process method receives the parameter values in *$1*, *$2*, and so on. Remember that arrays cannot be passed as parameters to a method. Furthermore, in the context of the **CALL WORKER** command, the following additional considerations need to be taken into account:

- Pointers to tables or fields are allowed.
- Pointers to variables, particularly local and process variables, are not recommended since these variables may be undefined at the moment they are being accessed by the process method.
- If you pass an Object type parameter, 4D creates a copy of the object in the destination process if the worker is in a process different from the one calling the **CALL WORKER** command.

A worker process remains alive until the application is closed or the **KILL WORKER** command is explicitly called for it. To free up memory, do not forget to call this command once a worker process is no longer needed.

## Example

In a form, a button starts a computation: for example, statistics for the selected year. The button creates or calls a worker process that computes the data while the user can continue to work in the form.

The method of the button is:

```
 //call the worker vWorkerName with the parameter
C_LONGINT(vYear)
vYear:=2015 // could have been selected by the user in the form
CALL WORKER("myWorker";"workerMethod";vYear;Current form window)
```

The code of *workerMethod* is:

```
 // this is the method of the worker
 // it can be preemptive or cooperative
C_LONGINT($1) //gets the year
C_LONGINT($2) //gets the window reference
C_OBJECT(vStatResults) //to store statistical results
... //compute statistics
 //once finished, calls the form back with calculated values
 //vStatResults can display results in the form
CALL FORM($2;"displayStats";vStatResults)
```

# CLEAR SEMAPHORE

CLEAR SEMAPHORE ( semaphore )

| Parameter | Type | | Description |
|---|---|---|---|
| semaphore | String | ⇒ | Semaphore to clear |

## Description

**CLEAR SEMAPHORE** erases *semaphore* previously set by the **Semaphore** function.

As a rule, all semaphores that have been created should be cleared. If semaphores are not cleared, they remain in memory until the process that creates them ends. A process can only clear semaphores that it has created. If you try to clear a semaphore from within a process that did not create it, nothing happens.

## Example

See the example for **Semaphore**.

# GET PROCESS VARIABLE

GET PROCESS VARIABLE ( process ; srcVar ; dstVar {; srcVar2 ; dstVar2 ; ... ; srcVarN ; dstVarN} )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇨ | Source process number |
| srcVar | Variable | ⇨ | Source variable |
| dstVar | Variable | ⇦ | Destination variable |

## Description

The **GET PROCESS VARIABLE** command reads the *srcVar* process variables (*srvVar2*, etc.) from the source process whose number is passed in *process*, and returns their current values in the *dstVar* variables ( *dstVar2*, etc.) of the current process.

Each source variable can be a variable, an array or an array element. However, see the restrictions listed later in this section.

In each couple of *srcVar;dstVar* variables, the two variables must be of compatible types, otherwise the values you obtain may be meaningless.

The current process “peeks” the variables from the source process—the source process is not warned in any way that another process is reading the instance of its variables.

**4D Server:** Using 4D Client, you can read variables in a destination process executed on the server machine (stored procedure). To do so, put a minus sign before the process ID number in the *process* parameter.
“Intermachine” process communication, provided by the commands **GET PROCESS VARIABLE**, **SET PROCESS VARIABLE** and **VARIABLE TO VARIABLE**, is possible from client to server only. It is always a client process that reads or write the variables of a stored procedure.

**Tip:** If you do not know the ID number of the server process, you can still use the interprocess variables of the server. To do so, you can use any negative value in *process*. In other words, it is not necessary to know the ID number of the process to be able to use the **GET PROCESS VARIABLE** command with the interprocess variables of the server. This is useful when a stored procedure is launched using the **On Server Startup database method**. As clients machines do not automatically know the ID number of that process, any negative value can be passed in the *process* parameter.

### Restrictions

**GET PROCESS VARIABLE** does not accept local variables as source variables.

On the other hand, the destination variables can be interprocess, process or local variables. You “receive” the values only into variables, not into fields.

**GET PROCESS VARIABLE** accepts any type of source process or interprocess variable, except:

- Pointers
- Array of pointers
- Two-dimensional arrays

The source process must be a user process; it cannot be a kernel process. If the source process does not exist, this command has no effect.

**Note:** In interpreted mode, if a source variable does not exist, the undefined value is returned. You can detect this by using the **Type** function to test the corresponding destination variable.

## Example 1

This line of code reads the value of the text variable *vtCurStatus* from the process whose number is *$vlProcess*. It returns the value in the process variable *vtInfo* of the current process:

```
GET PROCESS VARIABLE($vlProcess;vtCurStatus;vtInfo)
```

## Example 2

This line of code does the same thing, but returns the value in the local variable *$vtInfo* for the method executing in the current process:

```
GET PROCESS VARIABLE($vlProcess;vtCurStatus;$vtInfo)
```

## Example 3

This line of code does the same thing, but returns the value in the variable *vtCurStatus* of the current process:

```
GET PROCESS VARIABLE($vlProcess;vtCurStatus;vtCurStatus)
```

**Note:** The first *vtCurStatus* designates the instance of the variable in the source process The second *vtCurStatus* designates the instance of the variable in the current process.

## Example 4

This example sequentially reads the elements of a process array from the process indicated by *$vlProcess*:

```
GET PROCESS VARIABLE($vlProcess;vl_IPCom_Array;$vlSize)
For($vlElem;1;$vlSize)
   GET PROCESS VARIABLE($vlProcess;at_IPCom_Array{$vlElem};$vtElem)
  ` Do something with $vtElem
End for
```

**Note:** In this example, the process variable *vl_IPCom_Array* contains the size of the array *at_IPCom_Array*, and must be maintained by the source process.

## Example 5

This example does the same thing as the previous one, but reads the array as a whole, instead of reading the elements sequentially:

```
GET PROCESS VARIABLE($vlProcess;at_IPCom_Array;$anArray)
For($vlElem;1;Size of array($anArray))
  ` Do something with $anArray{$vlElem}
End for
```

## Example 6

This example reads the source process instances of the variables *v1*,*v2*,*v3* and returns their values in the instance of the same variables for the current process:

```
GET PROCESS VARIABLE($vlProcess;v1;v1;v2;v2;v3;v3)
```

## Example 7

See the example for the **DRAG AND DROP PROPERTIES** command.

# KILL WORKER

KILL WORKER {{ process )}

| Parameter | Type | | Description |
|---|---|---|---|
| process | Text, Longint | ⇒ | Number or name of process to kill (kills current process if omitted) |

## Description

The **KILL WORKER** command posts a message to the worker process whose name or number you passed in *process*, asking it to ignore any pending messages and to terminate its execution as soon as the current task ends.

This command can only be used with worker processes. For more information, please refer to the **About workers** section.

In *process*, you pass either the name or number of the worker process whose execution needs to be terminated. If no worker with the specified process name or number exists, **KILL WORKER** does nothing.
If you do not pass any parameter, **KILL WORKER** applies to the currently running worker and is therefore equivalent to ***KILL WORKER*** *(Current process)*.

If **KILL WORKER** is applied to a worker that was not created explicitly using the **CALL WORKER** command (for example, the main application worker), it only asks this worker to empty its message box. Consequently, ***KILL WORKER*** *(1)* does nothing.

## Example

The following code (executed from a form, for example) triggers the termination of a worker:

```
CALL WORKER(vWorkerName;"theWorker";"end")
```

In the worker method (*theWorker*), you add some code to handle this situation:

```
 //theWorker method
C_TEXT($1) //param

Case of
   :($1="call") //the worker is called
      ... //do something
   :($1="end") //the worker is asked to kill itself
      KILL WORKER
End case
```

# Semaphore

Semaphore ( semaphore {; tickCount} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| semaphore | String | ⇒ | Semaphore to test and set |
| tickCount | Longint | ⇒ | Maximum waiting time |
| Function result | Boolean | ⇐ | Semaphore has been successfully set (FALSE) or Semaphore was already set (TRUE) |

## Description

A semaphore is a flag shared among workstations or among processes on the same workstation. A semaphore simply exists or does not exist. The methods that each user is running can test for the existence of a semaphore. A semaphore can only be removed by the client workstation or process that created it. By creating and testing semaphores, methods can communicate between workstations. You do not use semaphores to protect record access. This is automatically done by 4D and 4D Server. Use semaphores to prevent several users from performing the same operation at the same time.

The **Semaphore** function returns TRUE and does nothing if *semaphore* already exists. If *semaphore* does not exist, **Semaphore** creates it and returns FALSE. Only one user at a time can create a semaphore. If **Semaphore** returns FALSE, it means that the semaphore did not exist, but it also means that the semaphore has been set for the process in which the call has been made.

**Semaphore** returns FALSE if the semaphore was not set. It also returns FALSE if the semaphore is already set by the same process in which the call has been made.

A semaphore is limited to 255 characters, including prefix ($). If you pass a longer string, the semaphore will be tested with the truncated string. Keep in mind that semaphore names are case-sensitive in 4D (for example, the program considers that "MySemaphore" is different from "mysemaphore").

The optional parameter *tickCount* allows you to specify a waiting time (in ticks) if *semaphore* is already set. In this case, the function will wait either for the semaphore to be freed or the waiting time to expire before returning **True**.

There are two types of semaphores in 4D: local semaphores and global semaphores.

- A local semaphore is accessible by all processes on the same workstation and only on the workstation. A local semaphore can be created by prefixing the name of the semaphore with a dollar sign ($). You use local semaphores to monitor operations among processes executing on the same workstation. For example, a local semaphore can be used to monitor access to an interprocess array shared by all the processes in your single-user database or on the workstation.
- A global semaphore is accessible to all users and all their processes. You use global semaphores to monitor operations among users of a multi-user database.

Global and local semaphores are identical in their logic. The difference resides in their scope.

In client-server mode, global semaphores are shared among all the processes running on all clients and servers. A local semaphore is only shared among the processes running on the machine where it has been created.

In 4D, global or local semaphores have the same scope because you are the only user. However, if your database is being used in both setups, make sure to use global or local semaphores depending on what you want to do.

**Note:** We recommend using local semaphores when you need a semaphore to manage a local aspect for a client of the application, such as the interface or an array of interprocess variables. If you use a global semaphores in this case, it would not only cause unnecessary network exchanges but could also affect other client machines unnecessarily. Using a local semaphore would avoid these undesirable side effects.

## Example 1

Here is typical code for using a semaphore:

```
While(Semaphore("MySemaphore";300))
   IDLE
End while
 // place code protected by semaphore here
CLEAR SEMAPHORE("MySemaphore")
```

## Example 2

In this example, you want to prevent two users from doing a global update of the prices in a Products table. The following method uses semaphores to manage this:

```
If(Semaphore("UpdatePrices")) ` Try to create the semaphore
   ALERT("Another user is already updating prices. Retry later.")
Else
   DoUpdatePrices ` Update all the prices
   CLEAR SEMAPHORE("UpdatePrices")) ` Clear the semaphore
End if
```

## Example 3

The following example uses a local semaphore. In a database with several processes, you want to maintain a To Do list. You want to maintain the list in an interprocess array and not in a table. You use a semaphore to prevent simultaneous access. In this situation, you only need to use a local semaphore, because your To Do list is only for your use.

The interprocess array is initialized in the Startup method:

```
ARRAY TEXT(◊ToDoList;0) ` The To Do list is initially empty
```

Here is the method used for adding items to the To Do list:

```
 ` ADD TO DO LIST project method
 ` ADD TO DO LIST ( Text )
 ` ADD TO DO LIST ( To do list item )
C_TEXT($1)
If(Not(Semaphore("$AccessToDoList";300)))
 ` Wait 5 seconds if the semaphore already exists
   $vlElem:=Size of array(◊ToDoList)+1
   INSERT IN ARAY(◊ToDoList;$vlElem)
   ◊ToDoList{$vlElem}:=$1
   CLEAR SEMAPHORE("$AccessToDoList") ` Clear the semaphore
End if
```

You can call the above method from any process.

## Example 4

This method allows you to not execute a method when a semaphore is present; the method alerts the calling method with an error code and plain text.

Syntax:

```
$L_Error:=Semaphore_proof(->$T_Text_error)
```

```
 // Protective structure using semaphores
C_LONGINT($0)
C_POINTER($1) // error message

 // Start of method
C_LONGINT($L_MyError)
$L_MyError:=1

C_TEXT($T_Sema_local)
$T_Sema_local:="$tictac"

If(Semaphore($T_Sema_local;300))
 // We expected 300 ticks but the semaphore
 // was not released by the one that placed it:
 // we end up here
   $L_MyError:=-1

Else
```

```
    // This method is only run by one process at a time

    // We placed the semaphore as we entered
    // so we're the only ones that can remove it

    // Do something
      ...
    // Then finish by removing the semaphore
      CLEAR SEMAPHORE($T_Sema_local)
End if

C_TEXT($T_Message)
If($L_MyError=-1)
   $T_Message:="The semaphore "+$T_Sema_local+" has blocked access to the rest of the code"
Else
   $T_Message:="OK"
End if

$0:=$L_MyError
$1->:=$T_Message  // The calling method receives an error code and an explanation in plain text
```

# SET PROCESS VARIABLE

SET PROCESS VARIABLE ( process ; dstVar ; expr {; dstVar2 ; expr2 ; ... ; dstVarN ; exprN} )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ➡ | Destination process number |
| dstVar | Variable | ➡ | Destination variable |
| expr | Variable | ➡ | Source expression (or source variable) |

## Description

The **SET PROCESS VARIABLE** command writes the *dstVar* process variables (*dstVar2*, etc.) of the destination process whose number is passed in *process* using the values passed in *expr1* (*expr2*, etc.).

Each destination variable can be a variable or an array element. However, see the restrictions listed later in this section.

For each couple of *dstVar;expr* variables, the expression must be of a type compatible with the destination variable, otherwise you may end up with a meaningless value in the variable. In interpreted mode, if a destination variable does not exist, it is created and assigned with the expression.

The current process “pokes” the variables of the destination process—the destination process is not warned in any way that another process is writing the instance of its variables.

**4D Server:** Using 4D Client, you can write variables in a destination process executed on the server machine (stored procedure). To do so, put a minus sign before the process ID number in the *process* parameter.
“Intermachine” process communication, provided by the commands **SET PROCESS VARIABLE**, **GET PROCESS VARIABLE** and **VARIABLE TO VARIABLE**, is possible from client to server only. It is always a client process that reads or write the variables of a stored procedure.

**Tip:** If you do not know the ID number of the server process, you can still use the interprocess variables of the server. To do so, use any negative value in *process*. In other words, it is not necessary to know the ID number of the process to be able to use the **SET PROCESS VARIABLE** command with the interprocess variables of the server. This is useful when a stored procedure is launched using the **On Server Startup database method**. As client machines do not automatically know the ID number of that process, any negative value can be passed in the *process* parameter.

### Restrictions

**SET PROCESS VARIABLE** does not accept local variables as destination variables.

**SET PROCESS VARIABLE** accepts any type of destination process or interprocess variable, except:

- Pointers
- Arrays of any type. To write an array as a whole from one process to another one, use the command **VARIABLE TO VARIABLE**. Note, however, that **SET PROCESS VARIABLE** allows you to write the element of an array.
- You cannot write the element of an array of pointers or the element of a two-dimensional array.

The destination process must be a user process; it cannot be a kernel process. If the destination process does not exist, an error is generated. You can catch this error using an error-handling method installed with **ON ERR CALL**.

## Example 1

This line of code sets (to the empty string) the text variable *vtCurStatus* of the process whose number is *$vlProcess*:

```
SET PROCESS VARIABLE($vlProcess;vtCurStatus;"")
```

## Example 2

This line of code sets the text variable *vtCurStatus* of the process whose number is *$vlProcess* to the value of the variable *$vtInfo* from the executing method in the current process:

```
SET PROCESS VARIABLE($vlProcess;vtCurStatus;$vtInfo)
```

## Example 3

This line of code sets the text variable *vtCurStatus* of the process whose number is *$vlProcess* to the value of the same variable in the current process:

```
SET PROCESS VARIABLE($vlProcess;vtCurStatus;vtCurStatus)
```

**Note:** The first *vtCurStatus* designates the instance of the variable in the destination process. The second *vtCurStatus* designates the instance of the variable in the current process.

## Example 4

This example sequentially sets to uppercase all elements of a process array from the process indicated by *$vlProcess*:

```
GET PROCESS VARIABLE($vlProcess;vl_IPCom_Array;$vlSize)
For($vlElem;1;$vlSize)
   GET PROCESS VARIABLE($vlProcess;at_IPCom_Array{$vlElem};$vtElem)
   SET PROCESS VARIABLE($vlProcess;at_IPCom_Array{$vlElem};Uppercase($vtElem))
End for
```

**Note:** In this example, the process variable *vl_IPCom_Array* contains the size of the array *at_IPCom_Array* and must be maintained by the source/destination process.

## Example 5

This example writes the destination process instance of the variables *v1*, *v2* and *v3* using the instance of the same variables from the current process:

```
SET PROCESS VARIABLE($vlProcess;v1;v1;v2;v2;v3;v3)
```

# Test semaphore

Test semaphore ( semaphore ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| semaphore | String | ⇒ | Name of the semaphore to test |
| Function result | Boolean | ⇐ | True = the semaphore exists, False = the semaphore doesn't exist |

## Description

The **Test semaphore** command tests for the existence of a semaphore.

The difference between the **Semaphore** function and the **Test semaphore** function is that **Test semaphore** doesn't create the *semaphore* if it doesn't exist. If the *semaphore* exists, the function returns **True**. Otherwise, it returns **False**.

## Example

The following example allows you to know the state of a process (in our case, while modifying the code) without modifying *semaphore*:

```
$Win:=Open window(x1;x2;y1;y2;-Palette window)
Repeat
   If(Test semaphore("Encrypting code"))
      POSITION MESSAGE($x3;$y3)
      MESSAGE("Encrypting code being modified.")
   Else
      POSITION MESSAGE($x3;$y3)
      MESSAGE("Modification of the encrypting code authorized.")
   End if
Until(StopInfo)
CLOSE WINDOW
```

# VARIABLE TO VARIABLE

VARIABLE TO VARIABLE ( process ; dstVar ; srcVar {; dstVar2 ; srcVar2 ; ... ; dstVarN ; srcVarN} )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ➡ | Destination process number |
| dstVar | Variable | ➡ | Destination variable |
| srcVar | Variable | ➡ | Source variable |

## Description

The **VARIABLE TO VARIABLE** command writes the *dstVar* process variables (*dstVar2*, etc.) of the destination process whose number is passed in *process* using the values of the variables *srcVar1 srcVar2*, etc.

**VARIABLE TO VARIABLE** has the same action as **SET PROCESS VARIABLE**, with the following differences:

- You pass source expressions to **SET PROCESS VARIABLE**, and therefore cannot pass an array as a whole. You must exclusively pass source variables to **VARIABLE TO VARIABLE**, and therefore can pass an array as a whole.
- Each destination variable of **SET PROCESS VARIABLE** can be a variable or an array element, but cannot be an array as a whole. Each destination variable of **VARIABLE TO VARIABLE** can be a variable or an array or an array element.

**4D Server:** "Intermachine" process communication, provided by the commands **GET PROCESS VARIABLE**, **SET PROCESS VARIABLE** and **VARIABLE TO VARIABLE**, is possible from client to server only. It is always a client process that reads or write the variables of a stored procedure.

For each couple of *dstVar;expr* variables, the source variable must be of a type compatible with the destination variable, otherwise you may end up with a meaningless value in the variable. In interpreted mode, if a destination variable does not exist, it is created and assigned with the type and value of the source variable.

The current process "pokes" the variables of the destination process—the destination process is not warned in any way that another process is writing the instance of its variables.

### Restrictions

**VARIABLE TO VARIABLE** does not accept local variables as destination variables.

**VARIABLE TO VARIABLE** accepts any type of destination process or interprocess variables except:

- Pointers
- Array of pointers
- Two-dimensional arrays

The destination process must be a user process; it cannot be a kernel process. If the destination process does not exist, an error is generated. You can catch this error using an error-handling method installed with **ON ERR CALL**.

## Example

The following example reads a process array from the process indicated by *$vlProcess*, sequentially sets the elements to uppercase and then writes back the array as a whole:

```
GET PROCESS VARIABLE($vlProcess;at_IPCom_Array;$anArray)
For($vlElem;1;Size of array($anArray))
   $anArray{$vlElem}:=Uppercase($anArray{$vlElem})
End for
VARIABLE TO VARIABLE($vlProcess;at_IPCom_Array;$anArray)
```

# Process (User Interface)

- BRING TO FRONT
- Frontmost process
- HIDE PROCESS
- SHOW PROCESS

# BRING TO FRONT

BRING TO FRONT ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇨ | Process number of the process to pass to the frontmost level |

## Description

**BRING TO FRONT** brings all the windows belonging to *process* to the front. If the process is already the frontmost process, the command does nothing. If the process is hidden, you must use **SHOW PROCESS** to display the process, otherwise **BRING TO FRONT** has no effect.

The Main and Design processes can be brought to the front using this command.

**Note:** When the process contains several windows and you want to pass a specific one to the front, it is preferable to use, for example, the **SET WINDOW RECT** command.

## Example

The following example is a method that can be executed from a menu. It checks to see if *◊vlAddCust_PID* is the frontmost process. If not, the method brings it to the front:

```
If(Frontmost process#◊vlAddCust_PID)
   BRING TO FRONT(◊vlAddCust_PID)
End if
```

# Frontmost process

Frontmost process {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Process number for first non-floating window |
| Function result | Integer | ⇐ | Number of the process whose windows are in the front |

## Description

**Frontmost process** returns the number of the process whose window (or windows) are in the front.

When you have one or more floating windows open, there are two window layers:

- Regular windows
- Floating windows

If the **Frontmost process** function is used from within a floating window form method or object method, the function returns the process reference number of the frontmost floating window in the floating window layer. If you specify the optional * parameter, the function returns the process reference number of the frontmost active window in the regular window layer.

## Example

See the example for **BRING TO FRONT**.

# HIDE PROCESS

HIDE PROCESS ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇨ | Process number or process to be hidden |

## Description

**HIDE PROCESS** hides all windows that belong to *process*. All interface elements of *process* are hidden until the next **SHOW PROCESS**. The menu bar of the process is also hidden. This means that opening a window while the process is hidden does not make the screen redraw or display. If the process is already hidden, the command has no effect.

The only exception to this rule is the Debugger window. If the Debugger window is displayed when *process* is a hidden process, *process* is displayed and becomes the frontmost process.

If you do not want a *process* to be displayed when it is created, **HIDE PROCESS** should be the first command in the process method. The Main Process and Cache Manager processes cannot be hidden using this command.

Even though a process may be hidden, the process is still executing.

## Example

The following example hides all the windows belonging to the current process:

```
HIDE PROCESS(Current process)
```

# SHOW PROCESS

SHOW PROCESS ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ➡ | Process number of process to be shown |

## Description

**SHOW PROCESS** displays all the windows belonging to *process*. This command does not bring the windows of *process* to the frontmost level. To do this, use the **BRING TO FRONT** command.

If the process was already displayed, the command has no effect.

## Example

The following example displays a process called Customers, if it has been previously hidden. The process reference to the Customers process is stored in the interprocess variable ◊*Customers*:

```
SHOW PROCESS(◊Customers)
```

# Processes

# Processes

Multi-tasking in 4D is the ability to have distinct database operations that are executed simultaneously. These operations are called processes.

Multiple processes are like multiple users on the same computer, each working on his or her own task. This essentially means that each method can be executed as a distinct database task.

This section covers the following topics:

- Creating and clearing processes
- Elements of a process
- User processes
- Processes created by 4D
- Local and global processes
- Record locking between processes

**Note**: This section does not cover stored procedures. See the **Stored Procedures** section in the 4D Server Reference manual.

## Creating and Clearing Processes

There are several ways to create a new process:

- Execute a method in the Design environment after checking the **New Process** check box in the **Execute Method** dialog box. The method chosen in the Execute Method dialog box is the process method.
- Processes can be run by choosing menu commands. In the **Menu Bar editor**, select the menu command and click the **Start a New Process** check box. The method associated with the menu command is the process method.
- Use the **New process** function. The method passed as a parameter to the **New process** function is the process method.
- Use the **Execute on server** function in order to create a stored procedure on the server. The method passed as a parameter of the function is the process method.
- Use the **CALL WORKER** command. If the worker process does not already exist, it is created.

A process can be cleared under the following conditions. The first two conditions are automatic:

- When the process method finishes executing
- When the user quits from the database
- If you stop the process procedurally or use the Abort button in the Debugger
- If you choose **Abort** in the Runtime Explorer
- If you call the **KILL WORKER** command (to delete a worker process only).

A process can create another process. Processes are not organized hierarchically—all processes are equal, regardless of the process from which they have been created. Once the “parent” process creates a “child” process, the child process will continue regardless of whether or not the parent process is still executing.

## Elements of a Process

Each process contains specific elements. There are three types of distinctly different elements in a process:

- **Interface elements**: Elements that are necessary to display a process.
- **Data elements**: Information that is related to the data in the database.
- **Language elements**: Elements that are used procedurally or are that are important for developing your own application.

### Interface Elements

Interface elements consist of the following:

- **Menu bar**: Each process can have its own current menu bar. The menu bar of the frontmost process is the current menu bar for the database.
- **One or more windows**: Each process can have more than one window open simultaneously. On the other hand, some processes have no windows at all.
- **One active (frontmost) window**: Even though a process can have several windows open simultaneously, each process has only one active window. To have more than one active window, you must start more than one process.

**Notes:**

- Processes do not include menu bars by default which means that the standard **Edit** menu shortcuts (in particular, cut/copy/paste) are not availalbe in process windows. When you call dialog boxes or 4D editors (form editor, query editor, **Request**, etc.) from a process, if you want for the user to be able to benefit from keyboard shortcuts like copy/paste, you need to make sure that the equivalent of an **Edit** menu is installed in the process.
- Preemptive processes and processes that are executed on the server (stored procedures) must not contain elements of the interface.

### Data Elements

Data elements refer to the data used by the database. The data elements are:

- **Current selection per table**: Each process has a separate current selection. One table can have a different current selection in different processes.
- **Current record per table**: Each table can have a different current record in each process.

**Note**: This description of the data elements is valid if your processes are global in scope. By default, all processes are global. See the "**Global and Local Processes**" section below.

### Language Elements

The language elements of a process are the elements related to programming in 4D.

- **Variables**: Every process has its own process variables. See **Variables** for more information. Process variables are recognized only within the domain of their native process.
- **Default table**: Each process has its own default table. However, note that the **DEFAULT TABLE** command is only a typing convention for programming.
- **Input and Output forms**: Default input and output forms can be set procedurally for each table in each process.
- **Process sets**: Each process has its own process sets. *LockedSet* is a process set. Process sets are cleared as soon as the process method ends.
- **On Error Call per process**: Each process has its own error-handling method.
- **Debugger window**: Each process can have its own Debugger window.

## User Processes

User processes are processes that you create to perform certain tasks. They share processing time with the kernel processes. As an example, Web connection processes are user processes.

The 4D application also creates processes for its own needs. The following processes are created and managed by 4D:

- **Main process**: The main process manages the display windows of the user interface.
- **Design process**: The Design process manages the windows and editors of the Design environment. There is no Design process in a compiled database that does not contain interpreted code.
- **Web Server process**: The Web Server process runs when the database is published on the Web. See the **Web server configuration and connection management** section for more information.
- **Cache Manager process**: The Cache Manager process manages disk I/ O for the database. This process is created as soon as 4D or 4D Server are run.
- **Indexing process**: The Indexing process manages the indexing of fields in a database as a separate process. This process is created when an index for a field is built or deleted.
- **On Event Manager process**: This process is created when an event-handling method is installed by the **ON EVENT CALL** command. It executes the event method installed by **ON EVENT CALL** whenever there is an event. The event method is the process method for this process. This process executes continuously, even if no method is executing. Event handling also occurs in the Design environment.

## Cooperative and preemptive processes

Starting with 4D v15 R5 64 bits, 4D allows you to create preemptive user processes in compiled mode. In previous versions, only cooperative user processes were available.

When run in *preemptive* mode, a process is dedicated to a CPU. Process management is then delegated to the system, which can allocate each CPU separately on a multi-core machine. When run in *cooperative* mode, all processes are managed by the parent application thread and share the same CPU, even on a multi-core machine.

As a result, in preemptive mode, overall performance of the application is improved, especially on multi-core machines, since multiple processes (*threads*) can *truly* run simultaneously. However, actual gains depend on the operations being executed. In return, since each thread is independent from the others in preemptive mode, and not managed directly by the application, there are specific constraints applied to methods that you want to be compliant with preemptive use. Additionally, preemptive execution is only available in certain specific contexts.

Management of preemptive processes is covered in the **Preemptive 4D processes** section.

## Global and Local Processes

Processes can be either global or local in scope. By default, all processes are global.

Global processes can perform any operation, including accessing and manipulating data. In most cases, you will want to use global processes.

Local processes should be used only for operations that do not access data. For example, you can use a local process to run an event-handling method or to control interface elements such as floating windows.

You specify that a process is local in scope through its name. The name of local process must start with a dollar sign (`$`).

**Warning**: If you attempt to access data from a local process, you access it though the main process, risking conflicts with operations performed within that process.

**4D Server**: Using local processes on the Client side for operations that do not require data access reserves more processing time for server-intensive tasks.

## Record Locking Between Processes

A record is locked when another process has successfully loaded the record for modification. A locked record can be loaded by another process, but cannot be modified. The record is unlocked only in the process in which the record is being modified. A table must be in read/write mode for a record to be loaded unlocked. For more information, refer to the **Record Locking** section.

# Preemptive 4D processes

4D Developer Edition 64-bit for Windows and OS X offers a powerful feature allowing you to **execute 4D code in preemptive processes**. Thanks to this new feature, your 4D compiled applications will be able to take full advantage of multi-core computers so that their execution will be faster and they can support more connected users.

## What is a preemptive process?

When run in *preemptive* mode, a process is dedicated to a CPU. Process management is then delegated to the system, which can allocate each CPU separately on a multi-core machine.

When run in *cooperative* mode (the only mode available in 4D until 4D v15 R5), all processes are managed by the parent application thread and share the same CPU, even on a multi-core machine.

As a result, in preemptive mode, overall performance of the application is improved, especially on multi-core machines, since multiple processes (*threads*) can *truly* run simultaneously. However, actual gains depend on the operations being executed.

In return, since each thread is independent from the others in preemptive mode, and not managed directly by the application, there are specific constraints applied to methods that you want to be compliant with preemptive use. Additionally, preemptive execution is only available in certain specific contexts.

## Availability of preemptive mode

The use of preemptive mode is available in **4D 64-bit versions** only. The following execution contexts are currently supported:

| | Preemptive execution |
|---|---|
| 4D Server | X |
| 4D remote | - |
| 4D single-user | X |
| Compiled mode | X |
| Interpreted mode | - |

If the execution context supports preemptive mode and if the method is "thread-safe", a new 4D process launched using the **New process** or **CALL WORKER** commands, or the "Run method" menu item, will be executed in a preemptive thread.

Otherwise, if you call **New process** or **CALL WORKER** from an execution context that is not supported (for example on a remote 4D machine), the process is always cooperative.

**Note:** You can run a process in preemptive mode from a 4D remote by starting a stored procedure on the server with the language, for example using **Execute on server**.

## Thread-safe vs thread-unsafe

4D code can only be run in a preemptive thread when certain specific conditions are met. Each part of the code being executed (commands, methods, variables, etc.) must be compliant with preemptive use. Elements that can be run in preemptive threads are called **thread-safe** and those that cannot be run in preemptive threads are called **thread-unsafe**.

**Note:** Since a thread is handled independently starting from the parent process method, the entire call chain must not include any thread-unsafe code; otherwise, preemptive execution will not be possible. This point is discussed in the **When is a process started preemptively?** paragraph.

The "thread safety" property of each element depends on the element itself:

- 4D commands: thread safety is an internal property. In the *Language Reference*, thread-safe commands are identified by the  icon. A large part of 4D commands can run in preemptive mode.
- Project methods: conditions for being thread-safe are listed in the **Writing a thread-safe method** paragraph.

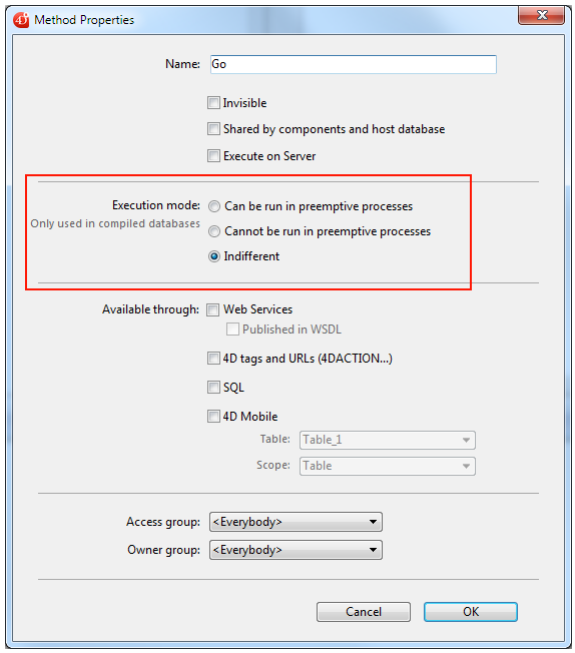
Basically, code to be run in preemptive threads cannot call parts with external interactions, such as plug-in code or interprocess variables. Accessing data, however, is allowed since the 4D data server supports preemptive execution.

## Declaration of preemptive execution mode

By default, 4D executes all the project methods of your application in cooperative mode. If you want to benefit from the preemptive mode feature, the first step consists in explicitly declaring all methods that you want to be started in preemptive mode whenever possible -- that is, methods that you consider capable of being run in a preemptive process. The compiler will check that these methods are actually thread-safe (see for more information). You can also disallow preemptive mode for some methods, if necessary.

Keep in mind that declaring a method "capable" of preemptive use makes it eligible for preemptive execution but does not guarantee that it will actually be executed in preemptive mode at runtime. Starting a process in preemptive mode results from an evaluation performed by 4D regarding the properties of all the methods in the call chain of the process (for more information, see the paragraph).

To declare your method eligible for use in preemptive mode, you need to use the **Execution mode** declaration option in the Method Properties dialog box:



The following options are provided:

- **Can be run in preemptive processes**: By checking this option, you declare that the method is capable of being run in a preemptive process and therefore should be run in preemptive mode whenever possible. The "preemptive" property of the method is set to "capable".
  When this option is checked, the 4D compiler will verify that the method is actually capable and will return errors if this is not the case -- for example, if it directly or indirectly calls commands or methods that cannot be run in preemptive mode (the entire call chain is parsed but errors are only reported to the first sublevel). You can then edit the method so that it becomes thread-safe, or select another option.
  If the method's preemptive capability is approved, it is tagged "thread-safe" internally and will be executed in preemptive mode whenever the required conditions are met. This property defines its eligibility for preemptive mode but does not guarantee that the method will actually be run in preemptive mode, since this execution mode requires a specific context (see **When is a process started preemptively?**).

- **Cannot be run in preemptive processes**: By checking this option, you declare that the method must never be run in preemptive mode, and therefore must always be run in cooperative mode, like in previous 4D versions. The "preemptive" property of the method is set to "incapable".
  When this option is checked, the 4D compiler will not verify the ability of the method to run preemptively; it is automatically tagged "thread-unsafe" internally (even if it is theoretically capable). When called at runtime, this method will "contaminate" any other methods in the same thread, thus forcing this thread to be executed in cooperative mode, even if the other methods are thread-safe.

- **Indifferent** (default): By checking this option, you declare that you do not want to handle the preemptive property for the method. The "preemptive" property of the method is set to "indifferent".
  When this option is checked, the 4D compiler will evaluate the preemptive capability of the method and will tag it internally as "thread-safe" or "thread-unsafe". No error related to preemptive execution is returned. If the method is evaluated as thread-safe, at runtime it will not prevent preemptive thread execution when called in a preemptive

context. Conversely, if the method is evaluated "thread-unsafe", at runtime it will prevent any preemptive thread execution when called.
Note that with this option, whatever the internal thread safety evaluation, the method will always be executed in cooperative mode when called directly by 4D as the first parent method (for example through the **New process** command). If tagged "thread-safe" internally, it is only taken into account when called from other methods inside a call chain.

**Note:** A component method declared as "Shared with components and host databases" must also be declared "capable" in order to be run in a preemptive thread by the host database.

When exporting the method code using, for example, **METHOD GET CODE**, the "preemptive" property is exported in the "%attributes" comment with a value of "capable" or "incapable" (the property is not available if the option is "Indifferent"). The **METHOD GET ATTRIBUTES** and **METHOD SET ATTRIBUTES** commands also get or set the "preemptive" attribute with a value of "indifferent", "capable", or "incapable".

The following table summarizes the effects of the preemptive mode declaration options:

| Option | Preemptive property value (interpreted) | Compiler action | Internal tag (compiled) | Execution mode if call chain is thread-safe |
|---|---|---|---|---|
| Can be run in preemptive processes | capable | Check capability and return errors if incapable | thread-safe | Preemptive |
| Cannot be run in preemptive processes | incapable | No evaluation | thread-unsafe | Cooperative |
| Indifferent | indifferent | Evaluationbut no errors returned | thread-safe or thread-unsafe | If thread-safe: preemptive; if thread-unsafe: cooperative; if called directly: cooperative |

## When is a process started preemptively?

**Reminder:** Preemptive execution is only available in compiled mode.

In compiled mode, when starting a process created by either **New process** or **CALL WORKER** methods, 4D reads the preemptive property of the process method (also named *parent* method) and executes the process in preemptive or cooperative mode, depending on this property:

- If the process method is thread-safe (validated during compilation), the process is executed in a preemptive thread.
- If the process method is thread-unsafe, the process is run in a cooperative thread.
- If the preemptive property of the process method was set to "indifferent", by compatibility the process is run in a cooperative thread (even if the method is actually capable of preemptive use). Note however that this compatibility feature is only applied when the method is used as a process method: a method declared "indifferent" but internally tagged "thread-safe" by the compiler can be called preemptively by another method (see below).

The actual thread-safe property depends on the call chain. If a method with the property declared as "capable" calls a thread-unsafe method at either of its sublevels, a compilation error will be returned: if a single method in the entire call chain is thread-unsafe, it will "contaminate" all other methods and preemptive execution will be rejected by the compiler. A preemptive thread can be created only when the entire chain is thread-safe and the process method has been declared "Can be run in preemptive process".
On the other hand, the same thread-safe method may be executed in a preemptive thread when it is in one call chain, and in a cooperative thread when it is in another call chain.

For example, consider the following project methods:

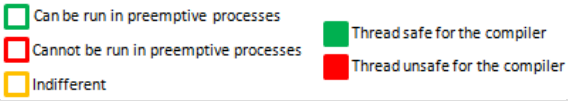
```
 //MyDialog project method
 //contains interface calls: will be internally thread unsafe
$win:=Open form window("tools";Palette form window)
DIALOG("tools")
```

```
 //MyComp project method
 //contains simple computing: will be internally is thread safe
C_LONGINT($0;$1)
$0:=$1*2
```

```
 //CallDial project method
C_TEXT($vName)
MyDialog
```

```
 //CallComp project method
C_LONGINT($vAge)
MyCom($vAge)
```

Executing a method in preemptive mode will depend on it "execution" property and the call chain. The following table illustrates these various situations:



| Declaration and call chain | Compilation | Resulting thread safety | Execution | Comment |
|---|---|---|---|---|
|  | OK |  | Preemptive | CallComp is the parent method, declared "capable" of preemptive use; since MyComp is thread-safe internally, CallComp is thread-safe and the process is preemptive |
|  | Error |  | Execution is impossible | CallDial is the parent method, declared "capable"; MyDialog is "indifferent". However, since MyDialog is thread-unsafe internally, it contaminates the call chain. The compilation fails because of a conflict between the declaration of CallDial and its actual capability. The solution is either to modify MyDialog so that it becomes thread-safe so that execution is preemptive, or to change the declaration of CallDial 's property in order to run as cooperative |
|  | OK |  | Cooperative | Since CallDial is declared "incapable" of preemptive use, compilation is thread-unsafe internally; thus execution will always be cooperative, regardless of the status of MyDialog |
|  | OK |  | Cooperative | Since CallComp is the parent method with property "Indifferent", then the process is cooperative even if the entire chain is thread-safe. |
|  | OK |  | Cooperative | Since CallDial is the parent method (property was "Indifferent"), then the process is cooperative and compilation is successful |

### How to find out the actual execution mode

4D allows you to identify the execution mode of processes in compiled mode:

- The **PROCESS PROPERTIES** command allows you to find out whether a process is run in preemptive or cooperative mode.
- Both the Runtime Explorer and the 4D Server administration window display specific icons for preemptive processes (as well as worker processes):

| Process type | Icon |
|---|---|
| Preemptive stored procedure |  |
| Preemptive worker process |  |
| Cooperative worker process |  |

## Writing a thread-safe method

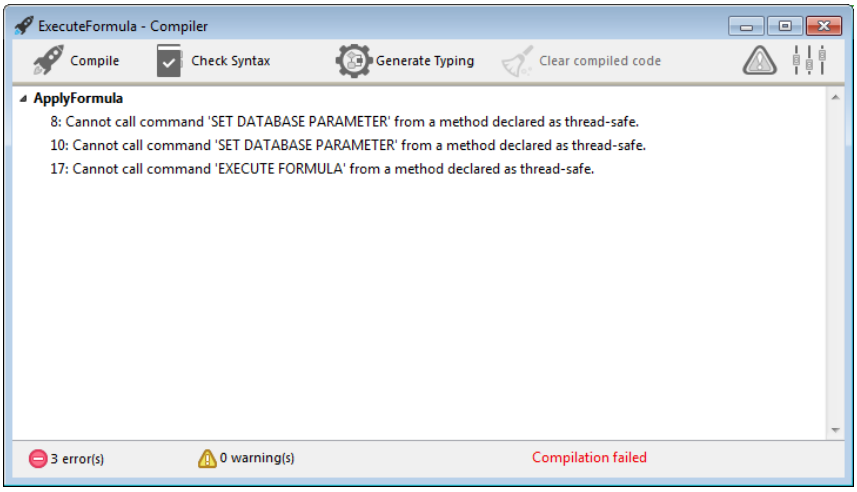
To be thread-safe, a method must respect the following rules:

- It must have either the "Can be run in preemptive processes" or "Indifferent" property
- It must not call a 4D command that is thread-unsafe.
- It must not call another project method that is thread-unsafe
- It must not call a plug-in
- It must not use **Begin SQL/End SQL** code blocks
- It must not use any interprocess variables(*)
- It must not call interface objects(**) (there are exceptions however, see below).

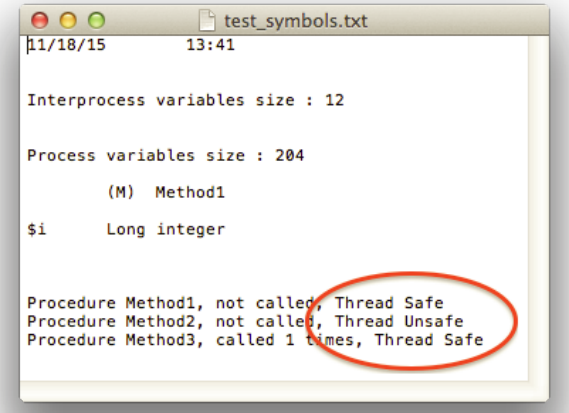
**Note:** In the case of a "Shared by components and host databases" method, the "Can be run in preemptive processes" property must be selected.

(*) Work processes allow you to exchange data between any processes, including preemptive processes. For more information, please refer to the **About workers**.
(**) The **CALL FORM** command provides an elegant solution to call interface objects from a preemptive process.

Methods with the "Can be run in preemptive processes" property will be checked by 4D during compilation. A compilation error is issued whenever the compiler finds something that prevents it from being thread-safe:



The symbol file, if enabled, also contains the thread safety status for each method:



### User interface

Since they are "external" accesses, calls to user interface objects such as forms, as well as to the Debugger, are not allowed in preemptive threads.

The only possible accesses to the user interface from a preemptive thread are:

- Standard error dialog. The dialog is displayed in the user mode process (on 4D single-user) or the server user interface process (4D Server). The **Trace** button is disabled.
- Standard progress indicators
- **ALERT**, **Request** and **CONFIRM** dialogs. The dialog is displayed in the user mode process (on 4D single-user) or the server user interface process (4D Server).

Note that if 4D Server has been launched as a service on Windows with no user interaction allowed, the dialogs will not be displayed.

### Thread-safe 4D commands

A significant number of 4D commands are thread-safe. In the documentation, the  icon in the command property area indicates that the command is thread-safe. You can get a list of thread-safe commands in the *Language Reference* manual. You can also use **Command name** which can return the thread safety property for each command.

### Triggers

When a method uses a command that can call a trigger, the 4D compiler evaluates the thread safety of the trigger in order to check the thread safety of the method:

```
SAVE RECORD([Table_1]) //trigger on Table_1, if it exists, must be thread-safe
```

Here is the list of commands that are checked at compilation time for trigger thread safety:

- SAVE RECORD
- SAVE RELATED ONE
- DELETE RECORD
- DELETE SELECTION
- ARRAY TO SELECTION
- JSON TO SELECTION
- APPLY TO SELECTION
- IMPORT DATA
- IMPORT DIF
- IMPORT ODBC
- IMPORT SYLK
- IMPORT TEXT

If the table is passed dynamically, the compiler may sometimes not be able to find out which trigger it needs to evaluate. Here are some examples of such situations:

```
DEFAULT TABLE([Table_1])
SAVE RECORD
SAVE RECORD($ptrOnTable->)
SAVE RECORD(Table(myMethodThatReturnsATableNumber())->)
```

In this case, all triggers are evaluated. If a thread-unsafe command is detected in at least one trigger, the whole group is rejected and the method is declared thread-unsafe.

### Error-handling methods

Error-catching methods installed by the **ON ERR CALL** command must be thread-safe if they are likely to be called from a preemptive process. In order to handle this case, the compiler now checks the thread safety property of error-catching project methods passed to the **ON ERR CALL** command during compilation and returns appropriate errors if they do not comply with preemptive execution.

Note that this checking is only possible when the method name is passed as a constant, and is not computed, as shown below:

```
ON ERR CALL("myErrMethod1") //will be checked by the compiler
ON ERR CALL("myErrMethod"+String($vNum)) //will not be checked by the compiler
```

In addition, starting with 4D v15 R5, if an error-catching project method cannot be called at runtime (following a thread safety issue, or for any reason like "method not found"), the new error -10532 "Cannot call error handling project method 'methodName'" is generated.

### Pointers compatibility

A process can dereference a pointer to access the value of another process variable only if both processes are cooperative; otherwise, 4D will throw an error. In a preemptive process, if some 4D code tries to dereference a pointer to an interprocess variable, 4D will throw an error.

Example with the following methods:

Method1:

```
myVar:=42
$pid:=New process("Method2";0;"process name";->myVar)
```

Method2:

```
$value:=$1->
```

If either the process running Method1 or the process running Method2 is preemptive, then the expression "$value:=$1->" will throw an execution error.

### DocRef document reference

The use of *DocRef* type parameters (opened document reference, used or returned by **Open document**, **Create document**, **Append document**, **CLOSE DOCUMENT**, **RECEIVE PACKET**, **SEND PACKET**) is limited to the following contexts:

- When called from a preemptive process, a *DocRef* reference is only usable from that preemptive process.
- When called from a cooperative process, a *DocRef* reference is usable from any other cooperative process.

For more information about the *DocRef* reference, please refer to the **DocRef: Document reference number** section.

# Count tasks

Count tasks -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of open processes (including kernel processes) |

## Description

**Count tasks** returns the number of processes open in 4D Client, 4D Server (stored procedures) or a single-user version of 4D.

This number takes into account all processes, even those that are automatically managed by 4D. These include the Main process, Design process, Cache Manager process, Indexing process, and Web Server process.

The number returned by **Count tasks** also takes into account processes that have been aborted.

## Example

See the example for **Process state** and for the **On Exit database method**.

# Count user processes

Count user processes -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint |  | Number of live processes (excluding internal processes) |

## Description

**Count user processes** returns the current number of "live" processes in the 4D application whose type is different from -25 (Internal Timer Process), -31 (Client Manager Process) and -15 (Server Interface Process). For more information about process types, please refer to the **PROCESS PROPERTIES** command and to the **Process Type** constants theme.

The **Count user processes** function returns the number of processes opened directly or indirectly by the user (processes for which the *origin* parameter returned by the **PROCESS PROPERTIES** command is greater than or equal to 0).

**Note:** The "live" processes are processes whose status is neither *aborted*, nor *does not exist* (see the **Process state** command).

# Count users

Count users -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint |  | Number of users connected to the server |

## Description

When it is called from a stored procedure on the server, the **Count users** command returns the number of users connected to the server machine.

If the server is running at least one stored procedure and if **Count users** is called from another context (client machine, Web method), the command returns the number of users +1.

In the case of a 4D single-user version, **Count users** returns 1.

# Current process

Current process -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint |  | Process number |

## Description

**Current process** returns the process reference number of the process within which this command is called.

## Example

See the examples for **DELAY PROCESS** and **PROCESS PROPERTIES**.

# Current process name

Current process name -> Function result

| Parameter | Type | Description |
| --- | --- | --- |
| Function result | Text | Name of current process |

## Description

The **Current process name** command returns the name of the process within which this command is called.

This command is particularly useful in the context of worker processes (see the **About workers** section). It can be used to identify the worker process to call when writing generic code.

## Example

You want to call a worker and pass the calling process name as parameter:

```
CALL WORKER(1;"myMessage";Current process name;"Start:"+String(vMax))
```

# DELAY PROCESS

DELAY PROCESS ( process ; duration )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇒ | Process number |
| duration | Real | ⇒ | Duration expressed in ticks |

## Description

**DELAY PROCESS** delays the execution of a *process* for a number of ticks (1 tick = 1/60th of a second). During this period, *process* does not take any processing time. Even though the execution of a process may be delayed, it is still in memory.

You can delay a process for less than one tick. For example, if you pass 0.5 in *duration*, the process will be delayed for a 1/2 tick, i.e. 1/120th of a second.

If the process is already delayed, this command delays it again. The *duration* parameter is not added to the time remaining, but replaces it. Therefore pass zero (0) for *duration* if you no longer want to delay a process.

If the process does not exist, the command does nothing.

**Note:** You cannot use this command to assign a stored procedure on the server machine from a client machine (*process*<0).

## Example 1

See example in **Record Locking**.

## Example 2

See example for the command **Process number**.

# EXECUTE ON CLIENT

EXECUTE ON CLIENT ( clientName ; methodName {; param}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| clientName | String | ➡ | 4D Client's registered name |
| methodName | String | ➡ | Name of the method to execute |
| param | | ➡ | Method's parameter(s) |

## Description

The **EXECUTE ON CLIENT** command forces the execution of the *methodName* method, with the parameters *param1... paramN*, if necessary, on the registered 4D Client whose name is *clientName*. 4D Client's registered name is defined by the **REGISTER CLIENT** command.

This command can be called from a 4D Client or a stored method from 4D Server.

If the method requires one or more parameters, pass them after the name of the method.
The execution of the method on 4D Client is done in a process automatically created on the client workstation, and its name will be the 4D Client's registered name.

If this command is called many times in a row on the same 4D Client, the execution orders will be stacked. Therefore, the methods will be treated one after another in asynchronous mode. The more methods that are stacked, the bigger the workload is for the 4D Client. You can know the state of the workload of each client by using the **GET REGISTERED CLIENTS** command.

**Note:** The stacking of the execution orders cannot be modified or stopped unless 4D Client is unregistered by using the **UNREGISTER CLIENT** command.

You can simultaneously execute the same method on many or all of the registered 4D Clients. To do so, use the wildcard character (@) in the *clientName* parameter.

## Example 1

Let's assume that you want to execute the "GenerateNums" method on the "Client1" client station:

```
EXECUTE ON CLIENT("Client1";"GenerateNums";12;$a;"Text")
```

## Example 2

If you want all the clients to execute the "EmptyTemp" method:

```
EXECUTE ON CLIENT("@";"EmptyTemp")
```

## Example 3

Refer to the example of the **REGISTER CLIENT** command.

## System variables and sets

The **OK** system variable is equal to 1 if 4D Server has correctly received the execution request of a method; however, this does not guarantee that the method has been properly executed by 4D Client.

# Execute on server

Execute on server ( procedure ; stack {; name {; param {; param2 ; ... ; paramN}}}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| procedure | String | ➡ | Procedure to be executed within the process |
| stack | Longint | ➡ | Stack size in bytes |
| name | String | ➡ | Name of the process created |
| param | Expression | ➡ | Parameter(s) to the procedure |
| * | Operator | ➡ | Unique process |
| Function result | Longint | ↩ | Process number for newly created process or already executing process |

## Description

The **Execute on server** command starts a new process on the Server machine (if it is called in Client/Server) or on the same machine (if it is called in single-user) and returns the process number for that process.

You use this function to start a stored procedure. For more information about stored procedures, see the section **Stored Procedures** in the 4D Server Reference manual.

If you call **Execute on server** on a Client machine, the command returns a negative process number. If you call it on the Server machine, it returns a positive process number. Note that calling **New process** on the Server machine does the same thing as calling **Execute on server**.

If the process could not be created (for example, if there is not enough memory), **Execute on server** returns zero (0) and an error is generated. You can catch this error using an error-handling method installed using **ON ERR CALL**.

### Process Method

In *procedure*, you pass the name of the process method for the new process. After 4D has set up the context for the new process, it starts executing this method, which therefore becomes the process method.

### Process Stack

The *stack* parameter allows you indicate the amount of memory allocated for the stack of the process. It is the space in memory used to “pile up” method calls, local variables, parameters in subroutines, and stacked records.

- Pass 0 in *stack* to use a default stack size, suitable for most applications (recommended setting).
- In certain particular cases, you may want to use a custom value. It must be expressed in bytes. It is recommended to pass a minimum of 64 KB (around 64,000 bytes) and you case use values above 512 KB in particular if the process can perform large chain calls (subroutines calling subroutines in cascade.

**Note:** The stack is NOT the total memory for the process. Processes share memory for records, interprocess variables, and so on. A process also uses extra memory for storing its process variables. The stack contains various items of 4D internal information; the amount of information kept on the stack depends on the number of nested method calls the process will employ, the number of forms that it will open before closing them and the number and size of local variables used in each nested method call.

**Note for 64-bit 4D Server**: The stack for a process executed on a 64-bit 4D Server usually requires more memory than on a 32-bit 4D Server (about twice as much). Make sure that you check this parameter when your code is intended for execution on a 64-bit 4D Server.

### Process Name

You pass the name of the new process in *name*. In single-user, this name will appear in the list of processes of the Runtime Explorer and will be returned by the **PROCESS PROPERTIES** command when applied to this new process. In Client/Server, this name will appear in blue in the Stored Procedure list of the 4D Server main window.

You can omit this parameter; if you do so, the name of the process will be the empty string.

**Warning:** Contrary to **New process**, do not attempt to make a process local in scope by prefixing its name with the dollar sign ($) while using **Execute on server**. This will work in single-user, because **Execute on server** acts as **New process** in this environment. On the other hand, in Client/Server, this will generate an error.

### Parameter to Process Method

You can pass parameters to the process method. You can pass parameters in the same way as you would pass them to a subroutine. However, there is a restriction—you cannot pass pointer expressions. Also, remember that arrays cannot be

passed as parameters to a method. Upon starting execution in the context of the new process, the process method receives the parameters values in *$1*, *$2*, etc.

**Note:** If you pass parameters to the process method, you must pass the *name* parameter; it cannot be omitted in this case.

If you pass a 4D object (**C_OBJECT**) as param or return value, the JSON form is used in UTF-8 for the server. If the **C_OBJECT** object contains pointers, their dereferenced values are sent, and not the pointers themselves.

### Optional * Parameter

Specifying this last parameter tells 4D to first check whether or not a process with the name you passed in *name* is already running. If it is, 4D does not start a new process and returns the process number of the process with that name.

## Example

The following example shows how importing data can be dramatically accelerated in Client/Server. The ***Regular Import*** method listed below allows you to test how long it takes to import records using the **IMPORT TEXT** command on the Client side:

```
  ` Regular Import Project Method
$vhDocRef:=Open document("")
If(OK=1)
   CLOSE DOCUMENT($vhDocRef)
   FORM SET INPUT([Table1];"Import")
   $vhStartTime:=Current time
   IMPORT TEXT([Table1];Document)
   $vhEndTime:=Current time
   ALERT("It took "+String(0+($vhEndTime-$vhStartTime))+" seconds.")
End if
```

With the regular import data, 4D Client performs the parsing of the text file, then, for each record, create a new record, fills out the fields with the imported data and sends the record to the Server machine so it can be added to the database. There are consequently many requests going over the network. A way to optimize the operation is to use a stored procedure to do the job locally on the Server machine. The Client machine loads the document into a BLOB, start a stored procedure passing the BLOB as parameter. The stored procedure stores the BLOB into a document on the server machine disk, then imports the document locally. The import data is therefore performed locally at a single-user version-like speed because most the network requests have been eliminated. Here is the ***CLIENT IMPORT*** project method. Executed on the Client machine, it starts the *SERVER IMPORT* stored procedure listed just below:

```
  ` CLIENT IMPORT Project Method
  ` CLIENT IMPORT ( Pointer ; String )
  ` CLIENT IMPORT ( -> [Table] ; Input form )

C_POINTER($1)
C_TEXT($2)
C_TIME($vhDocRef)
C_BLOB($vxData)
C_LONGINT(spErrCode)

  ` Select the document do be imported
$vhDocRef:=Open document("")
If(OK=1)
  ` If a document was selected, do not keep it open
   CLOSE DOCUMENT($vhDocRef)
   $vhStartTime:=Current time
  ` Try to load it in memory
   DOCUMENT TO BLOB(Document;$vxData)
   If(OK=1)
  ` If the document could be loaded in the BLOB,
  ` Start the stored procedure that will import the data on the server machine
      $spProcessID:=Execute on server("SERVER IMPORT";0;
      "Server Import Services";Table($1);$2;$vxData)
  ` At this point, we no longer need the BLOB in this process
      CLEAR VARIABLE($vxData)
  ` Wait for the completion of the operation performed by the stored procedure
      Repeat
         DELAY PROCESS(Current process;300)
         GET PROCESS VARIABLE($spProcessID;spErrCode;spErrCode)
         If(Undefined(spErrCode))
```

```
    ` Note: if the stored procedure has not initialized its own instance
    ` of the variable spErrCode, we may be returned an undefined variable
              spErrCode:=1
           End if
        Until(spErrCode<=0)
    ` Tell the stored procedure that we acknowledge
        spErrCode:=1
        SET PROCESS VARIABLE($spProcessID;spErrCode;spErrCode)
        $vhEndTime:=Current time
        ALERT("It took "+String(0+($vhEndTime-$vhStartTime))+" seconds.")
     Else
        ALERT("There is not enough memory to load the document.")
     End if
  End if
```

Here is the ***SERVER IMPORT*** project method executed as a stored procedure:

```
    ` SERVER IMPORT Project Method
    ` SERVER IMPORT ( Long ; String ; BLOB )
    ` SERVER IMPORT ( Table Number ; Input form ; Import Data )

  C_LONGINT($1)
  C_TEXT($2)
  C_BLOB($3)
  C_LONGINT(spErrCode)

    ` Operation is not finished yet, set spErrCode to 1
  spErrCode:=1
  $vpTable:=Table($1)
  FORM SET INPUT($vpTable->;$2)
  $vsDocName:="Import File "+String(1+Random)
  DELETE DOCUMENT($vsDocName)
  BLOB TO DOCUMENT($vsDocName;$3)
  IMPORT TEXT($vpTable->;$vsDocName)
  DELETE DOCUMENT($vsDocName)
    ` Operation is finished, set spErrCode to 0
  spErrCode:=0
    ` Wait until the requester Client got the result back
  Repeat
     DELAY PROCESS(Current process;1)
  Until(spErrCode>0)
```

Once these two project methods have been implemented in a database, you can perform a “Stored Procedure-based” import data by, for instance, writing:

```
  CLIENT IMPORT(->[Table1];"Import")
```

With some benchmarks you will discover that using this method you can import records up to 60 times faster than the regular import.

# GET REGISTERED CLIENTS

GET REGISTERED CLIENTS ( clientList ; methods )

| Parameter | Type | | Description |
|---|---|---|---|
| clientList | Text array | ⇦ | List of the saved 4D Clients |
| methods | Longint array | ⇦ | List of the methods to be executed |

## Description

The **GET REGISTERED CLIENTS** command fills two arrays:

- *clientLists* contains the list of clients who were “registered” by using the **REGISTER CLIENT** command.
- *methods* supplies the list of each client’s “workload”. The workload is the number of methods that a 4D Client must still execute by calling the **EXECUTE ON CLIENT** command (for more information, please refer to the description of the **EXECUTE ON CLIENT** command).

## Example 1

Let’s assume that you want to obtain a list of all the registered clients and the methods that remain to be executed:

```
ARRAY TEXT($clients;0)
ARRAY LONGINT($methods;0)
GET REGISTERED CLIENTS($clients;$methods)
```

## Example 2

Refer to the example of the **REGISTER CLIENT** command.

## System variables and sets

If the operation was successful, the *OK* system variable is equal to 1.

# New process

New process ( method ; stack {; name {; param {; param2 ; ... ; paramN}}}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| method | String | ➡ | Method to be executed within the process |
| stack | Longint | ➡ | Stack size in bytes |
| name | String | ➡ | Name of the process created |
| param | Expression | ➡ | Parameter(s) to the method |
| * | Operator | ➡ | Unique process |
| Function result | Longint | ↩ | Process number for newly created process or already executing process |

## Description

The **New process** command starts a new process (on the same machine) and returns the process number for that process.

If the process could not be created (for example, if there is not enough memory), **New process** returns zero (0) and an error is generated. You can catch this error using an error-handling method installed using **ON ERR CALL**.

### Process Method

In *method*, you pass the name of the process method for the new process. After 4D has set up the context for the new process, it starts executing this method, which therefore becomes the process method.

### Process Stack

The *stack* parameter allows you to indicate the amount of memory allocated for the stack of the process. This is the space in memory used to "pile up" method calls, local variables, parameters in subroutines, and stacked records.

- Pass 0 in *stack* to use a default stack size, suitable for most applications (recommended setting).
- In certain particular cases, you may want to use a custom value. It must be expressed in bytes. It is recommended to pass a minimum of 64 KB (around 64,000 bytes) and you case use values above 512 KB in particular if the process can perform large chain calls (subroutines calling subroutines in cascade.

**Note:** The stack is NOT the total memory for the process. Processes share memory for records, interprocess variables, and so on. A process also uses extra memory for storing its process variables. The stack contains various items of 4D information; the amount of information kept on the stack depends on the number of nested method calls the process will employ, the number of forms that it will open before closing them and the number and size of local variables used in each nested method call.

**Note for 64-bit 4D Server**: The stack for a process executed on a 64-bit 4D Server usually requires more memory than on a 32-bit 4D Server (about twice as much). Make sure that you check this parameter when your code is intended for execution on a 64-bit 4D Server.

### Process Name

You pass the name of the new process in *name*. This name will appear in the list of processes of the Runtime Explorer and will be returned by the **PROCESS PROPERTIES** command when applied to this new process. You can omit this parameter; if you do so, the name of the process will be the empty string. You can make a process local in scope by prefixing its name with the dollar sign (*$*).

**Important:** Remember that local processes should not access data in Client/Server.

### Parameters to Process Method

You can pass parameters to the process method using one or more *param* parameters. You pass parameters in the same way as you would pass them to a subroutine (see the **Passing Parameters to Methods** section). Upon starting execution in the context of the new process, the process method receives the parameters values in *$1*, *$2*, etc. Remember that arrays cannot be passed as parameters to a method. Furthermore, these additional considerations are to be taken into account in the context of the **New process** command:

- pointers to tables or fields are allowed.
- pointers to variables, particularly local and process variables, are not recommended since these variables may be undefined at the time when they are being accessed by the process method.
- if you pass an Object type parameter, 4D will create in this case a copy of the object in the destination process.

**Note:** If you pass parameters to the process method, you must pass the *name* parameter; it cannot be omitted in this case.

### Optional * Parameter

Specifying this last parameter tells 4D to first check whether or not a process with the name you passed in *name* is already running. If it is, 4D does not start a new process and returns the process number of the process with that name.

## Example

Given the following project method:

```
  ` ADD CUSTOMERS
SET MENU BAR(1)
Repeat
   ADD RECORD([Customers];*)
Until(OK=0)
```

If you attach this project method to a custom menu item **Menu Bar Editor** window whose **Start a New Process** property is set, 4D will automatically start a new process running that method. The call **SET MENU BAR**(1) adds a menu bar to the new process. In the absence of any window (that you could open with **Open window**), the call to **ADD RECORD** will automatically open one.

To be able to start this Add Customers process when you click on a button in a custom control panel, you can write:

```
  ` bAddCustomers button object method
$vlProcessID:=New process("Add Customers";0;"Adding Customers")
```

The button does the same thing as the custom menu item.

While choosing the menu item or clicking the button, if you want to start the process (if it does not exist) or bring it to the front (if it is already running), you can create the method ***START ADD CUSTOMERS***:

```
  ` START ADD CUSTOMERS
$vlProcessID:=New process("Add Customers";0;"Adding Customers";*)
If($vlProcessID#0)
   BRING TO FRONT($vlProcessID)
End if
```

The object method of the *bAddCustomers* becomes:

```
  ` bAddCustomers button object method
START ADD CUSTOMERS
```

In the Menu Bar editor, you replace the method ***ADD CUSTOMERS*** with the method ***START ADD CUSTOMERS***, and you deselect the **Start a New Process** property for the menu item.

# PAUSE PROCESS

PAUSE PROCESS ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇨ | Process number |

## Description

**PAUSE PROCESS** suspends the execution of *process* until it is reactivated by the **RESUME PROCESS** command. During this period, *process* does not take any time on your machine. Even though a process may be paused, the process is still in memory.

If *process* is already paused, **PAUSE PROCESS** does nothing. If the process has been delayed using the **DELAY PROCESS** command, the process is paused. **RESUME PROCESS** resumes the process immediately.

While process execution is suspended, the windows belonging to this process are not enterable. In this case, to avoid confusing the user, consider hiding the process. If *process* does not exist, the command does nothing.

**Warning:** Use **PAUSE PROCESS** only in processes that you have started. It will not affect the main process.

**Note:** You cannot use this command to assign a stored procedure on the server machine from a client machine (*process*<0).

# Process aborted

Process aborted -> Function result

| Parameter | Type | Description |
| --- | --- | --- |
| Function result | Boolean | True = the process is about to be aborted, False = the process is not about to be aborted |

## Description

The **Process aborted** command returns **True** if the process in which it is called is about to be interrupted unexpectedly, which means that the execution of the command was unable to reach its “normal” completion. For example, this can occur after calling **QUIT 4D**.

# Process number

Process number ( name {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| name | String | ⇒ | Name of process for which to retrieve the process number |
| * | | ⇒ | Return the process number from the server |
| Function result | Longint | ⇐ | Process number |

## Description

**Process number** returns the number of the process whose name you pass in *name*. If no process is found, Process number returns 0.

The optional parameter * allows you to retrieve, from 4D Client, the process ID of a process that is executed on the server (a stored procedure). In this case, the returned value is negative. This option is especially useful when using the **GET PROCESS VARIABLE**, **SET PROCESS VARIABLE** and **VARIABLE TO VARIABLE** commands. Please refer to the descriptions of these commands for details.

If the command is executed with the * parameter from a process on the server machine, the returned value is positive.

## Example

You create a custom floating window, run in a separate process, in which you implement your own tools to interact with the Design environment. For example, when selecting an item in a hierarchical list of keywords, you want to paste some text into the frontmost window of the Design environment. To do so, you can use the pasteboard, but the pasting event must occur within the Design process. The following small function returns the process number of the Design process (if running):

```
  ` Design process number Project Method
  ` Design process number -> LongInt
  ` Design process number -> Design process number

$0:=Process number("Design Process")
  ` Note: This can break in the future if the process name changes
```

Using this function, the following project method pastes the text received as parameter to the frontmost window of the Design environment (if applicable):

```
  ` PASTE TEXT TO DESIGN Project Method
  ` PASTE TEXT TO DESIGN ( Text )
  ` PASTE TEXT TO DESIGN ( Text to Paste in frontmost Design window )

C_TEXT($1)
C_LONGINT($vlDesignPID;$vlCount)

$vlDesignPID:=Design process number
If($vlDesignPID #0)
  ` Put the text into the pasteboard
   SET TEXT TO PASTEBOARD($1)
  ` Post a Ctrl-V / Command-V event
   POST KEY(Character code("v");Command key mask;$vlDesignPID)
  ` Call repeatedly DELAY PROCESS so the scheduler gets a chance
  ` to pass over the event to the Design process
   For($vlCount;1;5)
      DELAY PROCESS(Current process;1)
   End for
End if
```

# PROCESS PROPERTIES

PROCESS PROPERTIES ( process ; procName ; procState ; procTime {; procMode {; uniqueID {; origin}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ⇒ | Process number |
| procName | String | ⇐ | Process name |
| procState | Longint | ⇐ | Process state |
| procTime | Longint | ⇐ | Cumulative time taken by process in ticks |
| procMode | Boolean, Longint | ⇐ | If Boolean: Visible (True) or Hidden (False)<br>If Longint (bit field): bit 0 = Visibility, bit 1 = Preemptive execution |
| uniqueID | Integer | ⇐ | Unique process number |
| origin | Longint | ⇐ | Origin of the process |

## Description

The **PROCESS PROPERTIES** command returns various information about the process whose process number you pass in *process*.

After the call:

- *procName* returns the name of the process. Some things to note about the process name:
  - If the process was started from the **Execute Method** dialog box (with the **New Process** option selected), its name is “**P_**” followed by a number.
  - If the process was started from a custom menu item whose **Start a New Process** property is checked, the name of the process is “M_” or “ML_” followed by a number.
  - If the process was started by the Web server, its name is "Web Process#" followed by an UUID.
  - If the process has been aborted (and its “slot” not reused yet), the name of the process is still returned. To detect if a process is aborted, test *procState=-1* (see below).
- *procState* returns the state of the process at the moment of the call. This parameter can return one of the values provided by the following predefined constants:

| Constant | Type | Value |
|---|---|---|
| Aborted | Longint | -1 |
| Delayed | Longint | 1 |
| Does not exist | Longint | -100 |
| Executing | Longint | 0 |
| Hidden modal dialog | Longint | 6 |
| Paused | Longint | 5 |
| Waiting for input output | Longint | 3 |
| Waiting for internal flag | Longint | 4 |
| Waiting for user event | Longint | 2 |

- *procTime* returns the cumulative time that the process has used since it started, in ticks (1/60th of a second) .
- The optional *procMode* parameter can be a Boolean or longint type variable:
  - If it is a Boolean type, it returns True if the process is visible and False if it is hidden.
  - If it is a longint type, after the method is executed, it contains a bit field where the two first bits are set:
    - bit 0 returns the visibility property: set to 1 if process is visible, and 0 if it is hidden
    - bit 1 returns the preemptive mode property: set to 1 if process runs in preemptive mode, and 0 if it runs in cooperative mode.

      **Note:** This property is only useful in 64-bit 4D applications, where processes can be run preemptively or cooperatively. For more information, please refer to the **Preemptive 4D processes** section.
- *uniqueID*, if specified, returns the unique process number. Actually, each process has attributed a process number to it as well as a unique process number per session. The unique number allows you to differentiate between two processes or two process sessions. It corresponds to the process number having been started during 4D’s session.
- *origin*, if specified, returns a value that describes the origin of the process. 4D offers the following predefined constants (in the "**Process Type**" theme):

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Web process with context | Longint | -11 | |
| Apple event manager | Longint | -7 | |
| Backup process | Longint | -19 | |
| Cache manager | Longint | -4 | |
| Client manager process | Longint | -31 | |
| Created from execution dialog | Longint | 3 | |
| Created from menu command | Longint | 2 | |
| Design process | Longint | -2 | |
| Event manager | Longint | -8 | |
| Execute on client process | Longint | -14 | |
| Execute on server process | Longint | 1 | |
| External task | Longint | -9 | |
| Indexing process | Longint | -5 | |
| Internal 4D server process | Longint | -18 | |
| Internal timer process | Longint | -25 | |
| Log file process | Longint | -20 | |
| Main process | Longint | -1 | |
| Method editor macro process | Longint | -17 | |
| Monitor process | Longint | -26 | |
| MSC process | Longint | -22 | |
| None | Longint | 0 | |
| On exit process | Longint | -16 | |
| Other 4D process | Longint | -10 | |
| Other user process | Longint | 4 | |
| Restore Process | Longint | -21 | |
| Serial Port Manager | Longint | -6 | |
| Server interface process | Longint | -15 | |
| SQL Method execution process | Longint | -24 | |
| Web process on 4D remote | Longint | -12 | |
| Web process with no context | Longint | -3 | |
| Web server process | Longint | -13 | |
| Worker process | Longint | 5 | Worker process launched by user |

**Note:** 4D's internal processes return a negative value and the processes generated by the user return a positive value.

If the process does not exist, which means you did not pass a number in the range 1 to **Count tasks**, **PROCESS PROPERTIES** leaves the variable parameters unchanged.

## Example 1

The following example returns the name, state, and time taken in the variables *vName*, *vState,* and *vTimeSpent* for the current process:

```
C_STRING(80;vName) ` Initialize the variables
C_INTEGER(vState)
C_INTEGER(vTime)
PROCESS PROPERTIES(Current process;vName;vState;vTimeSpent)
```

## Example 2

See example for **On Exit database method**.

## Example 3

You want to find out the visibility and execution mode of the current process. You can write:

```
C_TEXT(vName)
C_LONGINT(vState)
C_LONGINT(vTime)
C_LONGINT(vFlags)
C_BOOLEAN(isVisible)
C_BOOLEAN(isPreemptive)
PROCESS PROPERTIES(Current process;vName;vState;vTime;vFlags)
isVisible:=vFlags?? 0 //true if visible
isPreemptive:=vFlags?? 1 //true if preemptive
```

# Process state

Process state ( process ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ➡ | Process number |
| Function result | Longint | ⮌ | State of the process |

## Description

The **Process state** command returns the state of the process whose number you pass in *process*.

The function result can be one of the values provided by the following predefined constants:

| Constant | Type | Value |
|---|---|---|
| Aborted | Longint | -1 |
| Delayed | Longint | 1 |
| Does not exist | Longint | -100 |
| Executing | Longint | 0 |
| Hidden modal dialog | Longint | 6 |
| Paused | Longint | 5 |
| Waiting for input output | Longint | 3 |
| Waiting for internal flag | Longint | 4 |
| Waiting for user event | Longint | 2 |

If the process does not exist (which means you did not pass a number in the range 1 to **Count tasks**), **Process state** returns Does not exist (-100).

## Example

The following example puts the name and process reference number for each process into the *asProcName* and *aiProcNum* arrays. The method checks to see if the process has been aborted. In this case, the process name and number are not added to the arrays:

```
$vlNbTasks:=Count tasks
ARRAY TEXT(asProcName;$vlNbTasks)
ARRAY INTEGER(aiProcNum;$vlNbTasks)
$vlActualCount:=0
For($vlProcess;1;$vlNbTasks)
   If(Process state($vlProcess)>=Executing)
      $vlActualCount:=$vlActualCount+1
      PROCESS PROPERTIES($vlProcess;asProcName{$vlActualCount};$vlState;$vlTime)
      aiProcNum{$vlActualCount}:=$vlProcess
   End if
End for
 ` Eliminate unused extra elements
ARRAY TEXT(asProcName;$vlNbTasks)
ARRAY INTEGER(aiProcNum;$vlActualCount)
```

# REGISTER CLIENT

REGISTER CLIENT ( clientName {; period}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| clientName | String | ➡ | Name of the 4D client session |
| period | Longint | ➡ | ***Ignored since version 11.3*** |
| * | Operator | ➡ | Local process |

## Description

The **REGISTER CLIENT** command “registers” a 4D client station with the name specified in *clientName* on 4D Server, so as to allow other clients or eventually 4D Server (by using stored methods) to execute methods on it by using the **EXECUTE ON CLIENT** command. Once it is registered, a 4D client can then execute one or more methods for other clients.

**Notes:**

- You can also automatically register each client station that connects to 4D Server by using the “Register Clients at Startup...” option in the Preferences dialog box.
- If this command is used with 4D in local mode, it has no effect.
- More than one 4D client station can have the same registered name.

When this command is executed, a process, named *clientName*, is created on the client station. This process can only be aborted by the **UNREGISTER CLIENT** command.
If you pass the optional * parameter, the created process is local. 4D will automatically add the dollar sign ($) at the beginning of the process name. Otherwise, the process is global.

**Compatibility Note:** Since version 11.3 of 4D, the server/client communication mechanisms have been optimized. Now the server sends execution requests directly to the registered clients when necessary (technology "push"). The previous principle where clients queried the server periodically is no longer used. The *period* parameter is ignored if it is passed.

Once the command is executed, it is not possible to modify a 4D client’s name on the fly. To do so, you must call the **UNREGISTER CLIENT** command, then the **REGISTER CLIENT** command.

## Example

In the following example, we are going to create a small messaging system that allows the client workstations to communicate between themselves.

1) This method, Registration, allows you to register a 4D client and to keep it ready to receive a message from another 4D client:

```
  `You must unregister before registering under another name
UNREGISTER CLIENT
Repeat
   vPseudoName:=Request("Enter your name:";"User";"OK";"Cancel")
Until((OK=0)|(vPseudoName#""))
If(OK=0)
   ... ` Don't do anything
Else
   REGISTER CLIENT(vPseudoName)
End if
```

2) The following instruction allows you to get a list of the registered clients. It can be placed in the **On Startup database method**:

```
PrClientList:=New process("4D Client List";32000;"List of registered clients")
```

3) The method 4D Client List allows you to recuperate all the registered 4D clients and those that can receive messages:

```
If(Application type=4D Remote Mode)
  ` the code below is only valid in client-server mode
   $Ref:=Open window(100;100;300;400;-(Palette window+Has window title);"List of registered clients")
   Repeat
```

```
      GET REGISTERED CLIENTS($ClientList;$ListeCharge)
   `Retrieve the registered clients in $ClientList
      ERASE WINDOW($Ref)
      GOTO XY(0;0)
      For($p;1;Size of array($ClientList))
         MESSAGE($ClientList{$p}+Char(Carriage return))
      End for
   `Display each second
      DELAY PROCESS(Current process;60)
   Until(False) ` Infinite loop
End if
```

4) The following method allows you to send a message to another registered 4D client. It calls the Display_Message method (see below).

```
$Addressee:=Request("Addressee of the message:";"")
 ` Enter the name of the people visible in the window generated by the
 ` On Startup database method
If(OK#0)
   $Message:=Request("Message:") ` message
   If(OK#0)
      EXECUTE ON CLIENT($Addressee;"Display_Message";$Message) ` Send message
   End if
End if
```

5) Here is the Display_Message method:

```
C_TEXT($1)
ALERT($1)
```

6) Finally, this method allows a client station to no longer be visible by the other 4D clients and to no longer receive messages:

```
UNREGISTER CLIENT
```

## System variables and sets

If the 4D client is correctly registered, the **OK** system variable is equal to 1. If the 4D client was already registered, the command doesn't do anything and **OK** is equal to 0.

# RESUME PROCESS

RESUME PROCESS ( process )

| Parameter | Type | | Description |
|---|---|---|---|
| process | Longint | ➡ | Process number |

## Description

**RESUME PROCESS** resumes a *process* whose execution has been paused or delayed. If *process* is not paused or delayed, the command does nothing.

If *process* has been delayed before, see the **PAUSE PROCESS** or **DELAY PROCESS** commands. If *process* does not exist, the command does nothing.

**Note:** You cannot use this command to assign a stored procedure on the server machine from a client machine (*process*<0).

# UNREGISTER CLIENT

UNREGISTER CLIENT
Does not require any parameters

## Description

The **UNREGISTER CLIENT** command “unregisters” a 4D client station. The client must have already been registered by the **REGISTER CLIENT** command.

**Note:** A 4D client is automatically unregistered when the user quits the application.

If the client workstation was not previously registered or if the command was executed on 4D in local mode, the command has no effect.

## Example

Refer to the example for the **REGISTER CLIENT** command.

## System variables and sets

If the client is correctly unregistered, the OK system variable is set to 1. If the client was not registered, OK is set to 0.

# Queries

- DESCRIBE QUERY EXECUTION
- Find in field
- Get last query path
- Get last query plan
- GET QUERY DESTINATION
- Get query limit
- ORDER BY
- ORDER BY FORMULA
- QUERY
- QUERY BY ATTRIBUTE
- QUERY BY EXAMPLE
- QUERY BY FORMULA
- QUERY SELECTION
- QUERY SELECTION BY ATTRIBUTE New 16.0
- QUERY SELECTION BY FORMULA
- QUERY SELECTION WITH ARRAY
- QUERY WITH ARRAY
- SET QUERY AND LOCK
- SET QUERY DESTINATION
- SET QUERY LIMIT

# DESCRIBE QUERY EXECUTION

DESCRIBE QUERY EXECUTION ( status )

| Parameter | Type | | Description |
|---|---|---|---|
| status | Boolean | ⇒ | True=Enable internal query analysis, False=Disable internal query analysis |

## Description

The **DESCRIBE QUERY EXECUTION** command enables or disables the query analysis mode for the current process. The command only works in the context of 4D language query commands such as **QUERY**.

Calling the command with the *status* parameter set to **True** enables the query analysis mode. In this mode, the 4D engine records internally two specific pieces of information for each subsequent query carried out on the data:

- A detailed internal description of the query just before its execution, in other words, what was planned to be executed (the query plan),
- A detailed internal description of the query that was actually executed (the query path).

The information recorded includes the type of query (indexed, sequential), the number of records found and the time needed for every query criteria to be executed. Y ou can then read this information using the **Get last query plan** and **Get last query path** commands.

Usually, the description of the query plan and its path are the same, but they may nevertheless differ because 4D might implement dynamic optimizations during the query execution in order to improve performance. For example, an indexed query may be converted dynamically into a sequential query if the 4D engine estimates that this might be faster — this is sometimes the case, more particularly, when the number of records being queries is low.

Pass **False** in the *status* parameter when you no longer need to analyze queries. The query analysis mode can slow down the application.

## Example

The following example illustrates the type of information obtained using these commands:

```
C_TEXT($vResultPlan;$vResultPath)
DESCRIBE QUERY EXECUTION(True) //analysis mode
QUERY([Employees];[Employees]LastName="T@";*) // Search for employees whose last name starts with T...
QUERY([Employees]; & ;[Companies]Name="H@";*) // that work for a company whose name starts with H
QUERY([Employees]; & ;[Employees]Salary>2500;*) // whose salary is > 2500
QUERY([Employees]; & ;[Cities]Pop<50000) // that live in a city with less than 50,000 inhabitants
$vResultPlan:=Get last query plan(Description in text format)
$vResultPath:=Get last query path(Description in text format)
DESCRIBE QUERY EXECUTION(False) //End of analysis mode
```

After executing this code, *$vResultPlan* and *$vResultPath* contain descriptions of the queries performed, for example:

```
$vResultPlan :
   Employees.LastName == T@ And Employees.Salary > 2500 And Join on Table : Companies  :  Employees.Company =
Companies.Name [index : Companies.Name ] LIKE H@ And Join on Table : Cities  :  Employees.City = Cities.Name [index :
Cities.Pop ] < 50000
$vResultPath :
(Employees.LastName == T@ And Employees.Salary  > 2500) And (Join on Table : Companies  :  Employees.Company  =
Companies.Name with filter {[index : Companies.Name ] LIKE H@}) And (Join on Table : Cities  :  Employees.City =
Cities.Name with filter {[index : Cities.Pop ] < 50000})   (3 records found in 1 ms)
```

If the Description in XML Format constant is passed to the **Get last query path** command, *$vResultPath* contains the description of the query expressed in XML:

```
$vResultPath :   <QueryExecution>       <steps description="And" time="0" recordsfounds="1227">          <steps
description="[Merge] : ACTORS with CITIES" time="13" recordsfounds="1227">            <steps description="[Join] :
ACTORS.Birth_City_ID =CITIES.City_ID" time="13" recordsfounds="1227"/>          </steps>       </steps>
   </QueryExecution>
```

# Find in field

Find in field ( targetField ; value ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| targetField | Field | ⇒ | Field on which to execute the search |
| value | Field, Variable | ⇒ | Value to search |
| | | ⇐ | Value found |
| Function result | Longint | ⇒ | Number of the record found or -1 if no record was found |

## Description

The **Find in field** command returns the number of the first record whose *targetField* field is equal to *value*.
If no records are found, **Find in field** returns -1.

After calling this command, *value* contains the value found. This feature allows you to execute searches using the wildcard character (“@”) on Alpha fields and then retrieve the value found.

**Note:** Due to this principle, you cannot use a *parameter* ($1, $2, etc.) in *value* because this would cause malfunctions in compiled mode. Similarly, if you pass a field in the *value* parameter, keep in mind that its value will be reassigned if the query is successful (the command **Modified record**, in particular, will return True for the current record of the table).

This command doesn’t modify the current selection or the current record.
It is fast and particularly useful to avoid creating double entries during data entry.

**Historical note:** In earlier versions of 4D, the **Find in field** command was named **Find index key** and only worked with indexed fields. Beginning with 4D v11 SQL, this limitation was removed and the command was renamed.

## Example 1

In an audio CD database, during data entry let’s assume that you want to verify the singer’s name to see if it already exists in the database. Because homonyms can exist, you don’t want the [Singer]Name field to be unique. Therefore, in the input form, you can write the following code in the [Singer]Name field’s object method:

```
If(Form event=On Data Change)
   $RecNum:=Find in field([Singer]Name;[Singer]Name)
   If($RecNum #-1) ` If this name has already been entered
      CONFIRM("A singer with the same already exists. Do you want to see the record?";"Yes";"No")
      If(OK=1)
         GOTO RECORD([Singer];$RecNum)
      End if
   End if
End if
```

## Example 2

Here is an example that lets you verify the existence of a value:

```
C_LONGINT($id;$1)
$id:=$1
If(Find in field([MyTable]MyID;$id)>=0)
   $0:=True
Else
   $0:=False
End if
```

Note the >= that lets you cover all cases. In fact, the function returns a record number and the first record is numbered 0.

# Get last query path

Get last query path ( descFormat ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| descFormat | Longint | ⇒ | Description format (Text or XML) |
| Function result | String | ⇐ | Description of last executed query path |

## Description

The **Get last query path** command returns the detailed internal description of the actual path of the last query carried out on the data. For more information about query descriptions, please refer to the documentation of the **DESCRIBE QUERY EXECUTION** command.

This description is returned in Text or XML format depending on the value passed in the *descFormat* parameter. You can pass one of the following constants, found in the "**Queries**" theme:

| Constant | Type | Value |
|---|---|---|
| Description in text format | Longint | 0 |
| Description in XML format | Longint | 1 |

This command returns a significant value if the **DESCRIBE QUERY EXECUTION** command has been executed during the session.

The description of the last query path can be compared to the description of the query plan provided for the last query (obtained using the **Get last query plan** command) for optimization purposes.

# Get last query plan

Get last query plan ( descFormat ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| descFormat | Longint | ⇒ | Description format (Text or XML) |
| Function result | String | ⇐ | Description of last executed query plan |

## Description

The **Get last query plan** command returns the detailed internal description of the query plan for the last query carried out on the data. For more information about query descriptions, please refer to the documentation of the **DESCRIBE QUERY EXECUTION** command.

This description is returned in Text or XML format depending on the value passed in the *descFormat* parameter. You can pass one of the following constants, found in the "**Queries**" theme:

| Constant | Type | Value |
|---|---|---|
| Description in text format | Longint | 0 |
| Description in XML format | Longint | 1 |

This command returns a significant value if the **DESCRIBE QUERY EXECUTION** command has been executed during the session.

The description of the last query plan can be compared to the description of the actual path of the last query (obtained using the **Get last query path** command) for optimization purposes.

# GET QUERY DESTINATION

GET QUERY DESTINATION ( destinationType ; destinationObject ; destinationPtr )

| Parameter | Type | | Description |
|---|---|---|---|
| destinationType | Longint | ⇦ | 0=current selection, 1=set, 2=named selection, 3=variable |
| destinationObject | String | ⇦ | Name of the set or Name of the named selection or Empty string |
| destinationPtr | Pointer | ⇦ | Pointer to local variable if destinationType=3 |

## Description

The **GET QUERY DESTINATION** command returns the current destination of query results for the process underway. By default, query results modify the current selection, but you can change this using the **SET QUERY DESTINATION** command.

In the *destinationType* parameter, 4D returns a value indicating the current destination of queries and in the *destinationObject* parameter it returns the name of the destination (if applicable). You can compare the value of the *destinationType* parameter with the constants of the **Queries** theme:

| Constant | Type | Value |
|---|---|---|
| Into current selection | Longint | 0 |
| Into named selection | Longint | 2 |
| Into set | Longint | 1 |
| Into variable | Longint | 3 |

The value returned in the *destinationObject* parameter depends on the value of the *destinationType* parameter:

| destinationType parameter | destinationObject parameter |
|---|---|
| 0 (current selection ) | *destinationObject* is an empty string |
| 1 (set) | *destinationObject* contains the name of the set |
| 2 (named selection ) | *destinationObject* contains the name of the selection |
| 3 (variable) | *destinationObject* is an empty string (use the *destinationPtr* parameter) |

When the query destination is a local variable (*destinationType* returns 3), 4D returns a pointer to this variable in the *destinationPtr* parameter.

## Example

We want to modify the query destination temporarily and then restore the previous parameters:

```
GET QUERY DESTINATION($vType;$vName;$ptr)
 //retrieval of current parameters
SET QUERY DESTINATION(Into set;"$temp")
 //temporary modification of destination
QUERY(...) //query
SET QUERY DESTINATION($vType;$vName;$ptr)
 //restoring parameters
```

# Get query limit

Get query limit -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint |  | Limit number of records,<br>0 = unlimited number |

## Description

The **Get query limit** command returns the limit for the number of records that a query may find in the current process.

You set this limit using the **SET QUERY LIMIT** command.

By default, if no limit is set, the command returns 0.

# ORDER BY

ORDER BY ( {aTable ;}{ aField }{; > or < }{; aField2 ; > or <2 ; ... ; aFieldN ; > or <N}{; *} )

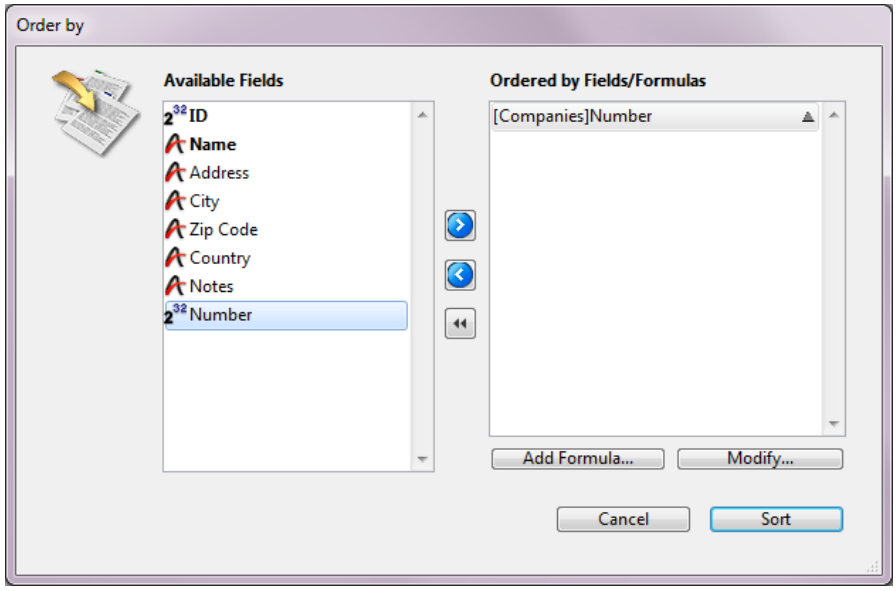
| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to order selected records, or Default table, if omitted |
| aField | Field | ⇒ | Field on which to set the order for each level |
| > or < | Operator | ⇒ | Ordering direction for each level: > to order in ascending order, or < to order in descending order |
| * | Operator | ⇒ | Continue order flag |

## Description

**ORDER BY** sorts (reorders) the records of the current selection of *aTable* for the current process. After the sort has been completed, the new first record of the selection becomes the current record.

If you omit the *aTable* parameter, the command applies to the default table, if it has been specified. Otherwise, 4D uses the table of the first field passed as a parameter. If you do not pass a parameter and if no default table has been specified, an error is returned.

If you do not specify the *aField*, the *> or <* or the * parameters, **ORDER BY** displays the Order By editor for *aTable*. The Order By editor is shown here:



For more information about using the Order By editor, refer to the 4D Design Reference manual.

If you specify the *aField* and *> or <* parameters, the standard Order By editor is not presented and the sort is defined programmatically. You can sort the selection on one level or on several levels. For each sort level, you specify a field in *aField* and the sorting order in *> or <*. If you pass the “greater than” symbol (>), the order is ascending. If you pass the “less than” symbol (<), the order is descending.
If you omit the sorting order parameter *> or <*, ascending order is the default.

If only one field is specified (one level sort) and it is indexed, the index is used for the order. If the field is not indexed or if there is more than one field, the order is performed sequentially (except in the case of composite indexes). The field may belong to the (selection’s) table being reordered or to a One table related to *aTable* with an automatic or manual relation. In this case, the sort is always sequential.
If the sorted fields are included in a composite index, **ORDER BY** uses the index for the order.

For multiple sorts (sorts on multiple fields), you can call **ORDER BY** as many times as necessary and specify the optional * parameter, except for the last **ORDER BY** call, which starts the actual sort operation. This feature is useful for multiple sorts management in customized user interfaces.
**Warning:** with this syntax, you can pass only one sort level (field) per **ORDER BY** call.

No matter what way a sort has been defined, if the actual sort operation is going to take some time to be performed, 4D automatically displays a message containing a progress thermometer. These messages can be turned on and off by using the commands **MESSAGES ON** and **MESSAGES OFF**. If the progress thermometer is displayed, the user can click the Stop button to interrupt the sort.

If the sort is performed without interruption, the OK variable is set to *1*. If the user clicks Cancel or Stop, the **ORDER BY** terminates with no sort actually performed, and sets the OK variable to *0* (zero).

**Note:** This command does not support Object type fields.

## Example 1

The following line displays the Order By editor for the [Products] table:

```
ORDER BY([Products])
```

## Example 2

The following line displays the Order By editor for the default table (if it has been set):

```
ORDER BY
```

## Example 3

The following line orders the selection of [Products] by name in ascending order:

```
ORDER BY([Products];[Products]Name;>)
```

## Example 4

The following line orders the selection of [Products] by name in descending order:

```
ORDER BY([Products];[Products]Name;<)
```

## Example 5

The following line orders the selection of [Products] by type and price in ascending order for both levels:

```
ORDER BY([Products];[Products]Type;>;[Products]Price;>)
```

## Example 6

The following line orders the selection of [Products] by type and price in descending order for both levels:

```
ORDER BY([Products];[Products]Type;<;[Products]Price;<)
```

## Example 7

The following line orders the selection of [Products] by type in ascending order and by price in descending order:

```
ORDER BY([Products];[Products]Type;>;[Products]Price;<)
```

## Example 8

The following line orders the selection of [Products] by type in descending order and by price in ascending order:

```
ORDER BY([Products];[Products]Type;<;[Products]Price;>)
```

## Example 9

The following line performs an indexed sort if [Products]Name is indexed:

```
ORDER BY([Products];[Products]Name;>)
```

## Example 10

The following line orders the selection of [Products] by name in ascending order:

```
ORDER BY([Products];[Products]Name)
```

## Example 11

The following line performs a sequential sort, whether or not the fields are indexed:

```
ORDER BY([Products];[Products]Type;>;[Products]Price;>)
```

## Example 12

The following line performs a sequential sort using a related field:

```
ORDER BY([Invoices];[Companies]Name;>) ` Invoices are sorted alphabetically on the Company name field
```

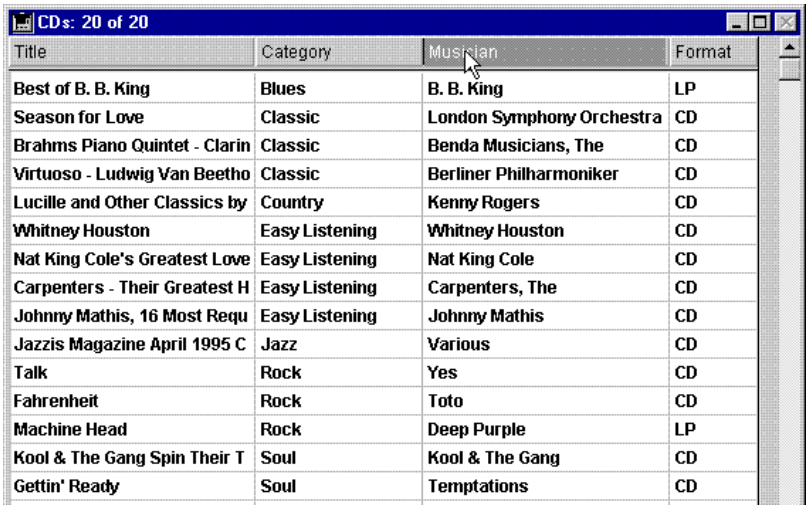
## Example 13

The following example carries out an indexed sort on two levels if a [Contacts]LastName + [Contacts]FirstName composite index has been specified in the database:

```
ORDER BY([Contacts];[Contacts]LastName;>;[Contacts]FirstName;>)
```

## Example 14

In an Output form displayed in the Application environment, you allow the users to order a column in ascending order by simply clicking in the column header.
If the user holds the **Shift** key down while clicking in other column headers, the sort is performed on several levels:



| Title | Category | Musician | Format |
|---|---|---|---|
| Best of B. B. King | Blues | B. B. King | LP |
| Season for Love | Classic | London Symphony Orchestra | CD |
| Brahms Piano Quintet - Clarin | Classic | Benda Musicians, The | CD |
| Virtuoso - Ludwig Van Beetho | Classic | Berliner Philharmoniker | CD |
| Lucille and Other Classics by | Country | Kenny Rogers | CD |
| Whitney Houston | Easy Listening | Whitney Houston | CD |
| Nat King Cole's Greatest Love | Easy Listening | Nat King Cole | CD |
| Carpenters - Their Greatest H | Easy Listening | Carpenters, The | CD |
| Johnny Mathis, 16 Most Requ | Easy Listening | Johnny Mathis | CD |
| Jazzis Magazine April 1995 C | Jazz | Various | CD |
| Talk | Rock | Yes | CD |
| Fahrenheit | Rock | Toto | CD |
| Machine Head | Rock | Deep Purple | LP |
| Kool & The Gang Spin Their T | Soul | Kool & The Gang | CD |
| Gettin' Ready | Soul | Temptations | CD |

Each column header contains a highlight button attached with the following object method:

```
MULTILEVEL(->[CDs]Title) `Title column header button
```

Each button calls the MULTILEVEL project method with a pointer to the corresponding column field. The MULTILEVEL project method is the following:

```
 ` MULTILEVEL Project Method
 ` MULTILEVEL (Pointer)
 ` MULTILEVEL (->[Table]Field)

C_POINTER($1)   `Sort level (field)
C_LONGINT($lLevelNb)

 `Getting sorting levels
If(Not(Shift down)) `Simple sort (one-level)
   ARRAY POINTER(aPtrSortField;1)
   aPtrSortField{1}:=$1
Else
   $lLevelNb:=Find in array(aPtrSortField;$1) `Is this field already sorted?
   If($lLevelNb<0) `If not
      INSERT IN ARRAY(aPtrSortField;Size of array(aPtrSortField)+1;1)
      aPtrSortField{Size of array(aPtrSortField)}:=$1
   End if
End if
 `Performing the sort
$lLevelNb:=Size of array(aPtrSortField)
If($lLevelNb>0) `There is at least one order level
   For($i;1;$lLevelNb)
      ORDER BY([CDs];(aPtrSortField{$i})->;>;*) `Building sort definition
   End for
   ORDER BY([CDs]) `No * ends the sort definition and starts the actual sort operation
End if
```

# ORDER BY FORMULA

ORDER BY FORMULA ( aTable ; expression {; > or <}{; expression2 ; > or <2 ; ... ; expressionN ; > or <N} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to order selected records |
| expression | Expression | ➡ | Expression on which to set the order for each level (can be of type Alphanumeric, Real, Integer, Long Integer, Date, Time or Boolean) |
| > or < | Operator | ➡ | Ordering direction for each level: > to order in ascending order, or < to order in descending order |

## Description

**ORDER BY FORMULA** sorts (reorders) the records of the current selection of *aTable* for the current process. After the sort has been completed, the new first record of the selection becomes the current record.

Note that you must specify *aTable*. You cannot use a default table.

You can sort the selection on one level or on several levels. For each sort level, you specify a expression in *expression* and the sorting order in *> or <*. If you pass the “greater than” symbol (>), the order is ascending. If you pass the “less than” symbol (<), the order is descending. If you do not specify the sorting order, ascending order is the default.

The parameter *expression* can be of type Alphanumeric, Real, Integer, Long Integer, Date, Time or Boolean.

No matter what way a sort has been defined, if the actual sort operation is going to take some time to be performed, 4D automatically displays a message containing a progress thermometer. These messages can be turned on and off by using the **MESSAGES ON** and **MESSAGES OFF** commands. If the progress thermometer is displayed, the user can click the Stop button to interrupt the sort. If the sort is completed, OK is set to 1. Otherwise, if the sort is interrupted, OK is set to 0 (zero).

**4D Server:** Beginning with version 11 of 4D Server, this command is executed on the server, which optimizes its execution. Note that when variables are called directly in the *expression*, the sort is calculated with the value of the variable on the client machine.

On the other hand, this principle does not apply for formulas using methods that, themselves, call variables (the values of the variables are evaluated on the server). In this context, it may be advisable to use the "Execute on server" method attribute that allows a method to be executed on the server while passing parameters (variables) to it (see the Design Reference manual).

In previous versions of 4D Server, this command was executed on the client machines. For compatibility's sake, this functioning is maintained in databases converted to version 11. A compatibility preference and a selector of the **SET DATABASE PARAMETER** command can nevertheless be used to adopt the functioning of version 11 (execution on the server) in these databases.

## Example

This example orders the records of the [People] table in descending order, based on the length of each person’s last name. The record for the person with the longest last name will be first in the current selection:

```
ORDER BY FORMULA([People];Length([People]Last Name);<)
```

# QUERY

QUERY ( {aTable }{;}{ queryArgument {; *}} )

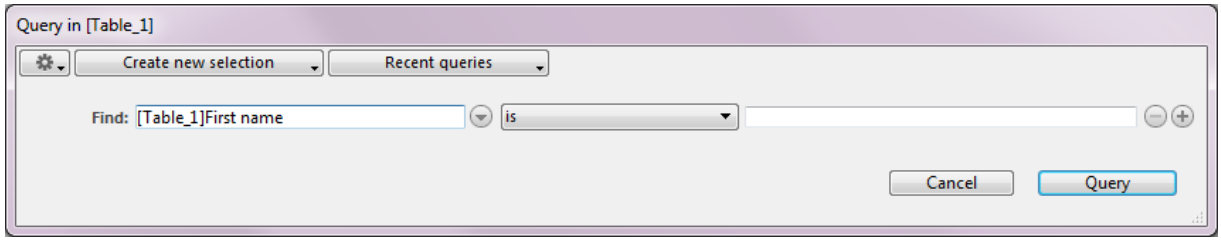
| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return a selection of records, or Default table, if omitted |
| queryArgument | Expression | ⇒ | Query argument |
| * | Operator | ⇒ | Continue query flag |

## Description

**QUERY** looks for records matching the criteria specified in *queryArgument* and returns a selection of records for *aTable*. **QUERY** changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record.

If the *aTable* parameter is omitted, the command applies to the default table. If no default table has been set, an error occurs.

If you do not specify *queryArgument* or the * parameters, **QUERY** displays the Query editor for *aTable* (except when it is the last row of a multiple query, see example 2):



For more information about using the Query Editor, refer to the 4D Design Reference manual.

The user builds the query, then clicks the Query button or chooses Query in selection to perform the query. If the query is performed without interruption, the OK variable is set to 1. If the user clicks Cancel, the **QUERY** terminates with no query actually performed, and sets the OK variable to *0* (zero).

## Example 1

The following line displays the Query editor for the [Products] table:

```
QUERY([Products])
```

## Example 2

The following line displays the Query editor for the default table (if it has been set)

```
QUERY
```

If you specify the *queryArgument* parameter, the standard Query editor is not presented and the query is defined programmatically. For simple queries (search on only one field) you call **QUERY** once with *queryArgument*. For multiple queries (search on multiple fields or with multiple conditions), you call **QUERY** as many times as necessary with *queryArgument*, and you specify the optional * parameter, except for the last **QUERY** call, which starts the actual query operation. The *queryArgument* parameter is described further in this section.

## Example 3

The following line looks for the [People] whose name starts with an “a”:

```
QUERY([People];[People]Last name="a@")
```

## Example 4

The following line looks for the [People] whose name starts with “a” or “b”:

```
QUERY([People];[People]Name="a@";*) ` * indicates that there are further search criteria
QUERY([People];|;[People]Name="b@") ` No * ends the query definition and starts the actual query operation
```

**Note:** The interpretation of @ characters in queries can be modified via an option in the Preferences. For more information, please refer to the **Comparison Operators** section.

## Specifying the Query Argument

The *queryArgument* parameter uses the following syntax:

*{ conjunction ; } field comparator value*

The conjunction is used to join **QUERY** calls when defining multiple queries. The conjunctions available are the same as those in the Query editor:

| Conjunction | Symbol to use with QUERY |
|---|---|
| AND | & |
| OR | \| |
| Except | # |

The *conjunction* is optional and not used for the first **QUERY** call of a multiple query, or if the query is a simple query. If you omit it within a multiply query, AND (&) is used by default.
The *field* is the field to query. The *field* may belong to another table if it belongs to a One table related to *aTable* with an automatic or manual relation.

The *comparator* is the comparison that is made between *field* and *value*. The *comparator* is one of the symbols shown here:

| Comparison | Symbol to use with QUERY |
|---|---|
| Equal to | = |
| Not equal to | # |
| Less than | < |
| Greater than | > |
| Less than or equal to | <= |
| Greater than or equal to | >= |
| Contains keyword | % |

**Note:** It is also possible to specify the comparison operator as an alphanumeric expression instead of a symbol. In this case, it is mandatory to use semi-colons in order to separate the items of the query string. This means that it is possible, for example, to create configurable query sequences by varying the comparison operator, or to build custom user query interfaces. Please refer to example 19.

The *value* is the data against which *field* will be compared. The value can be any expression that evaluates to the same data type as *field*. The value is evaluated once, at the beginning of the query. The value is not evaluated for each record. To query for a string contained in a string (a “contains” query), use the wildcard symbol (@) in *value* to isolate the string to be searched for as shown in this example "@Smith@". Note that in this case, the search only partially benefits from the index (compactness of data storage).

Searching by keywords is only available with Alpha or Text type fields. For more information about this type of query, please refer to the **Comparison Operators** section.

Here are the rules for building multiple queries:

- The first query argument must not contain a conjunction.
- Each successive query argument can begin with a conjunction. If you omit it, the AND (&) operator is used by default.
- The first query and every other query, except the last, must use the * parameter.
- To perform the query, do not specify the * parameter in the last **QUERY** command. Alternatively, you may execute the **QUERY** command without any parameters other than the table (the Query editor is not shown; instead, the multiple query you just defined is performed).

**Note:** Each table maintains its own current built query. This means that you can create multiple built queries simultaneously, one for each table. You must use the *aTable* parameter or set the default table to specify which table to use.

No matter which way a query has been defined:

- If the actual query operation is going to take some time to be performed, 4D automatically displays a message containing a progress thermometer. These messages can be turned on and off by using the **MESSAGES ON** and **MESSAGES OFF** commands. If the progress thermometer is displayed, the user can click on the Stop button to

interrupt the query. If the query is completed, OK is set to 1. Otherwise, if the query is interrupted, OK is set to 0 (zero).
- If any indexed fields are specified, the query is optimized every time that it is possible (indexed fields are searched first) resulting in a query that takes the least amount of time possible. The command makes use of composite indexes for queries using the AND (&).

## Example 5

The following command finds the records for all the people named Smith:

```
QUERY([People];[People]Last Name="Smith")
```

**Note:** If the Last Name field were indexed, the **QUERY** command would automatically use the index for a fast query.

**Reminder:** This query will find records like "Smith", "smith","SMITH", etc. To distinguish lowercase from uppercase, perform additional queries using the character codes.

## Example 6

The following example finds the records for all people named John Smith. The Last Name field is indexed. The First Name field is not indexed.

```
QUERY([People];[People]Last Name="smith";*) ` Find every person named Smith
QUERY([People];&;[People]First Name="john") ` with John as first name
```

When the query is performed, it quickly does an indexed search on Last Name and reduces the selection of records to those of people named Smith. The query then sequentially searches on First Name in this selection of records.

**Note:** This query is particularly optimized if the database contains a composite index including the *[People]Last Name+ [People]First Name* fields. In this case, the command takes advantage of the index and the query is completely indexed.

## Example 7

The following example finds the records of people named Smith or Jones. The Last Name field is indexed.

```
QUERY([People];[People]Last Name="smith";*) ` Find every person named Smith…
QUERY([People];|;[People]Last Name="jones") ` …or Jones
```

The **QUERY** command uses the Last Name index for both queries. The two queries are performed, and their results put into internal sets that are eventually combined using a union.

## Example 8

The following example finds the records for people who do not have a company name. It does this by finding entries with empty fields (the empty string).

```
QUERY([People];[People]Company="") ` Find every person with no company
```

## Example 9

The following example finds the record for every person whose last name is Smith and who works for a company based in New York. The second query uses a field from another table. This query can be done because the [People] table is related to the [Company] table with a many to one relation:

```
QUERY([People];[People]Last Name="smith";*) ` Find every person named Smith…
QUERY([People];&;[Company]State="NY") ` … who works for a company based in NY
```

## Example 10

The following example finds the record for every person whose name falls between A (included) and M (included):

```
QUERY([People];[People]Name<"n") ` Find every person from A to M
```

## Example 11

The following example finds the records for all the people living in the San Francisco or Los Angeles areas (ZIP codes beginning with 94 or 90):

```
QUERY([People];[People]ZIP Code ="94@";*) ` Find every person in the SF…
QUERY([People];|;[People]ZIP Code ="90@") ` …or Los Angeles areas
```

## Example 12

Searching by keyword: the following example searches the [Products] table for records where the Description field contains the word “easy”:

```
QUERY([Products];[Products]Description%"easy")
  ` Find products whose description contains the keyword easy
```

## Example 13

The following example finds the record that matches the invoice reference entered in the request dialog box:

```
vFind:=Request("Find invoice reference:") ` Get an invoice reference from the user
If(OK=1) ` If the user pressed OK
   QUERY([Invoice];[Invoice]Ref=vFind) ` Find the invoice reference that matches vFind
End if
```

## Example 14

The following example finds the records for the invoices entered in 1996. It does this by finding all records entered after 12/31/95 and before 1/1/97:

```
QUERY([Invoice];[Invoice]In Date>!12/31/95!;*) ` Find invoices after 12/31/95…
QUERY([Invoice];&;[Invoice]In Date<!1/1/97!) ` and before 1/1/97
```

## Example 15

The following example finds the record for each employee whose salary is between $10,000 and $50,000. The query includes the employees who make $10,000, but excludes those who make $50,000:

```
QUERY([Employee];[Employee]Salary >=10000;*) ` Find employees who make between…
QUERY([Employee];&;[Employee]Salary <50000) ` …$10,000 and $50,000
```

## Example 16

The following example finds the records for the employees in the marketing department who have salaries over $20,000. The Salary field is queried first because it is indexed. Notice that the second query uses a field from another table. It can do this because the [Dept] table is related to the [Employee] table with an automatic many to one relation:

```
QUERY([Employee];[Employee]Salary >20000;*) ` Find employees with salaries over $20,000 and…
QUERY([Employee];&;[Dept]Name="marketing") ` …who are in the marketing department
```

## Example 17

Given three tables related by Many-to-One relations: [City] -> [Department] -> [Region]. The following query finds all the regions with cities whose names begin with "Saint":

```
QUERY([Region];[City]Name="Saint@") ` Find all the regions with cities beginning with "Saint"
```

## Example 18

The following example queries for information that was entered into the variable *myVar*.

```
QUERY([Laws];[Laws]Text =myVar) ` Find all laws that match myVar
```

The query could have many different results, depending on the value of *myVar*. The query will also be performed differently. For example:

- If *myVar* equals *"Copyright@"*, the selection contains all laws with texts beginning with Copyright.
- If *myVar* equals *"@Copyright@"*, the selection contains all laws with texts containing at least one occurrence of Copyright.

## Example 19

The following example adds or does not add lines to a complex query depending on the value of the variables. This way, only valid criteria are taken into account for the query:

```
QUERY([Invoice];[Invoice]Paid=False;*)
If($city#"") ` if a city name has been specified
   QUERY([Invoice];[Invoice]Delivery_city=$city;*)
End if
If($zipcode#"") ` If a zip code has been specified
   QUERY([Invoice];[Invoice]ZipCode=$zipcode;*)
End if
QUERY([Invoice]) ` Execution of query on the criteria
```

## Example 20

This example illustrates the use of a comparison operator as an alphanumeric expression. The value of the comparison operator is specified using a pop-up menu placed in a custom query dialog box:

```
C_TEXT($oper)
$oper:=_popup_operator{_popup_operator} `$oper equals for example "#" or "="
If(OK=1)
   QUERY(Invoice];[Invoice]Amount;$oper;$amount)
End if
```

## Example 21

Using picture keyword indexes can greatly increase the speed of your applications.

```
QUERY([PICTURES];[PICTURES]Photos %"cats") // look for photos associated with the "cats" keyword
```

## System variables and sets

If the query is carried out correctly, the OK system variable is set to 1.
The OK variable is set to 0 if:

- the user clicks on the **Cancel**/**Stop** button,
- in 'query and lock' mode (see the **SET QUERY AND LOCK** command), the query has found at least one locked record. In this case as well, the LockedSet system set is updated.

# QUERY BY ATTRIBUTE

QUERY BY ATTRIBUTE ( {aTable}{;}{conjOp ;} objectField ; attributePath ; queryOp ; value {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to return a selection of records, or Default table if omitted |
| conjOp | Operator | ➡ | Conjunction operator to use to join multiple queries (if any) |
| objectField | Field | ➡ | Object field to query attributes |
| attributePath | String | ➡ | Name or path of attribute |
| queryOp | Operator, String | ➡ | Query operator (comparator) |
| value | Text, Number, Date, Time | ➡ | Value to compare |
| * | Operator | ➡ | Continue query flag |

## Description

**QUERY BY ATTRIBUTE** looks for records matching the query string defined using the *objectField*, *attributePath*, *queryOp* and *value* parameters, and returns a selection of records for *aTable*.

**Note:** For more information on Object fields (new in 4D v15), please refer to the section of the *Design Reference* manual.

**QUERY BY ATTRIBUTE** changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record. If the *aTable* parameter is omitted, the command applies to the default table. If no default table has been set, an error occurs.

The optional *conjOp* parameter is used to join **QUERY BY ATTRIBUTE** calls when defining multiple queries. The conjunction operators available are the same as the ones for the **QUERY** command:

| Conjunction | Symbol to use with QUERY BY ATTRIBUTE |
|---|---|
| AND | & |
| OR | \| |
| Except | # |

The *conjOp* parameter is not used for the first **QUERY BY ATTRIBUTE** call of a multiple query, or if the query is a simple query. If you omit it within a multiple query, the AND (&) operator is used by default.

In *objectField*, pass the Object field whose attribute(s) you want to query. If it belongs to a One table related to *aTable* with an automatic or manual relation, the *objectField* may belong to another table.
**QUERY BY ATTRIBUTE** supports 4D Write Pro custom attributes when documents are stored in Object fields. For more information about this point, please refer to the **Storing 4D Write Pro documents in 4D Object fields** section.

In *attributePath*, pass the path of the attribute whose values you want to compare for each record, for example "children.girls.age". If you pass a single name, for example "place", you designate the corresponding attribute found at the first level of the object field.
If an attribute "x" is an array, **QUERY BY ATTRIBUTE** will search records which contain an attribute "x" in which at least one element matches the criteria. To search in array attributes, it is necessary to indicate to the **QUERY BY ATTRIBUTE** command that attribute "x" is an array by appending "[]" to its name in *attributePath* (see example 3).

**Notes:**

- Keep in mind that attribute names are case-sensitive: you can have different "MyAtt" and "myAtt" attribute names in the same record.
- Attribute names are trimmed to eliminate extra spaces. For example, " my first attribute .my second attribute " is interpreted as "my first attribute.my second attribute".

The *queryOp* parameter is the comparison operator that is applied between *objectField* and *value*. You can pass one of the symbols shown here:

| Comparison | Symbol to use with QUERY BY ATTRIBUTE |
|---|---|
| Equal to | = |
| Not equal to | # |
| Less than | < |
| Greater than | > |
| Less than or equal to | <= |
| Greater than or equal to | >= |

**Note:** It is also possible to specify the comparison operator as an text expression instead of a symbol. See the **QUERY** command description for more information.

*value* is the data against which *attributePath* will be compared. The value can be any expression that evaluates to the same data type as *attributePath*. The value is evaluated once, at the beginning of the query. The value is not evaluated for each record. To query for a string contained within a string (a "contains" query), use the wildcard symbol (@) in *value* to isolate the string to be searched for as shown in this example: "@Smith@". Note that in this case, the search only partially benefits from the index (compactness of data storage).

Here is the structure of a query by attribute:

```
QUERY BY ATTRIBUTE([Table] ;[Table]ObjectField ;"attribute1.attribute2";=;value)
```

**Note:** An implicit criteria for all operators (except #) is that the Object field contains an attribute. However, for the # operator, it can be undefined (see below).

### Using the # operator (support for Null values)

Queries by attribute using the "#" operator can have different results depending on whether or not the property is checked for the object field:

- **Map NULL values to blank values** property checked (default option, recommended in most cases).
  In this case, the "#" operator should be seen as selecting records where "no attribute" of the field contains the value searched for. In this context, 4D considers in a similar manner:
  - fields where the value of the attribute is different from the value searched for,
  - fields where the attribute is not present (or contains a Null value).

  For example, the following query returns records for people who have a dog whose name is not Rex, as well as records for people who do not have a dog, or who have a dog with no name:

  ```
  QUERY BY ATTRIBUTE([People];[People]Animals;"dog.name";#;"Rex")
  ```

  Another example: this query will return all records for which *[Table]ObjectField* contains an object which contains an *attribute1* attribute which is itself an object containing an *attribute2* attribute whose value is not *value*, as well as records where the object field does not contain *attribute1* or *attribute*2):

  ```
  QUERY BY ATTRIBUTE([Table];[Table]ObjectField;"attribute1.attribute2";#;value)
  ```

  This principle also applies to array attributes. For example:

  ```
  QUERY BY ATTRIBUTE([People];[People]OB_Field;"locations[].city";#;"paris")
  ```

  This query will return records for people who do not have any address in Paris.

  To specifically obtain records where the attribute is undefined, you can use an empty object (see example 2). Note however that searching for NULL values in array elements is not supported.

- **Map NULL values to blank values** property unchecked ("SQL" mode).
  In this case, undefined attributes (attributes not present in the field or whose value is Null) are not considered as equivalent to blank values by default. As a result, queries of the type "attribute A is different from attribute B" will not return records where attribute A is undefined.
  To use the same example as above, when the **Map NULL values to blank values** option is not checked for the [People]Animals field, the following query will only return records for people who have a dog whose "name" attribute does not contain "Rex". Records for people who do not have a dog, or who have a dog with no name will not be returned in this case.

  ```
  QUERY BY ATTRIBUTE([People];[People]Animals;"dog.name";#;"Rex")
  ```

  This operation, closer to the SQL logic, is reserved for specific needs.

### Building multiple queries

Here are the rules for building multiple queries by attribute:

- The first query argument must not contain a conjunction.
- Each successive query argument can begin with a conjunction. If you omit it, the AND (&) operator is used by default.
- The first query and every other query, except the last, must use the * parameter.

- **QUERY BY ATTRIBUTE** can be mixed with **QUERY** commands (see example).
- To perform the query, do not specify the * parameter in the last **QUERY BY ATTRIBUTE** command. Alternatively, you can execute the **QUERY** command without any parameters other than the table.

**Note:** Each table maintains its own currently-built query. This means that you can create multiple queries simultaneously, one for each table.

No matter which way a query has been defined:

- If the actual query operation is going to take some time to be performed, 4D automatically displays a message containing a progress thermometer. These messages can be turned on and off by using the **MESSAGES ON** and **MESSAGES OFF** commands. If a progress thermometer is displayed, the user can click on the Stop button to interrupt the query. If the query is completed, OK is set to 1. Otherwise, if the query is interrupted, OK is set to 0 (zero).
- If any indexed object fields are specified, the query is optimized every time that it is possible (indexed fields are searched first) resulting in a query that takes the least amount of time possible.

### Date values in the object

Dates are stored in objects according to database settings; by default, the time zone is taken into account (see the JSON use local time selector in the **SET DATABASE PARAMETER** command).

```
!1973-05-22! -> "1973-05-21T23:00:00.000Z"
```

This setting is also taken into account during queries, so you do not have to worry about it if you always use your database at the same place and if settings are the same on all machines that access the data. In this case, the following query will correctly return records whose Birthday attribute equals !1973-05-22! (saved as "1973-05-21T23:00:00.00Z"):

```
QUERY BY ATTRIBUTE([Persons];[Persons]OB_Info;"Birthday";=;!1973-05-22!)
```

If you do not want to use the GMT settings, you can modify these settings using the following instruction:

```
SET DATABASE PARAMETER(JSON use local time;0)
```

Keep in mind that the scope of this setting is the process only. If you execute this instruction, then October 1st, 1965 will be stored "1965-10-01T00:00:00.000Z" but you will need to set the same parameter before launching your queries:

```
SET DATABASE PARAMETER(JSON use local time;0)
QUERY BY ATTRIBUTE([Persons];[Persons]OB_Info;"Birthday";=;!1976-11-27!)
```

### Using the virtual length property

You can use the virtual "length" property with this command. This property is available automatically for all array type attributes and returns the size of the array, i.e. the number of elements it contains. It can be used in the context of executing the **QUERY BY ATTRIBUTE** command (see example 4).

## Example 1

In this example, the "age" attribute is either a string or an integer and we want to find people whose age is between 20 and 29. The first two lines query the attribute as an integer (>=20 and < 30) and the last ones query the field as a string (starts with "2" but is different from "2".)

```
QUERY BY ATTRIBUTE([Persons];[Persons]OB_Info;"age";>=;20;*)
QUERY BY ATTRIBUTE([Persons]; & ;[Persons]OB_Info;"age";<;30;*)
QUERY BY ATTRIBUTE([Persons];|;[Persons]OB_Info;"age";=;"2@";*)
QUERY BY ATTRIBUTE([Persons]; & ;[Persons]OB_Info;"age";#;"2") //no final * to launch execution
```

## Example 2

The **QUERY BY ATTRIBUTE** command can be used to find records where certain attributes are defined (or are not defined). To do this, you have to use an empty object.

```
 //Find records where e-mail is defined in the object field
C_OBJECT($undefined)
QUERY BY ATTRIBUTE([Persons];[Persons]Info;"e-mail";#;$undefined)
```

```
//Find records where zip code is NOT defined in the object field
C_OBJECT($undefined)
QUERY BY ATTRIBUTE([Persons];[Persons]Info;"zip code";=;$undefined)
```

**Note:** This specific syntax is not supported with array type attributes. Searching for NULL values in array elements will give invalid results.

## Example 3

You want to search a field containing array attributes. With the following two records:

*Record1:*
[People]name: "martin"
[People]OB_Field:
```
   "locations" : [ {
            "kind":"office",
            "city":"paris"
         } ]
```
*Record2:*
[People]name: "smith"
[People]OB_Field:
```
   "locations" : [ {
            "kind":"home",
            "city":"lyon"
         } , {
            "kind":"office",
            "city":"paris"
         } ]
```
... **QUERY BY ATTRIBUTE** will find people with a location in "paris" using this statement:

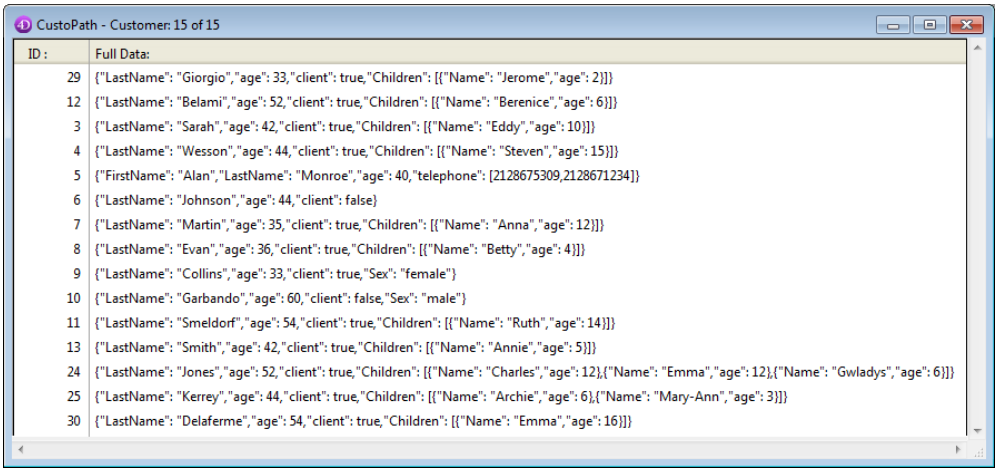
```
//flag the array attribute with "[]" syntax
QUERY BY ATTRIBUTE([People];[People]OB_Field;"locations[].city";=;"paris")
//selects "martin" and "smith"
```

**Note:** If you defined several criteria on the same array attribute, the matched criteria will not necessarily apply to the same array element. In the following example, the query returns "smith" because it has a "locations" element whose "kind" is "home" and a "locations" element whose "city" is "paris", even if it's not the same element:

```
QUERY BY ATTRIBUTE([People];[People]OB_Field;"locations[].kind";=;"home";*)
QUERY BY ATTRIBUTE([People]; & ;[People]OB_Field;"locations[].city";=;"paris")
//selects "smith"
```

## Example 4

This example illustrates the use of the virtual "length" property. Your database has a [Customer]full_Data object field with the following data:



You want to get the records for any customers who have two or more children. To do this, you can write:

```
QUERY BY ATTRIBUTE([Customer];[Customer]full_Data;"Children.length";>=;2)
```

## System variables and sets

If the query is carried out correctly, the OK system variable is set to 1.
The OK variable is set to 0 if:

- the user clicks on the **Cancel**/**Stop** button,
- in 'query and lock' mode (see the **SET QUERY AND LOCK** command), the query has found at least one locked record. In this case as well, the LockedSet system set is updated.

# QUERY BY EXAMPLE

QUERY BY EXAMPLE ( {aTable}{;}{*} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return a selection of records, or Default table, if omitted |
| * | Operator | ⇒ | If passed, the scrolling bar will not be displayed |

## Description

**QUERY BY EXAMPLE** performs the same action as the Query by Example menu command in the Design environment. It displays the current input form as a query window. **QUERY BY EXAMPLE** queries *aTable* for the data that the user enters into the query window. The form must contain the fields that you want the user to be able to query. The query is optimized; indexed fields are automatically used to optimize the query.

See the 4D Design Reference manual for information about using the Query by Example menu command in the Design environment.

## Example

The method in this example displays the MyQuery form to the user. If the user accepts the form and performs the query (that is, if the OK system variable is set to 1), the records that meet the query criteria are displayed:

```
FORM SET INPUT([People];"MyQuery") ` Switch to query form
QUERY BY EXAMPLE([People]) ` Display form and perform query
If(OK=1) ` If the user performed the query
   DISPLAY SELECTION([People]) ` Display the records
End if
```

## System variables and sets

If the user clicks the Accept button or presses the Enter key, the OK system variable is set to 1 and the query is performed. If the user clicks the Cancel button or presses the “cancel” key combination, the OK system variable is set to 0 and the query is canceled.

# QUERY BY FORMULA

QUERY BY FORMULA ( aTable {; queryFormula} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return a selection of records |
| queryFormula | Boolean | ⇒ | Query formula |

## Description

**QUERY BY FORMULA** looks for records in *aTable*. It changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record.

**QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** work exactly the same way, except that **QUERY BY FORMULA** queries every record in the entire table and **QUERY SELECTION BY FORMULA** queries only the records in the current selection.

Both commands apply *queryFormula* to each record in the table or selection. The *queryFormula* is a Boolean expression that must evaluate to either TRUE or FALSE. If *queryFormula* evaluates as TRUE, the record is included in the new selection.

The *queryFormula* may be simple, perhaps comparing a field to a value; or it may be complex, perhaps performing a calculation or even evaluating information in a related table. The *queryFormula* can be a 4D function (command), or a function (method) or expression you have created. You can use wildcards (@) in *queryFormula* when working with Alpha or text fields as well as the "contains" (%) operator for keyword queries. For more information, please refer to the description of the **QUERY** command.

If *queryFormula* is omitted, 4D displays the query dialog box (the user can add a line of formula by **Alt+clicking** on the sur le **[+]** button).

When the query is complete, the first record of the new selection is loaded from disk and made the current record.

These commands are optimized and can more particularly take advantage of indexes. When the type of query allows it, these commands execute queries equivalent to the **QUERY** command. For example, the statement **QUERY BY FORMULA**([mytable]; [mytable]myfield=value) will be executed just like **QUERY**([mytable]; [mytable]myfield=value), which will allow the use of indexes. 4D can also optimize queries containing parts that cannot be optimized, by first executing the optimized parts and then combining the results with the rest of the query. For example, the statement **QUERY BY FORMULA**[mytable];Length(myfield)=value) will not be optimized. On the other hand, **QUERY BY FORMULA**([mytable];Length(myfield)=value1 | myfield=value2) will be partially optimized.

These commands by default carry out "joins" like SQL when you compare fields from different tables. This means that it is not necessary for a structural automatic relation to exist between the tables. For example, you can execute a statement of the type **QUERY BY FORMULA([Table_A];([Table_A]field_X = [Table_B]field_Y) & ([Table_B]field_Y = "abc"))** (see example 3). The first part of the formula (*[Table_A]field_X = [Table_B]field_Y*) establishes the join between the two fields and the second part (*[Table_B]field_Y = "abc"*) defines the search criteria (at least one criterion must be set).
If they exist, the relations between the tables are not used as a rule. However, these commands will use automatic relations in the following cases:

- If the formula cannot be broken down into elements of the *{ field ; comparator ; value}* form
- If two fields of the same table are compared.

**Note:** For compatibility reasons, it is possible to deactivate the joins mechanism, either globally via the database Preference (converted databases only) or per process using the **SET DATABASE PARAMETER** command.

**4D Server:** Beginning with version 11 of 4D Server, these commands are run on the server, which optimizes their execution. Keep in mind that when variables are called directly in *queryFormula*, the query is calculated with the value of the variables on the client machine. For example, the statement **QUERY BY FORMULA**([mytable];[mytable]myfield=myvariable) will be run on the server but with the contents of the myvariable variable of the client machine.

On the other hand, this principle is not applied for formulas using methods that, themselves, call variables (the values of the variables are evaluated on the server). In this context, it may be advisable to use the "Execute on server" method attribute, which allows the method to be executed on the server while passing parameters (variables) to it (see the Design Reference manual).

In previous versions of 4D Server, these commands were executed on client machines. For compatibility's sake, this functioning is maintained for databases converted to version 11. A compatibility preference and a selector of the **SET**

**DATABASE PARAMETER** command can nevertheless be used to adopt the functioning of version 11 (execution on the server) in converted databases

## Example 1

This example finds the records for all invoices that were entered in December of any year. It does this by applying the **Month of** function to each record. This query could not be performed any other way without creating a separate field for the month:

```
QUERY BY FORMULA([Invoice];Month of([Invoice]Entered)=12) ` Find the invoices entered in December
```

## Example 2

This example finds records for all the people who have names with more than ten characters:

```
QUERY BY FORMULA([People];Length([People]Name)>10) ` Find names longer than ten characters
```

## Example 3

This example activates SQL joins for a specific query by formula:

```
$currentVal:=Get database parameter(QUERY BY FORMULA Joins)
SET DATABASE PARAMETER(QUERY BY FORMULA Joins;2) `Activate SQL joins
 `Query all the lines of "ACME" client invoices even though the tables are not related
QUERY BY FORMULA([invoice_line];([invoice_line]invoice_id=[invoice]id&[invoice]client="ACME"))
SET DATABASE PARAMETER(QUERY BY FORMULA Joins;$currentVal) `We re-establish the current settings
```

# QUERY SELECTION

QUERY SELECTION ( {aTable }{;}{ queryArgument {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return a selection of records, or Default table, if omitted |
| queryArgument | Expression | ⇒ | Query argument |
| * | Operator | ⇒ | Continue query flag |

## Description

**QUERY SELECTION** looks for records in *aTable*.The **QUERY SELECTION** command changes the current selection of *table* for the current process and makes the first record of the new selection the current record.

**QUERY SELECTION** works and performs the same actions as **QUERY**. The difference between the two commands is the scope of the query:

- **QUERY** looks for records among all the records in the table.
- **QUERY SELECTION** looks for records among the records currently selected in the table.

For more information, see the description of the **QUERY** command.

The **QUERY SELECTION** command is useful when a query cannot be defined using a sequence of **QUERY** calls joined with the * parameter. Typically, it is the case when you want to query a current selection that does not result from a previous query, but from a command such as **USE SET**.

## Example

You want to query the records that have been previously highlighted by the user in a list form. You can write:

```
USE SET("UserSet") //replace the current selection with the highlighted records
QUERY SELECTION([Company];[Company]City="New York City";*)
QUERY SELECTION([Company]Type Business="Stock Exchange")
```

You will find all companies located in New York City, with a Stock Exchange activity, among the initial user selection.

# QUERY SELECTION BY ATTRIBUTE

QUERY SELECTION BY ATTRIBUTE ( {aTable}{;}{conjOp ;} objectField ; attributePath ; queryOp ; value {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to return a selection of records, or Default table if omitted |
| conjOp | Operator | ➡ | Conjunction operator to use to join multiple queries (if any) |
| objectField | Field | ➡ | Object field to query attributes |
| attributePath | String | ➡ | Name or path of attribute |
| queryOp | Operator, String | ➡ | Query operator (comparator) |
| value | Text, Number, Date, Time | ➡ | Value to compare |
| * | Operator | ➡ | Continue query flag |

## Description

**QUERY SELECTION BY ATTRIBUTE** works and performs the same actions as **QUERY BY ATTRIBUTE**. The difference between these two commands is the scope of the query:

- **QUERY BY ATTRIBUTE** looks for records among all the records in the table.
- **QUERY SELECTION BY ATTRIBUTE** looks for records among the records currently selected in the table.

**QUERY SELECTION BY ATTRIBUTE** looks for records in *aTable*. The **QUERY SELECTION BY ATTRIBUTE** command changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record.

For more information, see the description of the **QUERY BY ATTRIBUTE** command.

The **QUERY SELECTION BY ATTRIBUTE** command is useful when a query cannot be defined using a combination of **QUERY BY ATTRIBUTE** (and even **QUERY**) calls joined with the * parameter. Typically, this is the case when you want to query a current selection that does not result from a previous query, but from a command such as **USE SET**.

## Example

You want to find people with an age between 20 and 30, among the records that were previously highlighted by the user:

```
USE SET("UserSet") //creates a new current selection
QUERY SELECTION BY ATTRIBUTE([People];[People]OB_Info;"age";>;20;*)
QUERY SELECTION BY ATTRIBUTE([People];&;[People]OB_Info;"age";<;30) //triggers the query
```

# QUERY SELECTION BY FORMULA

QUERY SELECTION BY FORMULA ( aTable {; queryFormula} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return a selection of records |
| queryFormula | Boolean | ⇒ | Query formula |

## Description

**QUERY SELECTION BY FORMULA** looks for records in *aTable*. **QUERY SELECTION BY FORMULA** changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record.

**QUERY SELECTION BY FORMULA** performs the same actions as **QUERY BY FORMULA**. The difference between the two commands is the scope of the query:

- **QUERY BY FORMULA** looks for records among all the records in the table.
- **QUERY SELECTION BY FORMULA** looks for records among the records currently selected in the table.

For more information, see the description of the **QUERY BY FORMULA** command.

# QUERY SELECTION WITH ARRAY

QUERY SELECTION WITH ARRAY ( targetField ; array )

| Parameter | Type | | Description |
|---|---|---|---|
| targetField | Field | ⇒ | Field used to compare the values |
| array | Array | ⇒ | Array of searched values |

## Description

The **QUERY SELECTION WITH ARRAY** command searches the table of the field passed as first parameter for the records where the value of *targetField* is equal to at least one of the values of the elements in the *array*. The records found will become the new current selection.

**QUERY SELECTION WITH ARRAY** functions in the same way as **QUERY WITH ARRAY**. The difference between these two commands is the scope of the search:

- **QUERY WITH ARRAY** searches all the records of the table containing *targetField*.
- **QUERY SELECTION WITH ARRAY** only searches the records of the current selection of the table containing *targetField*.

For more information, please refer to the description of the **QUERY WITH ARRAY** command.

# QUERY WITH ARRAY

QUERY WITH ARRAY ( targetField ; array )

| Parameter | Type | | Description |
|---|---|---|---|
| targetField | Field | ⇒ | Field used to compare the values |
| array | Array | ⇒ | Array of the searched values |

## Description

The **QUERY WITH ARRAY** command searches all the records for which the value of *targetField* is equal, at least, to one of the values of the elements in *array*. The records found will become the new current selection.

This command allows you to quickly and simply build a search on multiple values.

**Notes:**

- This command cannot be used with fields of the Picture or BLOB type.
- *targetField* and *array* must be of the same data type. Exception: you can use a Longint array with a field of the Time type.

## Example

The following example allows you to retrieve the records of both French and American clients:

```
ARRAY STRING(2;SearchArray;2)
SearchArray{1}:="FR"
SearchArray{2}:="US"
QUERY WITH ARRAY([Clients]Country;SearchArray)
```

# SET QUERY AND LOCK

SET QUERY AND LOCK ( lock )

| Parameter | Type | | Description |
|---|---|---|---|
| lock | Boolean | ⇒ | True = Lock the records found by queries False = Do not lock records |

## Description

The **SET QUERY AND LOCK** command can be used to request the automatic locking of records found by all queries that follow the calling of this command in the current transaction. This means that the records cannot be modified by a process other than the current process between a query and the handling of results.

By default, the records found by queries are not locked. Pass **True** in the *lock* parameter to activate locking.

It is imperative for this command to be used within a transaction. If it is called outside of this context, an error is generated. This allows for better control of record locking. The records found will stay locked as long as the transaction has not been terminated (whether validated or cancelled). After the transaction is completed, all the records are unlocked.

The records are locked for all the tables in the current transaction.

When a **SET QUERY AND LOCK**(True) statement has been executed, the query commands (for example **QUERY**) adopt a specific functioning if a record that is already locked is found:

- The query is stopped and the system variable OK is set to 0,
- The current selection is cleared,
- The *LockedSet* system set contains the locked record that caused the query to be stopped.

Consequently, in this context it is necessary to test the *LockedSet* set after a fruitless query (current selection empty and/or OK variable set to 0) in order to determine the cause of the failure.

Call **SET QUERY AND LOCK**(False) in order to disable this mechanism afterward.

**SET QUERY AND LOCK** only modifies the behavior for query commands, in other words:

- **QUERY**
- **QUERY SELECTION**
- **QUERY BY EXAMPLE**
- **QUERY BY FORMULA**
- **QUERY BY SQL**
- **QUERY SELECTION BY FORMULA**
- **QUERY SELECTION WITH ARRAY**
- **QUERY WITH ARRAY**
- **QUERY BY ATTRIBUTE**
- **QUERY SELECTION BY ATTRIBUTE**

However, **SET QUERY AND LOCK** does not affect other commands that modify the current selection such as **ALL RECORDS**, **RELATE MANY**, etc.

## Example

In this example, it is not possible to delete a client who would have been passed from category “C” to category “A” in another process between the **QUERY** and **DELETE SELECTION** commands:

```
START TRANSACTION
SET QUERY AND LOCK(True)
QUERY([Customers];[Customers]Category=C)
 `At this moment, the records found are automatically locked for all other processes
DELETE SELECTION([Customers])
SET QUERY AND LOCK(False)
VALIDATE TRANSACTION
```

## Error management

If the command is not called in the context of a transaction, an error is generated.

# SET QUERY DESTINATION

SET QUERY DESTINATION ( destinationType {; destinationObject {; destinationPtr}} )

| Parameter | Type | | Description |
|---|---|---|---|
| destinationType | Longint | ⇒ | 0 = current selection, 1 = set, 2 = named selection, 3 = variable |
| destinationObject | String, Variable | ⇒ | Name of the set, or Name of the named selection, or Variable |
| destinationPtr | Pointer | ⇒ | Pointer to local variable if destinationType=3 |

## Description

**SET QUERY DESTINATION** enables you to tell 4D where to put the result of any subsequent query for the current process.

You specify the type of the destination in the parameter *destinationType*. 4D provides the following predefined constants, found in the "**Queries**" theme:

| Constant | Type | Value |
|---|---|---|
| Into current selection | Longint | 0 |
| Into named selection | Longint | 2 |
| Into set | Longint | 1 |
| Into variable | Longint | 3 |

You specify the destination of the query itself in the optional *destinationObject* parameter according to the following table:

| destinationType parameter | destinationObject parameter |
|---|---|
| 0 (current selection) | You omit the parameter |
| 1 (set) | You pass the name of a set (existing or to be created) |
| 2 (named selection) | You pass the name of a named selection (existing or to be created) |
| 3 (variable) | You pass a numeric variable (existing or to be created) or an empty string "" to use the *destinationPtr* parameter |

With:

```
SET QUERY DESTINATION(Into current selection)
```

The records found by any subsequent query will end up in a new current selection for the table involved by the query.

With:

```
SET QUERY DESTINATION(Into set;"mySet")
```

The records found by any subsequent query will end up in the set *"mySet"*. The current selection and the current record for the table involved by the query are left unchanged.

With:

```
SET QUERY DESTINATION(Into named selection;"myNamedSel")
```

The records found by any subsequent query will end up in the named selection *"myNamedSel"*. The current selection and the current record for the table involved by the query are left unchanged.

**Notes:**

- If the named selection does not exist beforehand, it will be created automatically at the end of the query.
- This command manages named selections like the **CUT NAMED SELECTION** command: only references are kept. Once the named selection is used, it no longer exists.

With:

```
SET QUERY DESTINATION(Into variable;$vlResult)
```

Or:

```
SET QUERY DESTINATION(Into variable;"";->$vlResult)
```

**Note:** This second syntax facilitates the joint use of the command with **GET QUERY DESTINATION**.

The number of records found by any subsequent query will end up in the variable *$vlResult*. The current selection and the current record for the table involved by the query are left unchanged.

**Warning: SET QUERY DESTINATION** affects all subsequent queries made within the current process. REMEMBER to always counterbalance a call to **SET QUERY DESTINATION** (where *destinationType#0*) with a call to **SET QUERY DESTINATION**(0) in order to restore normal query mode.

**SET QUERY DESTINATION** changes the behavior of the query commands only:

- **QUERY**
- **QUERY SELECTION**
- **QUERY BY EXAMPLE**
- **QUERY BY FORMULA**
- **QUERY BY SQL**
- **QUERY SELECTION BY FORMULA**
- **QUERY SELECTION WITH ARRAY**
- **QUERY WITH ARRAY**
- **QUERY BY ATTRIBUTE**
- **QUERY SELECTION BY ATTRIBUTE**

On the other hand, **SET QUERY DESTINATION** does not affect other commands that may change the current selection of a table such as **ALL RECORDS**, **RELATE MANY** and so on.

## Example 1

You create a form that will display the records from a *[Phone Book]* table. You create a Tab Control named *asRolodex* (with the 26 letters of the alphabet) and a subform displaying the *[Phone Book]* records. Choosing one Tab from the Tab Control displays the records whose names start with the corresponding letter.

In your application, the *[Phone Book]* table contains a set of quite static data, so you do not want to (or need to) perform a query each time you select a Tab. In this way, you can save precious database engine time.

To do so, you can redirect your queries into named selections that you reuse as needed. You write the object method of the Tab Control *asRolodex* as follows:

```
  ` asRolodex object method
Case of
   :(Form event=On Load)
  ` Before the form appears on the screen,
  ` initialize the rolodex and an array of Booleans that
  ` will tell us if a query for the corresponding letter
  ` has been performed or not
      ARRAY STRING(1;asRolodex;26)
      ARRAY BOOLEAN(abQueryDone;26)
      For($vlElem;1;26)
         asRolodex{$vlElem}:=Char(64+$vlElem)
         abQueryDone{$vlElem}:=False
      End for

   :(Form event=On Clicked)
  ` When a click on the Tab control occurs, check whether the corresponding query
  ` has been performed or not
      If(Not(abQueryDone{asRolodex}))
  ` If not, redirect the next query(ies) toward a named selection
         SET QUERY DESTINATION(Into named selection;"temp")
  ` Perform the query
         QUERY([Phone Book];[Phone Book]Last name=asRolodex{asRolodex}+"@")
  ` Restore normal query mode
         SET QUERY DESTINATION(Into current selection)
  ` Use the records found
         USE NAMED SELECTION("temp")
         COPY NAMED SELECTION([Phone book];"Rolodex+asRolodex{asRolodex})
  ` Next time we choose that letter, we won't perform the query again
```

```
            abQueryDone{asRolodex}:=True
         Else
   ` Use the existing named selection for displaying the records corresponding to the chosen letter
            USE NAMED SELECTION("Rolodex"+asRolodex{asRolodex}
         End if

      :(Form event=On Unload)
   ` After the form disappeared from the screen
   ` Clear the named selections we created
         For($vlElem;1;26)
            If(abQueryDone{$vlElem})
               CLEAR NAMED SELECTION("Rolodex"+asRolodex{$vlElem})
            End if
         End for
   ` Clear the two arrays we no longer need
         CLEAR VARIABLE(asRolodex)
         CLEAR VARIABLE(abQueryDone)
   End case
```

## Example 2

The ***Unique values*** project method in this example allows you to verify the uniqueness of the values for any number of fields in a table. The current record can be an existing or a newly created record.

```
   //Unique values project method
   //Unique values ( Pointer ; Pointer { ; Pointer... } ) -> Boolean
   //Unique values ( ->Table ; ->Field { ; ->Field2... } ) -> Yes or No

   C_BOOLEAN($0)
   C_POINTER(${1})
   C_LONGINT($vlField;$vlNbFields;$vlFound;$vlCurrentRecord)
   $vlNbFields:=Count parameters-1
   $vlCurrentRecord:=Record number($1->)
   If($vlNbFields>0)
      If($vlCurrentRecord#-1)
         If($vlCurrentRecord<0)
   //The current record is an unsaved new record (record number is -3);
   //therefore we can stop the query as soon as at least one record is found
            SET QUERY LIMIT(1)
         Else
   //The current record is an existing record;
   //therefore we can stop the query as soon as at least two records are found
            SET QUERY LIMIT(2)
         End if
   //The query will return its result in $vlFound
   //without changing the current record nor the current selection
         SET QUERY DESTINATION(Into variable;$vlFound)
   //Make the query according to the number of fields that are specified
         Case of
            :($vlNbFields=1)
               QUERY($1->;$2->=$2->)
            :($vlNbFields=2)
               QUERY($1->;$2->=$2->;*)
               QUERY($1->;&;$3->=$3->)
            Else
               QUERY($1->;$2->=$2->;*)
               For($vlField;2;$vlNbFields-1)
                  QUERY($1->;&;${1+$vlField}->=${1+$vlField}->;*)
               End for
               QUERY($1->;&;${1+$vlNbFields}->=${1+$vlNbFields}->)
         End case
         SET QUERY DESTINATION(Into current selection) //Restore normal query mode
         SET QUERY LIMIT(0) //No longer limit queries
   //Process query result
         Case of
            :($vlFound=0)
               $0:=True //No duplicated values
            :($vlFound=1)
```

```
            If($vlCurrentRecord<0)
               $0:=False //Found an existing record with the same values as the unsaved new record
            Else
               $0:=True //No duplicated values; just found the very same record
            End if
         :($vlFound=2)
            $0:=False //Whatever the case is, the values are duplicated
      End case
   Else
      If(◊DebugOn) //Does not make sense; signal it if development version
         TRACE //WARNING! Unique values is called with NO current record
      End if
      $0:=False //Can't guarantee the result
   End if
Else
   If(◊DebugOn) //Does not make sense; signal it if development version
      TRACE //WARNING! Unique values is called with NO query condition
   End if
   $0:=False //Can't guarantee the result
End if
```

After this project method is implemented in your application, you can write:

```
 //...
If(Unique values(->[Contacts];->[Contacts]Company);->[Contacts]Last name;->[Contacts]First name)
 //Do appropriate actions for that record which has unique values
Else
   ALERT("There is already a Contact with this name for this Company.")
End if
 //...
```

# SET QUERY LIMIT

SET QUERY LIMIT ( limit )

| Parameter | Type | | Description |
|---|---|---|---|
| limit | Longint | ➡ | Number of records, or 0 for no limit |

## Description

**SET QUERY LIMIT** allows you to tell 4D to stop any subsequent query for the current process as soon as at least the number of records you pass in *limit* has been found.

For example, if you pass *limit* equal to 1, any subsequent query will stop browsing an index or the data file as soon as one record that matches the query conditions has been found.

To restore queries with no limit, call **SET QUERY LIMIT** again with *limit* equal to 0.

**Warning: SET QUERY LIMIT** affects all the subsequent queries made within the current process. REMEMBER to always counterbalance a call to **SET QUERY LIMIT***(limit)* (where *limit>0*) with a call to **SET QUERY LIMIT***(0)* in order to restore queries with no limit.

**SET QUERY LIMIT** changes the behavior of the query commands:

- **QUERY**
- **QUERY SELECTION**
- **QUERY BY EXAMPLE**
- **QUERY BY FORMULA**
- **QUERY BY SQL**
- **QUERY SELECTION BY FORMULA**
- **QUERY SELECTION WITH ARRAY**
- **QUERY WITH ARRAY**
- **QUERY BY ATTRIBUTE**
- **QUERY SELECTION BY ATTRIBUTE**

On the other hand, **SET QUERY LIMIT** does not affect the other commands that may change the current selection of a table, such as **ALL RECORDS**, **RELATE MANY**, and so on.

## Example 1

To perform a query corresponding to the request "...give me any ten customers whose gross sales are greater than $1 M...", you would write:

```
SET QUERY LIMIT(10)
QUERY([Customers];[Customers]Gross sales>1000000)
SET QUERY LIMIT(0)
```

## Example 2

See the second example for the **SET QUERY DESTINATION** command.

# Quick Report

# QR BLOB TO REPORT

QR BLOB TO REPORT ( area ; blob )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| blob | BLOB | ➡ | BLOB that houses the report |

## Description

The **QR BLOB TO REPORT** command places the report contained in *blob* in the Quick Report area passed in *area*.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *blob* parameter, the error -9852 will be generated.

## Example 1

The following code allows you to display, in MyArea, a report file named “report.4qr” located next to the database structure. The report file does not have to be created with 4D version 2003; it can originate from previous versions:

```
C_BLOB($doc)
C_LONGINT(MyArea)
DOCUMENT TO BLOB("report.4qr";$doc)
QR BLOB TO REPORT(MyArea;$doc)
```

## Example 2

The following statement retrieves the Quick Report stored in Field4 and displays it in MyArea:

```
QR BLOB TO REPORT(MyArea;[Table 1]Field4)
```

# QR Count columns

QR Count columns ( area ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| Function result | Longint | ⇐ | Number of columns in area |

## Description

The **QR Count columns** command returns the number of columns present in the Quick Report *area*.

If you pass an invalid area number, the error -9850 will be generated.

## Example

The following code retrieves the column count and inserts a column to the right of the rightmost existing column:

```
$ColNb:=QR Count columns(MyArea)
QR INSERT COLUMN(MyArea;$ColNb+1;->[Table 1]Field2)
```

# QR DELETE COLUMN

QR DELETE COLUMN ( area ; colNumber )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| colNumber | Longint | ⇒ | Column number |

## Description

The **QR DELETE COLUMN** command deletes the column in *area* whose number was passed in *colNumber*. This command does not apply to cross-table reports.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *column* number, the error -9852 will be generated.

## Example

The following example makes sure the report is a list report and deletes the third column:

```
If(QR Get report kind(MyArea)=qr list report)
   QR DELETE COLUMN(MyArea;3)
End if
```

# QR DELETE OFFSCREEN AREA

QR DELETE OFFSCREEN AREA ( area )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area to delete |

## Description

The **QR DELETE OFFSCREEN AREA** command deletes in memory the Quick Report offscreen *area* whose reference was passed as parameter.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR EXECUTE COMMAND

QR EXECUTE COMMAND ( area ; command )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| command | Longint | ⇒ | Menu command to be executed |

## Description

The **QR EXECUTE COMMAND** command executes the menu command or toolbar button whose reference was passed in *command*. The most common use for this command is to execute a command after the user selected that command and your code intercepted it through the **QR ON COMMAND** command.

In *command*, you can pass a value or one of the constants of the **QR Commands** constant theme:

| Constant | Type | Value |
| --- | --- | --- |
| qr cmd 4D View destination | Longint | 2503 |
| qr cmd add column | Longint | 2608 |
| qr cmd alt back color palette | Longint | 1004 |
| qr cmd automatic width | Longint | 2605 |
| qr cmd average | Longint | 507 |
| qr cmd back color palette | Longint | 1003 |
| qr cmd back colors toolbar | Longint | 2052 |
| qr cmd bold | Longint | 500 |
| qr cmd borders | Longint | 2609 |
| qr cmd center justified | Longint | 504 |

| Constant | Type | Value |
| --- | --- | --- |
| qr cmd underline | Longint | 502 |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *command* number, the error -9852 will be generated.

# QR Find column

QR Find column ( area ; expression ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| expression | String, Pointer | ➡ | Column object |
| Function result | Longint | ↩ | Number of the column |

## Description

The **QR Find column** command returns the number of the first column whose contents match the *expression* passed in parameter.

*expression* can either be a string or a pointer.

**QR Find column** returns -1 if nothing has been found.

If you pass an invalid area number, the error -9850 will be generated.

## Example

The following code retrieves the column number that holds the field [G.NQR Tests]Quarter and deletes that column:

```
$NumColumn:=QR Find column(MyArea;->[G.NQR Tests]Quarter)
```

or:

```
$NumColumn:=QR Find column(MyArea;"[G.NQR Tests]Quarter")
```

followed by:

```
If($NumColumn#-1)
   QR DELETE COLUMN(MyArea;$NumColumn)
End if
```

# QR Get area property

QR Get area property ( area ; property ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| property | Longint | ⇒ | Interface element designated |
| Function result | Longint | ⇐ | 1 = displayed, 0 = hidden |

## Description

The **QR Get area property** command returns 0 if the interface element (toolbar or menu bar) passed in *property* is not displayed; otherwise, it returns 1.

The menu bar and toolbars are numbered from 1 to 6 (top to bottom) and the value 7 is dedicated to the context menu.

You can use the constants from the **QR Area Properties** theme to designate the interface item:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr view color toolbar | Longint | 5 | Display status of the Color toolbar (Displayed=1, Hidden=0) |
| qr view column toolbar | Longint | 6 | Display status of the Column toolbar (Displayed=1, Hidden=0) |
| qr view contextual menus | Longint | 7 | Display status of the Contextual menu (Displayed=1, Hidden=0) |
| qr view menubar | Longint | 1 | Display status of the menu bar (Displayed=1, Hidden=0) |
| qr view operators toolbar | Longint | 4 | Display status of the Operators toolbar (Displayed=1, Hidden=0) |
| qr view standard toolbar | Longint | 2 | Display status of the Standard toolbar (Displayed=1, Hidden=0) |
| qr view style toolbar | Longint | 3 | Display status of the Style toolbar (Displayed=1, Hidden=0) |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *property* parameter, the error -9852 will be generated.

# QR GET BORDERS

QR GET BORDERS ( area ; column ; row ; border ; line {; color} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| column | Longint | ⇒ | Column number |
| row | Longint | ⇒ | Row number |
| border | Longint | ⇒ | Border value |
| line | Longint | ⇐ | Line thickness |
| color | Longint | ⇐ | Border color |

## Description

The **QR GET BORDERS** command allows you to retrieve the border style for a border of a given cell.

*area* is the reference of the Quick Report area.

*column* is the column number of the cell.

*row* designates the row number of the cell. You can either:

- pass a positive integer value to designate the corresponding subtotal (break) level that is affected.
- pass one of the following constants of the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr grand total | Longint | -3 | Grand total area |
| qr title | Longint | -1 | Title of report |

*border* is the value that indicates which cell border is affected. Pass one of the constants from the **QR Borders** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr bottom border | Longint | 8 | Bottom border |
| qr inside horizontal border | Longint | 32 | Inside horizontal border |
| qr inside vertical border | Longint | 16 | Inside vertical border |
| qr left border | Longint | 1 | Left border |
| qr right border | Longint | 4 | Right border |
| qr top border | Longint | 2 | Top border |

**Note:** Unlike the command **QR SET BORDERS**, **QR GET BORDERS** does not accept a cumulative value. You must test all the parameters separately to have an overall view of the cell border.

*line* is the thickness of the line:

- 0 indicates no line
- 1 indicates a thickness of 1/4 point
- 2 indicates a thickness of 1/2 point
- 3 indicates a thickness of 1 point
- 4 indicates a thickness of 2 points.

*color* is the color of the line; it returns the value of the color applied to the line segment.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *column* number, the error -9852 will be generated.
If you pass an invalid *row* number, the error -9853 will be generated.
If you pass an invalid *border* parameter, the error -9854 will be generated.

# QR Get command status

QR Get command status ( area ; command {; value} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| command | Longint | ⇒ | Command number |
| value | Longint, Text | ⇐ | Value for the selected sub-item |
| Function result | Longint | ⇐ | Command status |

## Description

The **QR Get command status** command returns 0 if the *command* is disabled or 1 if it is enabled.

*value* returns the value of the selected sub-item, if any. For example, if the command that was selected is the **Font** menu (1000) and the font selected was “Arial”, *value* would return “Arial”, or if the command that was selected is a color menu (1002, 1003 or 1004), *value* would return the color number.

You can use the command in two types of contexts:

- As a simple statement to determine whether a command is enabled or disabled.
- In the method installed by **QR ON COMMAND**, to allow you to know which sub-item was selected. In that method, *$1* is the reference of the area and *$2* is the number of the command.

In *command*, you can pass a value or one of the constants of the **QR Commands** constant theme.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *command* number, the error -9852 will be generated.

# QR GET DESTINATION

QR GET DESTINATION ( area ; type {; specifics} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| type | Longint | ⇐ | Type of the report |
| specifics | String, Variable | ⇐ | Specifics linked to the output type |

## Description

The **QR GET DESTINATION** command retrieves the output *type* of the report for the area whose reference was passed in *area*.

You can compare the value of the *type* parameter with the constants of the **QR Output Destination** theme.

The following table describes the values that can be retrieved in both *type* and *specifics* parameters:

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr 4D Chart area | Longint | 4 | *** Obsolete constant *** |
| qr 4D View area | Longint | 3 | *specifics*: N.A. |
| qr HTML file | Longint | 5 | *specifics*: Pathname to the file. |
| qr printer | Longint | 1 | *specifics*: "*" to remove the print dialog boxes |
| qr text file | Longint | 2 | *specifics*: Pathname to the file. |

If you pass an invalid *area* number, the error -9850 will be generated.

# QR Get document property

QR Get document property ( area ; property ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| property | Longint | ⇒ | 1 = Print Dialog, 2 = Document unit |
| Function result | Longint | ⇐ | Value for the property |

## Description

The **QR Get document property** command retrieves the display status for the print dialog box or the unit used for the document that are present in *area*.

In *property*, you can use the following constants, located in the **QR Document Properties** constant theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr printing dialog | Longint | 1 | Display of the print dialog box:<br>• If value = 0, the print dialog is not displayed prior to printing.<br>• If value = 1, the print dialog is displayed prior to printing (default value). |
| qr unit | Longint | 2 | Document unit:<br>• If value = 0, the document unit is points.<br>• If value = 1, the document unit is centimeters.<br>• If value = 2, the document unit is inches. |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *property* value, the error -9852 will be generated.

# QR Get drop column

QR Get drop column ( area ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| Function result | Longint | ⇐ | Drop value |

## Description

The **QR Get drop column** command returns a value depending on where the drop was performed:

- if the value is negative, it indicates a column number (i.e., -3 if the the drop was performed on column number 3)
- if the value is positive, it indicates that the drop was performed on a separator preceding the column (i.e., 3 if the drop was performed after column 2). Keep in mind that the drop does not have to take place before an existing column.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR GET HEADER AND FOOTER

QR GET HEADER AND FOOTER ( area ; selector ; leftTitle ; centerTitle ; rightTitle ; height {; picture {; pictAlignment}} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| selector | Longint | ➡ | 1 = Header, 2 = Footer |
| leftTitle | String | ⬅ | Text displayed on the left side |
| centerTitle | String | ⬅ | Text displayed in the middle |
| rightTitle | String | ⬅ | Text displayed on the right side |
| height | Longint | ⬅ | Header or footer height |
| picture | Picture | ⬅ | Picture to display |
| pictAlignment | Longint | ⬅ | Alignment attribute for the picture |

## Description

The **QR GET HEADER AND FOOTER** command retrieves the contents and size of the header or footer.

*selector* allows you to select the header or the footer:

- if *selector* equals 1, the header information will be retrieved;
- if *selector* equals 2, the footer information will be retrieved.

*leftTitle*, *centerTitle* and *rightTitle* returns the values for, respectively, the left, center and right header/footer.

*height* returns the height of the header/footer, expressed in the unit selected for the report.

*picture* returns a picture that is displayed in the header or footer.

*pictAlignment* is the alignment attribute for the picture displayed in the header/footer.

- If *pictAlignment* returns 1, the picture is aligned to the left.
- If *pictAlignment* returns 2, the picture is centered.
- If *pictAlignment* returns 3, the picture is aligned to the right.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *selector* value, the error -9852 will be generated.

## Example

The following code retrieves the values of the header titles as well as the header size and displays them in alerts:

```
QR GET HEADER AND FOOTER(MyArea;1;$LeftText;$CenterText;$RightText;$height)
Case of
   :($LeftText #"")
      ALERT("The left title is "+Char(34)+$LeftText+Char(34))
   :($CenterText #"")
      ALERT("The center title is "+Char(34)+$CenterText+Char(34))
   :($RightText #"")
      ALERT("The right title is "+Char(34)+$RightText+Char(34))
   Else
      ALERT("No header title in this report.")
End case
ALERT("The height of the header is "+String($height))
```

# QR Get HTML template

QR Get HTML template ( area ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| Function result | Text | ⮌ | HTML code used as template |

## Description

The **QR Get HTML template** command returns the HTML template currently used for the Quick Report *area*. The returned value is a text value and includes all the contents of the HTML template.

If no specific template was defined, the template that is returned is the default template. Please note that no template will be returned if the output was not set to HTML file, either manually or programmatically.

If you pass an invalid area number, the error -9850 will be generated.

# QR GET INFO COLUMN

QR GET INFO COLUMN ( area ; colNum ; title ; object ; hide ; size ; repeatedValue ; displayFormat {; resultVar} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| colNum | Longint | ➡ | Column number |
| title | Text | ⬅ | Column title |
| object | Text | ⬅ | Object assigned for that column |
| hide | Longint | ⬅ | 0 = displayed, 1 = hidden |
| size | Longint | ⬅ | Column size |
| repeatedValue | Longint | ⬅ | 0 = not repeated, 1 = repeated |
| displayFormat | Text | ⬅ | Display format for the data |
| resultVar | Text | ⬅ | Name of the formula variable |

## Description

### List mode

The **QR GET INFO COLUMN** command retrieves the parameters of an existing column.

*area* is the reference of the Quick Report area.

*colNum* is the number of the column to modify.

*title* returns the title that will be displayed in the header of the column.

*object* returns the field name or the formula assigned to the column.

**Note:** The command does not take into account any virtual structure defined by means of the **SET TABLE TITLES** and **SET FIELD TITLES** commands. The actual name of the field is returned in the *object* parameter.

*hide* returns whether the column is displayed or hidden:

- if *hide* equals 1, the column is hidden;
- if *hide* equals 0, the column is displayed.

*size* returns the size of the column in pixels. If the value returned is negative, the size of the column is automatic.

*repeatedValue* returns the status for data repetition. For example, if the value for a field or variable does not change from one record to the other, it may or may not be repeated when they do not change:

- if *repeatedValue* equals 0, values are not repeated,
- if *repeatedValue* equals 1, values are repeated.

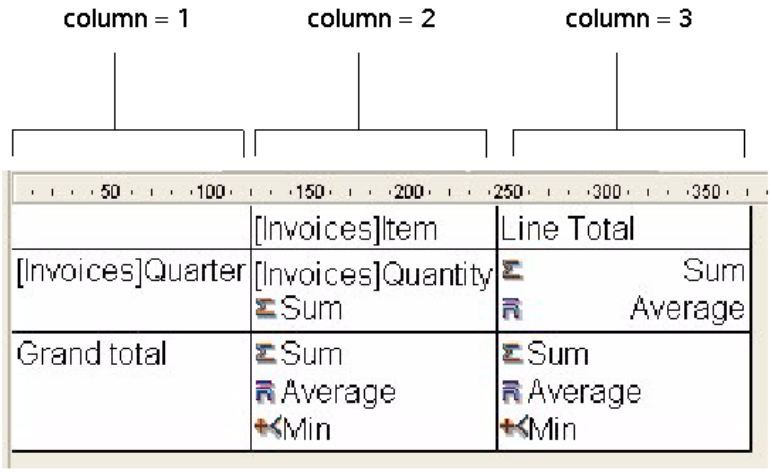
*format* returns the display format. Display formats are the 4D formats compatible with the data displayed.

When passed, the optional *resultVar* parameter returns the name of the variable automatically assigned by the Quick Report editor to the formula column (if any): "C1" for the first formula column, "C2" for the second, and so on. 4D uses this variable to store the results from the last execution of the column's formula when generating the report.

### Cross-table mode

The **QR GET INFO COLUMN** command retrieves the same parameters but the reference of the areas to which it applies is different and varies depending on the parameter you want to set. First of all, the *title*, *hide*, and *repeatedValue* parameters are meaningless when this command is used in cross-table mode. The value to use for *colNum* varies depending on whether you want to retrieve the column size or the data source and display format.

- Column size
  This is a “visual” attribute, therefore columns are numbered from left to right, as depicted below:

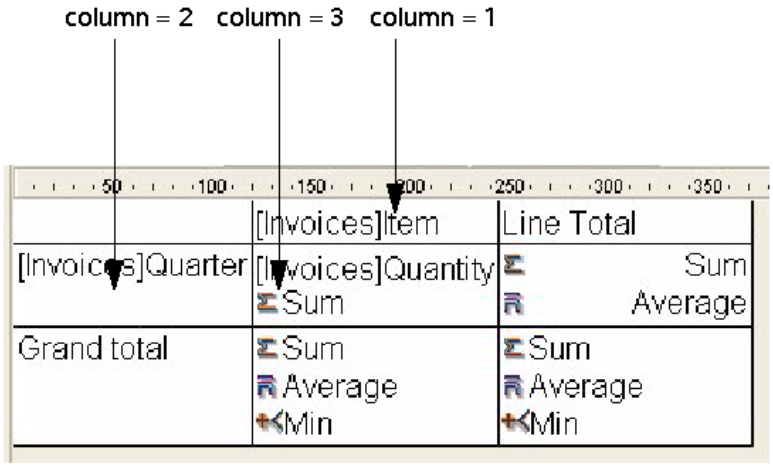


The following statement sets the size to automatic for all the columns in a cross-table report and leaves other elements unchanged:

```
For($i;1;3)
   QR GET INFO COLUMN(qr_area;$i;$title;$obj;$hide;$size;$rep;$format)
   QR SET INFO COLUMN(qr_area;$i;$title;$obj;$hide;0;$rep;$format)
End for
```

You will notice that since you want to alter only the column size, you have to use **QR GET INFO COLUMN** to retrieve the column properties and pass them to **QR SET INFO COLUMN** to leave it unchanged, except for the column size.

- Data source (object) and display format
  In this case, the numbering of columns operates as depicted below:



If you pass an invalid area number, the error -9850 will be generated.
If you pass an invalid ColNum value, the error -9852 will be generated.

## Example

You have designed the following report:

| | [People]LastName | [People]FirstName | C1 | [People]City | [People]Salary |
|---|---|---|---|---|---|
| Title | LastName | FirstName | Age | City | Salary |
| Detail | | | | | |
| Grand total | | | | | |

You can write:

```
C_TEXT($vTitle;$vObject;$vDisplayFormat;$vResultVar)
C_LONGINT($area;$vHide;$vSize;$vRepeatedValue)
QR GET INFO COLUMN($area;3;$vTitle;$vObject;$vHide;$vSize;$vRepeatedValue;$vDisplayFormat;$vResultVar)
 //$vTitle = "Age"
 //$vObject = "[People]Birthdate-Current date"
 //$vHide = 0
 //$vSize = 57
 //$vRepeatedValue = 1
```

```
    //$vDisplayFormat = ""
    //$vResultVar = "C1"
```

# QR Get info row

QR Get info row ( area ; row ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area created |
| row | Longint | ⇒ | Row designator |
| Function result | Longint | ⇐ | 0 = displayed, 1 = hidden |

## Description

The **QR Get info row** command retrieves the display status of the row whose reference was passed in *row*.

*row* designates which row is affected by the command. You can pass either:

- a positive integer value to designate the corresponding subtotal (break) level,
- one of the following constants from the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr grand total | Longint | -3 | Grand total area |
| qr title | Longint | -1 | Title of report |

The value returned by **QR Get info row** indicates whether the contents of the row are displayed or hidden. If it equals 1, the contents of the row are hidden; if it equals 0, the contents of the row are displayed.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *row* value, the error -9852 will be generated.

# QR Get report kind

QR Get report kind ( area ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| Function result | Longint | ⇐ | Type of the report |

## Description

The **QR Get report kind** command retrieves the report type for the area whose reference was passed in *area*.

- If the command returns 1, the report type is list.
- If the command returns 2, the report type is cross-table.

You can also compare the function result with the constants of the **QR Report Types** theme:

| Constant | Type | Value |
|---|---|---|
| qr cross report | Longint | 2 |
| qr list report | Longint | 1 |

If you pass an invalid *area* number, the error -9850 will be generated.

# QR Get report table

QR Get report table ( area ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| Function result | Longint | ⇐ | Table number |

## Description

The **QR Get report table** command returns the current table number for the report area whose reference was passed in *area*.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR GET SELECTION

QR GET SELECTION ( area ; left ; top {; right {; bottom}} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| left | Longint | ⇐ | Left boundary |
| top | Longint | ⇐ | Top boundary |
| right | Longint | ⇐ | Right boundary |
| bottom | Longint | ⇐ | Bottom boundary |

## Description

The **QR GET SELECTION** command returns the coordinates of the cell that is selected.

*left* returns the number of the column that is the left boundary of the selection. If *left* equals 0, the entire row is selected.

*top* returns the number of the row that is the top boundary of the selection. If *top* equals 0, the entire column is selected.

**Note:** If both *left* and *top* equal 0, the entire area is highlighted.

*right* is the number of the column that is the right boundary of the selection.

*bottom* is the number of the row that is the top boundary of the selection.

**Note:** If there is no selection, *left*, *top*, *right* and *bottom* are set to -1.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR GET SORTS

QR GET SORTS ( area ; aColumns ; aOrders )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇨ | Reference of the area |
| aColumns | Real array | ⇦ | Sorted columns |
| aOrders | Real array | ⇦ | Sort orders |

## Description

The **QR GET SORTS** command populates two arrays:

- *aColumns*
  This array includes all the columns that have a sort order.
- *aOrders*
  Each element of this array contains the sort orders for the matching column.
  - If *aOrders{$i}* equals 1, the sort order is ascending.
  - If *aOrders{$i}* equals -1, the sort order is descending.

### Cross-table mode

In the case of cross-table mode, the resulting arrays cannot have more than two elements since sorts can only be performed on columns (1) and rows (2). (Values for *aColumns*).

If you pass an invalid *area* number, the error -9850 will be generated.

# QR Get text property

QR Get text property ( area ; colNum ; rowNum ; property ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| colNum | Longint | ⇒ | Column number |
| rowNum | Longint | ⇒ | Row number |
| property | Longint | ⇒ | Property number |
| Function result | Longint, String | ⇐ | Value for the selected property |

## Description

The **QR Get text property** command returns the property value of the text attributes for the cell determined by *colNum* and *RowNum*.

*area* is the reference of the Quick Report area.

*colNum* is the number of the cell column.

*rowNum* is the reference of the cell row. You can either pass:

- a positive value designating the corresponding subtotal (break) level,
- one of the constants of the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr footer | Longint | -5 | Page footer |
| qr grand total | Longint | -3 | Grand total area |
| qr header | Longint | -4 | Page header |
| qr title | Longint | -1 | Title of report |

**Note:** When passing -4 or -5 as *rowNum*, you still need to pass a column number in *colNum*, even if it is not used.

**Note:** In cross-table mode, the principle is similar except for the row values, which are always positive.

*property* is the value of the text attribute to get. You can use the constants of the **QR Text Properties** theme, and the following values can be returned:

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr font | Longint | 1 | Obsolete since 4D v14R3 (use qr font name) |
| qr alternate background color | Longint | 9 | Alternate background color number |
| qr background color | Longint | 8 | Background color number |
| qr bold | Longint | 3 | Bold style attribute (0 or 1) |
| qr font name | Longint | 10 | Name of font as returned for example by the **FONT LIST** command |
| qr font size | Longint | 2 | Font size expressed in points (9 to 255) |
| qr italic | Longint | 4 | Italic style attribute (0 or 1) |
| qr justification | Longint | 7 | Justification attribute (0 for default, 1 for left, 2 for center or 3 for right) |
| qr text color | Longint | 6 | Color number attribute (Longint) |
| qr underline | Longint | 5 | Underline style attribute (0 or 1) |

If you pass an invalid *area* number, the error -9850 will be generated.

If you pass an invalid *colNum* number, the error -9852 will be generated.

If you pass an invalid *rowNum* number, the error -9853 will be generated.

If you pass an invalid *property* number, the error -9854 will be generated.

# QR GET TOTALS DATA

QR GET TOTALS DATA ( area ; colNum ; breakNum ; operator ; text )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| colNum | Longint | ⇒ | Column number |
| breakNum | Longint | ⇒ | Break number |
| operator | Longint | ⇐ | Operator value for the cell |
| text | String | ⇐ | Contents of the cell |

## Description

### List Mode

The **QR GET TOTALS DATA** command retrieves the details of a specific break.

*area* is the reference of the Quick Report area.

*colNum* is the number of the column whose data will be retrieved.

*breakNum* is the number of the break whose data will be retrieved (subtotal or grand total). For a subtotal row, *breakNum* corresponds to the row number. For a grand total, *breakNum* is -3 (you can also use the *qr grand total* constant from the **QR Rows for Properties** theme).

*operator* returns the sum of all the operators present in the cell. You can use the constants of the **QR Operators** theme to process the returned value:

| Constant | Type | Value |
|---|---|---|
| qr average | Longint | 2 |
| qr count | Longint | 16 |
| qr max | Longint | 8 |
| qr min | Longint | 4 |
| qr standard deviation | Longint | 32 |
| qr sum | Longint | 1 |

If the value returned is 0, there is no operator.

*text* returns the text present in the cell.

**Note:** *operator* and *text* are mutually exclusive, so you either have a result returned through *operator* or through *text*.

### Cross-table Mode

The **QR GET TOTALS DATA** command retrieves the details of a specific cell.

*area* is the reference of the Quick Report area.

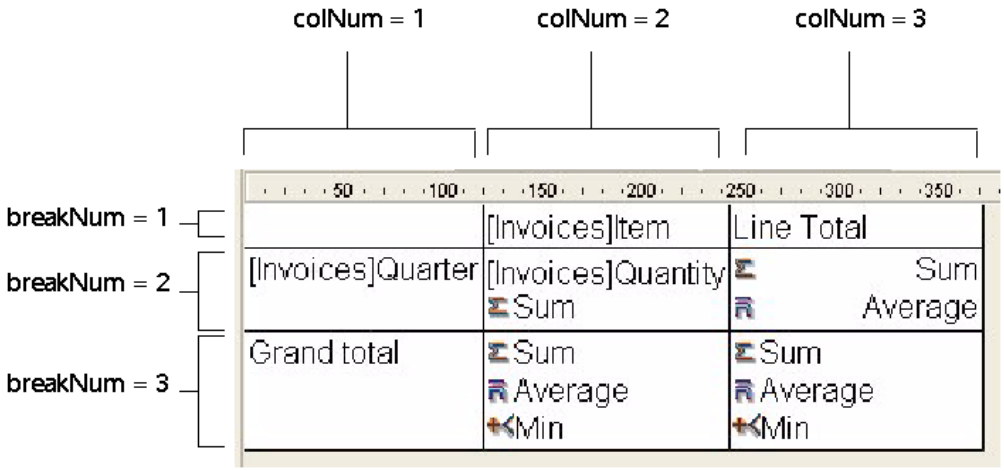
*colNum* is the column number of the cell whose data is going to be retrieved.

*breakNum* is the row number of the cell whose data is going to be retrieved.

*operator* returns the sum of all the operators present in the cell. You can use the constants of the **QR Operators** theme to process the returned value (see above).

*text* returns the text in the cell.

Here is a depiction of how the parameters *colNum* and *breakNum* have to be combined in cross-table mode:



If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *colNum* number, the error -9852 will be generated.
If you pass an invalid *breakNum* number, the error -9853 will be generated.

# QR GET TOTALS SPACING

QR GET TOTALS SPACING ( area ; subtotal ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| subtotal | Longint | ➡ | Subtotal number |
| value | Longint | ⬅ | 0=no space, 32000=inserts a page break, >0=spacing added below the break level, <0=proportional increase |

## Description

The **QR GET TOTALS SPACING** command retrieves a space below a subtotal row. It applies only to the list mode.

*area* is the reference of the Quick Report area.

*subtotal* is the subtotal level (or break level) that will be affected. *subtotal* is a value between 1 and the number of the subtotal/sort.

*value* defines the value of the spacing:

- If *value* is 0, no space is added.
- If *value* is 32000, a page break is inserted.
- If *value* is a positive value, it expresses the spacing value in pixels.
- If *value* is a negative value, it expresses the spacing as a percentage of the subtotal row. For example, -100 will set a space of 100% below the subtotal row.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *subtotal*, the error -9852 will be generated.

# QR INSERT COLUMN

QR INSERT COLUMN ( area ; colNumber ; object )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| colNumber | Longint | ➡ | Column number |
| object | Field, Variable, Pointer | ➡ | Object to be inserted in the column |

## Description

The **QR INSERT COLUMN** command inserts or creates a column at the specified position. Columns located to the right of that position will be shifted accordingly.

*position* is the number of the column, established from left to right.

The default title for the column will be the value passed in *object*.

If you pass an invalid *area* number, the error -9850 will be generated.

**Note:** This command cannot be used with a cross-table report.

## Example

The following statement inserts (or creates) a first column in a Quick Report area, inserts “Field1” as column title (default behavior) and populates the contents of the body with values from Field1.

```
QR INSERT COLUMN(MyArea;1;->[Table 1]Field1)
```

# QR MOVE COLUMN

QR MOVE COLUMN ( area ; column ; newPos )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| column | Longint | ➡ | Column number |
| newPos | Longint | ➡ | New position for column |

## Description

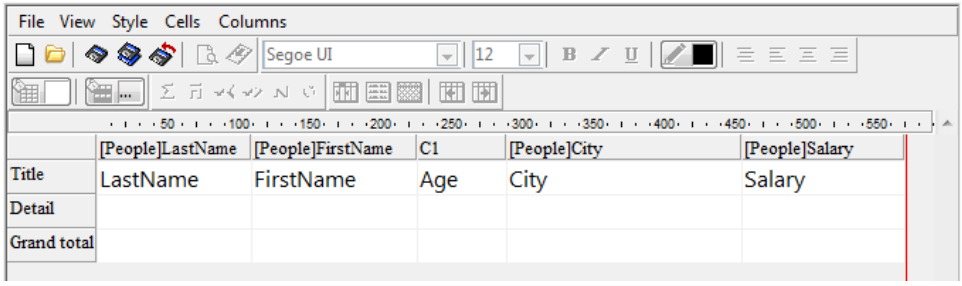
The **QR MOVE COLUMN** command moves the column currently found at the *column* position to the *newPos* position.

Both the *column* and *newPos* parameters must be valid column numbers (between 1 and the total number of columns in the report); otherwise, the error -9852 is returned.

**Note:** This command can be used with list reports only.

## Example

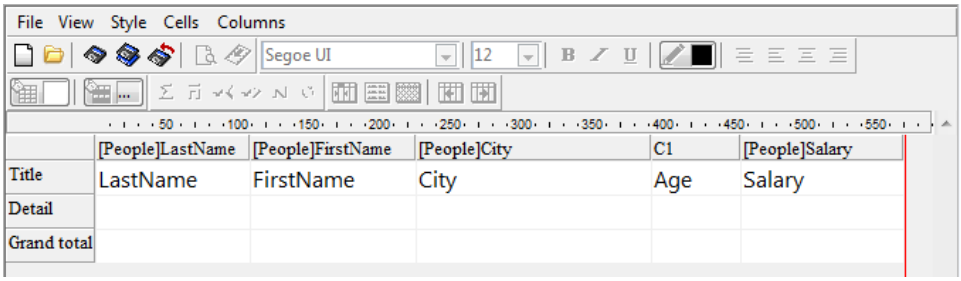
You have designed the following report:



If you execute:

```
QR MOVE COLUMN(area;3;4)
```

The result is:



# QR NEW AREA

QR NEW AREA ( ptr )

| Parameter | Type | | Description |
|---|---|---|---|
| ptr | Pointer | ⇨ | Pointer to a variable |

## Description

The **QR NEW AREA** command creates a new Quick Report area and stores its reference number in the longint variable referenced by the *ptr* pointer.

# QR New offscreen area

QR New offscreen area -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Reference of the area created |

## Description

The **QR New offscreen area** command creates a new Quick Report offscreen area and returns its reference.

# QR ON COMMAND

QR ON COMMAND ( area ; methodName )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| methodName | String | ⇒ | Name of the replacement method |

## Description

The **QR ON COMMAND** command executes the 4D method passed in *methodName* when a Quick Report command is invoked by the user, by the selection of a menu command or by a click on a button.

If *area* equals zero, *methodName* will apply to each Quick Report area until the database is closed or until the following call to the command is made: **QR ON COMMAND**(0;"").

*methodName* receives two parameters:

- *$1* is the reference of the area (Longint).
- *$2* is the command number of the command that was selected (Longint). You can compare this value with the constants of the **QR Commands** theme.

**Note:** When planning on compiling the database, it is necessary to declare both *$1* and *$2* as Longints, even if you do not use them.

If you want the initial command to be executed, you need to include the following in the called method: **QR EXECUTE COMMAND**($1;$2).

If you pass an invalid *area* number, the error -9850 will be generated.

# QR REPORT

QR REPORT ( {aTable ;} document {; hierarchical {; wizard {; search {; methodName {; *}}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to use for the report, or Default table if omitted |
| document | String | ⇒ | Quick Report document to load |
| hierarchical | Boolean | ⇒ | True = Display related Many tables, False or omitted = Do not display (default) |
| wizard | Boolean | ⇒ | True = Display the wizard button, False or omitted = Do not display (default) |
| search | Boolean | ⇒ | True = Display the search tools and master table choice, False or omitted = Do not display (default) |
| methodName | String | ⇒ | Name of method to call |
| * | Operator | ⇒ | Deletion of printing dialog boxes |

## Description

**QR REPORT** prints a report for *aTable*, created with the Quick Report editor. This editor allows users to create their own reports. For more information about creating reports with the Quick Report editor, refer to the **Quick reports** or **Quick reports (64-bit)** sections of the 4D *Design Reference* manual.

**Notes:**

- The editor does not appear if the *table* has been declared “Invisible.”
- When the editor is called using the **QR REPORT** command, relations between tables keep their manual status, where applicable. This allows the developer to manage this status himself using the **SET AUTOMATIC RELATIONS** and **SET FIELD RELATION** command. In 32-bit versions, the **All relations in automatic** option that is used to modify the automatic/manual status of the relations is hidden.
- The editor is called in an external window and it is not possible to use the **QR ON COMMAND** command in this context. However, you can use the *methodName* parameter to execute custom code when an interface command is activated (see below).

The *document* parameter is a report document that was created with the Quick Report editor and saved on disk. The document stores the specifications of the report, not the records to be printed.
If an empty string ("") is specified for *document*, **QR REPORT** displays an Open File dialog box and the user can select the report to print.
If the *document* parameter specifies a document that does not exist (for example, pass **Char(1)** in *document*), the Quick Report editor is displayed.

32-bit versions only:

- The *hierarchical* parameter defines whether the related Many tables are displayed in the field selection list. By default, this value is set to 0 (no display for related Many tables).
- The *wizard* parameter indicates whether the Open Wizard button is going to be displayed in the Quick Report editor, therefore either allowing or disallowing access to the wizard. By default, this value is set to False (no access to the wizard).
- The *search* parameter indicates whether the New Query button and the Master table drop-down menu are going to be displayed in the Quick Report editor, therefore either allowing or disallowing modification of the current table and current master table. By default, this value is set to False (no access to the search tools and master table).
- *The methodName* parameter designates a 4D project method that will be executed each time a command of the Quick Report editor is called by selecting a menu item or clicking on a button. Using this parameter is equivalent to using **QR ON COMMAND** in the context of the Quick Report editor window (**QR ON COMMAND** only works within the context of an included area). More particularly, you can use this new parameter to change the character set used by the quick report.
  The *methodName* method receives two parameters:
  - *$1* contains the area reference (longint).
  - *$2* contains the number of the command selected (longint). You can compare this value with the constants of the **QR Commands** theme.

  **Note:** If you want to compile your database using the Compiler, you must declare the $1 et $2 parameters explicitly as longints, even if you do not use them.

  If you want to execute the initial command chosen by the user, use the following statement in the *methodName* method:

```
QR EXECUTE COMMAND($1;$2)
```

If the *methodName* parameter is an empty string ("") or is omitted, no method is called and the standard operation of **QR REPORT** is applied.

After a report is selected, the dialog boxes for printing are displayed, unless the * parameter is specified. If this parameter is specified, these dialog boxes are not displayed. The report is then printed.

If the Quick Report editor is not involved, the OK variable is set to 1 if a report is printed; otherwise, it is set to 0 (zero) (i.e., if the user clicked **Cancel** in the printing dialog boxes).

**4D Server:** This command can be executed on 4D Server within the framework of a stored procedure. In this context:

- Make sure that no dialog box appears on the server machine (except for a specific requirement). To do this, it is necessary to call the command with the * parameter.
- The syntax which makes the Quick Report editor appear does not work with 4D Server; in this case, the system variable OK is set to 0.
- In the case of a problem concerning the printer (out of paper, printer disconnected, etc.), no error message is generated.

## Example 1

The following example lets the user query the [People] table, and then automatically prints the report “Detailed Listing”:

```
QUERY([People])
If(OK=1)
   QR REPORT([People];"Detailed Listing";False;False;False;*)
End if
```

## Example 2

The following example lets the user query the [People] table, and then lets the user choose which report to print:

```
QUERY([People])
If(OK=1)
   QR REPORT([People];"";False;False;False)
End if
```

## Example 3

The following example lets the user query the [People] table, and then displays the Quick Report editor so the user can design, save, load and print any reports with or without the wizard:

```
QUERY([People])
If(OK=1)
   QR REPORT([People];Char(1);False;True)
End if
```

## Example 4

Refer to the example of the **SET FIELD RELATION** command.

## Example 5

You want to convert the character set used in a quick report called using **QR REPORT** into Mac Roman:

```
QR REPORT([MyTable];Char(1);False;False;False;"myCallbackMeth")
```

The ***myCallbackMeth*** method converts the report when it is generated:

```
C_LONGINT($1;$2)
If($2=gr cmd generate) //if we generated a report
   C_BLOB($myblob)
   C_TEXT($path;$text)
   C_LONGINT($type)
   QR EXECUTE COMMAND($1;$2) //execution of command
   QR GET DESTINATION($1;$type;$path) //retrieval of destination
   If(($type=gr HTML file)|($type=gr text file))
      DOCUMENT TO BLOB($path;$myblob)
 //conversion to text using UTF-8
      $text:=Convert to text($myblob;"UTF-8")
 //use of MacRoman set
      CONVERT FROM TEXT($text;"MacRoman";$myblob)
 //Return of converted report
      BLOB TO DOCUMENT($path;$myblob)
   End if
Else //otherwise, execution of the command
   QR EXECUTE COMMAND($1;$2)
End if
```

# QR REPORT TO BLOB

QR REPORT TO BLOB ( area ; blob )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇨ | Reference of the area |
| blob | BLOB | ⇦ | BLOB to house the Quick Report |

## Description

The **QR REPORT TO BLOB** command places the report whose reference was passed in *area* in a BLOB (variable or field).
If you pass an invalid *area* number, the error -9850 will be generated.

## Example

The following statement assigns the Quick Report stored in MyArea into a BLOB Field.

```
QR REPORT TO BLOB(MyArea;[Table 1]Field4)
```

# QR RUN

QR RUN ( area )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area to execute |

## Description

The **QR RUN** command executes the report *area* whose reference was passed as parameter with the Quick Report current settings, including the output type. You can use the **QR SET DESTINATION** command to modify the output type.

The report is executed on the table to which the area belongs. When *area* designates an offscreen area, it is necessary to specify the table to be used via the **QR SET REPORT TABLE** command.

If you pass an invalid *area* number, the error -9850 will be generated.

**4D Server:** This command can be executed on 4D Server as part of a stored procedure. In this context, make sure that no dialog box appears on the server machine (except for specific requirements). To do this, you need to call the **QR SET DESTINATION** command with the "*" parameter. In case of a printer problem (out of paper, printer disconnected, etc.), no error message is generated.

# QR SET AREA PROPERTY

QR SET AREA PROPERTY ( area ; property ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| property | Longint | ⇒ | Interface element designated |
| value | Longint | ⇒ | 1 = displayed, 0 = hidden |

## Description

The **QR SET AREA PROPERTY** command shows or hides the interface element (toolbar or menu bar) whose reference is passed in *property*.

The menu bar and toolbars are numbered from 1 to 6 (top to bottom) and the value 7 is dedicated to the context menu. You can use the constants from the **QR Area Properties** theme to designate the interface item:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr view color toolbar | Longint | 5 | Display status of the Color toolbar (Displayed=1, Hidden=0) |
| qr view column toolbar | Longint | 6 | Display status of the Column toolbar (Displayed=1, Hidden=0) |
| qr view contextual menus | Longint | 7 | Display status of the Contextual menu (Displayed=1, Hidden=0) |
| qr view menubar | Longint | 1 | Display status of the menu bar (Displayed=1, Hidden=0) |
| qr view operators toolbar | Longint | 4 | Display status of the Operators toolbar (Displayed=1, Hidden=0) |
| qr view standard toolbar | Longint | 2 | Display status of the Standard toolbar (Displayed=1, Hidden=0) |
| qr view style toolbar | Longint | 3 | Display status of the Style toolbar (Displayed=1, Hidden=0) |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *property* parameter, the error -9852 will be generated.

# QR SET BORDERS

QR SET BORDERS ( area ; column ; row ; border ; line {; color} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| column | Longint | ➡ | Column number |
| row | Longint | ➡ | Row number |
| border | Longint | ➡ | Border composite value |
| line | Longint | ➡ | Line thickness |
| color | Longint | ➡ | Border color |

## Description

The **QR SET BORDERS** command sets the border style for a given cell.

*area* is the reference of the Quick Report area.

*column* is the column number of the cell.

*row* is the row number of the cell. You can pass either:

- a positive integer value to designate the corresponding subtotal (break) level,
- one of the following constants located in the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr grand total | Longint | -3 | Grand total area |
| qr title | Longint | -1 | Title of report |

*border* is a composite value that indicates which borders of the cell are to be affected. Pass one of the constants from the **QR Borders** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr bottom border | Longint | 8 | Bottom border |
| qr inside horizontal border | Longint | 32 | Inside horizontal border |
| qr inside vertical border | Longint | 16 | Inside vertical border |
| qr left border | Longint | 1 | Left border |
| qr right border | Longint | 4 | Right border |
| qr top border | Longint | 2 | Top border |

*border* can contain an accumulation of several values in order to designate several borders simultaneously. For example, a value of 5 passed in *border* would affect the right and left borders.
*line* is the thickness of the line:

- 0 indicates no line
- 1 indicates a thickness of 1/4 point
- 2 indicates a thickness of 1/2 point
- 3 indicates a thickness of 1 point
- 4 indicates a thickness of 2 points

*color* is the color of the line:

- If *color* is a positive value, it indicates a specific color.
- If *color* equals 0, the color is black.
- If *color* equals -1, no changes are to be made.

**Note:** The default color is black.

If you pass an invalid area number, the error -9850 will be generated.
If you pass an invalid column number, the error -9852 will be generated.
If you pass an invalid row number, the error -9853 will be generated.
If you pass an invalid border parameter, the error -9854 will be generated.
If you pass an invalid line parameter, the error -9855 will be generated.

# QR SET DESTINATION

QR SET DESTINATION ( area ; type {; specifics} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| type | Longint | ⇒ | Type of the report |
| specifics | String, Variable | ⇒ | Specifics linked to the output type |

## Description

The **QR SET DESTINATION** command sets the output *type* of the report for the area whose reference was passed in *area*.

In the *type* parameter, you can pass one of the constants of the **QR Output Destination** theme. The contents of the *specifics* parameter depends on the value of *type*. The following table describes the values that can be passed in both *type* and *specifics* parameters:

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr 4D Chart area | Longint | 4 | *** Obsolete constant *** |
| qr 4D View area | Longint | 3 | *specifics*: N.A. |
| qr HTML file | Longint | 5 | *specifics*: Pathname to the file. |
| qr printer | Longint | 1 | *specifics*: "*" to remove the print dialog boxes |
| qr text file | Longint | 2 | *specifics*: Pathname to the file. |

*qr printer* (1): If you pass a string containing a star ("*") in the *specifics* parameter, no dialog box will be displayed during printing and the current print settings will be used automatically. This setting is necessary when you want to print the report on the server.

*qr text file* (2): If you pass an empty string in the *specifics* parameter, a Save file dialog is displayed; otherwise the file is saved at the location indicated by the path.
The default field delimiter is the tab character (code 9). The default record delimiter is the carriage return character (code 13). You can change these defaults by assigning values to the two delimiter system variables: FldDelimit and RecDelimit. If under Windows, FldDelimit equals 13, a char 10 (line feed) will be appended after the carriage return. Be aware that these variables are used by other commands such as **IMPORT TEXT** for example. Changing them for the Quick Report editor, changes them everywhere in the application.

*qr 4D View area* (3): If 4D View is active for the user, a 4D View external window is created and populated with the results of the current settings of the Quick Report area.

*qr HTML file* (5): An HTML file is created using the template set by **QR SET HTML TEMPLATE**. For detailed information on how the translation is performed, please refer to the Design Reference manual.

If you pass an invalid *area* number, the error -9850 will be generated.
If the value of the destination *type* is incorrect, the error -9852 will be generated.

## Example

The following code sets the destination as being the text file "Mydoc.txt" and executes the Quick Report:

```
QR SET DESTINATION(MyArea;qr text file;"MyDoc.txt")
QR RUN(MyArea)
```

# QR SET DOCUMENT PROPERTY

QR SET DOCUMENT PROPERTY ( area ; property ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| property | Longint | ⇒ | 1 = Printing dialog, 2 = Document unit |
| value | Longint | ⇒ | Value for the property |

## Description

The **QR SET DOCUMENT PROPERTY** command displays the printing dialog or sets the unit used for the document.

In *property*, you can pass the following constants, located in the **QR Document Properties** constant theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr printing dialog | Longint | 1 | Display of the print dialog box:<br>• If value = 0, the print dialog is not displayed prior to printing.<br>• If value = 1, the print dialog is displayed prior to printing (default value). |
| qr unit | Longint | 2 | Document unit:<br>• If value = 0, the document unit is points.<br>• If value = 1, the document unit is centimeters.<br>• If value = 2, the document unit is inches. |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid value in the *property* or *value* parameter, the corresponding error (-9852 or -9853) is generated.

# QR SET HEADER AND FOOTER

QR SET HEADER AND FOOTER ( area ; selector ; leftTitle ; centerTitle ; rightTitle ; height {; picture {; pictAlignment}} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| selector | Longint | ➡ | 1 = Header, 2 = Footer |
| leftTitle | String | ➡ | Text displayed on the left side |
| centerTitle | String | ➡ | Text displayed in the middle |
| rightTitle | String | ➡ | Text displayed on the right side |
| height | Longint | ➡ | Header or footer height |
| picture | Picture | ➡ | Picture to display |
| pictAlignment | Longint | ➡ | Alignment attribute for the picture |

## Description

The **QR SET HEADER AND FOOTER** command sets the contents and size of the header or footer.

*selector* selects the header or the footer:

- If *selector* is 1, the header is affected;
- If *selector* is 2, the footer is affected.

*leftTitle*, *centerTitle* and *rightTitle* are the values for, respectively, the left, center and right header/footer.

*height* is the height of the header/footer, expressed in the unit selected for the quick report.

*picture* is a picture that will be displayed in the header or footer.

*pictAlignment* is the alignment attribute for the picture passed in *picture*.

- If *pictAlignment* is 1, the picture is aligned to the left.
- If *pictAlignment* is 2, the picture is centered.
- If *pictAlignment* is 3, the picture is aligned to the right.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *selector* value, the error -9852 will be generated.

## Example

The following statement places the title “Center title” in the header for the Quick Report in MyArea and sets the header height to 200 points:

```
QR SET HEADER AND FOOTER(MyArea;1;"";"Center title";"";200)
```

# QR SET HTML TEMPLATE

QR SET HTML TEMPLATE ( area ; template )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| template | Text | ➡ | HTML template |

## Description

The **QR SET HTML TEMPLATE** command sets the HTML template currently used for the Quick Report *area*. The template will be used when building the report in HTML format.

The template uses a set of tags to process the data in order to either retain a layout close to the original report or to adopt your own custom HTML.

**Note:** You first need to call **QR SET DESTINATION** to set the output to HTML file.

## HTML Tags

*<!--#4DQRheader--> ... <!--/#4DQRheader-->*
The HTML contents that are included between these tags come from the column titles. You will typically use these tags to define the title row of the report.

*<!--#4DQRrow--> ... <!--/#4DQRrow-->*
The HTML contents that are included between these tags are repeated for each data row (including detail and subtotal rows).

*<!--#4DQRcol--> ... <!--/#4DQRcol-->*
The HTML contents that are included between these tags are repeated for each data column within a row. The column order will remain identical to the order in the report. When used in conjunction with *<!--#4DQRcol;n--> ... <!--/#4DQRcol;n-->*, the tags *<!--#4DQRcol--> ... <!--/#4DQRcol-->* will only go through the columns whose contents are not inserted using *<!--#4DQRcol;n--> ... <!--/#4DQRcol;n-->*.
For example, in a report that has five columns, you choose to use *<!--#4DQRcol;2--> ... <!--/#4DQRcol;2-->* to insert data from the second column, *<!--#4DQRcol--> ... <!--/#4DQRcol-->* will go, for each row, through columns 1, 3, 4, and 5. These last tags ignore the column whose contents are published using *<!--#4DQRcol;2--> ... <!--/#4DQRcol;2-->*.

*<!--#4DQRcol;n--> ... <!--/#4DQRcol;n-->*
The HTML contents that are included between these tags are extracted from the column in the report whose number is “n”. If, for example, you want to display a different column order in the HTML output for a three-column report, you could use:
*<!--#4DQRrow--> <!--#4DQRcol;3--> ... <!--/#4DQRcol;3--><!--#4DQRcol;2--> ... <!--/#4DQRcol;2--><!--#4DQRcol;1--> ... <!--/#4DQRcol;1--> <!--/#4DQRrow-->*
In this example, the columns are inserted in the opposite order of the report.

*<!--#4DQRfont--> ... <!--/#4DQRfont-->*
The HTML contents that are included between these tags will be assigned the font of the current column or cell. *<!--#4DQRfont-->* will be replaced by an HTML font definition and *<!--/#4DQRfont-->* will be replaced by the matching closing tag (*</font>*).

*<!--#4DQRface--> ... <!--/#4DQRface-->*
The HTML contents that are included between these tags will be assigned the font style of the current column or cell. *<!--#4DQRface-->* will be replaced by an HTML face definition and *<!--#4DQRface-->* will be replaced by the matching closing tag (*</face>*).

*<!--#4DQRbgcolor-->*
This color tag will be replaced by the current color for the current cell.

*<!--#4DQRdata-->*
This tag will be replaced by the current data for the current cell.

*<!--#4DQRlHeader--><!--#4DQRdata--><!--/#4DQRlHeader-->*
*<!--#4DQRcHeader--><!--#4DQRdata--><!--/#4DQRcHeader-->*
*<!--#4DQRrHeader--><!--#4DQRdata--><!--/#4DQRrHeader-->*
These tags will be replaced respectively by the data in the left, center or right header.

*<!--#4DQRlFooter--><!--#4DQRdata--><!--/#4DQRlFooter-->*
*<!--#4DQRcFooter--><!--#4DQRdata--><!--/#4DQRcFooter-->*
*<!--#4DQRrFooter--><!--#4DQRdata--><!--/#4DQRrFooter-->*
These tags will be replaced respectively by the data in the left, center or right footer.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR SET INFO COLUMN

QR SET INFO COLUMN ( area ; colNum ; title ; object ; hide ; size ; repeatedValue ; displayFormat )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| colNum | Longint | ➡ | Column number |
| title | String | ➡ | Title of the column |
| object | Field, Variable | ➡ | Object assigned for that column |
| hide | Longint | ➡ | 0 = displayed, 1 = hidden |
| size | Longint | ➡ | Column size |
| repeatedValue | Longint | ➡ | 0 = not repeated, 1 = repeated |
| displayFormat | String | ➡ | Format for the data |

## Description

### List mode

The **QR SET INFO COLUMN** command sets the parameters of an existing column.

*area* is the reference of the Quick Report area.

*colNum* is the number of the column to modify.

*title* is the title that will be displayed in the header of the column.

*object* is the actual object of the column (variable, field or formula).

*hide* specifies whether the column is shown or hidden:

- If *hide* is 1, the column is hidden;
- If *hide* is 0, the column is shown.

*size* is the size in pixels to assign to the column. If *size* is -1, the size is made automatic.

*repeatedValue* is the status for data repetition. For example, if the value for a field or variable does not change from one record to the other, it may or may not be repeated when they do not change.

- If *repeatedValue* equals 0, values are not repeated.
- If *repeatedValue* equals 1, values are repeated.

*displayFormat* is the display format. Display formats are the 4D formats compatible with the data displayed.

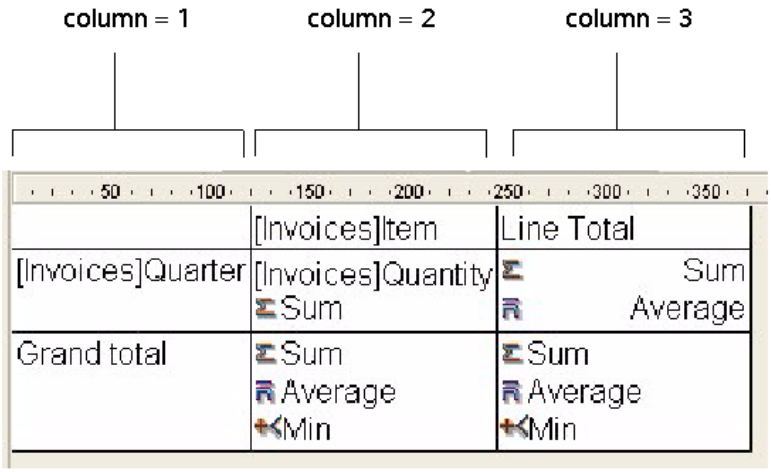
The following statement sets the title of column #1 to Title, sets the contents of the body to Field2, makes the column visible with a width of 150 pixels and sets the format to ###,##.

```
QR SET INFO COLUMN(area;1;"Title";"[Table 1]Field2";0;150;0;"###,##")
```

### Cross-table mode

The **QR SET INFO COLUMN** command allows you to set the same parameters but the reference of the areas to which it applies is different and varies depending on the parameter you want to set.
First of all, the *title*, *hide*, and *repeatedValue* parameters are not used when this command is used in cross-table mode. The value to use for *colNum* varies depending on whether you want to set the column size or the data source and display format.

- Column size
  This is a “visual” attribute, therefore columns are numbered from left to right, as depicted below.

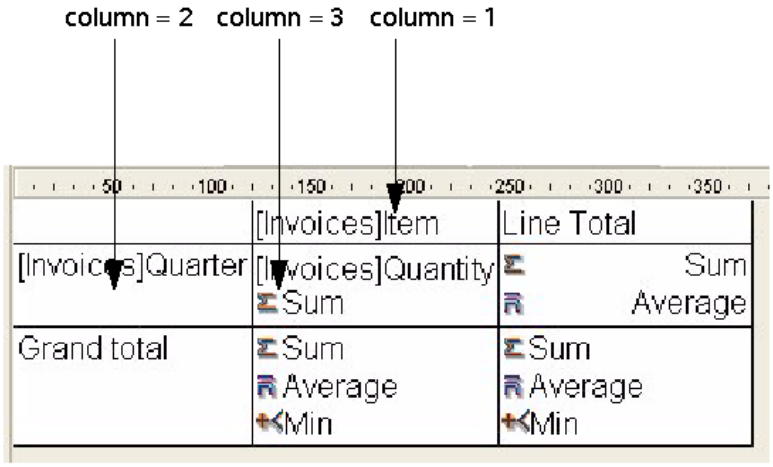


The following statement will set the size to automatic for all the columns in a cross-table report and will leave other elements unchanged:

```
For($i;1;3)
   QR GET INFO COLUMN(qr_area;$i;$title;$obj;$hide;$size;$rep;$format)
   QR SET INFO COLUMN(qr_area;$i;$title;$obj;$hide;0;$rep;$format)
End for
```

You will notice that since you want to alter only the column size, you have to use **QR GET INFO COLUMN** to retrieve the column properties and pass them to **QR SET INFO COLUMN** to leave it unchanged, except for the column size.

- Data source (object) and display format
  In this case the numbering of columns operates as depicted below:

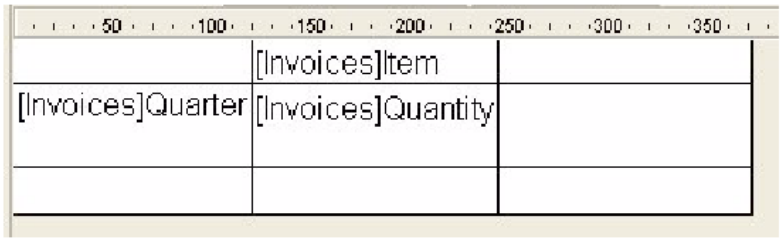


You will notice that not all cells can be addressed using the **QR SET INFO COLUMN** command, the cells that are not numbered above are addressed using **QR SET TOTALS DATA**.

The following code assigns data sources to the three cells required for creating a basic cross-table report:

```
QR SET REPORT TABLE(qr_area;Table(->[Invoices]))
ALL RECORDS([Invoices])
QR SET REPORT KIND(qr_area;2)
QR SET INFO COLUMN(qr_area;1;"";->[Invoices]Item;1;-1;1;"")
QR SET INFO COLUMN(qr_area;2;"";->[Invoices]Quarter;1;-1;1;"")
QR SET INFO COLUMN(qr_area;3;"";->[Invoices]Quantity;1;-1;1;"")
```

This would be the resulting report area:



If you pass an invalid *area* number, the error -9850 will be generated.

If you pass an invalid *colNum* value, the error -9852 will be generated.

# QR SET INFO ROW

QR SET INFO ROW ( area ; row ; hide )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area created |
| row | Longint | ➡ | Row designator |
| hide | Longint | ➡ | 0 = displayed, 1 = hidden |

## Description

The **QR SET INFO ROW** command shows/hides the row whose reference was passed in *row*.

*row* designates which row is affected. You can pass either:

- a positive integer value to designate the corresponding subtotal (break) level,
- one of the following constants from the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr grand total | Longint | -3 | Grand total area |
| qr title | Longint | -1 | Title of report |

*hide* specifies whether the line is shown or hidden:

- If *hide* is 1, the row is hidden;
- If *hide* is 0, the row is shown.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *row* value, the error -9852 will be generated.

## Example

The following statement hides the detail row:

```
QR SET INFO ROW(area;qr detail;1)
```

# QR SET REPORT KIND

QR SET REPORT KIND ( area ; type )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| type | Longint | ⇒ | Type of the report |

## Description

The **QR SET REPORT KIND** command sets the report *type* for the area whose reference was passed in *area*.

- If *type* equals 1, the report type is list.
- If *type* equals 2, the report type is cross-table.

You can also use the constants of the **QR Report Types** theme:

| Constant | Type | Value |
|---|---|---|
| qr cross report | Longint | 2 |
| qr list report | Longint | 1 |

If you set a new type for an existing current report, it removes the previous settings and creates a new empty report, ready to be set.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *type* value, the error -9852 will be generated.

# QR SET REPORT TABLE

QR SET REPORT TABLE ( area ; aTable )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| aTable | Longint | ⇒ | Table number |

## Description

The **QR SET REPORT TABLE** command sets the current table for the report area whose reference was passed in *area* to the table whose number was passed in *aTable*.

It is necessary for a table to be assigned to the report since the report editor will be using the current selection for that table to display the data, perform computations and propagate relations, if needed.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *table* value, the error -9852 will be generated.

# QR SET SELECTION

QR SET SELECTION ( area ; left ; top {; right {; bottom}} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| left | Longint | ➡ | Left boundary |
| top | Longint | ➡ | Top boundary |
| right | Longint | ➡ | Right boundary |
| bottom | Longint | ➡ | Bottom boundary |

## Description

The **QR SET SELECTION** command highlights a cell, a row, a column or the entire *area* as you would with a mouse click. It also lets you deselect the current selection.

*left* is the number of the left boundary. If *left* is 0, the entire row is selected.

*top* is the number of the top boundary. If *top* is 0, the entire column is selected.

*right* is the number of the right boundary.

*bottom* is the number of the bottom boundary.

**Notes:**

- If both *left* and *top* are 0, the entire area is highlighted.
- If you want no selection, pass -1 to *left*, *right*, *top* and *bottom*.

If you pass an invalid *area* number, the error -9850 will be generated.

# QR SET SORTS

QR SET SORTS ( area ; aColumns {; aOrders} )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| aColumns | Real array | ➡ | Columns |
| aOrders | Real array | ➡ | Sort orders |

## Description

The **QR SET SORTS** command sets the sort orders for the columns in the report whose reference is passed in *area*.

*aColumns*: in this array, you need to store the column numbers of columns to which you want to assign a sort order.

*aOrders*: each element of this array must contain the sort orders for the matching column in the *aColumns* array.

- If *aOrders{$i}* is 1, the sort order is ascending.
- If *aOrders{$i}* is -1, the sort order is descending.

### Cross-table mode

In the case of cross-table mode, you cannot have more than two items in the array. You can only sort columns (1) and rows (2). The data (that are the intersection of columns and rows) cannot be sorted.

Here is the code to sort only the rows in the case of a cross-table report:

```
ARRAY REAL($aColumns;1)
$aColumns{1}:=2
ARRAY REAL($aOrders;1)
$aOrders{1}:=-1 `Alphabetic sort for rows
QR SET SORTS(qr_area;$aColumns;$aOrders)
```

If you pass an invalid *area* number, the error -9850 will be generated.

# QR SET TEXT PROPERTY

QR SET TEXT PROPERTY ( area ; colNum ; rowNum ; property ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ➡ | Reference of the area |
| colNum | Longint | ➡ | Column number |
| rowNum | Longint | ➡ | Row number |
| property | Longint | ➡ | Property number |
| value | Longint, String | ➡ | Value for the selected property |

## Description

The **QR SET TEXT PROPERTY** command sets the text attributes for the cell determined by *colNum* and *rowNum*.

*area* is the reference of the Quick Report area.

*colNum* is the number of the cell column.

*rowNum* is the reference of the cell row. You can pass either:

- a positive value designating the corresponding subtotal (break) level,
- one of the constants from the **QR Rows for Properties** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr footer | Longint | -5 | Page footer |
| qr grand total | Longint | -3 | Grand total area |
| qr header | Longint | -4 | Page header |
| qr title | Longint | -1 | Title of report |

**Note:** When passing -4 or -5 as *rowNum*, you still need to pass a column number in *colNum*, even if it is not used.

**Note:** In cross-table mode, the principle is similar except for the row values, which are always positive.

*property* is the value of the text attribute to assign. You can use the constants of the **QR Text Properties** theme, and the following values can be set:

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr font | Longint | 1 | Obsolete since 4D v14R3 (use qr font name) |
| qr alternate background color | Longint | 9 | Alternate background color number |
| qr background color | Longint | 8 | Background color number |
| qr bold | Longint | 3 | Bold style attribute (0 or 1) |
| qr font name | Longint | 10 | Name of font as returned for example by the **FONT LIST** command |
| qr font size | Longint | 2 | Font size expressed in points (9 to 255) |
| qr italic | Longint | 4 | Italic style attribute (0 or 1) |
| qr justification | Longint | 7 | Justification attribute (0 for default, 1 for left, 2 for center or 3 for right) |
| qr text color | Longint | 6 | Color number attribute (Longint) |
| qr underline | Longint | 5 | Underline style attribute (0 or 1) |

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *colNum* number, the error -9852 will be generated.
If you pass an invalid *rowNum* number, the error -9853 will be generated.
If you pass an invalid *property* number, the error -9854 will be generated.

## Example

This method defines several attributes of the first column's title:

```
 //Assigns the Times font:
QR SET TEXT PROPERTY(qr_area;1;-1;qr font name;"Times")
```

```
 //Assigns 10-point font size:
QR SET TEXT PROPERTY(qr_area;1;-1;qr font size;10)
 //Assigns the bold attribute:
QR SET TEXT PROPERTY(qr_area;1;-1;qr bold;1)
 //Assigns the italic attribute:
QR SET TEXT PROPERTY(qr_area;1;-1;qr italic;1)
 //Assigns the underline attribute:
QR SET TEXT PROPERTY(qr_area;1;-1;qr underline;1)
 //Assigns the light green color:
QR SET TEXT PROPERTY(qr_area;1;-1;qr text color;0x0000FF00)
```

# QR SET TOTALS DATA

QR SET TOTALS DATA ( area ; colNum ; breakNum ; operator | value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| colNum | Longint | ⇒ | Column number |
| breakNum | Longint | ⇒ | Break number |
| operator \| value | Longint, String | ⇒ | Operator value for the cell or Cell content |

## Description

**Note:** This command cannot create a subtotal.

### List Mode

The **QR SET TOTALS DATA** command sets the details of a specific break (total or subtotal).

*area* is the reference of the Quick Report area.

*colNum* is the column number of the cell whose data is going to be set.

*breakNum* is the number of the break whose data will be set (subtotal or grand total). For a Subtotal, *breaknum* is the sort number. For the Grand total, *breaknum* equals -3 or the constant qr grand total of the **QR Operators** theme.

*operator* is an addition of all the operators present in the cell. You can use the constants of the **QR Operators** theme to set the value:

| Constant | Type | Value |
|---|---|---|
| qr average | Longint | 2 |
| qr count | Longint | 16 |
| qr max | Longint | 8 |
| qr min | Longint | 4 |
| qr standard deviation | Longint | 32 |
| qr sum | Longint | 1 |

If *operator* is 0, there is no operator.

*value* is the text to be placed in the cell.

**Note:** Operator/value is mutually exclusive, so you either set an operator or a text.

You can pass the following values:
- # for the value that triggered the break or subtotal
- ##S will be replaced by the sum.
- ##A will be replaced by the Average.
- ##C will be replaced by the Count
- ##X will be replaced by the Max.
- ##N will be replaced by the Min.
- ##D will be replaced by the Standard deviation.
- ##xx, where xx is a column number. This will be replaced by that column's value, using its formatting. If this column does not exist, then it will not be replaced.

### Cross-table Mode

The **QR SET TOTALS DATA** command sets the details of a specific cell.

*area* is the reference of the Quick Report area.

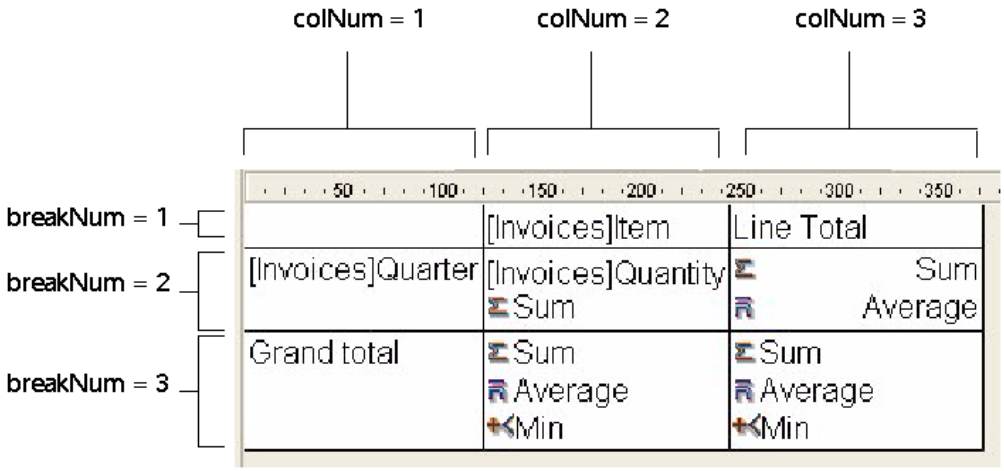
*colNum* is the column number of the cell whose data is going to be set.

*breakNum* is the row number of the cell whose data is going to be set.

*operator* is an addition of all the operators present in the cell. You can use the constants of the **QR Operators** theme to set the value (see above).

*value* is the text to be placed in the cell.

Here is a depiction of how the parameters column and break have to be combined in cross-table mode:



### Supported Types of Data

The types of data that you can pass are of two basic kinds:

- Title
  A title is passed through the parameter *value*. The value is actually a string and can be passed only for the following cells: *colNum=3 breakNum=1* and *colNum=1 breakNum=3*.
- Operator
  An operator or a combination of operators (as described above) can be passed for the following cells:
  *colNum*=2, *breakNum*=2
  *colNum*=3, *breakNum*=2
  *colNum*=2, *breakNum*=3
  Please note that these last two values affect the cell (Column 3; Row 3) as well. If a computation is defined in the cell (Column 2; Row 3), the contents of this cell (Column 2; Row 3) always define the contents of the cell (Column 3; Row 3).

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *colNum* number, the error -9852 will be generated.
If you pass an invalid *breakNum* number, the error -9853 will be generated.

# QR SET TOTALS SPACING

QR SET TOTALS SPACING ( area ; subtotal ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| area | Longint | ⇒ | Reference of the area |
| subtotal | Longint | ⇒ | Subtotal number |
| value | Longint | ⇒ | 0=no space, 32000=inserts a page break, >0=spacing added below the break level, <0=proportional increase |

## Description

The **QR SET TOTALS SPACING** command sets a space below a subtotal row. It applies only to the list mode.

*area* is the reference of the Quick Report area.
*subtotal* is the subtotal level (or break level) that will be affected.

*value* defines the value of the spacing:

- If *value* is 0, no space is added.
- If *value* is 32000, a page break is inserted.
- If *value* is a positive value, it expresses the spacing value in pixels.
- If *value* is a negative value, it expresses the spacing as a percentage of the subtotal row. For example, -100 will set a space of 100% below the subtotal row.

**Note:** If the space below a subtotal row “pushes” the next row onto the following page, there will be no space inserted above the row on that page.

If you pass an invalid *area* number, the error -9850 will be generated.
If you pass an invalid *subtotal*, the error -9852 will be generated.

# Record Locking

- Record Locking
- Get locked records info
- LOAD RECORD
- Locked
- LOCKED BY
- READ ONLY
- Read only state
- READ WRITE
- UNLOAD RECORD

# Record Locking

4D and 4D Server automatically manage databases by preventing multi-user or multi-process conflicts. Two users or two processes cannot modify the same record or object at the same time. However, the second user or process can have read-only access to the record or object at the same time.

There are several reasons for using the multi-user commands:

- Modifying records by using the language.
- Using a custom user interface for multi-user operations.
- Saving related modifications inside a transaction.

There are three important concepts to be aware of when using commands in a multi-processing database:

1. In a process, each table is in either a read-only or a read/write state.
2. Records become locked when they are loaded and unlocked when they are unloaded.
3. A locked record cannot be modified.

As a convention in the following sections, the person performing an operation on the multi-user database is referred to as the **local user**. Other people using the database are referred to as the **other users**. The discussion is from the perspective of the local user. Also, from a multi-process perspective, the process executing an operation on the database is the **current process**. Any other executing process is referred to as **other processes**. The discussion is from the point of view of the current process.

## Locked Records

A locked record cannot be modified by the local user or the current process. A locked record can be loaded, but cannot be modified. A record is locked when one of the other users or processes has successfully loaded the record for modification, or when the record is stacked. Only the user who is modifying the record sees that record as unlocked. All other users and processes see the record as locked, and therefore unavailable for modification. A table must be in a read/write state for a record to be loaded unlocked.

## Read-Only and Read/Write States

Each table in a database is in either a read/write or a read-only state for each user and process of the database. **Read-only** means that records for the table can be loaded but not modified. **Read/write** means that records for the table can be loaded and modified if no other user has locked the record first.

Note that if you change the status of a table, the change takes effect for the next record loaded. If there is a record currently loaded when you change the table's status, that record is not affected by the status change.

### Read-Only State

When a table is read-only and a record is loaded, this record is always locked. In other words, locked records can be displayed, printed, and otherwise used, but they cannot be modified.

Note that the read-only state applies only to editing existing records. A read-only state does not affect the creation of new records. You can still add records to a read-only table using **CREATE RECORD** and **ADD RECORD**, or the menu commands of the Design environment (in this case, the records being created are locked for all other users/processes). Note that the **ARRAY TO SELECTION** command is not affected by the read-only state since it can both create and modify records.

4D automatically sets a table to read-only for commands that do not require write access to records. These commands are: **DISPLAY SELECTION, DISTINCT VALUES, EXPORT DIF, EXPORT SYLK, EXPORT TEXT, _o_GRAPH TABLE, PRINT SELECTION, PRINT LABEL, QR REPORT, SELECTION TO ARRAY, SELECTION RANGE TO ARRAY**.

You can find out the state of a table at any time using the **Read only state** function.

Before executing any of these commands, 4D saves the current state of the table (read-only or read/write) for the current process. After the command has executed, this state is restored.

### Read/Write State

When a table is read/write and a record is loaded, the record will become unlocked if no other user has locked the record first. If the record is locked by another user, the record is loaded as a locked record that cannot be modified by the local user.

A table must be set to read/write and the record loaded for it to become unlocked and thus modifiable.

If a user loads a record from a table in read/write mode, no other users can load that record for modification. However, other users can add records to the table, either through the **CREATE RECORD** and **ADD RECORD** commands or manually in the Design environment.

Read/write is the default state for all tables when a database is opened and a new process is started.

### Changing the Status of a Table

You can use the **READ ONLY** and **READ WRITE** commands to change the state of a table. If you want to change the state of a table in order to make a record read-only or read/write, you must execute the command before this record is loaded. Any record that is already loaded is not affected by the **READ ONLY** and **READ WRITE** commands.

Each process has its own state (read-only or read/write) for each table in the database.

By default, if you do not use the **READ ONLY** command, all tables are in read/write mode.

## Loading, Modifying and Unloading Records

Before the local user can modify a record, the table must be in the read/write state and the record must be loaded and unlocked.

Any of the commands that loads a current record (if there is one) — such as **NEXT RECORD**, **QUERY**, **ORDER BY**, **RELATE ONE**, etc. — sets the record state as locked or unlocked. The record is loaded according to the current state of its table (read-only or read/write) and its availability. A record may also be loaded for a related table by any of the commands that cause an automatic relation to be established.

If a table is in the read-only state for a process or a user, then this table's records are loaded in read-only mode, which means they cannot be modified or deleted by this process or user. This is recommended for viewing or retrieving data because it does not prevent other users or processes from accessing the records of this table in read/write mode if necessary.

If a table is in the read/write state for a process or a user, then any record from this table is also loaded in read/write mode, but only if no other user or process has already locked this record. If a record is successfully loaded in read/write mode, it is unlocked for the current process or user (it can be modified and saved) and is locked for all other users or processes. A table must be put into the read/write state before loading a record for modification and then saving it.

If the record is to be modified, you use the **Locked** function to test whether or not a record is locked by another user. If a record is locked (**Locked** returns True), load the record with the **LOAD RECORD** command and again test whether or not the record is locked. This sequence must be continued until the record becomes unlocked (**Locked** returns False).

When modifications to be made to a record are finished, the record must be released (and therefore unlocked for the other users) with **UNLOAD RECORD**. If a record is not unloaded, it will remain locked for all other users until a different current record is selected. Changing the current record of a table automatically unlocks the previous current record. You need to explicitly call **UNLOAD RECORD** if you do not change the current record. This discussion applies to existing records. When a new record is created, it can be saved regardless of the state of the table to which it belongs.

**Note:** When it is used in a transaction, the **UNLOAD RECORD** command unloads the current record only for the process that manages the transaction. For other processes, the record stays locked as long as the transaction has not been validated (or cancelled).

Use the **LOCKED BY** command to see which user and/or process have locked a record.

**Note:** A good practice is to place all tables in read-only mode when each process is started (using the syntax **READ ONLY(*)**) then put each table in read/write mode only when necessary. Access to tables in read-only mode is faster and more memory-efficient. Moreover, changing the state of a table is optimized in client/server mode because it does not cause any additional network traffic: information is only sent to the server when executing a command that requires adequate access to the table.

## Loops to Load Unlocked Records

The following example shows the simplest loop with which to load an unlocked record:

```
READ WRITE([Customers]) ` Set the table's state to read/write
Repeat ` Loop until the record is unlocked
   LOAD RECORD([Customers]) ` Load record and set locked status
Until(Not(Locked([Customers])))
 ` Do something to the record here
READ ONLY([Customers]) ` Set the table's state to read-only
```

The loop continues until the record is unlocked.

A loop like this is used only if the record is unlikely to be locked by anyone else, since the user would have to wait for the loop to terminate. Thus, it is unlikely that the loop would be used as is unless the record could only be modified by means of a method.

The following example uses the previous loop to load an unlocked record and modify the record:

```
READ WRITE([Inventory])
Repeat ` Loop until the record is unlocked
   LOAD RECORD([Inventory]) ` Load record and set it to locked
Until(Not(Locked([Inventory])))
[Inventory]Part Qty:=[Inventory]Part Qty 1 ` Modify the record
SAVE RECORD([Inventory]) ` Save the record
UNLOAD RECORD([Inventory]) ` Let other users modfiy it
READ ONLY([Inventory])
```

The **MODIFY RECORD** command automatically notifies the user if a record is locked, and prevents the record from being modified. The following example avoids this automatic notification by first testing the record with the **Locked** function. If the record is locked, the user can cancel.

This example efficiently checks to see if the current record is locked for the table [Commands]. If it is locked, the process is delayed by the procedure for one second. This technique can be used both in a multi-user or multi-process situation:

```
Repeat
   READ ONLY([Commands]) ` You do not need read/write right now
   QUERY([Commands])
 ` If the search was completed and some records were returned
   If((OK=1) & (Records in selection([Commands])>0))
      READ WRITE([Commands]) ` Set the table to read/write state
      LOAD RECORD([Commands])
      While(Locked([Commands]) & (OK=1)) `If the record is locked,
 ` loop until the record is unlocked
 ` Who is the record locked by?
         LOCKED BY([Commands];$Process;$User;$SessionUser;$Name)
         If($Process=-1) ` Has the record been deleted?
            ALERT("The record has been deleted in the meantime.")
            OK:=0
         Else
            If($User="") ` Are you in single-user mode
               $User:="you"
            End if
            CONFIRM("The record is already used by "+$User+" in the "+$Name+" Process.")
            If(OK=1) ` If you want to wait for a few seconds
               DELAY PROCESS(Current process;120) ` Wait for a few seconds
               LOAD RECORD([Commands]) ` Try to load the record
            End if
         End if
      End while
      If(OK=1) ` The record is unlocked
         MODIFY RECORD([Commands]) ` You can modify the record
         UNLOAD RECORD([Commands])
      End if
      READ ONLY([Commands]) ` Switch back to read-only
      OK:=1
   End if
Until(OK=0)
```

## Using Commands in Multi-user or Multi-process Environment

A number of commands in the language perform specific actions when they encounter a locked record. They behave normally if they do not encounter a locked record.

Here is a list of these commands and their actions when a locked record is encountered.

- **MODIFY RECORD**: Displays a dialog box stating that the record is in use. The record is not displayed, therefore the user cannot modify the record. In the Design environment, the record is shown in read-only state.

- **MODIFY SELECTION**: Behaves normally except when the user double-clicks a record to modify it. **MODIFY SELECTION** displays dialog box stating that the record is in use and then allows read-only access to the record.
- **APPLY TO SELECTION**: Loads a locked record, but does not modify it. **APPLY TO SELECTION** can be used to read information from the table without special care. If the command encounters a locked record, the record is put into the **LockedSet** system set.
- **DELETE SELECTION**: Does not delete any locked records; it skips them. If the command encounters a locked record, the record is put into the *LockedSet* system set.
- **DELETE RECORD**: This command is ignored if the record is locked. No error is returned. You must test that the record is unlocked before executing this command.
- **SAVE RECORD**: This command is ignored if the record is locked. No error is returned. You must test that the record is unlocked before executing this command.
- **ARRAY TO SELECTION**: Does not save any locked records. If the command encounters a locked record, the record is put into the *LockedSet* system set.
- **GOTO RECORD**: Records in a multi-user/multi-process database may be deleted and added by other users, therefore the record numbers may change. Use caution when directly referencing a record by number in a multi-user database.
- **Sets**: Take special care with sets, as the information that the set was based on may be changed by another user or process.

# Get locked records info

Get locked records info ( aTable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table where you want to get locked records |
| Function result | Object | ⇐ | Description of locked records (if any) |

## Description

The **Get locked records info** command returns an *object* containing different information about the currently locked record(s) in *aTable*.

The returned object contains a "records" property which is an array of objects:

```
{
   "records": [
      description object,
      (…)
   ]
}
```

Each "description object" array element identifies a locked record in the specified table and has the following properties:

| Property | Type | Description |
|---|---|---|
| contextID | UUID (String) | UUID of the database context responsible for the lock |
| contextAttributes | Object | Object containing information similar to the **LOCKED BY** command but applied to the record, the difference being that **Get locked records info** returns the user name defined in the system and not that of the 4D user, as well as additional information (see below). |
| recordNumber | Longint | Record number of the locked record |

The *contextAttributes* object is made up of the following properties:

| Property | Type | Description |
|---|---|---|
| task_id | Number | Process reference number |
| user_name | String | User name defined by operating system |
| user4d_id | Number | 4D user number(*) |
| host_name | String | Name of host machine |
| task_name | String | Process name |
| client_version | Number | Version of client application |
| *Only when command is executed on 4D Server and if record locking comes from a remote 4D:* | | |
| is_remote_context | Boolean | Indicates whether a remote 4D is the origin of the locking(always *true* since otherwise it is not present) |
| client_uid | UUID (String) | UUID of 4D remote at the origin of the locking |

(*) You can get the 4D user name from the value of *user4d_id* by using the following code:

```
GET USER LIST($arrNames;$arrIDs)
$User4DName:=Find in array($arrIDs;user4d_id)
```

**Note:** The command works only with 4D and 4D Server. It always return an invalid object when called from 4D Remote or a component. However, it can be called in these contexts if the "Execute on server" option is activated. In this case, the object returned will contain, respectively, information about the server or the host database.

## Example

You execute the following code:

```
$vOlocked :=Get locked records info([Table])
```

If two records were locked in the [Table] table, the following object is returned in $vOlocked:

```
{
    "records": [
        {
            "contextID": "A9BB84C0E57349E089FA44E04C0F2F25",
            "contextAttributes": {
                "task_id": 8,
                "user_name": "roland",
                "user4d_id": 1,
                "host_name": "iMac de roland",
                "task_name": "P_RandomLock",
                "client_version": -1342106592
            },
            "recordNumber": 1
        },
        {
            "contextID": "8916338D1B8A4D86B857D92F593CCAC3",
            "contextAttributes": {
                "task_id": 9,
                "user_name": "roland",
                "user4d_id": 1,
                "host_name": "iMac de roland",
                "task_name": "P_RandomLock",
                "client_version": -1342106592
            },
            "recordNumber": 2
        }
    ]
}
```

If the code is executed on a 4D Server and the locking is caused by a remote client machine, the following object is returned in $vOlocked:

```
{
    "records": [
        {
            "contextID": "B0EC087DC2FA704496C0EA15DC011D1C",
            "contextAttributes": {
                "task_id": 2,
                "user_name": "achim",
                "user4d_id": 1,
                "host_name": "achim-pcwin",
                "task_name": "P_RandomLock",
                "is_remote_context": true,
                "client_uid": "0696E66F6CD731468E6XXX581A87554A",
                "client_version": -268364752
            },
            "recordNumber": 1
        }
    ]
}
```

# LOAD RECORD

LOAD RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇨ | Table for which to load record, or Default table, if omitted |

## Description

**LOAD RECORD** loads the current record of *aTable*. If there is no current record, **LOAD RECORD** has no effect.
You can then use the **Locked** function to determine whether you can modify the record:

- If the table is in read-only state, the **Locked** function returns TRUE, and you cannot modify the record.
- If the table is in read/write state but the record was already locked, the record will be read-only, and you cannot modify the record.
- If the table is in read/write state and the record is not locked, you can modify the record in the current process. The **Locked** function returns TRUE for all other users and processes.

**Note:** If the **LOAD RECORD** command is executed after a **READ ONLY**, the record is automatically unloaded and loaded without having to use the **UNLOAD RECORD** command.

Usually, you do not need to use the **LOAD RECORD** command, because commands like **QUERY**, **NEXT RECORD**, **PREVIOUS RECORD**, etc., automatically load the current record.

In multi-user and multi-process environments, when you need to modify an existing record, you must access the table (to which the record belongs) in read/write mode. If a record is locked and not loaded, **LOAD RECORD** allows you to attempt to load the record again at a later time. By using **LOAD RECORD** in a loop, you can wait until the record becomes available in read/write mode.

**Tip:** The **LOAD RECORD** command can be used to reload the current record in the context of an input form. All the data modified are then replaced by their previous values. In this case, the **LOAD RECORD** command carries out a sort of general cancellation of data entry.

# Locked

Locked {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to check for locked current record, or Default table, if omitted |
| Function result | Boolean | ⇐ | Record is locked (TRUE), or Record is unlocked (FALSE) |

## Description

**Locked** tests whether or not the current record of *aTable* is locked. Use this function to find out whether or not the record is locked; then take appropriate action, such as giving the user the choice of waiting for the record to be free or skipping the operation.

If **Locked** returns TRUE, then the record cannot be saved because it is locked by another user or another process, or it is stacked in the current process. In this case, use **LOAD RECORD** to reload the record until **Locked** returns FALSE.

If **Locked** returns FALSE, then the record is unlocked, meaning that the record is locked for all other users. Only the local user or current process can modify and save the record. A table must be in read/write state in order for you to modify the record.

If you try to load a record that has been deleted, **Locked** continues to return TRUE. To avoid waiting for a record that does not exist anymore, use the **LOCKED BY** command. If the record has been deleted, the **LOCKED BY** command returns -1 in the process parameter.

**Note: Locked** returns False when there is no current record in *table*, in other words, when **Record number** returns -1.

During transaction processing, **LOAD RECORD** and **Locked** are often used to test record availability. If a record is locked, it is common to cancel the transaction.

# LOCKED BY

LOCKED BY ( {aTable ;} process ; 4Duser ; sessionUser ; processName )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to check for record locked, or Default table, if omitted |
| process | Longint | ⇐ | Process reference number |
| 4Duser | String | ⇐ | 4D user name |
| sessionUser | String | ⇐ | Name of user that opened work-session |
| processName | String | ⇐ | Process name |

## Description

**LOCKED BY** returns information about the user and process that have locked a record. The process number(*), the user name in the 4D application and in the system as well as the process name are returned in the *process*, *4Duser*, *sessionUser*, and *processName* variables. You can use this information in a custom dialog box to warn the user when a record is locked.

(*) This is the number of the process on the machine where the code that actually locked the record is executed. In the case of a trigger or a method that is executed on the server, the number of the "twin" process on the server machine is returned. In the case of a method that is executed on a remote application, the number of the process on the remote machine is returned.

If the record is not locked, *process* returns 0 and *4Duser*, *sessionUser*, and *processName* return empty strings. If the record you try to load in read/write has been deleted, *process* returns -1 and *4Duser*, *sessionUser*, and *processName* return empty strings.

The *4Duser* parameter returned is the user name from the 4D password system, even if user name is blank. If there is no password system, “Designer” is returned.

The *sessionUser* parameter returned corresponds to the name of the user that opened the session on the client machine (this name is displayed more particularly in the 4D Server administration window for each open process).

# READ ONLY

READ ONLY {( aTable | * )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable \| * | Table, Operator | ⇨ | Table for which to set read-only state, or * for all the tables, or Default table, if omitted |

## Description

**READ ONLY** changes the state of *aTable* to read-only for the process in which it is called. All subsequent records that are loaded are locked, and you cannot make any changes made to them. If the optional * parameter is specified, all tables are changed to read-only state.

Use **READ ONLY** when you do not need to modify the record or records.

**Note:** This command is not retroactive. A record is loaded according to the table's read/write status at the time of loading. To load a record from a read/write table in read-only mode, you must first change the table state to read-only.

# Read only state

Read only state {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to test read-only state, or Default table, if omitted |
| Function result | Boolean | ⮌ | Access to table is read-only (TRUE), or Access to table is read-write (FALSE) |

## Description

This function tests whether or not the state of *aTable* is read-only for the process in which it is called. **Read only state** returns TRUE if the state of *aTable* is read-only. **Read only state** returns FALSE if the state of *aTable* is read/ write.

## Example

The following example tests the state of an [Invoice] table. If the state of the [Invoice] table is read-only, it is set to read/write, and then the current record is reloaded.

```
If(Read only state([Invoice]))
   READ WRITE([Invoice])
   LOAD RECORD([Invoice])
End if
```

**Note:** The invoice record is reloaded to allow the user to modify it. A record that was previously loaded in a read-only state will remain locked until it is reloaded in a read/write state.

# READ WRITE

READ WRITE {( aTable | * )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable \| * | Table, Operator | ⇒ | Table for which to set read-write state, or * for all the tables, or Default table, if omitted |

## Description

**READ WRITE** changes the state of *aTable* to read/write for the process in which it is called. If the optional * parameter is specified, all tables are changed to read/write state.

After a call to **READ WRITE**, when a record is loaded, the record is unlocked if no other user has locked the record. This command does not change the status of the currently loaded record, only that of subsequently loaded records.

The default state for all tables is read/write.

Use **READ WRITE** when you must modify a record and save the changes. Also use **READ WRITE** when you must lock a record for other users, even if you are not making any changes. Setting a table to read/write mode prevents other users from editing that table. However, other users can create new records.

**Note:** This command is not retroactive. A record is loaded according to the table's read/write status at the time of loading. To load a record from a read-only table in read/write mode, you must first change the table state to read/write.

# UNLOAD RECORD

UNLOAD RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to unload record, or Default table, if omitted |

## Description

**UNLOAD RECORD** unloads the current record of *table*.

If the record is unlocked for the local user (locked for the other users), **UNLOAD RECORD** unlocks the record for the other users.

Although **UNLOAD RECORD** unloads it from memory, the record remains the current record. When another record is made the current record, the previous current record is automatically unloaded and therefore unlocked for other users. Always execute this command when you have finished modifying a record and want to make it available to other users, while retaining the record as your current record.

If a record has a large amount of data, picture fields, or external documents (such as 4D Write or 4D Draw documents), you may not want to keep the current record in memory unless you need to modify it. In this case, use the **UNLOAD RECORD** command to keep the current record without having it in memory. You free the memory occupied by the record, but you do not have access to its field values. If you later need access to the values of the record, use the **LOAD RECORD** command.

**Note:** When it is used in a transaction, the **UNLOAD RECORD** command unloads the current record only for the process that manages the transaction. For other processes, the record stays locked as long as the transaction has not been validated (or cancelled).

# Records

- About Record Numbers
- Using the Record Stack
- CREATE RECORD
- DELETE RECORD
- DISPLAY RECORD
- DUPLICATE RECORD
- GOTO RECORD
- Is new record
- Is record loaded
- Modified record
- POP RECORD
- PUSH RECORD
- Record number
- Records in table
- SAVE RECORD
- Sequence number

# About Record Numbers

There are three numbers associated with a record:

- Record number
- Selected record number
- Sequence number

## Record Number

The record number is the absolute/physical record number for a record. A record number is automatically assigned to each new record and remains constant for the record until the record is deleted. Record numbers start at zero. They are not unique because record numbers of deleted records are reused for new records. They also change when the database is compacted or repaired.

## Selected Record Number

The selected record number is the position of the record in the current selection, and so depends on the current selection. If the selection is changed or sorted, the selected record number will probably change. Numbering for the selected record number starts at one (1).

## Sequence Number

The sequence number is a unique non-repeating number that may be assigned to a field of a record (via the **Autoincrement** property, the SQL AUTO_INCREMENT attribute or the **Sequence number** command). It is not automatically stored with each record. It starts by default at 1 and is incremented for each new record that is created. Unlike record numbers, a sequence number is not reused when a record is deleted or when a database is compacted or repaired. Sequence numbers provide a way to have unique ID numbers for records. If a sequence number is incremented during a transaction, the number is not decremented if the transaction is canceled.

**Note:** 4D does not carry out any check when you modify the automatic number internal counter of a table using the **SET DATABASE PARAMETER** command. If you decrement this counter, the new records created may have numbers that have already been assigned.

## Record Number Examples

The following tables illustrate the numbers that are associated with records. Each line in the table represents information about a record. The order of the lines is the order in which records would be displayed in an output form.

- **Data column**: The data from a field in each record. For our example, it contains a person's name.
- **Record Number column**: The record's absolute record number. This is the number returned by the **Record number** function.
- **Selected Record Number column**: The record's position in the current selection. This is the number returned by the **Selected record number** function.
- **Sequence Number column**: The record's unique sequence number. This is the number returned by the **Sequence number** function when the record was created. This number is stored in a field.

### After the Records Are Entered

The first table shows the records after they are entered.

- The default order for the records is by record number.
- The record number starts at 0.
- The selected record number and the sequence number start at 1.

| Data | Record Number | Selected Record Number | Sequence Number |
|---|---|---|---|
| Tess | 0 | 1 | 1 |
| Terri | 1 | 2 | 2 |
| Sabra | 2 | 3 | 3 |
| Sam | 3 | 4 | 4 |
| Lisa | 4 | 5 | 5 |

**Note**: The records remain in the default order after a command changes the current selection without reordering it; for example, after the Show All menu command is chosen in the Design environment, or after the **ALL RECORDS** command is executed.

### After the Records Are Sorted

The next table shows the same records sorted by name.

- The same record number remains associated with each record.
- The selected record numbers reflect the new position of the records in the sorted selection.
- The sequence numbers never change, since they were assigned when each record was created and are stored in the record.

| Data | Record Number | Selected Record Number | Sequence Number |
|---|---|---|---|
| Lisa | 4 | 1 | 5 |
| Sabra | 2 | 2 | 3 |
| Sam | 3 | 3 | 4 |
| Terri | 1 | 4 | 2 |
| Tess | 0 | 5 | 1 |

### After a Record Is Deleted

The following table shows the records after Sam is deleted.

- Only the selected record numbers have changed. Selected record numbers reflect the order in which the records are displayed.

| Data | Record Number | Selected Record Number | Sequence Number |
|---|---|---|---|
| Lisa | 4 | 1 | 5 |
| Sabra | 2 | 2 | 3 |
| Terri | 1 | 3 | 2 |
| Tess | 0 | 4 | 1 |

### After a Record Is Added

The next table shows the records after a new record has been added for Liz.

- A new record is added to the end of the current selection.
- Sam’s record number is reused for the new record.
- The sequence number continues to increment.

| Data | Record Number | Selected Record Number | Sequence Number |
|---|---|---|---|
| Tess | 0 | 1 | 1 |
| Terri | 1 | 2 | 2 |
| Sabra | 2 | 3 | 3 |
| Lisa | 4 | 4 | 5 |
| Liz | 3 | 5 | 6 |

### After the Selection is Changed and Sorted

The following table shows the records after the selection was reduced to three records and then sorted.

- Only the selected record number associated with each record changes.

| Data | Record Number | Selected Record Number | Sequence Number |
|---|---|---|---|
| Sabra | 2 | 1 | 3 |
| Liz | 3 | 2 | 6 |
| Terri | 1 | 3 | 2 |

## Using the Record Stack

---

The **PUSH RECORD** and **POP RECORD** commands allow you to put (“push”) records onto the record stack, and to remove (“pop”) them from the stack.

Each process has its own record stack for each table. 4D maintains the record stacks for you. Each record stack is a last-in-first-out (LIFO) stack. Stack capacity is limited by memory.

**PUSH RECORD** and **POP RECORD** should be used with discretion. Each record that is pushed uses part of free memory. Pushing too many records can cause an out-of-memory or stack full condition.

4D clears the stack of any unpopped records when you return to the menu at the end of execution of your method.

**PUSH RECORD** and **POP RECORD** are useful when you want to examine records in the same file during data entry. To do this, you push the record, search and examine records in the file (copy fields into variables, for example), and finally pop the record to restore the record.

While entering a record, if you have to check a multiple field unique value, use the **SET QUERY DESTINATION** command. This will save you the calls to **PUSH RECORD** and **POP RECORD** that you were making before and after the call to **QUERY** in order to preserve the data entered in the current record. **SET QUERY DESTINATION** allows you to make a query that does not change the selection nor the current record.

# CREATE RECORD

CREATE RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇨ | Table for which to create a new record, or Default table, if omitted |

## Description

**CREATE RECORD** creates a new empty record for *aTable*, but does not display the new record. Use **ADD RECORD** to create a new record and display it for data entry.

**CREATE RECORD** is used instead of **ADD RECORD** when data for the record is assigned with the language. The new record becomes the current record but the current selection is left untouched.

The record exists in memory only until a **SAVE RECORD** command is executed for the table. If the current record is changed (for example, by a query) before the record is saved, the new record is lost.

**Note:** This command does not require *aTable* to be in read/write mode. It can be used even when the table is in read-only mode (see **Record Locking**).

## Example

The following example archives records that are over 30 days old. It does does this by creating new records in an archival table. When the archiving is finished, the records that were archived are deleted from the [Accounts] table:

```
  ` Find records more than 30 days old
QUERY([Accounts];[Accounts]Entered<(Current date-30))
For($vlRecord;1;Records in selection([Accounts])) ` Loop once for each record
   CREATE RECORD([Archive]) ` Create a new archive record
   [Archive]Number:=[Account]Number ` Copy fields to the archive record
   [Archive]Entered:=[Account]Entered
   [Archive]Amount:=[Account]Amount
   SAVE RECORD([Archive]) ` Save the archive record
   NEXT RECORD([Accounts]) ` Move to the next account record
End for
DELETE SELECTION([Accounts]) ` Delete the account records
```

# DELETE RECORD

DELETE RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table where the current record will be deleted, or Default table, if omitted |

## Description

**DELETE RECORD** deletes the current record of *aTable* in the process. If there is no current record for *aTable* in the process, **DELETE RECORD** has no effect. In a form, you can create a Delete Record button instead of using this command.

**Notes:**

- If the current record is unloaded from memory before calling **DELETE RECORD** (for example, subsequent to an **UNLOAD RECORD**), the current selection of *table* is empty after the deletion occurs.
- The **DELETE RECORD** command does nothing when the table is in **READ ONLY** mode, regardless of whether the record to be deleted is locked or not.

Deleting records is a permanent operation and cannot be undone.

If a record is deleted, the record number will be reused when new records are created. Do not use the record number as the record identifier if you will ever delete records from the database.

## Example

The following example deletes an employee record. The code asks the user what employee to delete, searches for the employee's record, and then deletes it:

```
vFind:=Request("Employee ID to delete:") ` Get an employee ID
If(OK=1)
   QUERY([Employee];[Employee]ID =vFind) ` Find the employee
   DELETE RECORD([Employee]) ` Delete the employee
End if
```

# DISPLAY RECORD

DISPLAY RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to display the current record, or Default table, if omitted |

## Description

The **DISPLAY RECORD** command displays the current record of *aTable*, using the current input form. The record is displayed only until an event redraws the window. Such an event might be the execution of an **ADD RECORD** command, returning to an input form, or returning to the menu bar. **DISPLAY RECORD** does nothing if there is no current record.

**DISPLAY RECORD** is often used to display custom progress messages. It can also be used to generate a free-running slide show.

If a form method exists, an On Load event will be generated.

**WARNING:** Do not call **DISPLAY RECORD** from within a Web connection process, because the command will be executed on the 4D Web server machine and not on the Web browser client machine.

## Example

The following example displays a series of records as a slide show:

```
ALL RECORDS([Demo]) ` Select all of the records
FORM SET INPUT([Demo];"Display") ` Set the form to use for display
For($vlRecord;1;Records in selection([Demo])) ` Loop through all of the records
   DISPLAY RECORD([Demo]) ` Display a record
   DELAY PROCESS(Current process;180) ` Pause for 3 seconds
   NEXT RECORD([Demo]) ` Move to the next record
End for
```

# DUPLICATE RECORD

DUPLICATE RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to duplicate the current record, or Default table, if omitted |

## Description

**DUPLICATE RECORD** creates a new record for *aTable* that is a duplicate of the current record. The new record becomes the current record. If there is no current record, then **DUPLICATE RECORD** does nothing. You must use **SAVE RECORD** to save the new record.

**DUPLICATE RECORD** can be executed during data entry. This allows you to create a clone of the currently displayed record. Remember that you must first execute **SAVE RECORD** in order to save any changes made to the original record.

**Compatibility note:** Beginning with version 11 of 4D, this command no longer supports subtables.

# GOTO RECORD

GOTO RECORD ( {aTable ;} record )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table in which to go to the record, or Default table, if omitted |
| record | Longint | ⇒ | Number returned by Record number |

## Description

**GOTO RECORD** selects the specified record of *aTable* as the current record. The *record* parameter is the number returned by the **Record number** function. After executing this command, the record is the only record in the selection.

If *record* is less than the smallest record number in the database or greater than the greatest record number in the database, 4D generates an error message stating that the record number is out of range. If *record* is equal to the record number of a deleted record, 4D returns the error -10503 and the selection becomes empty.

## Example

See the example for **Record number**.

# Is new record

Is new record {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table of the record to examine or Default table if this parameter is omitted |
| Function result | Boolean | ⇐ | True if the record is being created, False otherwise |

## Description

The **Is new record** command returns True when *aTable*'s current record is being created and has not yet been saved in the current process.

**Compatibility Note:** You can obtain the same information by using the existing **Record number** command, and by testing if it returns -3.
However, we strongly advise you to use **Is new record** instead of **Record number** in this case. In fact, the **Is new record** command ensures compatibility with future versions of 4D.

**4D Server:** This command returns a different result for the On Validate form event depending on whether it is executed on 4D in local mode or 4D in remote mode. In local mode, the command returns False (the record is considered as already created). In remote mode, the command returns True because, in this case, the record is already created on the server but the information has not yet been sent to the client.

## Example

The following two statements are identical. The second one is strongly advised so that the code will be compatible with future versions of 4D:

```
If(Record number([Table])=-3) `Not advised
   ...
End if

If(Is new record([Table])) `Strongly advised
   ...
End if
```

# Is record loaded

Is record loaded {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table of the record to examine or Default table if this parameter is omitted |
| Function result | Boolean | ⇐ | True if the record is loaded Otherwise False |

## Description

The **Is record loaded** command returns True if *aTable*'s current record is loaded in the current process.

**4D Server**: In principle, when tables are linked by automatic relations, the current records of related tables are loaded automatically (see **About Relations**). However, for optimization reasons, 4D Server only loads these records when necessary, for example when reading or assigning a field of the related record. As a result, in this context the **Is record loaded** command will return False in remote mode (it returns True in local mode).

## Example

Instead of using the “Next record” or “Previous record” automatic actions, you can write object methods for these buttons to improve their operation. The “Next” button will display the beginning of the selection if the user is at the end of the selection and the “Previous” button will show the end of the selection when the user is at the beginning of the selection.

```
  ` Object method of the  “Previous”  button (without an automatic action)
If(Form event=On Clicked)
   PREVIOUS RECORD([Group])
   If(Not(Is record loaded([Group])))
      GOTO SELECTED RECORD([Group];Records in selection([Group]))
  `Go to the last record in the selection
   End if
End if

  ` Object method of the  “Next”  button (without an automatic action)
If(Form event=On Clicked)
   NEXT RECORD([Group])
   If(Not(Is record loaded([Group])))
      GOTO SELECTED RECORD([Groups];1)
  `Go to the first record in the selection
   End if
End if
```

# Modified record

Modified record {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to test if current record has been modified, or Default table, if omitted |
| Function result | Boolean | ⇐ | Record has been modified (True), or Record has not been modified (False) |

## Description

**Modified record** returns True if the current record of *aTable* has been modified but not saved; otherwise it returns False. This function allows the designer to quickly test whether or not the record needs to be saved. It is especially valuable in input forms to check whether or not to save the current record before proceeding to the next one. This function always returns True for a new record.

Note that this function always returns True in the following contexts:

- the current record is a new record,
- after the execution of the **PUSH RECORD** and **POP RECORD** commands,
- as soon as a value has been assigned to a field of the record, even if it is the same value as the former one. For example, **Modified record** returns True after the following statement is executed:

```
[Table_1]Field_1:=[Table_1]Field_1
```

## Example

The following example shows a typical use for **Modified record**:

```
If(Modified record([Customers]))
   SAVE RECORD([Customers])
End if
```

# POP RECORD

POP RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇨ | Table for which to pop record, or Default table, if omitted |

## Description

**POP RECORD** pops a record belonging to *aTable* from the table's record stack, and makes the record the current record.

If you push a record, change the selection to not include the pushed record, and then pop the record, the current record is not in the current selection. To designate the popped record as the current selection, use **ONE RECORD SELECT**. If you use any commands that move the record pointer before saving the record, you will lose the copy in memory.

## Example

The following example pops the record for the customer off the record stack:

```
POP RECORD([Customers]) ` Pop customer' s record onto stack
```

# PUSH RECORD

PUSH RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to push record, or Default table, if omitted |

## Description

**PUSH RECORD** pushes the current record of *aTable* (and its subrecords, if any) onto the table's record stack. **PUSH RECORD** may be executed before a record is saved.

If you push a record that was unlocked, this record stays locked for all the other processes and users until you pop and unload it.

**Compatibility note:** Beginning with version 11 of 4D, this command no longer supports subtables.

## Example

The following example pushes the record for the customer onto the record stack:

```
PUSH RECORD([Customer]) ` Push customer's record onto stack
```

# Record number

Record number {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return the number of the current record, or Default table, if omitted |
| Function result | Longint | ⇐ | Current record number |

## Description

**Record number** returns the physical record number for the current record of *aTable*. If there is no current record, such as when the record pointer is before or after the current selection, **Record number** returns –1. If the record is a new record that has not been saved, **Record number** returns –3.

Record numbers can change. The record numbers of deleted records are reused.

**4D Server:** This command returns a different result for the On Validate form event depending on whether it is executed on 4D in local mode or 4D in remote mode. In local mode, the command returns a record number (the record is considered as already created). In remote mode, the command returns -3 because, in this case, the record is already created on the server but the information has not yet been sent to the client.

**Note:** It is recommended to use the **Is new record** command to check whether a record is in the process of being created.

## Example

The following example saves the current record number and then searches for any other records that have the same data:

```
$RecNum:=Record number([People]) ` Get the record number
QUERY([People];[People]Last =[People]Last) ` Anyone else with the last name?
 ` Display an alert with the number of people with the same last name
ALERT("There are "+String(Records in selection([People])+" with that name.")
GOTO RECORD([People];$RecNum) ` Go back to the same record
```

# Records in table

Records in table {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return the number of records, or Default table, if omitted |
| Function result | Longint | ⇐ | Total number of records in the table |

## Description

**Records in table** returns the total number of records in aTable. **Records in selection** returns the number of records in the current selection only. If **Records in table** is used within a transaction, records created during the transaction will be taken into account.

## Example

The following example displays an alert that shows the number of records in a table:

```
ALERT("There are "+String(Records in table([People]))+" records in the table.")
```

# SAVE RECORD

SAVE RECORD {{ aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to save the current record, or Default table, if omitted |

## Description

**SAVE RECORD** saves the current record of *aTable* in the current process. If there is no current record, then **SAVE RECORD** is ignored.

You use **SAVE RECORD** to save a record that you created or modified with code. A record that has been modified and validated by the user in a form does not need to be saved with **SAVE RECORD**. A record that has been modified by the user in a form, but has been canceled, can still be saved with **SAVE RECORD**.

If you call the **SAVE RECORD** command when no field has been modified in the record, the command does nothing (the trigger is not called).

Here are some cases where **SAVE RECORD** is required:

- To save a new record created with **CREATE RECORD** or **DUPLICATE RECORD**
- To save data from **RECEIVE RECORD**
- To save a record modified by a method
- To save a record that contains new or modified subrecord data following an **_o_ADD SUBRECORD**, **_o_CREATE SUBRECORD**, or **_o_MODIFY SUBRECORD** command
- During data entry to save the displayed record before using a command that changes the current record
- During data entry to save the current record

You should not execute a **SAVE RECORD** during the On Validate event for a form that has been accepted. If you do, the record will be saved twice.

## Example

The following example is part of a method that reads records from a document. The code segment receives a record, and then, if it is received properly, saves it:

```
RECEIVE RECORD([Customers]) ` Receive record from disk
If(OK=1) ` If the record is received properly…
   SAVE RECORD([Customers]) ` save it
End if
```

# Sequence number

Sequence number {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return the sequence number, or Default table, if omitted |
| Function result | Longint | ⇒ | Sequence number |

## Description

**Sequence number** returns the next sequence number for *aTable*. The sequence number is unique for each table. It is a non-repeating number that is incremented(*) for each new record created for the table.

(*) For optimization reasons, the incrementation is started only at the first call of the **Sequence number** command or of a feature that gets access to the sequence number (see below). In addition, the numbering can be modified using the **SET DATABASE PARAMETER** command. Consequently, the returned value should not be considered as the count of records created in the *aTable*.

By default, the numbering starts at 1. You can change the numbering for a table using the **SET DATABASE PARAMETER** command.

**Note:** If there is no current record and the numbering has been modified via the **SET DATABASE PARAMETER** command, this number is in fact reserved for the next record creation but it will only be returned by the **Sequence number** function when the **SAVE RECORD** command has actually been called.

The **Sequence number** function is useful in the following cases:

- The sequence number needs an increment greater than 1
- The sequence number is part of a code, for example a part number code.

To store the sequence number by means of a method, create a long integer field in the table and assign the sequence number to the field.

The sequence number returned by this function for the *aTable* is the same number as the one generated when you check the **Autoincrement** option for a field of the table using the Structure inspector, or as the one assigned by using the *#N* symbol as the default value for a field of the *table* in a form (see the 4D Design Reference manual).

**Note:** Automatic incrementation can also be set via the SQL AUTO_INCREMENT attribute.

If the sequence number needs to start at a number other than 1, just add the difference to **Sequence number**. For example, if the sequence number must start at 1000, you would use the following statement to assign the number:

```
[Table1]Seq Field :=Sequence number([Table1])+999
```

## Example

The following example is part of a form method. It tests to see if this is a new record; i.e., if the invoice number is an empty string. If it is a new part number, the method assigns an invoice number. The invoice number is formed from two pieces of information: the sequence number, and the operator's ID, which was entered when the database was opened. The sequence number is formatted as a 5-character string:

```
  ` If this is a new part number, create a new invoice number
If([Invoices]Invoice No="")
  ` The invoice number is a string that ends with the operator' s ID.
   [Invoices]Invoice No:=String(Sequence number;"00000")+[Invoices]OpID
End if
```

SET FIELD RELATION

# About Relations

The commands in this theme, in particular **RELATE ONE** and **RELATE MANY**, establish and manage the automatic and non-automatic relations between tables. Before using any of the commands in this theme, refer to the 4D Design Reference manual for information about creating relations between tables.

## Using Automatic Table Relations with Commands

Two tables can be related with automatic table relations. In general, when an automatic table relation is established, it loads or selects the related records in a related table. Many operations cause the relation to be established.

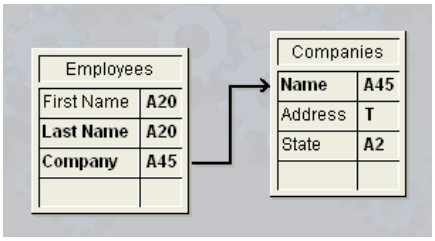
These operations include:

- Data entry
- Listing records on the screen in output forms
- Reporting
- Operations on a selection of records, such as queries, sorts, and applying a formula

To optimize performance, when 4D establishes automatic relations, only one record becomes the current record for a table. For each of the operations listed above, the related record is loaded according to the following principles:

- If a relation selects only one record of a related table, that record is loaded from disk.
- If a relation selects more than one record of a related table, a new selection of records is created for that table, and the first record in that selection is loaded from disk.

For example, using the database structure displayed here, if a record for the [Employees] table is loaded and displayed for data entry, the related record from the [Companies] table is selected and is loaded. Similarly, if a record for the [Companies] table is loaded and displayed for data entry, the related records from the [Employees] table are selected.



In this database structure, the [Employees] table is referred to as the **Many table**, and the [Companies] table is referred to as the **One table**. To remember this concept, think of “there are many employees related to one company” and “each company has many employees.”

Similarly, the Company field in the [Employees] table is referred to as the **Many field**, and the Name field in the [Companies] table is referred to as the **One field**.

It is not always possible to have the related field be unique. For example, the [Companies]Name field may have several company records containing the same value. This non-unique situation can be easily handled by creating a relation, which will always be unique, on another field in the related table. This field could be a company ID field.

The following table lists commands that use automatic relations to load related records during operation of the command. All of the commands will use existing automatic Many-to-One relations. Only those commands with Yes in the One-to-Many established column below will use automatic One-to-Many relations.

| Command | One-to-Many established |
|---|---|
| **ADD RECORD** | Yes |
| **_o_ADD SUBRECORD** | No |
| **APPLY TO SELECTION** | No |
| **DISPLAY SELECTION** | No |
| **EXPORT DIF** | No |
| **EXPORT SYLK** | No |
| **EXPORT TEXT** | No |
| **EXPORT DATA** | No |
| **MODIFY RECORD** | Yes |
| **_o_MODIFY SUBRECORD** | No |
| **MODIFY SELECTION** | Yes (in data entry) |
| **ORDER BY** | No |
| **ORDER BY FORMULA** | No |
| **QUERY BY FORMULA** | Yes |
| **QUERY SELECTION** | Yes |
| **QUERY** | Yes |
| **PRINT LABEL** | No |
| **PRINT SELECTION** | Yes |
| **QR REPORT** | No |
| **SELECTION TO ARRAY** | No |
| **SELECTION RANGE TO ARRAY** | No |

## Using Commands to Establish Table Relations

Automatic relations do not mean that the related record or records for a table will be selected simply because a command loads a record. In some cases, after using a command that loads a record, you must explicitly select the related records by using **RELATE ONE** or **RELATE MANY** if you need to access the related data.

Some of the commands listed in the previous table (such as the query commands) load a current record after the task is completed. In this case, the record that is loaded does not automatically select the records related to it. Again, if you need to access the related data, you must explicitly select the related records by using **RELATE ONE** or **RELATE MANY**.

# CREATE RELATED ONE

CREATE RELATED ONE ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇨ | Many field |

## Description

**CREATE RELATED ONE** performs two actions. If a related record does not exist for *aField* (that is, if a match is not found for the current value of *field*), **CREATE RELATED ONE** creates a new related record.

To save a value in the appropriate field, assign values to the One field from the Many field. Call **SAVE RELATED ONE** to save the new record.

If a related record exists, **CREATE RELATED ONE** acts just like **RELATE ONE** and loads the related record into memory.

# GET AUTOMATIC RELATIONS

GET AUTOMATIC RELATIONS ( one ; many )

| Parameter | Type | | Description |
|---|---|---|---|
| one | Boolean | ⇦ | Status of all Many-to-One relations |
| many | Boolean | ⇦ | Status of all One-to-Many relations |

## Description

The **GET AUTOMATIC RELATIONS** command lets you know if the automatic/manual status of all manual many-to-one and one-to-many relations of the database have been modified in the current process.

- *one*: This parameter returns **True** if a previous calll from the **SET AUTOMATIC RELATIONS** command made all manual many-to-one relations automatic — for example, **SET AUTOMATIC RELATIONS**(True;False).
  This parameter returns **False** if the **SET AUTOMATIC RELATIONS** command has not been called or if its previous execution did not modify manual many-to-one relations — for example, **SET AUTOMATIC RELATIONS**(False;False).
- *many*: This parameter returns **True** if a previous call from the **SET AUTOMATIC RELATIONS** command made all manual one-to-many relations automatic — for example, **SET AUTOMATIC RELATIONS**(True;True).
  This parameter returns **False** if the **SET AUTOMATIC RELATIONS** command has not been called or if its previous execution did not modify manual one-to-many relations — for example, **SET AUTOMATIC RELATIONS**(True;False).

## Example

Refer to the example of the **GET FIELD RELATION** command.

# GET FIELD RELATION

GET FIELD RELATION ( manyField ; one ; many {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| manyField | Field | ⇒ | Starting field of a relation |
| one | Longint | ⇐ | Status of the Many-to-One relation |
| many | Longint | ⇐ | Status of the One-to-Many relation |
| * | Operator | ⇒ | • If passed: one and many return the current status of the relation (values 2 or 3 only) • If omitted (default): one and many can return the value 1 if the relation has not been modified through programming |

## Description

The **GET FIELD RELATION** command lets you find out the automatic/manual status of the relation starting from *manyField* for the current process. You can view any relation, including automatic relations set in the Structure window.

- In *manyField*, pass the name of theMany table field from which the relation whose status you want to find out originates. If no relation originates from the *manyField* field, the *one* et *many* parameters return 0, an error is returned and the system variable OK is set to 0 (see below).
- After the command is executed, the *one* parameter contains a value indicating whether the Many-to-One relation specified is set as automatic:
  0 = There is no relation originating from *manyField*. Syntax error No. 16 (“The field has no relation”) is generated and the system variable OK is set to 0.
  1 = The automatic/manual status of the Many-to-One relation specified is that set by the **Auto Relate One** option in the Relation properties of the Design environment (it has not been modified by programming).
  2 = The Many-to-One relation is manual for the process.
  3 = The Many-to-One relation is automatic for the process.
- After the command is executed, the *many* parameter contains a value indicating whether the One-to-Many relation specified is set as automatic:
  0 = There is no relation originating from *manyField*. Syntax error No. 16 (“The field has no relation”) is generated and the system variable OK is set to 0.
  1 = The automatic/manual status of the One-to-Many relation specified is that set by the **Auto One to Many** option in the Relation properties of the Design environment (it has not been modified by programming).
  2 = The One-to-Many relation is manual for the process.
  3 = The One-to-Many relation is automatic for the process.

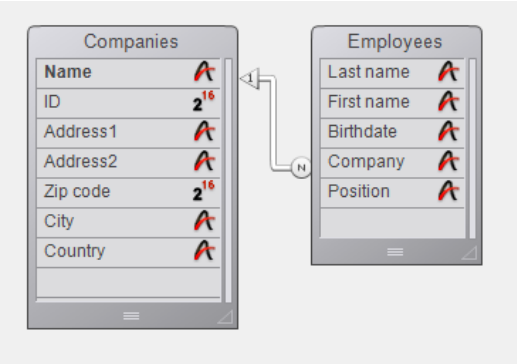
You can compare the values returned in the *one* and *many* parameters with the constants of the “**Relations**” theme:

| Constant | Type | Value |
|---|---|---|
| Automatic | Longint | 3 |
| Manual | Longint | 2 |
| No relation | Longint | 0 |
| Structure configuration | Longint | 1 |

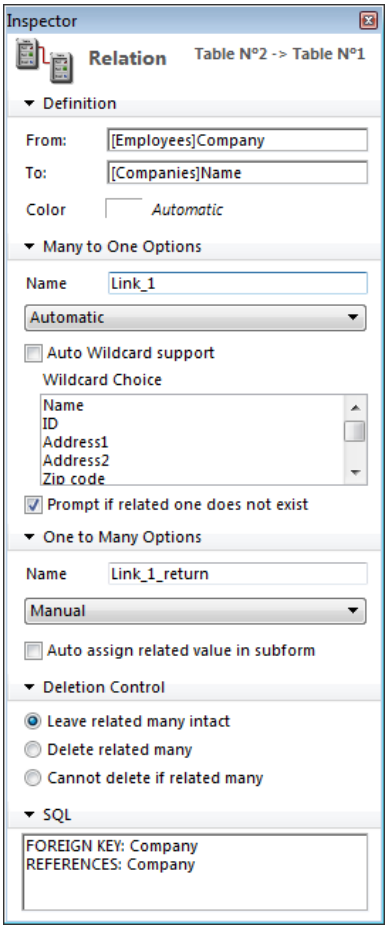
- The optional * parameter lets you “force” the reading of the current status of the relation, even if it has not been modified by programming. In other words, when you pass the * parameter, only the values 2 or 3 can be returned in the *one* and *many* parameters.

## Example

Given the following structure:



The properties of the relation linking the [Employees]Company field to the [Companies]Name field are the following:



The following code illustrates the various possibilities offered by the **GET FIELD RELATION**, **GET AUTOMATIC RELATIONS** and **SET FIELD RELATION**, **SET AUTOMATIC RELATIONS** commands along with their effects:

```
GET AUTOMATIC RELATIONS(one;many) `returns False, False
GET FIELD RELATION([Employees]Company;one;many) `returns 1,1
GET FIELD RELATION([Employees]Company;one;many;*) `returns 3,2

SET FIELD RELATION([Employees]Company;2;0) `changes Many-to-One relation to manual

GET FIELD RELATION([Employees]Company;one;many) `returns 2,1
GET FIELD RELATION([Employees]Company;one;many;*) `returns 2, 2

SET FIELD RELATION([Employees]Company;1;0) `re-establishes the parameters set in Design environment for Many-to-One relation

GET FIELD RELATION([Employees]Company;one;many) `returns 1,1
GET FIELD RELATION([Employees]Company;one;many;*) `returns 3,2

SET AUTOMATIC RELATIONS(True;True) `changes all relations of all tables to automatic

GET AUTOMATIC RELATIONS(one;many) `returns True, True
GET FIELD RELATION([Employees]Company;one;many) `returns 1,1
GET FIELD RELATION([Employees]Company;one;many;*) `returns 3,3
```

# OLD RELATED MANY

OLD RELATED MANY ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇨ | One field |

## Description

**OLD RELATED MANY** operates the same way **RELATE MANY** does, except that **OLD RELATED MANY** uses the old value in the one field to establish the relation.

**Note: OLD RELATED MANY** uses the old value of the many field as returned by the **Old** function. For more information, see the description of the **Old** command.

**OLD RELATED MANY** changes the selection of the related table, and selects the first record of the selection as the current record.

# OLD RELATED ONE

OLD RELATED ONE ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇨ | Many field |

## Description

**OLD RELATED ONE** operates the same way as **RELATE ONE** does, except that **OLD RELATED ONE** uses the old value of *aField* to establish the relation.

**Note: OLD RELATED ONE** uses the old value of the Many field as returned by the **Old** function. For more information, see the description of the **Old** command.

**OLD RELATED ONE** loads the record previously related to the current record. The fields in that record can then be accessed. If you want to modify this old related record and save it, you must call **SAVE RELATED ONE**. Note that there is no old related record for a newly created record.

## System variables and sets

If the command has been executed correctly and if the related records have been loaded, the OK system variable is set to 1. If the user clicked on **Cancel** in the record selection dialog box (that appears when the related record has been modified), the OK variable is set to 0.

# RELATE MANY

RELATE MANY ( oneTable | Field )

| Parameter | Type | | Description |
|---|---|---|---|
| oneTable \| Field | Table, Field | ⇒ | Table to establish all one-to-many relations, or One Field |

## Description

**RELATE MANY** has two forms.

The first form, **RELATE MANY**(oneTable), establishes all One-to-Many relations for *oneTable*. It changes the current selection for each table that has a One-to-Many relation to *oneTable*. The current selections in the Many tables depend on the current value of each related field in the One table. Each time this command is executed, the current selections of the Many tables will be regenerated and the first record of the selection is loaded as the current record..

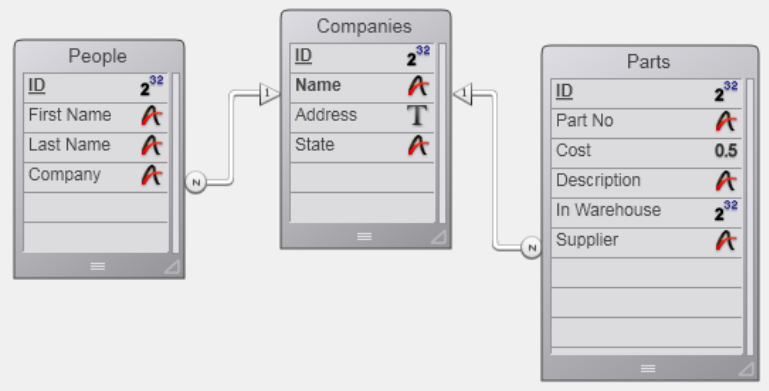
The second form, **RELATE MANY**(oneField), establishes the One-to-Many relation for *oneField*. It changes the current selection and the current record for only those tables that have relations with *oneField*. This means that the related records become the current selection for the Many table.

**Note:** If the current selection in the One table is empty while the **RELATE MANY** command is executed, it has no effect.

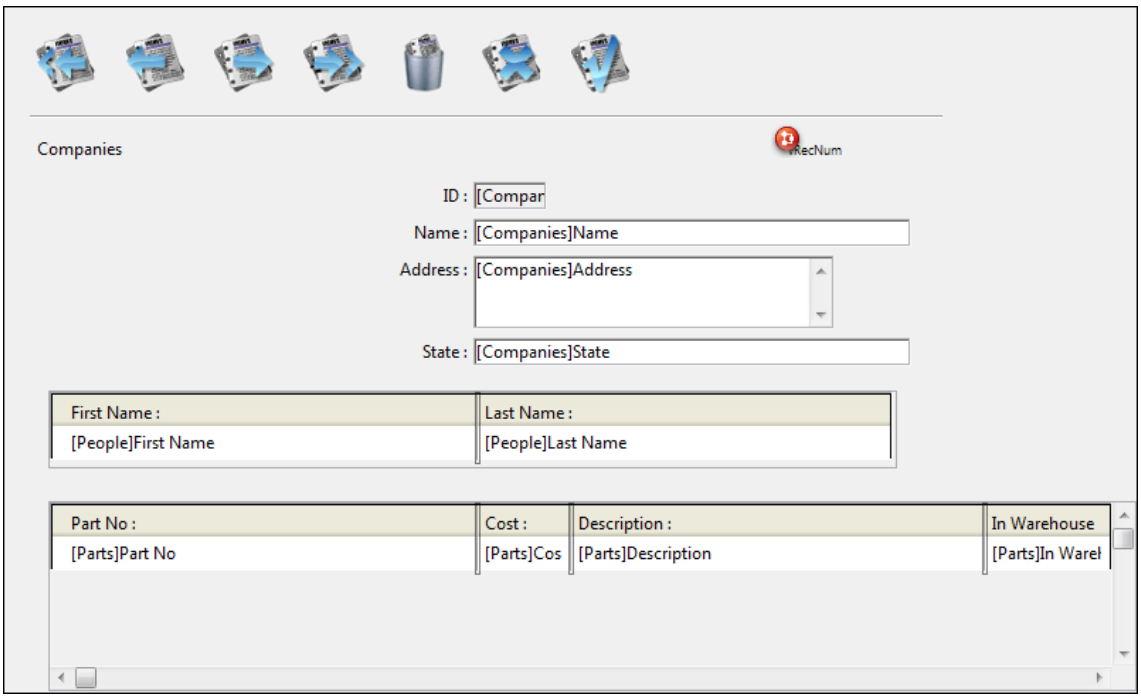
**Note:** This command does not support Object type fields.

## Example

In the following example, three tables are related with automatic relations. Both the [People] table and the [Parts] table have a Many-to-One relation to the [Companies] table.



This form for the [Companies] table will display related records from both the [People] and [Parts] tables.



When the People and Parts forms are displayed, the related records for both the [People] table and the [Parts] table are loaded and become the current selections in those tables.

On the other hand, the related records are not loaded if a record for the [Companies] table is selected programmatically. In this case, you must use the **RELATE MANY** command.

**Notes:**

- When the **RELATE MANY** command is applied to an empty selection, the command is not executed and the selection for the MANY table does not change.
- For the command to work, the foreign key fields (Many fields) must be indexed.

For example, the following method moves through each record of the [Companies] table. An alert box is displayed for each company. The alert box shows the number of people in the company (the number of related [People] records), and the number of parts they supply (the number of related [Parts] records). In the example, the argument to the **ALERT** command is printed on multiple lines for clarity.

Note that the **RELATE MANY** command is needed, even though the relations are automatic.

```
ALL RECORDS([Companies]) ` Select all records in the table
ORDER BY([Companies];[Companies]Name) ` Order records in alphabetical order
For($i;1;Records in table([Companies])) ` Loop once for each record
   RELATE MANY([Companies]Name) ` Select the related records
   ALERT("Company: "+[Companies]Name+Char(13)+"People in company: "
   +String(Records in selection([People]))+Char(13)+"Number of parts they supply: "+String(Records in selection([Parts])))
   NEXT RECORD([Companies]) ` Move to the next record
End for
```

# RELATE MANY SELECTION

RELATE MANY SELECTION ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Many table field (from which the relation starts) |

## Description

The **RELATE MANY SELECTION** command generates a selection of records in the Many table, based on a selection of records in the One table, and loads the first record of the Many table as the current record.

**Note: RELATE MANY SELECTION** changes the current record for the One table.

## Example

This example selects all invoices made to the customers whose credit is greater than or equal to $1,000. The [Invoices] table field *[Invoices]Customer ID* relates to the [Customer] table field *[Customers]ID Number*.

```
  ` Select the Customers
QUERY([Customers];[Customers]Credit>=1000)
  ` Find all invoices related to any of these customers
RELATE MANY SELECTION([Invoices]Customer ID)
```

# RELATE ONE

RELATE ONE ( manyTable | Field {; choiceField} )

| Parameter | Type | | Description |
|---|---|---|---|
| manyTable \| Field | Table, Field | ➡ | Table for which to establish all automatic relations, or Field with manual relation to one table |
| choiceField | Field | ➡ | Choice field from the one table |

## Description

**RELATE ONE** has two forms.

The first form, **RELATE ONE**(manyTable), establishes all automatic Many-to-One relations for *manyTable* in the current process. This means that for each field in *manyTable* that has an automatic Many-to-One relation, the command will select the related record in each related table. This changes the current record in the related tables for the process.

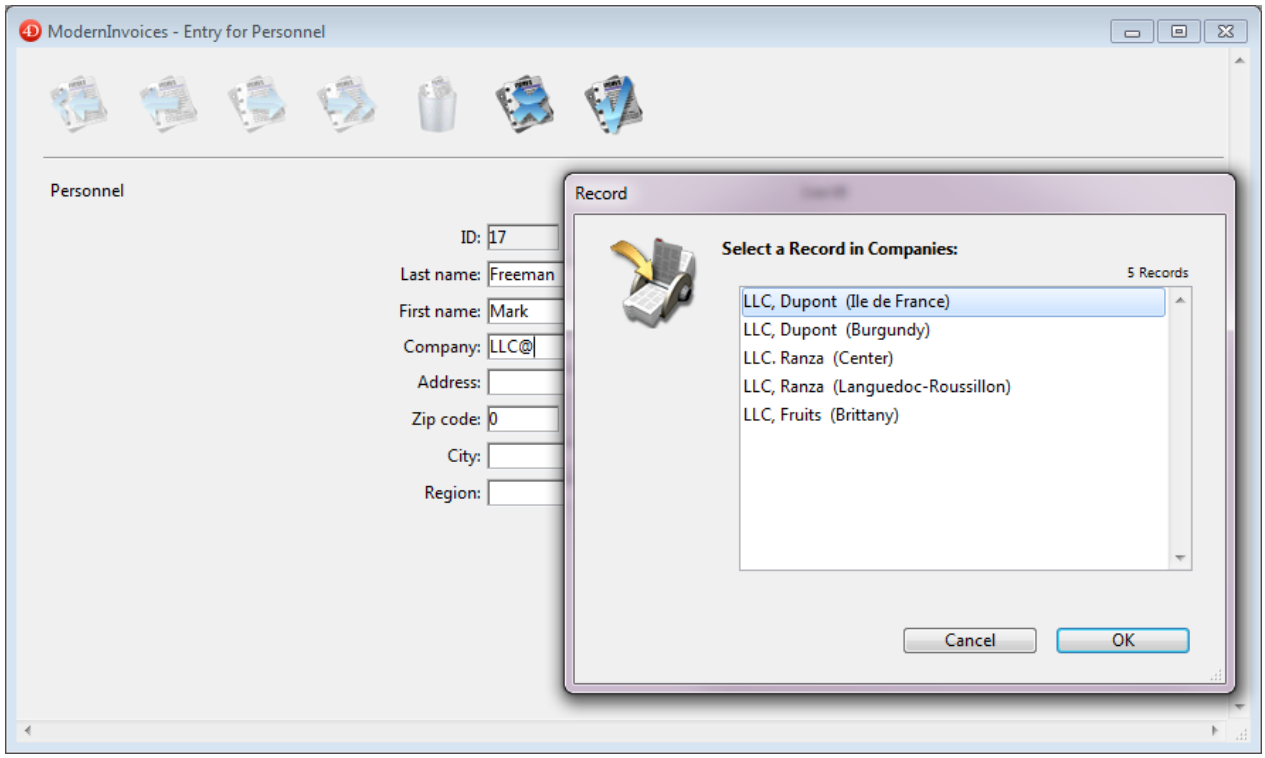
The second form, **RELATE ONE**(manyField{;choiceField}), looks for the record related to *manyField*. The relation does not need to be automatic. If it exists, **RELATE ONE** loads the related record into memory, making it the current record and current selection for its table.

The optional *choiceField* parameter must be a field in the related table. It can only be an Alpha, Text, Numeric, Date, Time, or Boolean field. More specifically, it cannot be a Picture or BLOB type field.

If *choiceField* is specified and more than one record is found in the related table, **RELATE ONE** displays a list of records that match the value in *manyField* so that the user can select a record. In this list, the left column displays related field values, and the right column displays *choiceField* values.

More than one record may be found if *manyField* ends with the wildcard character (@). If there is only one match, the list does not appear.

In the screen below, a record is being entered and a selection list is displayed in the foreground.



The following command is used to make the selection list appear:

```
RELATE ONE([Personnel]Company;[Companies]Region)
```

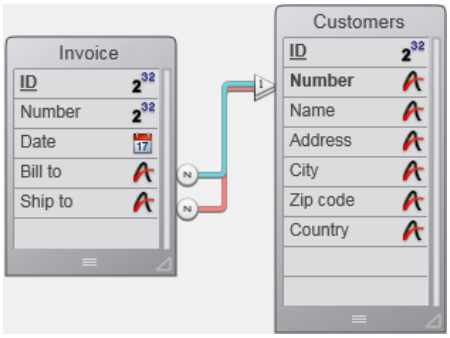
A user entered LLC@ to see a list of companies whose names begin with LLC, as well as their region.

Specifying *choiceField* is the same as specifying a wildcard choice when establishing the table relation. For information about specifying a wildcard choice, refer to the *4D Design Reference* manual.

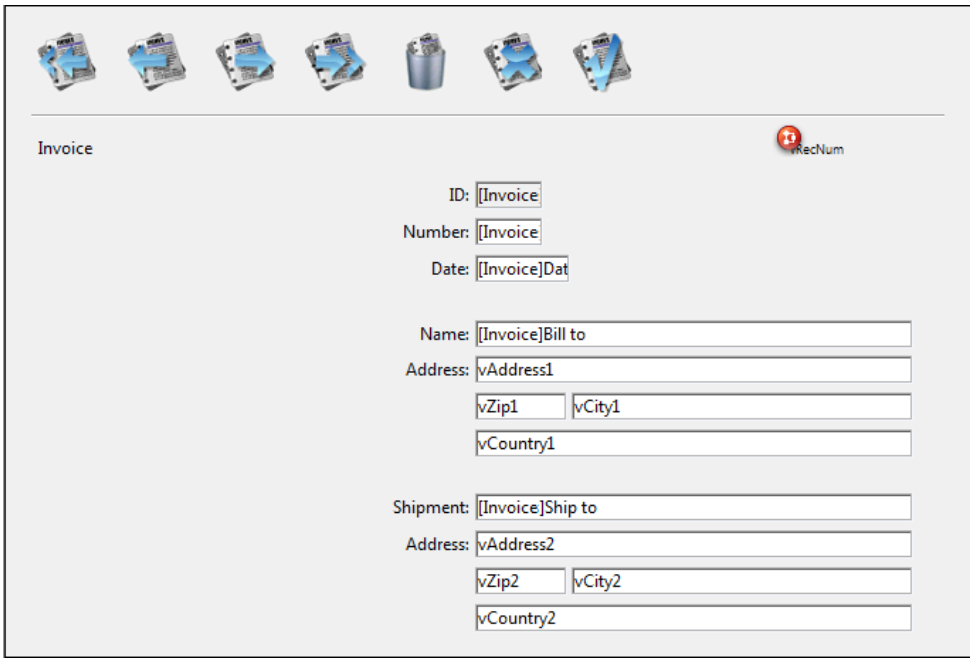
**Note:** This command does not support Object type fields.

## Example

Let's say you have an *[Invoice]* table related to a *[Customers]* table with two non-automatic relations. One relation is from *[Invoice]Bill to* to *[Customers]Number*, and the other relation is from *[Invoice]Ship to* to *[Customers]Number*.



Here is the form for the [Invoice] table displaying the "Bill to" and "Send to" information:



Since both relations are to the same table, *[Customers]*, you cannot obtain the billing and shipment information at the same time. Therefore, displaying both addresses in a form should be performed using variables and calls to **RELATE ONE**. If the *[Customers]* fields were displayed instead, data from only one of the relations would be displayed.

The following two methods are the object methods for the *[Invoice]Bill to* and *[Invoice]Ship to* fields. They are executed when the fields are entered.

Here is the object method for the *[Invoice]Bill to* field:

```
RELATE ONE([Invoice]Bill to)
vAddress1:=[Customers]Address
vCity1:=[Customers]City
vState1:=[Customers]State
vZIP1:=[Customers]ZIP
```

Here is the object method for the *[Invoice]Ship to* field:

```
RELATE ONE([Invoice]Ship to)
vAddress2:=[Customers]Address
vCity2:=[Customers]City
vState2:=[Customers]State
vZIP2:=[Customers]ZIP
```

## System variables and sets

If the command has been executed correctly and if the related records have been loaded, the OK system variable is set to 1. If the user clicked on **Cancel** in the record selection dialog box (that appears when the related record has been modified), the OK variable is set to 0.

# RELATE ONE SELECTION

RELATE ONE SELECTION ( manyTable ; oneTable )

| Parameter | Type | | Description |
|---|---|---|---|
| manyTable | Table | ⇒ | Many table name (from which the relation starts) |
| oneTable | Table | ⇒ | One table name (to which the relation refers) |

## Description

The **RELATE ONE SELECTION** command creates a new selection of records for the table *oneTable*, based on the selection of records in the table *manyTable* and loads the first record of the new selection as the current record.

This command can only be used if there is a relation from *manyTable* to *oneTable*. **RELATE ONE SELECTION** can work across several levels of relations. There can be several related tables between *manyTable* and *oneTable*. The relations can be manual or automatic.

**RELATE ONE SELECTION** uses the "shortest" path to pass from the starting table to the destination table. If there are existing paths of the same size, **RELATE ONE SELECTION** uses the first path found in the creation order of the fields in the starting table.

## Example

The following example finds all the clients whose invoices are due today.

Here is one way of creating a selection in the *[Customers]* table, given a selection of records in the *[Invoices]* table:

```
CREATE EMPTY SET([Customers];"Payment Due")
QUERY([Invoices];[Invoices]DueDate=Current date)
While(Not(End selection([Invoices])))
   RELATE ONE([Invoices]CustID)
   ADD TO SET([Customers];"Payment Due")
   NEXT RECORD([Invoices])
End while
```

The following technique uses **RELATE ONE SELECTION** to accomplish the same result:

```
QUERY([Invoices];[Invoices]DueDate=Current date)
RELATE ONE SELECTION([Invoices];[Customers])
```

**Note:** Since version 11, this code can be written as follows without any loss of performance:

```
QUERY([Customers];[Invoices]DueDate=Current date)
```

# SAVE RELATED ONE

SAVE RELATED ONE ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ➡ | Many field |

## Description

**SAVE RELATED ONE** saves the record related to *aField*. Execute this command to update a record created with **CREATE RELATED ONE**, or to save modifications to a record loaded with **RELATE ONE**.

**SAVE RELATED ONE** will not save a locked record. When using this command, you must first be sure that the record is unlocked. If the record is locked, the command is ignored, the record is not saved, and no error is returned.

# SET AUTOMATIC RELATIONS

SET AUTOMATIC RELATIONS ( one {; many} )

| Parameter | Type | | Description |
|---|---|---|---|
| one | Boolean | ⇨ | Status of all Many-to-One relations |
| many | Boolean | ⇨ | Status of all One-to-Many relations |

## Description

**SET AUTOMATIC RELATIONS** temporarily changes all the manual relations into automatic relations for the entire database in the current process. The relations stay automatic unless a subsequent call to **SET AUTOMATIC RELATIONS** is made.

- If *one* is true, then all manual Many-to-One relations will become automatic. If *one* is false, all previously changed Many-to-One relations will revert to manual relations.
- The same is true for the *many* parameter, except that manual One-to-Many relations are affected.

This command changes relations set as manual in the Design environment to automatic, just before executing operations that require them to be automatic (such as relational queries and sorts). After the operation is finished, relations can be changed back to manual by calling **SET AUTOMATIC RELATIONS** again.  Any relations set as automatic in the Design environment are not affected by this command.

**Note:** When you pass **True** to the **SET AUTOMATIC RELATIONS** command, the automatic mode is "locked" for all the manual relations during the session. In this case, any calls to the **SET FIELD RELATION** command during the same session are ignored, regardless of whether they are placed before or after **SET AUTOMATIC RELATIONS**. To "unlock" the automatic mode and take the calls to **SET FIELD RELATION** into account, pass **False** to **SET AUTOMATIC RELATIONS**.

## Example

The following example makes all manual Many-to-One relations automatic and reverts any previously changed One-to-Many relations:

```
SET AUTOMATIC RELATIONS(True;False)
```

# SET FIELD RELATION

SET FIELD RELATION ( manyTable | Field ; one ; many )

| Parameter | Type | | Description |
|---|---|---|---|
| manyTable \| Field | Table, Field | ⇒ | Starting table of relations or Starting field of a relation |
| one | Longint | ⇒ | Status of the Many-to-One relation starting from the field or the Many-to-One relations of the table |
| many | Longint | ⇒ | Status of the One-to-Many relation starting from the field or the One-to-Many relations of the table |

## Description

The **SET FIELD RELATION** command sets the automatic/manual status of each relation of the database separately for the current process, regardless of its initial status as specified in the Relation properties window in the Design environment.

In the first parameter, pass a table or field name:

- If you pass a field name (*manyField*), the command only applies to the relation starting from the specified Many field.
- If you pass a table name (*manyTable*), the command applies to all the relations starting from the specified Many table.
- If there is no relation starting from the *manyField* field or *manyTable* table, the syntax error No. 16 (“The field has no relation”) is generated and the system variable OK is set to 0.

In the *one* and *many* parameters, pass the values indicating the changing of the automatic/manual status to be applied respectively to the specified Many-to-One and One-to-Many relation(s). You can use the constants of the “**Relations**” theme:

- Do not modify (0) = Do not modify the current status of the relation(s).
- Structure configuration (1) = Use the configuration set for the relation(s) in the Structure window of the application.
- Manual (2) = Makes the relation(s) manual for the current process.
- Automatic (3) = Makes the relation(s) automatic for the current process.

**Note:** Changes made using this command only apply to the current process. The configuration of the relations set using the options in the Relation properties window is not modified.

**Note:** If you passed **True** to the **SET AUTOMATIC RELATIONS** command during the same session, calls to **SET FIELD RELATION** are ignored, regardless of whether they are placed before or after **SET AUTOMATIC RELATIONS**. To "lock" the automatic mode and take calls to **SET FIELD RELATION** into account, pass **False** to **SET AUTOMATIC RELATIONS**.

## Example

This command makes the management of relations easier in the Quick Report editor. In previous versions of 4D, it was necessary to set all relations as automatic to use them in the editor. Now, the following code allows setting only useful relations as automatic:

```
SET AUTOMATIC RELATIONS(False;False) `Reset of the relations
 `Only the following relations will be used
SET FIELD RELATION([Invoices]Cust_IDt;Automatic;Automatic)
SET FIELD RELATION([Invoice_Row]Invoice_ID;Automatic;Automatic)
QR REPORT([Invoices];Char(1);True;True;True)
```

# Resources

## Compatibility notes about writing resources (4D v13)

As announced with the release of 4D v11 (see section below), mechanisms based on the use of resources files are obsolete. **Commands in the "Resources" theme used to write in resources files must no longer be used; they will be removed from future versions of 4D.** Commands used to read resources are maintained for compatibility.

## Compatibility notes about resource management mechanisms (4D v11)

The management of resources has been modified in 4D beginning with version 11. In conformity with the directions specified by Apple and implemented in the most recent Mac OS versions, the concept of resources in the strictest sense (see definition below) is now obsolete and will be abandoned progressively. New mechanisms have been implemented to support the needs that were previously met by resources: XLIFF files for the translation of character strings, .png picture files, etc. In fact, resource files will be replaced in favor of standard type files. 4D supports this evolution and, beginning with version 11, provides new tools for the management of database translations, while maintaining compatibility with existing systems.

### Compatibility

To maintain compatibility and in order to permit the progressive adaptation of existing applications, the former resource mechanisms will containue to work in 4D v11, with just a few notable differences:

- When present, resource files are still supported by 4D and the principle of the“string of resource files” (successive opening of several resource files) remains valid. The “string of resource files” includes more particularly the .rsr or .4dr files of converted databases (opened automatically) and the custom resource files opened using the commands of this theme.
- However, for reasons related to the evolution of the internal architecture, it is no longer possible to access the resources of the 4D application nor those of the system directly, whether via the commands of this theme or using dynamic references. Certain developers make use of 4D internal resources for their interfaces (for example, resources containing the names of the months or those of the language commands). This practice is now strictly forbidden. In most cases, it is possible to use other means instead of 4D internal resources (constants, language commands, and so on). In order to limit the impact of this modification on existing databases, a substitution system has been implemented, based on the externalization of the resources that are most frequently used. It is nevertheless strongly recommended to change converted databases and to remove any calls to 4D internal resources they may contain.
- Starting with version 11, databases created by 4D will no longer contain .RSR (structure resources) and .4DR (data resources) files by default.

### Current resource management principles

In 4D v11, the notion of “resources” must be understood in the broader sense as “files that are necessary for the translation of application interfaces.” The current architecture of resources is based on a folder, named Resources, that must be located next to the database structure file (.4db or .4dc). In this folder, you need to put all the files that are necessary for the translation or customizing of the application interfaces (picture files, text files, XLIFF files, and so on).
It can also contain any “former generation” resource files of the database (.rsr files). Be careful, these files are not automatically included in the string of resources; they must be opened using standard 4D resource handling commands. 4D uses automatic mechanisms when working with the contents of this folder, in particular for the management of XLIFF files (this point is covered in the *Design Reference* manual). For compatibility reasons, the **Get indexed string** and **STRING LIST TO ARRAY** commands of the "Resources" theme can be used to take advantage of this architecture; however, it is now recommended to use the **Get localized string** command of the "String" theme.

# CLOSE RESOURCE FILE

CLOSE RESOURCE FILE ( resFile )

| Parameter | Type | | Description |
|---|---|---|---|
| resFile | DocRef | ⇨ | Resource file reference number |

## Description

The **CLOSE RESOURCE FILE** command closes the resource file whose reference number is passed in *resFile*.

Even if you have opened the same resource file several times, you need to call **CLOSE RESOURCE FILE** only once in order to close that file.

If you apply **CLOSE RESOURCE FILE** to the 4D application or database resource files, the command detects it and does nothing.

If you pass an invalid resource file reference number, the command does nothing.

Remember to eventually call **CLOSE RESOURCE FILE** for a resource file that you have opened using **Open resource file**. Note that when you quit the application (or open another database), 4D automatically closes all the resource files you opened.

# GET ICON RESOURCE

GET ICON RESOURCE ( resID ; resData {; fileRef} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ➡ | Icon resource ID number |
| resData | Picture | ➡ | Picture field or variable to receive the picture |
| | | ⬅ | Contents of the cicn resource |
| fileRef | DocRef | ➡ | Resource file reference number, or all open resource files, if omitted |

## Compatibility note

*This command is not supported in 64-bit versions of 4D. It returns an error if it is executed in this environment.*

## Description

The **GET ICON RESOURCE** command returns, in the picture field or variable *resData,* the icon stored in the color icon ("cicn") resource whose ID is passed in *resID*.

If the resource is not found, the *resData* parameter is left unchanged and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

## Example

The following example loads, in a Picture array, the color icons located in the active 4D application:

```
If(On Windows)
   $vh4DResFile:=Open resource file(Replace string(Application file;".EXE";".RSR"))
Else
   $vh4DResFile:=Open resource file(Application file)
End if
RESOURCE LIST("cicn";$alResID;$asResName;$vh4DResFile)
$vlNbIcons:=Size of array($alResID)
ARRAY PICTURE(ag4DIcon;$vlNbIcons)
For($vlElem;1;$vlNbIcons)
   GET ICON RESOURCE($alResID{$vlElem};ag4DIcon{$vlElem};$vh4DResFile)
End for
```

After this code has been executed, the array looks like this when displayed in a form:

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

# Get indexed string

Get indexed string ( resID ; strID {; resFile} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number or 'id' attribute of the 'group' element (XLIFF) |
| strID | Longint | ⇒ | String number or 'id' attribute of the 'trans-unit' element (XLIFF) |
| resFile | DocRef | ⇒ | Resource file reference number If omitted: all the XLIFF files or open resource files |
| Function result | String | ⇐ | Value of the indexed string |

## Description

The **Get indexed string** command returns:

- Either one of the strings stored in the string list (“STR#”) resource whose ID is passed in *resID*.
- Or a string stored in an open XLIFF file whose 'id' attribute of the 'group' element is passed in *resID* (see "Compatibility with XLIFF architecture" below).

You pass the number of the string in *strID*. The strings of a string list resource are numbered from 1 to N. To get all the strings (and their numbers) of a string list resource, use the **STRING LIST TO ARRAY** command.

If the resource or the string within the resource is not found, an empty string is returned and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

**Note:** A string of a string list resource can contain up to 255 characters.

### Compatibility with XLIFF architecture

The **Get indexed string** command is compatible with the XLIFF architecture of 4D beginning with version 11: the command first looks for values corresponding to *resID* and *strID* in all the open XLIFF files (when the *resFile* parameter is omitted). In this case, *resID* specifies the **id** attribute of the **group** element and *strID* specifies the **id** attribute of the **trans-unit** element. If the value is not found, the command continues searching in the open resources files. For more information about XLIFF architecture in 4D, refer to the Design Reference manual.

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

# GET PICTURE RESOURCE

GET PICTURE RESOURCE ( resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resData | Field, Variable | ⇒ | Picture field or variable to receive the picture |
| | | ⇐ | Contents of the PICT resource |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |

## Description

The **GET PICTURE RESOURCE** command returns in the picture field or variable *resData* the picture stored in the picture ("PICT") resource whose ID is passed in *resID*.

If the resource is not found, the *resData* parameter is left unchanged, and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

**Note:** A picture resource can be at least several megabytes in size.

## Example

See example for the **RESOURCE LIST** command.

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

## Error management

If there is not enough memory to load the picture, an error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# GET RESOURCE

GET RESOURCE ( resType ; resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resData | BLOB | ⇒ | BLOB field or variable to receive the data |
| | | ⇐ | Contents of the resource |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |

## Description

The **GET RESOURCE** command returns in the BLOB field or variable *resData* the contents of the resource whose type and ID is passed in *resType* and *resID*.

**Important:** You must pass a 4-character string in *resType*.

If the resource is not found, the *resData* parameter is left unchanged and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

**Note:** A resource can be at least several megabytes in size.

## Platform independence

Remember that you are working with Mac OS-based resources. No matter what the platform, internal resource data such as Long Integer is stored using Macintosh byte ordering. On Windows, the data for standard resources (such as string list and pictures resources) is automatically byte swapped when necessary. On the other hand, if you create and use your own internal data structures, it is up to you to byte swap the data you extract from the BLOB (i.e., passing Macintosh byte ordering to a command such as **BLOB to longint**).

## Example

See the example for the **_o_SET RESOURCE** command.

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

## Error management

If there is not enough memory to load the resource, an error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# Get resource name

Get resource name ( resType ; resID {; resFile} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |
| Function result | String | ⇐ | Name of the resource |

## Description

The **Get resource name** command returns the name of the resource whose type is passed in *resType* and whose ID number is passed in *resID*.

If you pass a valid resource file reference number in the parameter *resFile*, the resource is searched for within that file only. If you do not pass the parameter *resFile*, the resource is searched for within the current open resource files.

If the resource does not exist, **Get resource name** returns an empty string.

# Get resource properties

Get resource properties ( resType ; resID {; resFile} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |
| Function result | Longint | ⇐ | Resource attributes |

## Description

The **Get resource properties** command returns the attributes of the resource whose type is passed in *resType* and whose ID number is passed in *resID*.

If you pass a valid resource file reference number in the parameter *resFile*, the resource is searched for within that file only. If you do not pass the parameter *resFile*, the resource is searched for within the current open resource files.

If the resource does not exist, the command returns *0* (zero) and sets the OK variable to *0* (zero).

The numeric value returned by **Get resource properties** must be seen as a bit field value whose bits have special meaning.

## Example

See example for the **Get resource name** command.

## System variables and sets

The OK variable is set to 0 if the resource does not exist; otherwise, it is set to 1.

# Get string resource

Get string resource ( resID {; resFile} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |
| Function result | String | ⇐ | Contents of the STR resource |

## Description

The **Get string resource** command returns the string stored in the string (“STR ”) resource whose ID is passed in *resID*.

If the resource is not found, an empty string is returned and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

**Note:** A string resource can contain up to 255 characters.

## Example

The following example displays the contents of the string resource ID=20911, which must be located in at least one of the currently open resource files:

```
ALERT(Get string resource(20911))
```

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

# Get text resource

Get text resource ( resID {; resFile} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |
| Function result | Text | ⇐ | Contents of the TEXT resource |

## Description

The **Get text resource** command returns the text stored in the text (“TEXT”) resource whose ID is passed in *resID*.

If the resource is not found, empty text is returned, and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

**Note:** A text resource can contain up to 32,000 characters.

## Example

The following example displays the contents of the text resource ID=20800, which must be located in at least one of the currently open resource files:

```
ALERT(Get text resource(20800))
```

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

# Open resource file

Open resource file ( resFilename {; fileType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resFilename | String | ⇒ | Short or long name of resource file, or Empty string for standard Open File dialog box |
| fileType | String | ⇒ | Mac OS file type (4-character string), or Windows file extension (1- to 3-character string), or All files, if omitted |
| Function result | DocRef | ⇐ | Resource file reference number |

## Description

The **Open resource file** command opens the resource file whose name or pathname you pass in *resFileName*.

If you pass a file name, the file should be located in the same folder as the structure file of the database. Pass a pathname to open a resource file located in another folder.

If you pass an empty string in *resFileName*, the Open File dialog box is presented. You can then select the resource file to open. If you cancel the dialog, no resource file is open; **Open resource file** returns a null DocRef and sets the OK variable to 0.

By default, the command opens the resource fork of the file passed as parameter. If it is empty, the command opens the data fork of the file and accesses any resources found there. For more information, refer to the **Current date** section.

If the resource file is opened correctly, **Open resource file** returns its resource file reference number and sets the OK variable to 1. If the resource file does not exist, or if the file you try to open is not a resource file, an error is generated.

- On Macintosh, if you use the Open File dialog box, all files are presented by default. To show a particular type of file, specify the file type in the optional *fileType* parameter.
- On Windows, if you use the Open File dialog box, all files are presented by default. To show a particular type of file, in *fileType*, pass a 1- to 3-character Windows file extension or a Macintosh file type mapped using the **MAP FILE TYPES** command.

Remember to call **CLOSE RESOURCE FILE** for the resource file. Note, however, that when you quit the application (or open another database), 4D automatically closes all the resource files you opened using **Open resource file**.

Unlike the **Open document** command, which opens a document with exclusive read-write access by default, **Open resource file** does not prevent you from opening a resource file already open from within the 4D session. For example, if you try to open the same document twice using **Open document**, an I/O error will be returned at second attempt. On the other hand, if you try to open a resource file already open from within the 4D session, **Open resource file** will return the resource file reference number to the file already open. Even if you open a resource file several times, you need to call **CLOSE RESOURCE FILE** once in order to close that file. Note that this is permitted if the resource file is open from within the 4D session; if you try open a resource file already opened by another application, you will get an I/O error.

**WARNING:**

- It is forbidden to access a 4D application resource file as well as a 4D Desktop merged database resource file.
- Although it is technically possible, you are advised not to use the database structure resource file because your code will not work if the database is compiled and merged with 4D Desktop.
  However, if you access and intend to programmatically add, delete or modify its resources, be sure to test the environment in which you are running. With 4D Server, this will probably lead to serious issues. For example, if you modify a resource on the server machine (via a database method or a stored procedure), you will definitely affect the built-in 4D Server administration service that distributes resources (transparently) to the workstations. Note that with 4D Client, you do not have direct access to the structure file; it is located on the server machine.
- For these reasons, if you use resources, store them in your own files.
- When working with your own resources, do NOT use negative resource IDs; they are reserved for use by the Operating System. Do NOT use resource IDs in the range 0..14,999; this range is reserved for use by 4D. Use the range 15,000..32,767 for your own resources. Remember that once you have opened a resource file, it will be the first file to be searched in the resource files chain. If you store a resource in that file with an ID in the range of system or 4D resources, this resource will be found by commands such as **GET RESOURCE** and also by internal routines of the 4D application. This may be the result you want to achieve, but if you are not sure, do NOT use these ranges, as they may lead to system errors.

- Resource files are highly structured files and cannot accept more than 2,700 resources per file. If you work with files containing a large number of resources, it is a good idea to test that number before adding new resources to a file. See the ***Count resources*** method listed for the **RESOURCE TYPE LIST** command.

After you have opened a resource file, you can analyze the contents of the file using the **RESOURCE TYPE LIST** and **RESOURCE LIST** commands.

## Example 1

The following example tries to open, on Windows, the resource file “MyPrefs.res” located in the database folder:

```
$vhResFile:=Open resource file("MyPrefs";"res ")
```

On Macintosh, the example tries to open the file “MyPrefs”.

## Example 2

The following example tries to open, on Windows. the resource file “MyPrefs.rsr” located in the database folder:

```
$vhResFile:=Open resource file("MyPrefs";"rsr")
```

On Macintosh, the example tries to open the file “MyPrefs”.

## Example 3

The following example displays the Open file dialog box showing all types of files:

```
$vhResFile:=Open resource file("")
```

## Example 4

The following example displays the Open file dialog box showing files created by the **_o_Create resource file** command, using the default file type:

```
$vhResFile:=Open resource file("";"res ")
If(OK=1)
   ALERT("You just opened "+Document+.")
   CLOSE RESOURCE FILE($vhResFile)
End if
```

## System variables and sets

If the resource file is successfully opened, the OK variable is set to 1. If the resource file could not be opened or if the user clicked Cancel in the Open file dialog box, the OK variable is set to 0 (zero).

If the resource file is successfully opened using the Open file dialog box, the Document variable is set to the pathname of the file.

## Error management

If the resource file could not be opened due to a resource or I/O problem, an error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# RESOURCE LIST

RESOURCE LIST ( resType ; resIDs ; resNames {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resIDs | Longint array | ⇐ | Resource ID numbers for resources of this type |
| resNames | String array | ⇐ | Resource names for resources of this type |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |

## Description

The **RESOURCE LIST** command populates the arrays *resIDs* and *resNames* with the resource IDs and names of the resources whose type is passed in *resType*.

**Important:** You must pass a 4-character string in *resType*.

If you pass a valid resource file reference number in the optional parameter *resFile*, only the resources from that file are listed. If you do not pass the parameter *resFile*, all resources from the current open resource files are listed.

If you predeclare the arrays before calling **RESOURCE LIST**, you must predeclare *resIDs* as a Longint array and *resNames* as a String or Text array. If you do not predeclare the arrays, the command creates *resIDs* as a Longint array and *resNames* as a Text array.

After the call, you can test the number of resources found by applying the **Size of array** command to the array *resIDs* or *resNames*.

## Example 1

The following example populates the arrays *$alResID* and *$atResName* with the IDs and names of the string list resources present in the structure file of the database:

```
If(On Windows)
   $vhStructureResFile:=Open resource file(Replace string(Structure file;".4DB";".RSR"))
Else
   $vhStructureResFile:=Open resource file(Structure file)
End if
If(OK=1)
   RESOURCE LIST("STR#";$alResID;$atResName;$vhStructureResFile)
End if
```

## Example 2

The following example copies the picture resources present in all currently open resource files into the Picture Library of the database:

```
RESOURCE LIST("PICT";$alResID;$atResName)
Open window(50;50;550;120;5;"Copying PICT resources...")
For($vlElem;1;Size of array($alResID))
   GET PICTURE RESOURCE($alResID{$vlElem};$vgPicture)
   If(OK=1)
      $vsName:=$atResName{$vlElem}
      If($vsName="")
         $vsName:="PICT resID="+String($alResID{$vlElem})
      End if
      ERASE WINDOW
      GOTO XY(2;1)
      MESSAGE("Adding picture  ""+$vsName+""  to the DB Picture library.")
      SET PICTURE TO LIBRARY($vgPicture;$alResID{$vlElem};$vsName)
   End if
End for
CLOSE WINDOW
```

# RESOURCE TYPE LIST

RESOURCE TYPE LIST ( resTypes {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resTypes | String array | ⇐ | List of available resource types |
| resFile | DocRef | ⇒ | Resource file reference number, or all open resource files, if omitted |

## Description

The **RESOURCE TYPE LIST** command populates the array *resTypes* with the resource types of the resources present in the resource files currently open.

If you pass a valid resource file reference number in the optional parameter *resFile*, only the resources from that file are listed. If you do not pass the parameter *resFile*, all the resources from the current open resource files are listed.

You can predeclare the array *resTypes* as a String or Text array before calling **RESOURCE TYPE LIST**. If you do not predeclare the array, the command creates *resTypes* as a Text array.

After the call, you can test the number of resource types found by applying the command **Size of array** to the array *resTypes*.

## Example 1

The following example populates the array *atResType* with the resource types of the resources present in all the resource files currently open:

```
RESOURCE TYPE LIST(atResType)
```

## Example 2

The following example tells you if the Macintosh 4D structure file you are using contains old 4D plug-ins that will need to be updated in order to use the database on Windows:

```
$vhResFile:=Open resource file(Structure file)
RESOURCE TYPE LIST(atResType;$vhResFile)
If(Find in array(atResType;"4DEX")>0)
   ALERT("This database contains old model Mac OS 4D plug-ins."+(Char(13)*2)+
   "You will have to update them for using this database on Windows.")
End if
```

**Note:** The structure file is not the only file where old version plug-ins can be stored. The database can also include a Proc.Ext file.

## Example 3

The following project method returns the number of resources present in a resource file:

```
  ` Count resources project method
  ` Count resources ( Time ) -> Long
  ` Count resources ( DocRef ) -> Number of resources

C_LONGINT($0)
C_TIME($1)

$0:=0
RESOURCE TYPE LIST($atResType;$1)
For($vlElem;1;Size of array($atResType))
   RESOURCE LIST($atResType{$vlElem};$alResID;$atResName;$1)
   $0:=$0+Size of array($alResID)
End for
```

Once this project method is implemented in a database, you can write:

```
$vhResFile:=Open resource file("")
If(OK=1)
   ALERT("The file  ""+Document+""  contains "+String(Count resources($vhResFile))+" resource(s).")
   CLOSE RESOURCE FILE($vhResFile)
End if
```

# STRING LIST TO ARRAY

STRING LIST TO ARRAY ( resID ; strings {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number or 'id' attribute of the 'group' element (XLIFF) |
| strings | String array | ⇐ | Strings from the STR# resource or Strings from the 'group' element (XLIFF) |
| resFile | DocRef | ⇒ | Resource file reference number If omitted: all the XLIFF files or open resources files |

## Description

The **STRING LIST TO ARRAY** command populates the array *strings* with:

- Either the strings stored in the string list ("STR#") resource whose ID is passed in *resID*.
- Or a string stored in an open XLIFF file whose 'id' attribute of the 'group' element is passed in *resID* (see "Compatibility with XLIFF architecture" below).

If the resource is not found, the array *strings* is left unchanged and the OK variable is set to 0 (zero).

If you pass a valid resource file reference number in *resFile*, the resource is searched for in that file only. If you do not pass *resFile*, the first occurrence of the resource found in the resource files chain is returned.

Before calling **STRING LIST TO ARRAY**, you can predeclare the array *strings* as a String or Text array. If you do not predeclare the array, the command creates *strings* as a Text array.

**Note:** Each string of a string list resource can contain up to 255 characters.

**Tip:** Limit your use of string list resources to those up to 32K in total size, and a maximum of a few hundred strings per resource.

## Compatibility with XLIFF architecture

The **STRING LIST TO ARRAY** command is compatible with the XLIFF architecture of 4D v11: the command first looks for values corresponding to *resID* and *strID* in all the open XLIFF files (when the *resFile* parameter is omitted) and fills the *strings* array with the corresponding values. In this case, *resID* specifies the **id** attribute of the **group** element and the *strings* array contains all the strings of the element. If the value is not found, the command continues searching in the open resources files.
For more information about XLIFF architecture in 4D, refer to the Design Reference manual.

## System variables and sets

If the resource is found, OK is set to 1. Otherwise, it is set to 0 (zero).

# _o_ARRAY TO STRING LIST

_o_ARRAY TO STRING LIST ( strings ; resID {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| strings | String array | ⇒ | String or Text array (new contents for the STR# resource) |
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_Create resource file

_o_Create resource file ( resFilename {; fileType {; *}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resFilename | String | ⇒ | Short or long name of resource file, or empty string for standard Save File dialog box |
| fileType | String | ⇒ | Mac OS file type (4-character string), or Windows file extension (1- to 3-character string), or Resource ("res " / .RES) document, if omitted |
| * | | ⇒ | If passed = Use data fork |
| Function result | DocRef | ⇐ | Resource file reference number |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_DELETE RESOURCE

_o_DELETE RESOURCE ( resType ; resID {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Compatibility note

Since 4D v13, commands that write resources are deprecated and should no longer be used.

# _o_Get component resource ID

_o_Get component resource ID ( compName ; resType ; originalResNum ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| compName | String | ⇒ | Component name referencing the resource |
| resType | String | ⇒ | Resource type (4 characters), PICT or STR# |
| originalResNum | Longint | ⇒ | Resource original number before component installation |
| Function result | Longint | ⇐ | Current resource number |

## Description

**Compatibility Note:** This command worked with former generation components that are incompatible with version 11 and higher of 4D. It now has no effect and should no longer be used.

# _o_SET PICTURE RESOURCE

_o_SET PICTURE RESOURCE ( resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resData | Picture | ⇒ | New contents for the PICT resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_SET RESOURCE

_o_SET RESOURCE ( resType ; resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resData | BLOB | ⇒ | New contents for the resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_SET RESOURCE NAME

_o_SET RESOURCE NAME ( resType ; resID ; resName {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resName | String | ⇒ | New name for the resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_SET RESOURCE PROPERTIES

_o_SET RESOURCE PROPERTIES ( resType ; resID ; resAttr {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resType | String | ⇒ | 4-character resource type |
| resID | Longint | ⇒ | Resource ID number |
| resAttr | Longint | ⇒ | New attributes for the resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_SET STRING RESOURCE

_o_SET STRING RESOURCE ( resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resData | String | ⇒ | New contents for the STR resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# _o_SET TEXT RESOURCE

_o_SET TEXT RESOURCE ( resID ; resData {; resFile} )

| Parameter | Type | | Description |
|---|---|---|---|
| resID | Longint | ⇒ | Resource ID number |
| resData | String | ⇒ | New contents for the TEXT resource |
| resFile | DocRef | ⇒ | Resource file reference number, or current resource file, if omitted |

## Description

**Compatibility Note:** Commands that write resources are deprecated and should no longer be used.

# Secured Protocol

- GENERATE CERTIFICATE REQUEST
- GENERATE ENCRYPTION KEYPAIR

# GENERATE CERTIFICATE REQUEST

GENERATE CERTIFICATE REQUEST ( privKey ; certifRequest ; codeArray ; nameArray )

| Parameter | Type | | Description |
|---|---|---|---|
| privKey | BLOB | ⇒ | BLOB containing the private key |
| certifRequest | BLOB | ⇐ | BLOB receiving the certificate request |
| codeArray | Longint array | ⇒ | Information code list |
| nameArray | String array | ⇒ | Name list |

## Description

The **GENERATE CERTIFICATE REQUEST** command generates a certificate request at the PKCS format which can be directly used by certificate authorities such as Verisign(R) . The certificate plays an important part in the SSL secured protocol. It is sent to each browser connecting in SSL mode. It contains the “ID card” of the Web site (made from the information entered in the command), as well as its public key allowing the browsers to decrypt the received information. Furthermore, the certificate contains various information added by the certificate authority which guarantees its integrity.

**Note:** For more information on the SSL protocol use with 4D Web server, refer to the **Using TLS Protocol** section.

The certificate request uses keypairs generated with the **GENERATE ENCRYPTION KEYPAIR** command and contains various information. The certificate authority will generate its certificate combining this request with other parameters.

Pass in *privKey* a BLOB containing the private key generated with the **GENERATE ENCRYPTION KEYPAIR** command.

Pass in *certifRequest* an empty BLOB. Once the command has been executed, it contains the certificate request at the PKCS format encoded in base64. You can store the contents directly in a text file suffixed .pem, for example using the **BLOB TO DOCUMENT** command, to submit it to the certificate authority.

**Warning:** The private key is used to generate the request but should NOT be sent to the certificate authority.

The arrays *codeArray* (long integer) and *nameArray* (string) should be filled respectively with the code numbers and the information content required by the certificate authority.

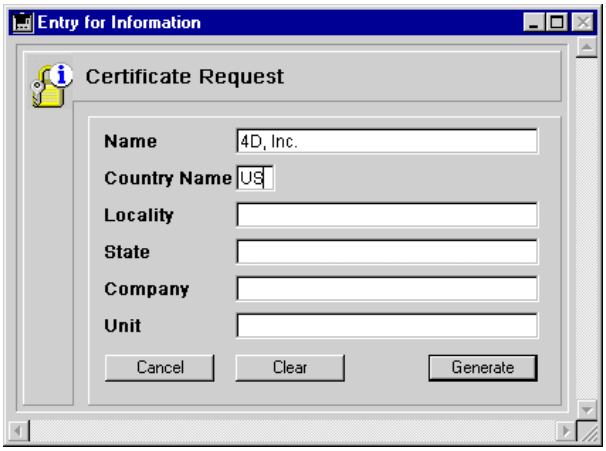
The required codes and names may change according to the certificate authority and the certificate use. However, within a normal use of the certificate (Web server connections via SSL), the arrays should contain the following items:

| Information to provide | codeArray | nameArray (Examples) |
|---|---|---|
| CommonName | 13 | www.4D.com |
| CountryName (two letters) | 14 | US |
| LocalityName | 15 | San Jose |
| StateOrProvinceName | 16 | California |
| OrganizationName | 17 | 4D, Inc. |
| OrganizationUnit | 18 | Web Administrator |

The code and information content entering order does not matter, however the two arrays must be synchronized: if the third item of the *codeArray* contains the value *15* (locality name), the *nameArray* third item should contain this information, in our example San Jose.

## Example

A “Certificate request” form contains the six fields necessary for a standard certificate request. The **Generate** button creates a document on disk containing the certificate request. The “Privatekey.txt” document containing the private key (generated with the **GENERATE ENCRYPTION KEYPAIR** command) should be on the disk:



Here is the **Generate** button method:

```
   ` bGenerate Object Method

C_BLOB($vbprivateKey;$vbcertifRequest)
C_LONGINT($tableNum)
ARRAY LONGINT($tLCodes;6)
ARRAY STRING(80;$tSInfos;6)

$tableNum:=Table(Current form table)
For($i;1;6)
   $tSInfos{$i}:=Field($tableNum;$i)->
   $tLCodes{$i}:=$i+12
End for
If(Find in array($tSInfos;"")#-1)
   ALERT("All fields should be filled.")
Else
   ALERT("Select your private key.")
   $vhDocRef:=Open document("")
   If(OK=1)
      CLOSE DOCUMENT($vhDocRef)
      DOCUMENT TO BLOB(Document;$vbprivateKey)
      GENERATE CERTIFICATE REQUEST($vbPrivateKey;$vbcertifRequest;$tLCodes;$tSInfos)
      BLOB TO DOCUMENT("Request.txt";$vbcertifRequest)
   Else
      ALERT("Invalid private key.")
   End if
End if
```

# GENERATE ENCRYPTION KEYPAIR

GENERATE ENCRYPTION KEYPAIR ( privKey ; pubKey {; length} )

| Parameter | Type | | Description |
|---|---|---|---|
| privKey | BLOB | ⇐ | BLOB to contain the private key |
| pubKey | BLOB | ⇐ | BLOB to contain the public key |
| length | Longint | ⇒ | Key length (bits) [386...2048] Default value = 512 |

## Description

The **GENERATE ENCRYPTION KEYPAIR** command generates a new pair of RSA keys. The security system offered in 4D is based on keys designed to encrypt/decrypt information. They can be used within the TLS/SSL protocol, with 4D Web server (encryption and secured communications) and in all databases (for data encryption).

Once the command has been executed, the BLOBs passed in *privKey* and *pubKey* parameters contain a new pair of encryption keys.

The optional parameter *length* can be used to set the key size (in bits). The larger the key, the more difficult it is to break the encryption code.

However, large keys require longer execution or reply time, especially within a secured connection.

By default (if the *length* parameter is omitted), the generated key size is set to 512 bits, which is a good compromise for the security/efficiency ratio. To increase the security factor, you can change keys more often, for example every six months.You can generate 2048 bits keys to increase the encryption security but the Web application connections will be slowed down.

This command will generate keys in PKCS format encoded in base64, which means that their content can be copied/pasted in an email without any change. Once the pair of keys has been generated, a text document in PEM format can be produced (using the **BLOB TO DOCUMENT** command for example) and the keys can be stored in a safe place.

**Warning:** The private key should always be kept secret.

## About RSA, private key and public key

The RSA cipher used by **GENERATE ENCRYPTION KEYPAIR** is based on a double key encryption system: a private key and a public key. As indicated by its name, the public key can be given to a third person and used to decrypt information. The public key is matched with a unique private key, used to encrypt the information. Thus, the private key is used for encryption; the public key for decryption (or vice versa). The information encrypted with one key can only be decrypted with the other one.

The TLS/SSL protocol encryption functionalities are based on this principle, the public key being included in the certificate sent to the browsers (for more information, see the section **Using TLS Protocol**).

This encryption mode is also used by the first syntax of the **ENCRYPT BLOB** and **DECRYPT BLOB** commands. The public key should be confidentially published.

It is possible to mix the public and private keys from two persons to encrypt information so that the recipient is the only person to be able to decrypt them and the sender is the only person to have encrypted them. This principle is given by the second syntax of the two **ENCRYPT BLOB** and **DECRYPT BLOB** commands.

## Example

See example for the **ENCRYPT BLOB** command.

# Selection

- ALL RECORDS
- APPLY TO SELECTION
- Before selection
- CREATE SELECTION FROM ARRAY
- DELETE SELECTION
- DISPLAY SELECTION
- Displayed line number
- End selection
- FIRST RECORD
- GET HIGHLIGHTED RECORDS
- GOTO SELECTED RECORD
- HIGHLIGHT RECORDS
- LAST RECORD
- MOBILE Return selection
- MODIFY SELECTION
- NEXT RECORD
- ONE RECORD SELECT
- PREVIOUS RECORD
- Records in selection
- REDUCE SELECTION
- SCAN INDEX
- Selected record number
- TRUNCATE TABLE

# ALL RECORDS

ALL RECORDS {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to select all records, or Default table, if omitted |

## Description

**ALL RECORDS** selects all the records of *aTable* for the current process. **ALL RECORDS** makes the first record the current record and loads the record from disk. **ALL RECORDS** returns the records to the default record order, which is the order in which the records are stored on disk.

## Example

The following example displays all the records from the [People] table:

```
ALL RECORDS([People]) ` Select all the records in the table
DISPLAY SELECTION([People]) ` Display records in output form
```

# APPLY TO SELECTION

APPLY TO SELECTION ( aTable ; statement )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to apply statement |
| statement | Statement | ➡ | One line of code or a method |

## Description

**APPLY TO SELECTION** applies *statement* to each record in the current selection of *aTable*. The *statement* can be a statement or a method. If *statement* modifies a record of *aTable*, the modified record is saved. If *statement* does not modify a record, the record is not saved. If the current selection is empty, **APPLY TO SELECTION** has no effect. If the relation is automatic, the *statement* can contain a field from a related table.

**APPLY TO SELECTION** can be used to gather information from the selection of records (for example, a total), or to modify a selection (for example, changing the first letter of a field to uppercase). If this command is used within a transaction, all changes can be undone if the transaction is canceled.

**4D Server:** The server does not execute any of the commands that may be passed in *statement*. Every record in the selection will be sent back to the local workstation to be modified.

The progress thermometer is displayed while **APPLY TO SELECTION** is executing. To hide it, use **MESSAGES OFF** prior to the call to **APPLY TO SELECTION**. If the progress thermometer is displayed, the user can cancel the operation.

## Example 1

The following example changes all the names in the table [Employees] to uppercase:

```
APPLY TO SELECTION([Employees];[Employees]Last Name:=Uppercase([Employees]Last Name))
```

## Example 2

If a record is locked during execution of **APPLY TO SELECTION** and that record is modified, the record will not be saved. Any locked records that are encountered are put in a set called *LockedSet*. After **APPLY TO SELECTION** has executed, test *LockedSet* to see if any records were locked. The following loop will execute until all records have been modified:

```
Repeat
   APPLY TO SELECTION([Employees];[Employees]Last Name:=Uppercase([Employees]Last Name))
   USE SET("LockedSet") ` Select only locked records
Until(Records in set("LockedSet")=0) ` Done when there are no locked records
```

## Example 3

This example uses a method:

```
ALL RECORDS([Employees])
APPLY TO SELECTION([Employees];M_Cap)
```

## System variables and sets

If the user clicks the Stop button in the progress thermometer, the OK system variable is set to 0. Otherwise, the OK system variable is set to 1.

# Before selection

Before selection {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to test if record pointer is before the first selected record, or Default table, if omitted |
| Function result | Boolean | ⇐ | Yes (TRUE) or No (FALSE) |

## Description

**Before selection** returns TRUE when the current record pointer is before the first record of the current selection of *table*.**Before selection** is commonly used to check whether or not **PREVIOUS RECORD** has moved the current record pointer before the first record. If the current selection is empty, **Before selection** returns TRUE.

To move the current record pointer back into the selection, use **FIRST RECORD**, **LAST RECORD** or **GOTO SELECTED RECORD**. **NEXT RECORD** does not move the pointer back into the selection.

**Before selection** also returns TRUE in the first header when a report is being printed with **PRINT SELECTION** or from the Print menu. You can use the following code to test for the first header and print a special header for the first page:

```
  ` Method of a form being used as output form for a summary report
$vpFormTable:=Current form table
Case of
  ` ...
  :(Form event=On Header)
  ` A header area is about to be printed
     Case of
        :(Before selection($vpFormTable->))
  ` Code for the first break header goes here
  ` ...
     End case
End case
```

## Example

This form method is used during the printing of a report. It sets a variable, *vTitle*, to print in the Header area on the first page:

```
  ` [Finances];"Summary" Form Method
Case of
  ` ...
  :(Form event=On Header)
     Case of
        :(Before selection([Finances))
           vTitle:="Corporate Report 1997" ` Set the title for the first page
        Else
           vTitle:="" ` Clear the title for all other pages
     End case
End case
```

# CREATE SELECTION FROM ARRAY

CREATE SELECTION FROM ARRAY ( aTable ; recordArray {; selectionName} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to create the selection |
| recordArray | Longint, Boolean array | ⇒ | Array of record numbers, or Array of booleans (True = the record is in the selection, False = the record is not in the selection) |
| selectionName | String | ⇒ | Name of the named selection to create, or Apply the command to the current selection if the parameter is omitted |

## Description

The **CREATE SELECTION FROM ARRAY** command creates the named selection *selectionName* from:

- either an array of absolute record numbers *recordArray* from *aTable*,
- or an array of Booleans. In this case, the values of the array indicate the belonging (**True**) or not (**False**) of each record in *table* to *selectionName*.

If you don’t pass *selectionName* or if you pass an empty string, the command will be applied to the current selection, which will then be updated.

When you use a Longint array with this command, all the numbers of the array represent the list of record numbers in *selectionName*. If a number is incorrect (record not created), error -10503 is generated.

**Note:** Be careful, you must make sure that the array does not contain any lines that have the same value, otherwise the resulting selection will be incorrect.

When you use a Boolean array with this command, the Xth element of the array indicates if the record number X is (**True**) or is not (**False**) in *selectionName*. The number of elements in *recordArray* must be equal to the number of records in *table*. If the array is smaller than the number of records, only the records defined by the array can make up the selection.

**Note:** With an array of booleans, the command uses elements from numbers 0 to X-1.

**Warning:** A named selection is created and loaded into memory. Therefore, make sure that you have enough memory before executing this command.

## Error management

If a record number is invalid (record not created), the error -10503 is generated. You can intercept this error using a method installed by the **ON ERR CALL** command.

# DELETE SELECTION

DELETE SELECTION {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to delete the current selection, or Default table, if omitted |

## Description

**DELETE SELECTION** deletes the current selection of records from *aTable*. If the current selection is empty, **DELETE SELECTION** has no effect. After the records are deleted, the current selection is empty. Records that are deleted during a transaction are locked to other users and other processes until the transaction is validated or canceled.

**Warning:** Deleting a selection of records is a permanent operation, and cannot be undone.

Unchecking the **Records definitively deleted** option in the table Inspector allows you to increase the speed of deletions when **DELETE SELECTION** is used (see **Records definitively deleted** in the *Design Reference* manual).

## Example 1

The following example displays all the records from the [People] table and allows the user to select which ones to delete. The example has two sections. The first is a method to display the records. The second is an object method for a Delete button. Here is the first method:

```
ALL RECORDS([People]) ` Select all records
FORM SET OUTPUT([People];"Listing") ` Set the form to list the records
DISPLAY SELECTION([People]) ` Display all records
```

The following is the object method for the Delete button, which appears in the Footer area of the output form. The object method uses the records the user selected (the *UserSet*) to delete the selection. Note that if the user did not select any records, **DELETE SELECTION** has no effect.

```
 ` Confirm that the user really wants to delete the records
CONFIRM("You selected "+String(Records in set("UserSet"))+" people to delete."+Char(13)+"Click OK to delete them.")
If(OK=1)
   USE SET("UserSet") ` Use the records chosen by the user
   DELETE SELECTION([People]) ` Delete the selection of records
End if
ALL RECORDS([People]) ` Select all records
```

## Example 2

If a locked record is encountered during the execution of **DELETE SELECTION**, that record is not deleted. Any locked records are put into a set called *LockedSet*. After **DELETE SELECTION** has executed, you can test the *LockedSet* to see if any records were locked. The following loop will execute until all the records have been deleted:

```
Repeat ` Repeat for any locked records
   DELETE SELECTION([ThisTable])
   If(Records in set("LockedSet")#0) ` If there are locked records
      USE SET("LockedSet") ` Select only the locked records
   End if
Until(Records in set("LockedSet")=0) ` Until there are no more locked records
```

# DISPLAY SELECTION

DISPLAY SELECTION ( {aTable}{; selectMode}{; enterList}{; *}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to display, or Default table, if omitted |
| selectMode | Longint | ⇒ | Selection mode |
| enterList | Boolean | ⇒ | Authorize Enter in list option |
| * | | ⇒ | Use output form for one record selection and hide scroll bars in the input form |
| * | | ⇒ | Show scroll bars in the input form (overrides second option of first optional *) |

## Description

**DISPLAY SELECTION** displays the selection of *aTable*, using the output form. The records are displayed in a scrollable list similar to that of the Design environment. If the user double-clicks a record, by default the record is displayed in the current input form. The list is displayed in the frontmost window.

To display a selection and also modify a record in the current input form after you have double-clicked on it (as you do in the Design environment window), or via the Enter in list mode, use **MODIFY SELECTION** instead of **DISPLAY SELECTION**.
All of the following information applies to both commands, except for the information on modifying records.

After **DISPLAY SELECTION** is executed, there may not be a current record. Use a command such as **FIRST RECORD** or **LAST RECORD** to select one.

The *selectMode* parameter is used to set the possibilities for selecting records in the list using the mouse. You can pass one of the following constants of the "**Form Parameters**" theme in this parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Multiple selection | Longint | 2 | The user can select several records at once. To select adjacent records, click on the first record to be selected, then press the **Shift** key before clicking on the last record you want to include in the selection. To select non-adjacent records, click on each record separately while holding down the **Ctrl** (under Windows) or **Command** (under Mac OS) key. |
| No selection | Longint | 0 | It is not be possible to select a record in the list |
| Single selection | Longint | 1 | Only one record can be selected at a time |

If you do not pass the *selectMode* parameter, the "Multiple Selection" mode is used by default.

The *enterList* parameter lets you authorize the "Enter in List" mode for the displayed list. This lets the user select and modify the record values directly in the output form. Pass **True** to enable this mode or **False** to disable it. By default, if you do not pass the *enterList* parameter, the "Enter in List" mode is disabled.
Keep in mind that with the **DISPLAY SELECTION** command, this parameter only allows the selection of the values in the list and not their modification. In fact, the **DISPLAY SELECTION** command loads the records of the current selection in Read only in the current process. Only the **MODIFY SELECTION** command allows the actual entry of values.

**Note:** The **OBJECT SET ENTERABLE** command can be used to enable or disable the Enter in list mode on the fly.

If the selection contains only one record and the first optional * is not used, the record appears in the input form instead of the output form. If the first optional * is specified, a one-record selection is displayed, using the output form. If the first optional * is specified and the user displays the record in the input form by double-clicking on it, the scroll bars will be hidden in the input form. To reverse this effect, pass the second optional *.

Custom buttons may be put in the Footer or Header area of the output form in order to terminate the execution of the **DISPLAY SELECTION** command. You can use automatic Accept or Cancel buttons to exit, or use an object method that calls **ACCEPT** or **CANCEL**. When an output form called by the **DISPLAY SELECTION** command has no buttons, only the **Escape** (Windows) or **Esc** (Mac OS) key can be used to exit the list.

During and after execution of **DISPLAY SELECTION**, the records that the user highlighted (selected) are kept in a set named *UserSet*. The *UserSet* is available within the selection display for object methods when a button is clicked or a menu item is chosen. It is also available to the project method that called **DISPLAY SELECTION** after the command was completed.

## Example 1

The following example selects all the records in the [People] table. It then uses **DISPLAY SELECTION** to display the records, and allows the user to select the records to print. Finally, it selects the records with **USE SET**, and prints them with **PRINT SELECTION**:

```
ALL RECORDS([People]) ` Select all records
DISPLAY SELECTION([People];*) ` Display the records
USE SET("UserSet") ` Use only records picked by user
PRINT SELECTION([People]) ` Print the records that the user picked
```

## Example 2

See example #6 for the **Form event** command. This example shows all the tests you may need to check in order to fully monitor the events that occur during a **DISPLAY SELECTION**.

## Example 3

To reproduce the functionality provided by, for example, the **Records** menu of the Design environment when you use **DISPLAY SELECTION** or **MODIFY SELECTION** in the Application environment, proceed as follows:

a. In the Design environment, create a menu bar with the menu commands you want, for example, Show All, Query and Order By.

b. Associate this menu bar (using the “Associated menu bar” menu in the form properties dialog box) with the output form used with **DISPLAY SELECTION** or **MODIFY SELECTION**.

c. Associate the following project methods to your menu commands:

```
 ` M_SHOW_ALL (attached to menu item Show All)
$vpCurTable:=Current form table
ALL RECORDS($vpCurTable->)

 ` M_QUERY (attached to menu item Query)
$vpCurTable:=Current form table
QUERY($vpCurTable->)

 ` M_ORDER_BY (attached to menu item Order By)
$vpCurTable:=Current form table
ORDER BY($vpCurTable->)
```

You can also use other commands, such as **PRINT SELECTION**, **QR REPORT**, and so on, to provide all the “standard” menu options you may want each time you display or modify a selection in the Application environment. Thanks to the **Current form table** command, these methods are generic, and the menu bar they support can be attached to any output form of any table.

# Displayed line number

Displayed line number -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of row being displayed |

## Description

The **Displayed line number** command only works with the On Display Detail form event. It returns the number of the row being processed while a list of records or list box rows is displayed on screen. If **Displayed line number** is called other than when displaying a list or a list box, it returns 0.

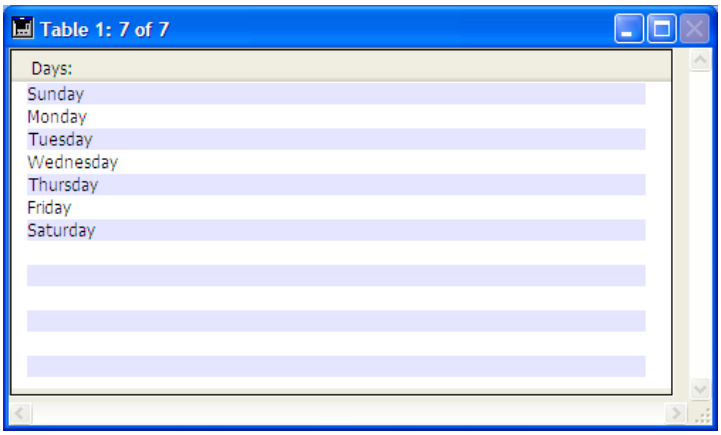
In the case of a list of records, when the displayed row is not empty (when it is linked to a record), the value returned by **Displayed line number** is identical to the value returned by **Selected record number**.

Like **Selected record number**, **Displayed line number** starts at 1. This command is useful if you want to process each row of a list form or list box displayed on screen, including empty rows.

## Example

This example lets you apply an alternating color to a list form displayed on screen, even for rows without records:

```
  `List form method
If(Form event=On Display Detail)
   If(Displayed line number% 2=0)
  `Black on white for even row text
      OBJECT SET RGB COLORS([Table 1]Field1;-1;0x00FFFFFF)
   Else
  `Black on light blue for odd row text
      OBJECT SET RGB COLORS([Table 1]Field1;-1;0x00E0E0FF)
   End if
End if
```



# End selection

End selection {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to test if record pointer is beyond the last selected record, or Default table, if omitted |
| Function result | Boolean | ⇐ | Yes (TRUE) or No (FALSE) |

## Description

**End selection** returns TRUE when the current record pointer is beyond the last record of the current selection of *aTable*. **End selection** is commonly used to check whether or not **NEXT RECORD** has moved the current record pointer past the last record. If the current selection is empty, **End selection** returns TRUE.

To move the current record pointer back into the selection, use **FIRST RECORD**, **LAST RECORD** or **GOTO SELECTED RECORD**. **PREVIOUS RECORD** does not move the pointer back into the selection.

**End selection** also returns TRUE in the last footer when a report is being printed with **PRINT SELECTION** or from the Print menu. You can use the following code to test for the last footer and print a special footer for the last page:

```
  ` Method of a form being used as output form for a summary report
$vpFormTable:=Current form table
Case of
  ` ...
  :(Form event=On Printing Footer)
  ` A footer is about to be printed
     If(End selection($vpFormTable->))
  ` Code for the last footer goes here
     Else
  ` Code for a footer goes here
     End if
End case
```

## Example

This form method is used during the printing of a report. It sets the variable *vFooter* to print in the Footer area on the last page:

```
  ` [Finances];"Summary" Form Method
Case of
  ` ...
  :(Form event=On Printing Footer)
     If(End selection([Finances]))
        vFooter:="©2001 Acme Corp." ` Set the footer for the last page
     Else
        vFooter:="" ` Clear the footer for all other pages
     End if
End case
```

# FIRST RECORD

FIRST RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to move to the first selected record, or Default table, if omitted |

## Description

**FIRST RECORD** makes the first record of the current selection of *aTable* the current record, and loads the record from disk. All query, selection, and sorting commands also set the current record to the first record. If the current selection is empty or if the current record is already the first record of the selection, **FIRST RECORD** has no effect.

This command is most often used after the **USE SET** command to begin looping through a selection of records from the first record. However, you can also call it from a subroutine if you are not sure whether or not the current record is actually the first.

## Example

The following example makes the first record of the [Customers] table the first record:

```
FIRST RECORD([Customers])
```

# GET HIGHLIGHTED RECORDS

GET HIGHLIGHTED RECORDS ( {aTable ;} setName )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table where the highlighted records will be read If omitted, table of the current form |
| setName | String | ⇒ | Set where the highlighted records will be stored |

## Description

The **GET HIGHLIGHTED RECORDS** command stores in the set designated by the *setName* parameter the highlighted records (i.e., the records highlighted by the user in the list form) in the *aTable* passed as parameter. If the *aTable* parameter is omitted, the table of the current form or subform is used.

In Design mode or when executing the **DISPLAY SELECTION** /**MODIFY SELECTION** commands, this command can be replaced by calling the UserSet system set which is automatically maintained by 4D. However, since this command allows you to pick the table that will receive highlighted records, the **GET HIGHLIGHTED RECORDS** command can also manage record selections in subforms as well. In this case, subform selections can also come from different tables. For more information about the UserSet set, refer to the **Sets** section.

The **GET HIGHLIGHTED RECORDS** command can also be called in a non-form context; however, the returned set is empty. The set designated by *setName* can be local/client, process or interprocess.

**Note:** In included subforms, the **GET HIGHLIGHTED RECORDS** command returns an empty set if the subform does not have the **Multiple** Selection Mode property. In this case, to find out the selected row, you must use the **Selected record number** command.

## Example

This method indicates how many records are selected in the subform displaying the records of the [CDs] table:

```
GET HIGHLIGHTED RECORDS([CDs];"$highlight")
ALERT(String(Records in set("$highlight"))"+"selected records.")
CLEAR SET("$highlight")
```

## System variables and sets

If the command was executed properly, the system variable OK is set to 1. Otherwise, it is set to 0.

# GOTO SELECTED RECORD

GOTO SELECTED RECORD ( {aTable ;} record )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table in which to go to the selected record, or Default table, if omitted |
| record | Longint | ⇒ | Position of record in the selection |

## Description

**GOTO SELECTED RECORD** moves to the specified record in the current selection of *aTable* and makes that record the current record. The current selection does not change. The *record* parameter is not the same as the number returned by **Record number**; it represents the record's position in the current selection. The record's position depends on how the selection is made and whether or not the selection is sorted.

**GOTO SELECTED RECORD** does nothing if:

- there are no records in the current selection
- *record* is not in the current selection,
- *record* is already the current record.

If you pass 0 in *record*, there will no longer be a current record in *aTable*. When the "single" selection mode is chosen, this allows you to deselect all the records in a list, in particular in the case of included subforms.

## Example

The following example loads data from the field [People]Last Name into the *atNames* array. An array of long integers, called *alRecNum*, is filled with numbers that will represent the selected record numbers. Both arrays are then sorted:

```
  ` Make any selection for the [People] table here
  ` ...
  ` Get the names
SELECTION TO ARRAY([People]Last Name;atNames)
  ` Create an array for the selected record numbers
$vlNbRecords:=Size of array(atNames)
ARRAY LONGINT(alRecNum;$vlNbRecords)
For($vlRecord;1;$vlNbRecords)
   alRecNum{$vlRecord}:=$vlRecord
End for
  ` Sort the arrays in alphabetical order
SORT ARRAY(atNames;alRecNum;>)
```

If the *atNames* array is displayed in a scrollable area, the user can click one of the items. Since the sorting of the two arrays is synchronized, any element in *alRecNum* provides the selected record number for the record whose name is stored in the corresponding element in *atNames*.

The following object method for *atNames* selects the correct record in the [People] selection, according to the name chosen in the scrollable area:

```
Case of
   :(Form event=On Clicked)
      If(atNames#0)
         GOTO SELECTED RECORD(alRecNum{atNames})
      End if
End case
```

# HIGHLIGHT RECORDS

HIGHLIGHT RECORDS ( {aTable }{;}{ setName {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table where records will be highlighted If omitted, table of current form |
| setName | String | ⇒ | Set of records to highlight or Userset if omitted |
| * | Operator | ⇒ | Disable the automatic scroll of the list |

## Description

The **HIGHLIGHT RECORDS** command highlights records in a list form. This operation is identical to manually selecting records in list mode by using the mouse or the **Shift+Click** or **Ctrl+Click** (Windows) or **Command+Click** (Mac OS) key combinations. The current selection is not modified.

**Note:** The set of "selected" records is updated after redrawing the records; that is, after executing the entire calling method — and not just immediately after executing **HIGHLIGHT RECORDS**.

The *aTable* parameter lets you designate the table where records will be "highlighted." This parameter can be used, in particular, to highlight the records of included subforms — which do not belong to the current table (see below).

- If you pass a valid set name to *setName*, the command is applied to the records in that set for the *table* defined.
- If you omit the *setName* parameter, the command only highlights the records in the current UserSet set. This set is only managed in Design mode and when calling the **DISPLAY SELECTION** /**MODIFY SELECTION** commands. If you want to highlight the records of a subform, you must pass a table name and set name. For more information about the UserSet set, refer to the **Sets** section.

The * parameter, when passed, disables the automatic scroll function of the list if the highlighted records are not visible. This mechanism allows customized scroll management using the **OBJECT SET SCROLL POSITION** command.

**Note:** Regarding included subforms, the **HIGHLIGHT RECORDS** command does nothing if the Selection Mode property **Multiple** is not selected for the subform. In this case, to highlight a line, you must use the **GOTO SELECTED RECORD** command.

## Example

In an output form displayed by the **MODIFY SELECTION** command, you want the user to be able to perform searches without the current selection being modified. To do this, place a **Search** button in the form and associate it with the following method:

```
SET QUERY DESTINATION(Into set;"UserSet")
QUERY
SET QUERY DESTINATION(Into current selection)
HIGHLIGHT RECORDS
```

When the user clicks the button, the standard query dialog box appears. Once the search has been validated, the records found will be highlighted without the current selection being modified.

# LAST RECORD

LAST RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to move to the last selected record, or Default table, if omitted |

## Description

**LAST RECORD** makes the last record of the current selection of *aTable* the current record and loads the record from disk. If the current selection is empty or if the current record is already the last one in the selection, **LAST RECORD** has no effect.

## Example

The following example makes the last record of the [People] table the current record:

```
LAST RECORD([People])
```

# MOBILE Return selection

MOBILE Return selection ( aTable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table whose current selection you want to return |
| Function result | Object | ⮌ | Wakanda-compliant selection |

## Description

The **MOBILE Return selection** command returns a JSON *object* that contains the current selection of *aTable* transformed into a Wakanda-compliant entity collection.

This command is intended to be called in the context of a 4D Mobile connection, usually between your 4D application and a Wakanda application (via REST). When a 4D Mobile connection is established and appropriate access rights have been configured, a Wakanda application can execute a 4D project method that returns a value in the *$0* parameter.

The **MOBILE Return selection** command allows you to return, in *$0*, the current selection of records of the *aTable* table, in the form of an *entity collection* object in JSON format. This object is compliant with Wakanda entity collections that contain a selection of records (i.e. of *entities*).

Keep in mind that 4D Mobile accesses require specific configurations in your 4D database:

- The Web server must be launched,
- The "Activate 4D Mobile Service" option must be checked in your Database settings,
- You must have a valid license,
- Tables and fields used must have the "Expose for 4D Mobile" option checked (set by default).
- Called methods must have the "Available through 4D Mobile call" option checked (not set by default).

Note that you can pass any valid table of the database in *aTable*, and not necessarily the table with which the project method has been associated in its properties. This parameter is only used on the Wakanda side to define the objects for which the method can be called.

For more information on 4D Mobile configuration, please refer to the **4D Mobile** documentation.

## Example

You want to display the current selection of the [Countries] table in a Wakanda grid, based on a query.

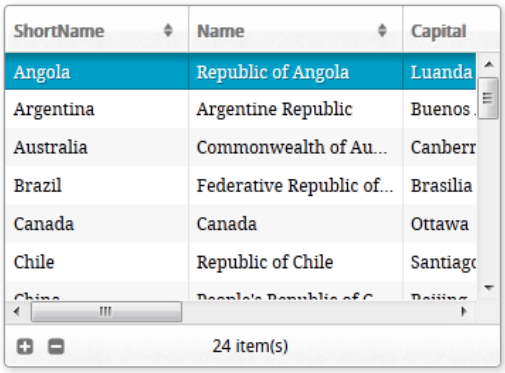
You write the following 4D method:

```
 //FindCountries project method
 //FindCountries( string ) -> object

C_TEXT($1)
C_OBJECT($0)
QUERY([Countries];[Countries]ShortName=$1+"@")
$0:=MOBILE Return selection([Countries])
```

The returned selection can be used directly in Wakanda as a valid collection.

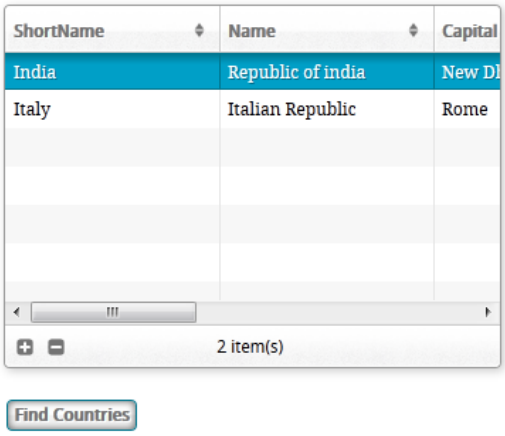
In the Wakanda server model connected to 4D via 4D Mobile, you have created a page with a grid bound to the 4D Countries table. By default, at runtime, all entities from the 4D table are displayed:



The code of the button is:

```
button1.click = function button1_click (event)      {          sources.countries.FindCountries("i", {  //we call the 4D method, "i" is passed as $1
            onSuccess:function(coll){  //callback function (asynchronous), receives $0 as parameter
sources.countries.setEntityCollection(coll.result); //replace the current entity collection                                    // with the one in the
coll.result object                  }             });            };
```

As a result, the grid is updated:



# MODIFY SELECTION

MODIFY SELECTION ( {aTable}{; selectMode}{; enterList}{; *}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to display and modify, or Default table, if omitted |
| selectMode | Longint | ⇒ | Selection mode |
| enterList | Boolean | ⇒ | Authorize Enter in list option |
| * | | ⇒ | Use output form for one record selection and hide scroll bars in the input form |
| * | | ⇒ | Show scroll bars in the input form (overrides second option of first optional *) |

## Description

**MODIFY SELECTION** does almost the same thing as **DISPLAY SELECTION**. Refer to the description of **DISPLAY SELECTION** for details. The differences between the two commands are:

1. **DISPLAY SELECTION** and **MODIFY SELECTION** enable you to display the current selected records in list mode, or in the input form when you double-click on a record. Using **MODIFY SELECTION**, you can also modify the fields of the record in the input form when you double-click on it, if it is not already in use by another process or user, or in “Enter in List” mode (if it is authorized).

2. **DISPLAY SELECTION** loads the records in Read-only mode in the current process, which means that they are not locked for writing in the other processes. **MODIFY SELECTION** places all the records of the selection in Read-Write mode, which means that they are automatically locked for writing in other processes. **MODIFY SELECTION** frees the records when its execution is completed.

# NEXT RECORD

NEXT RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to move to the next selected record, or Default table, if omitted |

## Description

**NEXT RECORD** moves the current record pointer to the next record in the current selection of *aTable* for the current process. If the current selection is empty, or if **Before selection** or **End selection** is TRUE, **NEXT RECORD** has no effect.

If **NEXT RECORD** moves the current record pointer past the end of the current selection, **End selection** returns TRUE, and there is no current record. If **End selection** returns TRUE, use **FIRST RECORD**, **LAST RECORD** or **GOTO SELECTED RECORD** to move the current record pointer back into the current selection.

## Example

See the example for **DISPLAY RECORD**.

# ONE RECORD SELECT

ONE RECORD SELECT {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table in which to reduce the selection to the current record, or Default table, if omitted |

## Description

**ONE RECORD SELECT** reduces the current selection of *aTable* to the current record. If no current record exists or if the current record is not loaded into memory (special case), **ONE RECORD SELECT** has no effect.

## Note

This command was useful to “return” a record that had been pushed and popped from the record stack back to the selection while the selection for the table was changed. **SET QUERY DESTINATION** allows you to make a query without changing the selection or the current record of a table; therefore, you no longer need to push and pop a current record in order to query its table. Consequently, **ONE RECORD SELECT** is less useful, unless you actually want to reduce the selection of a table to the current record.

# PREVIOUS RECORD

PREVIOUS RECORD {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to move to the previous selected record, or Default table, if omitted |

## Description

**PREVIOUS RECORD** moves the current record pointer to the previous record in the current selection of *aTable* for the current process. If the current selection is empty, or if **Before selection** or **End selection** is TRUE, **PREVIOUS RECORD** has no effect.

If **PREVIOUS RECORD** moves the current record pointer before the current selection, **End selection** returns TRUE, and there is no current record. If **End selection** returns TRUE, use **FIRST RECORD**, **LAST RECORD** or **GOTO SELECTED RECORD** to move the current record pointer back into the current selection.

# Records in selection

Records in selection {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return number of selected records, or Default table, if omitted |
| Function result | Longint | ⇐ | Records in selection of table |

## Description

**Records in selection** returns the number of records in the current selection of *aTable*. In contrast, **Records in table** returns the total number of records in the table.

## Example

The following example shows a loop technique commonly used to move through all the records in a selection. The same action can also be accomplished with the **APPLY TO SELECTION** command:

```
FIRST RECORD([People]) ` Start at first record in the selection
For($vlRecord;1;Records in selection([People])) ` Loop once for each record
   Do Something ` Do something with the record
   NEXT RECORD([People]) ` Move to the next record
End for
```

# REDUCE SELECTION

REDUCE SELECTION ( {aTable ;} number )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to reduce the selection, or Default table, if omitted |
| number | Longint | ⇒ | Number of records to keep selected |

## Description

**REDUCE SELECTION** creates a new selection of records for *aTable*. The command returns the first *number* of records from the current selection *table*. **REDUCE SELECTION** is applied to the current selection of *aTable* in the current process. It changes the current selection of *aTable* for the current process; the first record of the new selection is the current record.

**Note:** If the statement **REDUCE SELECTION***(aTable;0)* is executed, there is no longer any selection nor any current records in the table.

## Example

The following example first finds the correct statistics for a worldwide contest among the dealers in over 20 countries. For each country, the 3 best dealers who have sold product worth more than $50,000 and who are among the 100 best dealers in the world are awarded a prize. With a few lines of code, this complex request can be executed by using indexed searches:

```
CREATE EMPTY SET([Dealers];"Winners") ` Create an empty set
SCAN INDEX([Dealers]Sales amount;100;<) ` Scan from the end of the index
CREATE SET([Dealers];"100 best Dealers") ` Put the selected records in a set
For($Country;1;Records in table([Countries])) ` For each Country
 ` Search for the dealers in this country
   QUERY([Dealers];[Dealers]Country=[Countries]Name;*) ` ...who sold for more than $50,000
   QUERY(&;[Dealers];[Dealers]Sales amount>=50000)
   CREATE SET([Dealers];"WinnerDealers") ` Put them in a set
 ` They should be in the group of 100 best dealers
   INTERSECTION("WinnerDealers";"100 best Dealers";"WinnerDealers")
   USE SET("WinnerDealers") ` Potential winners for the country
 ` Sort them by the results in descending order
   ORDER BY([Dealers];[Dealers]Sales amount;<)
   REDUCE SELECTION([Dealers];3) ` Take the 3 best Dealers
   CREATE SET([Dealers];"WinnerDealers") ` The winners for the country
 ` Put them in the worldwide winners list
   UNION("WinnerDealers";"TheWinners";"TheWinners")
End for
CLEAR SET("100 best Dealers") ` Don't need this set anymore
CLEAR SET("WinnerDealers") ` Don't need this set anymore
USE SET("The Winners") ` Here you have the Winners
CLEAR SET("The Winners") ` Don't need this set anymore
OUTPUT FORM([Dealers];"Prize letter") ` Select the letter
PRINT SELECTION([Dealers]) ` Print the letters
```

# SCAN INDEX

SCAN INDEX ( aField ; number {; > or <} )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ➡ | Indexed field on which to scan index |
| number | Longint | ➡ | Number of records to return |
| > or < | Operator | ➡ | > from beginning of index < from end of index |

## Description

**SCAN INDEX** returns a selection of *number* records from the table containing the *aField* field. If you pass <, **SCAN INDEX** returns the *number* of records from the end of the index (high values). If you pass >, **SCAN INDEX** returns the *number* of records from the beginning of the index (low values). This command is very efficient because it uses the index to perform the operation.

**Note:** The selection obtained is not sorted.

**SCAN INDEX** only works on indexed fields. This command changes the current selection of the table for the current process and loads the first record of the selection as the current record.

If you specify more records than exist in the table, **SCAN INDEX** will return all the records.

**Note:** This command does not support Object type fields.

## Example

The following example mails letters to 50 of the worst customers and then to 50 of the best customers:

```
SCAN INDEX([Customers]TotalDue;50;<) ` Get the 50 worst customers
ORDER BY([Customers]Zipcode;>) ` Sort by Zip codes
FORM SET OUTPUT([Customers];"ThreateningMail")
PRINT SELECTION([Customers]) ` Print the letters
SCAN INDEX([Customers]TotalDue;50;>) ` Get the 50 best customers
ORDER BY([Customers]Zipcode;>) ` Sort by Zip codes
FORM SET OUTPUT([Customers];"Thanks Letter")
PRINT SELECTION([Customers]) ` Print the letters
```

# Selected record number

Selected record number {( aTable )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to return the selected record number or Default table, if omitted |
| Function result | Longint | ⇐ | Selected record number of current record |

## Description

**Selected record number** returns the position of the current record within the current selection of *aTable*.

If the selection is not empty and if the current record is within the selection, **Selected record number** returns a value between *1* and **Records in selection**. If the selection is empty, of if there is no current record, it returns *0* (zero).

The selected record number is not the same as the number returned by **Record number**, which returns the physical record number in the table. The selected record number depends on the current selection and the current record.

## Example

The following example saves the current selected record number in a variable:

```
CurSelRecNum:=Selected record number([People]) ` Get the selected record number
```

# TRUNCATE TABLE

TRUNCATE TABLE {( aTable )}

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table where all records will be deleted or Default table if this parameter is omitted |

## Description

The **TRUNCATE TABLE** command quickly deletes all the records of *aTable*. After calling the command, there is no longer any current selection or current record.

The effect of this command is similar to that of an **ALL RECORDS** / **DELETE SELECTION** sequence; however, its functioning differs on the following points:

- No trigger is called
- The referential integrity of the data is not checked.
- No transaction must be underway in the process executing **TRUNCATE TABLE**. If this if the case, the command does nothing and the OK system variable is set to 0
- If one or more records are locked by another process, the command fails: an error is generated and the OK system variable is set to 0. The LockedSet system set is not created.
- If *aTable* is already empty, **TRUNCATE TABLE** does nothing and sets the OK variable to 1.
- If *aTable* is in read-only, **TRUNCATE TABLE** does nothing and sets the OK variable to 0.
- The operation is recorded in the log file if there is one.

The **TRUNCATE TABLE** command should therefore be used with caution but is very effective in certain cases, for example, such as quickly deleting temporary data

**Note:** The concept and functioning of this command is similar to that of the SQL TRUNCATE (TABLE) command.

## System variables and sets

If the command has been executed correctly, the OK system variable is set to 1. Otherwise, it is set to 0.

# Sets

- Sets
- ADD TO SET
- CLEAR SET
- COPY SET
- CREATE EMPTY SET
- CREATE SET
- CREATE SET FROM ARRAY
- DIFFERENCE
- INTERSECTION
- Is in set
- LOAD SET
- Records in set
- REMOVE FROM SET
- SAVE SET
- UNION
- USE SET

# Sets

Sets offer you a powerful, swift means for manipulating record selections. Besides the ability to create sets, relate them to the current selection, and store, load, and clear sets, 4D offers three standard set operations:

- Intersection
- Union
- Difference.

## Sets and the Current Selection

A set is a compact representation of a selection of records. The idea of sets is closely bound to the idea of the current selection. Sets are generally used for the following purposes:

- To save and later restore a selection when the order does not matter
- To access the selection a user made on screen (the *UserSet*)
- To perform a logical operation between selections.

The current selection is a list of references that points to each record that is currently selected. The list exists in memory. Only currently selected records are in the list. A selection doesn't actually contain the records, but only a list of references to the records. Each reference to a record takes 4 bytes in memory. When you work on a table, you always work with the records in the current selection. When a selection is sorted, only the list of references is rearranged. There is only one current selection for each table inside a process.

Like a current selection, a set represents a selection of records. A set does this by using a very compact representation for each record. Each record is represented by one bit (one-eighth of a byte). Operations using sets are very fast, because computers can perform operations on bits very quickly. A set contains one bit for every record in the table, whether or not the record is included in the set. In fact, each bit is equal to 1 or 0, depending on whether or not the record is in the set.

Sets are very economical in terms of RAM space. The size of a set, in bytes, is always equal to the total number of records in the table divided by 8. For example, if you create a set for a table containing 10,000 records, the set takes up 1,250 bytes, which is about 1.2K in RAM.

There can be many sets for each table. In fact, sets can be saved to disk separately from the database. To change a record belonging to a set, first you must use the set as the current selection, then modify the record or records.

A set is never in a sorted order—the records are simply indicated as belonging to the set or not. On the other hand, a named selection is in sorted order, but it requires more memory in most cases. For more information about named selections, see the **Named Selections** section.

A set "remembers" which record was the current record at the time the set was created. The following table compares the concepts of the current selection and of sets:

| Comparison | Current Selection | Sets |
|---|---|---|
| Number per table | 1 | 0 to many |
| Sortable | Yes | No |
| Can be saved on disk | No | Yes |
| RAM per record(in bytes) | Number of selected records * 4 | Total number of records/8 |
| Combinable | No | Yes |
| Contains current record | Yes | Yes, as of the time the set was created |

When you create a set, it belongs to the table from which you created it. Set operations can be performed only between sets belonging to the same table.

Sets are independent from the data. This means that after changes are made to a file, a set may no longer be accurate. There are many operations that can cause a set to be inaccurate. For example, if you create a set of all the people from New York City, and then change the data in one of those records to "Boston" the set would not change, because the set is just a representation of a selection of records. Deleting records and replacing them with new ones also changes a set, as well as compacting the data. Sets can be guaranteed to be accurate only as long as the data in the original selection has not been changed.

## Process and Interprocess Sets

You can have the following three types of sets:

- **Process sets**: A process set can only be accessed by the process in which it has been created. **LockedSet** is a process set. Process sets are cleared as soon as the process method ends. Process sets do not need any special prefix in the name.
- **Interprocess sets**: A set is an interprocess set if the name of the set is preceded by the symbols (<>) — a "less than" sign followed by a "greater than" sign. **Note**: This syntax can be used on both Windows and Macintosh. Also, on Macintosh only, you can use the diamond (Option-Shift-V on a US keyboard).
  An interprocess set is "visible" to all the processes of the database.
  In client/server mode, an interprocess set is "visible" to processes of the machine where it was created (client or server).
  The name of an interprocess set must be unique in the database.
- **Local Sets/Client Sets**: Local/client sets are intended for use in client/server mode. The name of a local/client set is always preceded by the dollar sign ($) -- except for the **UserSet** system set. Unlike other types of sets, a local/client set is stored on the client machine.

**Notes:**

- The maximum size of a set name is 255 characters (excluding <> and $ symbols).
- For more information about the use of sets in client/server mode, please refer to **4D Server, Sets and Named Selections** of the 4D Server Reference Manual.

## Visibility of Sets

The following table indicates the principles concerning the visibility of sets depending on their scope and where they were created:

| | Client Process | Other client processes | Other clients | Server process | Other server processes |
|---|---|---|---|---|---|
| **Creation in a client process** | | | | | |
| $test | x | | | | |
| test | x | | | x (Trigger) | |
| <>test | x | x | | | |
| **Creation in a server process** | | | | | |
| $test | | | | x | |
| test | | | | x | |
| <>test | | | | x | x |

## Sets and Transactions

A set can be created inside a transaction. It is possible to create a set of the records created inside a transaction and a set of records created or modified outside of a transaction. When the transaction ends, the set created during the transaction should be cleared, because it may not be an accurate representation of the records, especially if the transaction was canceled.

## Set Example

The following example deletes duplicate records from a table which contains information about people. A *For...End for* loop moves through all the records, comparing the current record to the previous record. If the name, address, and zip code are the same, then the record is added to a set. At the end of the loop, the set is made the current selection and the (old) current selection is deleted:

```
CREATE EMPTY SET([People];"Duplicates")
  ` Create an empty set for duplicate records
ALL RECORDS([People])
  ` Select all records
  ` Sort the records by ZIP, address, and name so
  ` that the duplicates will be next to each other
ORDER BY([People];[People]ZIP;>;[People]Address;>;[People]Name;>)
  ` Initialize variables that hold the fields from the previous record
$Name:=[People]Name
$Address:=[People]Address
```

```
$ZIP:=[People]ZIP
 ` Go to second record to compare with first
NEXT RECORD([People])
For($i;2;Records in table([People]))
 ` Loop through records starting at 2
 ` If the name, address, and ZIP are the same as the
 ` previous record then it is a duplicate record.
   If(([People]Name=$Name) & ([People]Address=$Address) & ([People]ZIP=$ZIP))
 ` Add current record (the duplicate) to set
      ADD TO SET([People];"Duplicates")
   Else
 ` Save this record's name, address, and ZIP for comparison with the next record
      $Name:=[People]Name
      $Address:=[People]Address
      $ZIP:=[People]ZIP
   End if
 ` Move to the next record
   NEXT RECORD([People])
End for
 ` Use duplicate records that were found
USE SET("Duplicates")
 ` Delete the duplicate records
DELETE SELECTION([People])
 ` Remove the set from memory
CLEAR SET("Duplicates")
```

As an alternative to immediately deleting records at the end of the method, you could display them on screen or print them, so that a more detailed comparison can be made.

## The UserSet System Set

4D maintains a system set named *UserSet*, which automatically stores the most recent selection of records highlighted on screen by the user. Thus, you can display a group of records with **MODIFY SELECTION** or **DISPLAY SELECTION**, ask the user to select from among them and turn the results of that manual selection into a selection or into a set that you name.

**4D Server**: Although its name does not begin with the character "$", the *UserSet* system set is a client set. So, when using **INTERSECTION**, **UNION** and **DIFFERENCE**, make sure you compare *UserSet* only to client sets. For more information, please refer to the descriptions of these commands as well as to the **4D Server, Sets and Named Selections** section of the 4D Server Reference Manual.

There is only one *UserSet* for a process. Each table does not have its own *UserSet*. *UserSet* becomes “owned” by a table when a selection of records is displayed for the table.

4D manages the *UserSet* set for list forms displayed in Design mode or using the **MODIFY SELECTION** or **DISPLAY SELECTION** commands. However, this mechanism is not active for subforms.

The following method illustrates how you can display records, allow the user to select some of them, and then use *UserSet* to display the selected records:

```
 ` Display all records and allow user to select any number of them.
 ` Then display this selection by using UserSet to change the current selection.
FORM SET OUTPUT([People];"Display") ` Set the output layout
ALL RECORDS([People]) ` Select all people
ALERT("Press Ctrl or Command and Click to select the people required.")
DISPLAY SELECTION([People]) ` Display the people
USE SET("UserSet") ` Use the people that were selected
ALERT("You chose the following people.")
DISPLAY SELECTION([People]) ` Display the selected people
```

## The LockedSet System Set

The **APPLY TO SELECTION**, **DELETE SELECTION**, **ARRAY TO SELECTION** and **JSON TO SELECTION** commands create a set named **LockedSet** when used in a multi-processing environment.
Query commands also create a *LockedSet* system set when they find locked records in the 'query and lock' context (see the **SET QUERY AND LOCK** command).
*LockedSet* indicates which records were locked during the execution of the command.

# ADD TO SET

ADD TO SET ( {aTable ;} set )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Current record's table, or Default table, if omitted |
| set | String | ⇒ | Name of the set to which to add the current record |

## Description

**ADD TO SET** adds the current record of *aTable* to *set*. The set must already exist; if it does not, an error occurs. If a current record does not exist for *aTable*, **ADD TO SET** has no effect.

# CLEAR SET

CLEAR SET ( set )

| Parameter | Type | | Description |
|---|---|---|---|
| set | String | ⇒ | Name of the set to clear from memory |

## Description

**CLEAR SET** clears *set* from memory and frees the memory used by *set*. The command does not affect tables, selections, or records. To save a set before clearing it, use the **SAVE SET** command. Since sets use memory, it is good practice to clear them when they are no longer needed.

## Example

See the example for **USE SET**.

# COPY SET

COPY SET ( srcSet ; dstSet )

| Parameter | Type | | Description |
|---|---|---|---|
| srcSet | String | ⇨ | Source set name |
| dstSet | String | ⇨ | Destination set name |

## Description

The **COPY SET** command copies the contents of the set *srcSet* into the set *dstSet*.

Each of these sets can be of the process, interprocess or local/client type. The two sets do not have to be the same type (as shown in the examples below), so long as they are both visible on the machine. For more information about this point, refer to "**Visibility of Sets**".

## Example 1

The following example, in Client/Server, copies the local set "*$SetA",* maintained on the client machine, to the process set *"SetB",* maintained on the server machine:

```
COPY SET("$SetA";"SetB")
```

## Example 2

The following example, in Client/Server, copies the process set "*SetA*", maintained on the server machine, to the local process set *"$SetB",* maintained on the client machine:

```
COPY SET("SetA";"$SetB")
```

# CREATE EMPTY SET

CREATE EMPTY SET ( {aTable ;} set )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to create an empty set, or Default table, if omitted |
| set | String | ⇒ | Name of the new empty set |

## Description

**CREATE EMPTY SET** creates a new empty set, *set*, for *aTable*. You can add records to this set with the **ADD TO SET** command. If a set with the same name already exists, the existing set is cleared by the new set.

**Note:** You do not need to use **CREATE EMPTY SET** before using **CREATE SET**.

## Example

Please refer to the examples of the **Sets** section.

# CREATE SET

CREATE SET ( {aTable ;} set )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to create a set from the selection, or Default table, if omitted |
| set | String | ⇒ | Name of the new set |

## Description

**CREATE SET** creates a new set, *set*, for *aTable*, and places the current selection in *set*. The current record pointer for the table is saved with *set*. If *set* is used with **USE SET**, the current selection and current record are restored. As with all sets, there is no sorted order; when *set* is used, the default order is used. If a set with the same name already exists, the existing set is cleared by the new set.

## Example

The following example creates a set after doing a search, in order to save the set to disk:

```
QUERY([People]) ` Let the user do a search
CREATE SET([People];"SearchSet") ` Create a new set
SAVE SET("SearchSet";"MySearch") ` Save the set on disk
```

# CREATE SET FROM ARRAY

CREATE SET FROM ARRAY ( aTable ; recordsArray {; setName} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table of the set |
| recordsArray | Longint, Boolean array | ⇒ | Array of record numbers, or Array of booleans (True = the record is in the set, False = the record is not in the set) |
| setName | String | ⇒ | Name of the set to create, or Apply the command to the Userset if omitted |

## Description

The **CREATE SET FROM ARRAY** command creates *setName* from:

- Either an array of absolute record numbers *recordsArray* from *aTable*,
- Or an array of booleans *recordsArray*. In this case, the values of the array indicate if each record in the table belongs (**True**) or not (**False**) to *setName*.

When you use this command and pass a Longint array in *recordsArray*, all the numbers in the array represent the list of record numbers that are in *setName*. If a number is invalid (for example, if a record has not been created), the error -10503 is generated.

When you use this command and pass a Boolean array in *recordsArray*, the Nth element of the array indicates whether the "Nth" record is contained (**True**) or not (**False**) in *setName*. Usually, the number of elements in the array must equal the number of records in the table. If the array is smaller than the number of records, only the records defined by the array will be in the set.

**Note:** With a Boolean array, this command uses the elements from 0 to N-1.

If you do not pass the *setName* parameter or if you pass an empty string, the command will be applied to the *Userset* system set.

## Error management

In a Longint array, if a record number is invalid (record not created), the error -10503 is generated.

# DIFFERENCE

DIFFERENCE ( set1 ; set2 ; resultSet )

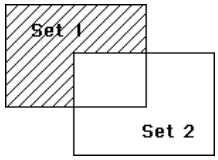
| Parameter | Type | | Description |
|---|---|---|---|
| set1 | String | ⇒ | Set |
| set2 | String | ⇒ | Set to subtract |
| resultSet | String | ⇒ | Resulting set |

## Description

**DIFFERENCE** compares *set1* and *set2* and excludes all records that are in *set2* from the *resultSet*. In other words, a record is included in the *resultSet* only if it is in *set1*, but not in *set2*. The following table shows all possible results of a set Difference operation.

| Set1 | Set2 | Result Set |
|---|---|---|
| Yes | No | Yes |
| Yes | Yes | No |
| No | Yes | No |
| No | No | No |

The result of a Difference operation is depicted here. The shaded area is the result set.



The *resultSet* is created by **DIFFERENCE**. The *resultSet* replaces any existing set having the same name, including *set1* and *set2*. Both *set1* and *set2* must be from the same table. The *resultSet* belongs to the same table as *set1* and *set2*.

**4D Server:** In Client/Server mode, sets are "visible" depending on their type (interprocess, process and local) and where they were created (server or client). **DIFFERENCE** requires all three sets to be visible on the same machine. See the paragraph **4D Server, Sets and Named Selections** in the 4D Server Reference manual for more information.

## Example

This example excludes the records that a user selects from a displayed selection. The records are displayed on screen with the following line:

```
DISPLAY SELECTION([Customers]) //Display the customers in a list
```

At the bottom of the list of records is a button with an object method. The object method excludes the records that the user has selected (the set named “UserSet”), and displays the reduced selection:

```
CREATE SET([Customers];"$Current") //Create a set of current selection
DIFFERENCE("$Current";"UserSet";"$Current") //Exclude selected records
USE SET("$Current") //Use the new set
CLEAR SET("$Current") //Clear the set
```

# INTERSECTION

INTERSECTION ( set1 ; set2 ; resultSet )

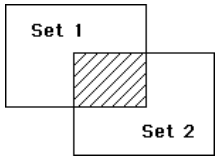
| Parameter | Type | | Description |
|---|---|---|---|
| set1 | String | ⇒ | First set |
| set2 | String | ⇒ | Second set |
| resultSet | String | ⇒ | Resulting set |

## Description

**INTERSECTION** compares *set1* and *set2* and selects only the records that are in both. The following table lists all possible results of a set Intersection operation.

| Set1 | Set2 | Result Set |
|---|---|---|
| Yes | No | No |
| Yes | Yes | Yes |
| No | Yes | No |
| No | No | No |

The graphical result of an Intersection operation is displayed here. The shaded area is the result set.



The *resultSet* is created by **INTERSECTION**. The *resultSet* replaces any existing set having the same name, including *set1* and *set2*. Both *set1* and *set2* must be from the same table. The *resultSet* belongs to the same table as *set1* and *set2*. If the same current record is set in both *set1* and *set2*, it remains memorized in the *resultSet*. Otherwise, *resultSet* does not have a current record.

**4D Server:** In Client/Server mode, sets are "visible" depending on their type (interprocess, process and local) and where they were created (server or client). **INTERSECTION** requires all three sets to be visible on the same machine. See the **4D Server, Sets and Named Selections** section in the 4D Server Reference manual for more information.

## Example

The following example finds the customers who are served by two sales representatives, Joe and Abby. Each sales representative has a set that represents his or her customers. The customers that are in both sets are represented by both Joe and Abby:

```
INTERSECTION("Joe";"Abby";"Both") ` Put customers in both sets in Both
USE SET("Both") ` Use the set
CLEAR SET("Both") ` Clear this set but save the others
DISPLAY SELECTION([Customers]) ` Display customers served by both
```

# Is in set

Is in set ( set ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| set | String | ⇒ | Name of the set to test |
| Function result | Boolean | ⇐ | Current record of set's table is in set (True) or Current record of set's table is not in set (False) |

## Description

**Is in set** tests whether or not the current record for the table is in *set*. The **Is in set** function returns TRUE if the current record of the table is in *set*, and returns FALSE if the current record of the table is not in *set*.

## Example

The following example is a button object method. It tests to see whether or not the currently displayed record is in the set of best customers:

```
If(Is in set("Best")) ` Check if it is a good customer
   ALERT("They are one of our best customers.")
Else
   ALERT("They are not one of our best customers.")
End if
```

# LOAD SET

LOAD SET ( {aTable ;} set ; document )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to which the set belongs, or Default table, if omitted |
| set | String | ⇒ | Name of the set to be created in memory |
| document | String | ⇒ | Document holding the set |

## Description

**LOAD SET** loads a set from *document* that was saved with the **SAVE SET** command.

The set that is stored in *document* must be from *aTable*. The set created in memory is overwritten if it already exists.

The *document* parameter is the name of the disk document containing the set. The document need not have the same name as the set. If you supply an empty string for *document*, an Open File dialog box appears so that the user can choose the set to load.

Remember that a set is a representation of a selection of records at the moment that the set is created. If the records represented by the set change, the set may no longer be accurate. Therefore, a set loaded from disk should represent a group of records that does not change frequently. A number of things can make a set invalid: modifying a record of the set, deleting a record of the set, or changing the criteria that determined a set.

## Example

The following example uses **LOAD SET** to load a set of the Acme locations in New York:

```
LOAD SET([Companies];"NY Acme";"NYAcmeSt") ` Load the set into memory
USE SET("NY Acme") ` Change current selection to NY Acme
CLEAR SET("NY Acme") ` Clear the set from memory
```

## System variables and sets

If the user clicks Cancel in the Open File dialog box, or there is an error during the load operation, the OK system variable is set to 0. Otherwise, it is set to 1.

# Records in set

Records in set ( set ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| set | String | ⇒ | Name of the set to test |
| Function result | Longint | ⇐ | Number of records in set |

## Description

**Records in set** returns the number of records in *set*. If *set* does not exist, or if there are no records in *set*, the command returns 0.

## Example

The following example displays an alert telling what percentage of the customers are rated as the best:

```
  ` First calculate the percentage
$Percent :=(Records in set("Best")/Records in table([Customers]))*100
  ` Display an alert with the percentage
ALERT(String($Percent;"##0%")+" of our customers are the best.")
```

# REMOVE FROM SET

REMOVE FROM SET ( {aTable ;} set )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Current record's table, or Default table, if omitted |
| set | String | ⇒ | Name of the set from which to remove the current record |

## Description

**REMOVE FROM SET** removes the current record of *aTable* from *set*. The set must already exist; if it does not, an error occurs. If a current record does not exist for *aTable*, the command has no effect.

# SAVE SET

SAVE SET ( set ; document )

| Parameter | Type | | Description |
|---|---|---|---|
| set | String | ⇒ | Name of the set to save |
| document | String | ⇒ | Name of the disk file to which to save the set |

## Description

**SAVE SET** saves *set* to *document*, a document on disk.

The *document* does not need to have the same name as the set. If you supply an empty string for *document*, a Create File dialog box appears so that the user can enter the name of the document. You can load a saved set with the **LOAD SET** command.

If the user clicks Cancel in the Save File dialog box, or if there is an error during the save operation, the OK system variable is set to 0. Otherwise, it is set to 1.

**SAVE SET** is often used to save to disk the results of a time-consuming search.

**WARNING:** Remember that a set is a representation of a selection of records at the moment that the set is created. If the records represented by the set change, the set may no longer be accurate. Therefore, a set saved to disk should represent a group of records that does not change frequently. A number of things can make a set invalid: modifying a record of the set, deleting a record of the set, or changing the criteria that determined the set. Also remember that sets do not save field values.

## Example

The following example displays the Save File dialog box, which the user can enter the name of the document that contains the set:

```
SAVE SET("SomeSet";"")
```

## System variables and sets

If the user clicks Cancel in the Save File dialog box, or if there is an error during the load operation, the OK system variable is set to 0. Otherwise, it is set to 1.

# UNION

UNION ( set1 ; set2 ; resultSet )

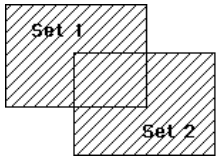
| Parameter | Type | | Description |
|---|---|---|---|
| set1 | String | ➡ | First set |
| set2 | String | ➡ | Second set |
| resultSet | String | ➡ | Resulting set |

## Description

**UNION** creates a set that contains all records from *set1* and *set2*. The following table shows all possible results of a set Union operation.

| Set1 | Set2 | Result Set |
|---|---|---|
| Yes | No | Yes |
| Yes | Yes | Yes |
| No | Yes | Yes |
| No | No | No |

The result of a Union operation is depicted here. The shaded area is the result set.



The *resultSet* is created by **UNION**. The *resultSet* replaces any existing set having the same name, including *set1* and *set2*. Both *set1* and *set2* must be from the same table. The *resultSet* belongs to the same table as *set1* and *set2*. The current record for the *resultSet* is the current record from *Set1*.

**4D Server:** In Client/Server mode, sets are "visible" depending on their type (interprocess, process and local) and where they were created (server or client). **UNION** requires that all three sets be visible on the same machine. See the paragraph **4D Server, Sets and Named Selections** in the 4D Server Reference manual for more information.

## Example

This example adds records to a set of best customers. The records are displayed on screen with the first line. After the records are displayed, a set of the best customers is loaded from disk, and any records that the user selected (the set named “UserSet”) are added to the set. Finally, the new set is saved on disk:

```
ALL RECORDS([Customers]) ` Select all the customers
DISPLAY SELECTION([Customers]) ` Display all the customers in a list
LOAD SET("$Best";"$SaveBest") ` Load the set of best customers
UNION("$Best";"UserSet";"$Best") ` Add any selected to the set
SAVE SET("$Best";"$SaveBest") ` Save the set of best customers
```

# USE SET

USE SET ( set )

| Parameter | Type | | Description |
|---|---|---|---|
| set | String | ➡ | Name of the set to use |

## Description

**USE SET** makes the records in *set* the current selection for the table to which the set belongs.

When you create a set, the current record is "remembered" by the set. **USE SET** retrieves the position of this record and makes it the new current record. If you delete this record before you execute **USE SET**, 4D selects the first record in the set as the current record. The set commands **UNION**, **INTERSECTION**, **DIFFERENCE** and **ADD TO SET** reset the current record. Also, if you create a set that does not contain the position of the current record, **USE SET** selects the first record in the set as the current record.

**WARNING:** Remember that a set is a representation of a selection of records at the moment that the set is created. If the records represented by the set do change, the set may no longer be accurate. Therefore, a set saved to disk should represent a group of records that does not change frequently. A number of things can invalidate a set invalid: modifying a record of the set, deleting a record of the set, or changing the criteria that determined the set.

## Example

The following example uses **LOAD SET** to load a set of the Acme locations in New York. It then uses **USE SET** to make the loaded set the current selection:

```
LOAD SET([Companies];"NY Acme";"NYAcmeSt") ` Load the set into memory
USE SET("NY Acme") ` Change current selection to NY Acme
CLEAR SET("NY Acme") ` Clear the set from memory
```

# Spell Checker

- Support of Hunspell dictionaries
- SPELL ADD TO USER DICTIONARY
- SPELL CHECK TEXT
- SPELL CHECKING
- SPELL Get current dictionary
- SPELL GET DICTIONARY LIST
- SPELL SET CURRENT DICTIONARY

## Support of Hunspell dictionaries

---

Beginning with versions 12.4 and 13, 4D supports OpenSource "Hunspell" dictionaries. For more information about these dictionaries, refer to the following site: http://hunspell.sourceforge.net/

4D uses the same format as MySpell and OpenOffice 2.x: an .aff file and a .dic file with the same name. For example, the "fr-modern" dictionary consists of the *fr-modern.aff* and *fr-modern.dic* files.

To be able to use a Hunspell dictionary in your 4D application, you must install its .aff and .dic files at one of the following locations:

- in the 4D application: <4D>/Resources/Spellcheck/Hunspell/
- in the 4D database: <Database_Files>/Resources/Hunspell

Both locations are compatible: the database folder is parsed first, then it is completed by the one in the 4D application, which means that you can encapsulate specialized dictionaries with your 4D databases. If two dictionaries with the same name are present in both locations, it is the one in the database that is taken into account.

You can download Hunspell dictionaries here: http://wiki.services.openoffice.org/wiki/Dictionaries

Users can also add existing dictionaries or create new ones. The process for creating these dictionaries is the same as that for Cordial user dictionaries (see **Appendix D: Use of specialized dictionaries** of the *Design Reference* manual). User dictionaries are stored in UTF-8 format.

# SPELL ADD TO USER DICTIONARY

SPELL ADD TO USER DICTIONARY ( words )

| Parameter | Type | | Description |
|---|---|---|---|
| words | Text, Text array | ⇒ | Word or list of words to add to user dictionary |

## Description

The **SPELL ADD TO USER DICTIONARY** command adds one or more words to the current user dictionary.

A user dictionary is a dictionary containing words added by the user to the current dictionary. This dictionary is a file named *UserDictionaryxxx.dic* (where xxx represents the ID of the current dictionary) that is created automatically in the current 4D folder. There is a user dictionary for each current dictionary used.

In *words*, pass a text string or a text array containing the word(s) to be added to the user dictionary. If one of the words is already found in the dictionary, it is ignored by the command.

## Example

Adding proper nouns to the user dictionary:

```
ARRAY TEXT($arrTwords;0)
APPEND TO ARRAY($arrTwords;"4D")
APPEND TO ARRAY($arrTwords;"Wakanda")
APPEND TO ARRAY($arrTwords;"Clichy")
SPELL ADD TO USER DICTIONARY($arrTwords)
```

# SPELL CHECK TEXT

SPELL CHECK TEXT ( text ; errPos ; errLength ; checkPos ; arrSuggest )

| Parameter | Type | | Description |
|---|---|---|---|
| text | Text | ➡ | Text to check |
| errPos | Longint | ⬅ | Position of first character of unknown word |
| errLength | Longint | ⬅ | Length of unknown word |
| checkPos | Longint | ➡ | Start position for check |
| arrSuggest | Text array | ⬅ | List of suggestions |

## Description

The **SPELL CHECK TEXT** command checks the contents of the *text* parameter beginning from the *checkPos* character and returns the position of the first unknown word it finds (if any).

This command returns the position of the first character of this unknown word in *errPos* and its length in *errLength*. The *arrSuggest* array receives the correction suggestion(s) proposed by the spell checker.

If the check starts without error and an unknown word is found, the OK system variable is set to 0. If an initialization error occurs during the check, or if no unknown words are found, OK is set to 1.

**Note OS X:** Under OS X, when the native spell checker is enabled, this command does not support grammar correction.

## Example

We want to count the number of possible errors in a text:

```
$pos:=1
$errCount:=0
ARRAY TEXT($tErrors;0)
ARRAY TEXT($tSuggestions;0)
Repeat
   SPELL CHECK TEXT($myText;$errPos;$errLength;$pos;$tSuggestions)
   If(OK=0)
      $errCount:=$errCount+1 // count any errors
      $errorWord:=Substring($myText;$errPos;$errLength)
      APPEND TO ARRAY($errors;$errorWord) // array of errors
      $pos:=$errPos+$errLength  //continue check
   End if
Until(OK=1)
 // In the end $errCount=Size of array($errorWord)
```

# SPELL CHECKING

SPELL CHECKING
Does not require any parameters

## Description

The **SPELL CHECKING** command triggers the spell check of the field or variable having the focus in the currently displayed form. The object checked must be of the string or text type.

**Note:** If you want to trigger the spellcheck by clicking a button in the form, make sure that this button does not have the "Focusable" property set.

Spell checking starts with the first word of the field or variable. If an unknown word is detected, the spell check dialog box appears (for more information, refer to the Design Reference manual of 4D). 4D uses the current dictionary (corresponding to the language of the application) unless you have used the **SPELL SET CURRENT DICTIONARY** command.

**Warning:** The **SPELL CHECKING** command affects the text that is being entered in the form, and not the associated data source (field or variable). This means that if you call this command from the On Data Change or On Losing Focus form events (not recommended), it will not affect the stored text since 4D has already assigned the entered text to the data source at this point. In this case, you need to assign the edited result to the data source yourself, using the **Get edited text** command. For example:

```
If(Form event=On Data Change)
   SPELL CHECKING
   theVariable:=Get edited text
End if
```

# SPELL Get current dictionary

SPELL Get current dictionary -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | ID of dictionary used for spell check |

## Description

The **SPELL Get current dictionary** command returns the ID number of the dictionary being used.

## Example

We want to display the language of the current dictionary:

```
 // List of loaded dictionaries
SPELL GET DICTIONARY LIST($IDs_al;$Codes_at;$Names_at)
$curLangCode:=SPELL Get current dictionary
$countryName:=$Names_at{Find in array($IDs_al;$curLangCode)}
 // Display message
ALERT("Current dictionary: "+$countryName) // Spanish
```

# SPELL GET DICTIONARY LIST

SPELL GET DICTIONARY LIST ( langID ; langFiles ; langNames )

| Parameter | Type | | Description |
|---|---|---|---|
| langID | Longint array | ⇦ | Unique ID of languages |
| langFiles | Text array | ⇦ | Names of language files installed |
| langNames | Text array | ⇦ | Local names of languages |

## Description

The **SPELL GET DICTIONARY LIST** command returns, in the *langID*, *langFiles* and *langNames* arrays, the IDs, file names and language names corresponding to the Hunspell dictionary files installed on the machine.

**Note:** For more information about Hunspell dictionaries, refer to the **Support of Hunspell dictionaries** section.

- *langID* receives the ID numbers generated automatically and used with the **SPELL SET CURRENT DICTIONARY** command.
  Note that the IDs are unique and based on the file names. This command is mainly useful during development; you do not have to regenerate the IDs each time the database is executed.
- *langFiles* receives the names of the dictionary files (without extensions) installed on the machine.
- *langNames* receives the names of the languages expressed in the current application language. For example, for a French dictionary, the value "français (France)" is returned on a machine configured in French and "French (France)" on an English system. The language name is followed by "- Hunspell". This field is only valid for files "known" by 4D. For unknown files (for example, custom files), the name "N/A - Hunspell" is returned. This does not prevent you from using the dictionary (if the file concerned is valid), the ID returned may be passed to the **SPELL SET CURRENT DICTIONARY** command.

## Example

You put "fr-classic+reform1990.aff" and "fr-classic+reform1990.dic" as well as "fr-dentist.aff" and "fr-dentist.dic" into the Hunspell directory:

```
ARRAY LONGINT($langID;0)
ARRAY TEXT($dicName;0)
ARRAY TEXT($langDesc;0)
SPELL GET DICTIONARY LIST($langID;$dictName;$langDesc)
```

| $langID | $dictName | $langDesc |
|---|---|---|
| 65536 | en_GB | English (UK) |
| 65792 | en_US | English (USA) |
| 131072 | de_DE | German (Germany) |
| 196608 | es_ES | Spanish |
| 262144 | fr_FR | French (France) |
| 589824 | nb_NO | Norwegian Bokmal (Norway) |
| 1074036166 | fr-classic+reform1990 | French (France) - Hunspell |
| 1073901273 | fr-dentist | No description - Hunspell |

# SPELL SET CURRENT DICTIONARY

SPELL SET CURRENT DICTIONARY ( dictionary )

| Parameter | Type | | Description |
|---|---|---|---|
| dictionary | Longint, Text | ⇒ | ID, Name, or Language code of dictionary to use for spell-check |

## Description

The **SPELL SET CURRENT DICTIONARY** command causes the replacement of the current dictionary with the one specified by the *dictionary* parameter. The current dictionary is used for the built-in spell-check feature in 4D (for more information, refer to the 4D *Design Reference* manual) as well as the one in the 4D Write and 4D View plug-ins. The modification of the current dictionary is reflected immediately in all the processes of the database for the session, as well as in the 4D Write and 4D View plug-in areas.

By default, 4D uses:

- under Windows, the Hunspell dictionary corresponding to the application language,
- under OS X, the native spell checker.

**Note:** For more information about Hunspell dictionaries, refer to the **Support of Hunspell dictionaries** section.

You can use the *dictionary* parameter to change the dictionary. You can pass either:

- a Hunspell dictionary ID number (returned by the **SPELL GET DICTIONARY LIST** command),
- a Hunspell dictionary name (corresponding to the file name of the Hunspell dictionary, with or without its extension),
- a BCP 47, ISO 639-1 or ISO 639-2 language code. For example, with the BCP 47 language code "en-US" indicates American English and "en-GB" specifies British English. These codes are redirected internally to the corresponding current dictionary (Hunspell or native OS X).

**Compatibility note:** In previous versions of 4D, "Cordial" dictionaries were supported. For compatibility, it is still possible to pass a "Cordial" dictionary number in the *dictionary* parameter (value or constant from the "**Dictionaries**" theme). In this case, however, the dictionary is redirected internally to an equivalent Hunspell dictionary (or the native dictionary under OS X).

## System variables and sets

If the *dictionary* is loaded correctly, the system variable OK is set to 1; otherwise, it is set to 0 and an error is returned.

## Example

Loading of the "fr-classic" dictionary found in the Hunspell folder:

```
SPELL SET CURRENT DICTIONARY("fr-classic")
 // SPELL SET CURRENT DICTIONARY ("FR-classic.dic") is valid
```

# SQL

- Overview of SQL Commands
- On SQL Authentication Database Method
- Begin SQL
- End SQL
- Get current data source
- GET DATA SOURCE LIST
- Is field value Null
- QUERY BY SQL
- SET FIELD VALUE NULL

- SQL LOAD RECORD
- SQL LOGIN
- SQL LOGOUT
- SQL SET OPTION
- SQL SET PARAMETER
- START SQL SERVER
- STOP SQL SERVER
- *_o_USE EXTERNAL DATABASE*
- *_o_USE INTERNAL DATABASE*

# Overview of SQL Commands

4D includes an integrated SQL kernel. The program also includes an SQL server that other 4D applications or third-party applications can query (via the 4D ODBC driver).

The SQL documentation in 4D is built upon two main parts:

- The **4D SQL Reference Guide** (**4D SQL Reference**). This manual describes the different ways of accessing the 4D SQL kernel, the configuration of the SQL server as well as the commands and keywords that can be used in SQL queries (for example **SELECT** or **UPDATE**). Please refer to this manual for any question regarding SQL language implementation in 4D.
- The **SQL theme of the "Language" manual** (**SQL**). This theme groups together various 4D high-level commands concerning the use of SQL in 4D:
  - Control of the SQL server: **START SQL SERVER** and **STOP SQL SERVER**
  - Direct access to the integrated SQL kernel: **SET FIELD VALUE NULL**, **Is field value Null**, **QUERY BY SQL**
  - Management of connections to external or internal data sources (SQL pass-through): **GET DATA SOURCE LIST**, **Get current data source**, **SQL LOGIN**, **SQL LOGOUT**.
  - High-level commands for handling data in the framework of direct SQL connections or via ODBC: **Begin SQL**, **End SQL**, **SQL CANCEL LOAD**, **SQL LOAD RECORD**, **SQL EXECUTE**, **SQL End selection**, **SQL SET OPTION**, **SQL SET PARAMETER**, **SQL GET LAST ERROR**, **SQL GET OPTION**.

## How high-level SQL commands work

The built-in SQL commands of 4D begin with the prefix "SQL" and implement the following principles:

- Unless indicated otherwise, you can use these commands with the 4D internal SQL kernel or in an external connection that is opened directly or via ODBC. The **SQL LOGIN** command lets you specify the type of connection to open.
- The scope of a connection is the process. If you want to manage several simultaneous connections, you must start a process by **SQL LOGIN**.
- You can intercept any ODBC errors generated during the execution of one of the high-level SQL commands using the **ON ERR CALL** command. The **SQL GET LAST ERROR** command can be used in this case to obtain additional information.

## Support of standard ODBC

The ODBC (Open DataBase Connectivity) standard specifies a library of standardized functions. These functions allow an application such as 4D to access any ODBC-compatible data management system (databases, spreadsheets, another 4D application, etc.) via SQL language.

**Note:** 4D also allows data to be imported from and exported to an ODBC source via the **IMPORT ODBC** and **EXPORT ODBC** commands or "manually" in Design mode. For more information, please refer to the 4D *Design Reference* manual.

Note: The high-level SQL commands of 4D can be used to implement simple solutions allowing 4D applications to communicate with ODBC data sources. If your applications require more extensive support of ODBC standards, you will need to have the “low level” ODBC plug-in for 4D, **4D ODBC Pro**.

## Correspondence of data types

The following table lists the correspondences that are automatically established by 4D between 4D and SQL data types:

| 4D Type | SQL Type |
|---|---|
| C_STRING | SQL_C_CHAR |
| C_TEXT | SQL_C_CHAR |
| C_REAL | SQL_C_DOUBLE |
| C_DATE | SQL_C_TYPE_DATE |
| C_TIME | SQL_C_TYPE_TIME |
| C_BOOLEAN | SQL_C_BIT |
| C_INTEGER | SQL_C_SHORT |
| C_LONGINT | SQL_C_SLONG |
| C_BLOB | SQL_C_BINARY |
| C_PICTURE | SQL_C_BINARY |
| C_GRAPH | SQL_C_BINARY |

**Note:** Object type data (**C_OBJECT**) is not supported by 4D's SQL kernel.

## Referencing 4D expressions in SQL requests

4D provides two ways for inserting 4D expressions (variables, arrays, fields, pointers, valid expressions) into SQL requests: direct association and the *setting* of parameters using **SQL SET PARAMETER**.

Direct association can be carried out in two ways:

- Insertion of the name of the 4D object between the **<<** and **>>** characters in the text of the request.
- Precede the reference with a colon ":".

```
SQL EXECUTE("INSERT INTO emp (empnum,ename) VALUES (<<vEmpnum>>,<<vEname>>)")
SQL EXECUTE("SELECT age FROM People WHERE name= :vName")
```

**Note:** In compiled mode, you cannot use references to local variables (beginning with the $ symbol).

In these examples, the current values of the 4D vEmpnum, vEname and vName variables will replace the parameters when the request is executed. This solution also works with 4D fields and arrays.

This easy-to-use syntax nevertheless has the drawback of not being compliant with the SQL standard and of not allowing the use of output parameters. To remedy this, you can use the **SQL SET PARAMETER** command. This command can be used to set each 4D object to be integrated into a request as well as its mode of use (input, output or both). The syntax produced is thus standard. For more information, please refer to the description of the **SQL SET PARAMETER** command.

1. This example executes an SQL query that directly uses the associated 4D arrays:

```
ARRAY TEXT(MyTextArray;10)
ARRAY LONGINT(MyLongintArray;10)

For(vCounter;1;Size of array(MyTextArray))
   MyTextArray{vCounter}:="Text"+String(vCounter)
   MyLongintArray{vCounter}:=vCounter
End for
SQL LOGIN("mysql";"root";"")
SQLStmt:="insert into app_testTable (alpha_field, longint_field) VALUES (<<MyTextArray>>, <<MyLongintArray>>)"
SQL EXECUTE(SQLStmt)
```

2. This example can be used to execute an SQL query that directly uses the associated 4D fields:

```
ALL RECORDS([Table 2])
SQL LOGIN("mysql";"root";"")
SQLStmt:="insert into app_testTable (alpha_field, longint_field) VALUES (<<[Table 2]Field1>"+">,<<[Table 2]Field2>>)"
SQL EXECUTE(SQLStmt)
```

3. This example lets you execute an SQL query by directly passing a variable via a dereferenced pointer:

```
C_LONGINT($vLong)
C_POINTER($vPointer)
$vLong:=1
$vPointer:=->$vLong
SQL LOGIN("mysql";"root";"")
```

```
SQLStmt:="SELECT Col1 FROM TEST WHERE Col1=:$vPointer"
SQL EXECUTE(SQLStmt)
```

### Use of local variables in compiled mode

In compiled mode, you can use local variable references (beginning with the $ character) in SQL statements under certain conditions:

- You can use local variables within a **Begin SQL** / **End SQL** sequence, except with the **EXECUTE IMMEDIATE** command;
- You can use local variables with the **SQL EXECUTE** command when these variables are used directly in the parameter of the SQL request and not through references.
  For example, the following code works in compiled mode:

  ```
  SQL EXECUTE("select * from t1 into :$myvar") // works in compiled mode
  ```

  The following code generates an error in compiled mode:

  ```
  C_TEXT(tRequest)
  tRequest:="select * from t1 into :$myvar"
  SQL EXECUTE(tRequest) // error in compiled mode
  ```

## Retrieving values in 4D

Retrieving values in the 4D language that result from SQL queries is carried out in two ways:

- Using the additional parameters of the **SQL EXECUTE** command (recommended solution).
- Using the INTO clause in the SQL query itself (solution reserved for special cases).

## Displaying the result of an SQL query in a list box

It is possible to place the results of an SQL query directly in an array type list box. This offers a rapid means for viewing the results of SQL queries. Only queries of the **SELECT** type can be used. This mechanism cannot be used with an external SQL database.

It works according to the following principles:

- Create the list box which will receive the query results. The data source of the list box must be **Arrays**.
- Execute an SQL query of the **SELECT** type and assign the result to the variable associated with the list box. You can use the **Begin SQL**/**End SQL** keywords (see the 4D *Language Reference* manual).
- List box columns can be sorted or modified by the user.
- Each new execution of a **SELECT** query with the list box leads to the resetting of the columns (it is not possible to fill the same list box progressively using several **SELECT** queries).
- It is recommended to give the list box the same number of columns as there will be in the SQL query result. If the number of list box columns is less than that required by the **SELECT** query, columns are added automatically. If the number of columns is more than required by the **SELECT** query, the unnecessary columns are automatically hidden.
  **Note:** The columns added automatically are bound to **Dynamic variables** of the array type. These dynamic arrays last as long as the form does. A dynamic variable is also created for each header. When the **LISTBOX GET ARRAYS** command is called, the *arrColVars* parameter contains pointers to the dynamic arrays and the *arrHeaderVars* parameter contains pointers to the dynamic header variables. If the added column is, for example, the fifth column, its name is *sql_column5* and its header name is *sql_header5*.
- In interpreted mode, existing arrays that are used by the list box can be retyped automatically according to the data sent by the SQL query.

**Example**

We want to retrieve all the fields of the PEOPLE table and put their contents into the list box having the variable name *vlistbox*. In the object method of a button (for example), simply write:

```
Begin SQL
   SELECT * FROM PEOPLE INTO <<vlistbox>>
End SQL
```

# On SQL Authentication Database Method

---

The **On SQL Authentication Database Method** can be used to filter requests sent to the integrated SQL server of 4D. This filtering can be based on the name and password as well as the (optional) IP address of the user. The developer can use their own table of users or that of the 4D users to evaluate the connection identifiers. Once the connection is authenticated, the **CHANGE CURRENT USER** command must be called in order to control access of requests within the 4D database.

When it exists, the **On SQL Authentication Database Method** is called automatically by 4D or 4D Server on each external connection to the SQL server. The internal system for managing 4D users is therefore not activated. The connection is only accepted if the database method returns **True** in $0 and if the **CHANGE CURRENT USER** command has been executed successfully. If one of these conditions is not met, the request is refused.

**Note**: The statement **SQL LOGIN**(**SQL_INTERNAL**;$user;$password) does not call the **On SQL Authentication Database Method** since it is an internal connection in this case.

The database method receives up to three parameters of the Text type, passed by 4D ($1, $2 and $3), and returns a Boolean, $0. Here is a description of these parameters:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | User name |
| $2 | Text | Password |
| $3 | Text | (optional) IP address of client at origin of the request(*) |
| $0 | Boolean | True = request accepted, False = request refused |

(*) 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

You must declare these parameters as follows:

```
  ` On Web Authentication database method

C_TEXT($1;$2;$3)
C_BOOLEAN($0)
  ` Code for method
```

The password ($2) is received as standard text.

You must check the identifiers of the SQL connection in the **On SQL Authentication Database Method**. For example, you can check the name and password using a custom table of users. If the identifiers are valid, pass **True** in $0 to accept the connection. Otherwise, pass **False** in $0; in this case, the connection is refused.

**Note:** If the **On SQL Authentication Database Method** does not exist, the connection is evaluated using the integrated user management system of 4D (if it is activated, in other words, if a password has been assigned to the Designer). If this system is not activated, users are connected with Designer access rights (free access).

If you have passed **True** in $0, you must then successfully call the **CHANGE CURRENT USER** command in the **On SQL Authentication Database Method** in order for the request to be accepted and for 4D to open an SQL session for the user.

The use of the **CHANGE CURRENT USER** command can be used to implement a virtual authentication system which has the double advantage of allowing the control of connection actions and of hiding the connection identifiers from the outside in the 4D SQL session.

This example of the **On SQL Authentication Database Method** checks whether the connection request comes from the internal network, validates the identifiers and then assigns access rights to the "sql_user" user for the SQL session.

```
C_TEXT($1;$2;$3)
C_BOOLEAN($0)
  `$1: user
  `$2: password
  `{$3: IP address of client}
ON ERR CALL("SQL_error")
If(checkInternalIP($3))
  `The checkInternalIP method checks whether the IP address is internal
   If($1="victor") & ($2="hugo")
      CHANGE CURRENT USER("sql_user";"")
```

```
      If(OK=1)
         $0:=True
      Else
         $0:=False
      End if
   Else
      $0:=False
   End if
Else
   $0:=False
End if
```

# Begin SQL

Begin SQL
Does not require any parameters

## Description

**Begin SQL** is a keyword used in the Method editor to indicate the beginning of a sequence of SQL commands that must be interpreted by the current data source of the process (the integrated SQL engine of 4D or any source specified via the **SQL LOGIN** command).

A sequence of SQL commands started with **Begin SQL** must be closed with the **Begin SQL** keyword.

These keywords work as follows:

- You can place one or more blocks of **Begin SQL/End SQL** tags in the same method. You can generate methods made up entirely of SQL code or mix 4D code and SQL code in the same method.
- You can write several SQL statements on the same line or on different lines by separating them with a semi-colon ";". For example, you can write:

```
Begin SQL
   INSERT INTO SALESREPS (NAME, AGE) VALUES (Henry,40);
   INSERT INTO SALESREPS (NAME, AGE) VALUES (Bill,35)
End SQL
```

or:

```
Begin SQL
   INSERT INTO SALESREPS (NAME, AGE) VALUES (Henry,40);INSERT INTO SALESREPS (NAME, AGE) VALUES (Bill,35)
End SQL
```

Note that the 4D **Debugger** will evaluate the SQL code line by line. In certain cases, it may be preferable to use more than one line.

# End SQL

End SQL

Does not require any parameters

## Description

**End SQL** is a keyword indicating the end of a sequence of SQL commands in the Method editor.

A sequence of SQL statements must be enclosed with the **Begin SQL** and **End SQL** keywords. For more information, refer to the description of the **Begin SQL** keyword.

# Get current data source

Get current data source -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ➲ | Name of current data source being used |

## Description

The **Get current data source** command returns the name of the current data source of the application. The current data source receives the SQL queries executed within **Begin SQL/End SQL** structures.

When the current data source is the local 4D database, the command returns the string “;DB4D_SQL_LOCAL;”, which corresponds to the value of the SQL_INTERNAL constant ("**SQL**" theme).

This command lets you check the current data source, generally before executing an SQL query.

# GET DATA SOURCE LIST

GET DATA SOURCE LIST ( sourceType ; sourceNamesArr ; driversArr )

| Parameter | Type | | Description |
|---|---|---|---|
| sourceType | Longint | ➡ | Source type: user or system |
| sourceNamesArr | Text array | ⬅ | Array of data source names |
| driversArr | Text array | ⬅ | Array of drivers for sources |

## Description

The **GET DATA SOURCE LIST** command returns, in the *sourceNamesArr* and *driversArr* arrays, the names and drivers of the *sourceType* type data sources defined in the ODBC manager of the operating system.

4D allows you to connect to an external ODBC data source directly via the language and execute SQL queries within a **Begin SQL/End SQL** tag structure. This works as follows: the **GET DATA SOURCE LIST** command can be used to get a list of data sources present on the machine. The **SQL LOGIN** command can then be used to designate the source to be used. You can then execute SQL queries using a **Begin SQL/End SQL** tag structure in the "current" source. To carry out queries using the 4D internal engine again, simply pass the **SQL LOGOUT** command. For more information about SQL commands in the Method editor, please refer to the **4D SQL Reference** manual.

In *sourceType*, pass the type of data source that you want to retrieve. You can use one of the following constants, found in the "**SQL**" theme:

| Constant | Type | Value |
|---|---|---|
| System data source | Longint | 2 |
| User data source | Longint | 1 |

**Note:** This command does not take file type data sources into account.

The command fills and sizes the *sourceNamesArr* and *driversArr* arrays with the corresponding values.

**Note:** If you want to connect to an external 4D data source via ODBC, you will need to have installed the 4D ODBC Driver on your machine. For more information, please refer to the 4D ODBC Driver Installation manual.

## Example

Example using a user data source:

```
ARRAY TEXT(arrDSN;0)
ARRAY TEXT(arrDSNDrivers;0)
GET DATA SOURCE LIST(User data source;arrDSN;arrDSNDrivers)
```

## System variables and sets

If the command is executed correctly, the OK system variable is set to 1. Otherwise, it is set to 0 and an error is generated.

# Is field value Null

Is field value Null ( aField ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Field to be evaluated |
| Function result | Boolean | ⇐ | True = field is NULL, False = field is not NULL |

## Description

The **Is field value Null** command returns **True** if the field designated by the *aField* parameter contains the NULL value, and **False** otherwise.

The NULL value is used by the SQL kernel of 4D. For more information, refer to the **4D SQL Reference** manual.

The value returned by this command is only meaningful if the "" option is not checked in the field definition of the Structure editor. Otherwise, it always returns **False**.

# QUERY BY SQL

QUERY BY SQL ( {aTable ;} sqlFormula )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table in which to return a selection of records or Default table if this parameter is omitted |
| sqlFormula | String | ⇒ | Valid SQL search formula representing the WHERE clause of the SELECT query |

## Description

The **QUERY BY SQL** command can be used to take advantage of the SQL kernel integrated into 4D. It can execute a simple SELECT query that can be written as follows:

```
SELECT *
   FROM table
   WHERE <sqlFormula>
```

*aTable* is the name of the table passed in the first parameter and *sqlFormula* is the query string passed in the second parameter.

For example, the following statement:

```
([Employees];"name=' smith' ")
```

is equivalent to the following SQL query:

```
SELECT*FROM Employees WHERE"name=' smith' "
```

The **QUERY BY SQL** command is similar to the **QUERY BY FORMULA** command. It looks for records in the specified table. It changes the current selection of *aTable* for the current process and makes the first record of the new selection the current record.

**Note:** The **QUERY BY SQL** command cannot be used in the context of an external SQL connection; it connects directly to the integrated SQL engine of 4D.

**QUERY BY SQL** applies *sqlFormula* to each record in the table selection. *sqlFormula* is a Boolean expression that must return **True** or **False**. As you may know, in the SQL standard, a search condition can yield a **True**, **False** or NULL result. All the records (rows) where the search condition returns **True** are included in the new current selection.

The *sqlFormula* expression may be simple, such as comparing a field (column) to a value; or it may be complex, such as performing a calculation. Like **QUERY BY FORMULA**, **QUERY BY SQL** is able to evaluate information in related tables (see example 4). *sqlFormula* must be a valid SQL statement that is compliant with the SQL-2 standard and with respect to the limitations of the current SQL implementation of 4D. For more information about SQL support in 4D, refer to the **4D SQL Reference** manual.

The *sqlFormula* parameter can use references to 4D expressions. The syntax to use is the same as for the integrated SQL commands or the code included between the **Begin SQL**/**End SQL** tags, i.e.: *<<MyVar>>* or *:MyVar*.

**Note:** This command is compatible with the **SET QUERY LIMIT** and **SET QUERY DESTINATION** commands.

**Reminder:** You cannot have references to local variables in compiled mode. For more information about SQL programming in 4D, refer to the section **Overview of SQL Commands**.

### About Relations

**QUERY BY SQL** does not use relations between tables defined in the 4D Structure editor. If you want to make use of related data, you will have to add a JOIN to the query. For example, assuming we have the following structure with a Many-to-One relation from[Persons]City to [Cities]Name:

```
[People]
   Name
   City
[Cities]
   Name
   Population
```

Using the **QUERY BY FORMULA** command, you can write:

```
QUERY BY FORMULA([People];[Cities]Population>1000)
```

Using **QUERY BY SQL**, you must write the following statement, regardless of whether the relation exists:

```
QUERY BY SQL([People];"people.city=cities.name AND cities.population>1000")
```

**Note: QUERY BY SQL** handles One-to-Many and Many-to-Many relations differently than **QUERY BY FORMULA**.

## Example 1

This example shows the offices where sales exceed 100. The SQL query is:

```
SELECT *
   FROM Offices
   WHERE Sales > 100
```

When using the **QUERY BY SQL** command:

```
C_STRING(30;$queryFormula)
$queryFormula:="Sales > 100"
QUERY BY SQL([Offices];$queryFormula)
```

## Example 2

This example shows the orders that fall into the 3000 to 4000 range. The SQL query is:

```
SELECT *
   FROM Orders
   WHERE Amount BETWEEN 3000 AND 4000
```

When using the **QUERY BY SQL** command:

```
C_STRING(40;$queryFormula)
$queryFormula:="Amount BETWEEN 3000 AND 4000"
QUERY BY SQL([Orders];$queryFormula)
```

## Example 3

This example shows how to get the query result ordered by a specific criterion. The SQL query is:

```
SELECT *
   FROM People
   WHERE City =' Paris'
      ORDER BY Name
```

When using the **QUERY BY SQL** command:

```
C_STRING(40;$queryFormula)
$queryFormula:="City=  'Paris'  ORDER BY Name"
QUERY BY SQL([People];$queryFormula)
```

## Example 4

This example shows a query using related tables in 4D. In SQL you should use a JOIN to simulate this relation. Assuming we have the two following tables:

```
[Invoices] with the following columns (fields):
   ID_Inv: Longint
   Date_Inv: Date
   Amount: Real
```

```
[Lines_Invoices] with the following columns (fields):
   ID_Line: Longint
   ID_Inv: Longint
   Code: Alpha (10)
```

There is a Many-to-One relation from [Lines_Invoices]ID_Inv to [Invoices]ID_Inv.
Using the **QUERY BY FORMULA** command, you could write:

```
QUERY BY FORMULA([Lines_Invoices];([Lines_Invoices]Code="FX-200") & (Month of([Invoices]Date_Inv)=4))
```

The SQL query is:

```
SELECT ID_Line
   FROM Lines_Invoices, Invoices
   WHERE Lines_Invoices.ID_Inv=Invoices.ID_Inv
      AND Lines_Invoices.Code='FX-200'
      AND MONTH(Invoices.Date_Inv) = 4
```

When using the **QUERY BY SQL** command:

```
C_STRING(40;$queryFormula)
$queryFormula:="Lines_Invoices.ID_Inv=Invoices.ID_InvAND Lines_Invoices.Code=' FX-200'  AND MONTH(Invoices.Date_Inv)=4"
QUERY BY SQL([Lines_Invoices];$queryFormula)
```

## System variables and sets

If the format of the search condition is correct, the system variable OK is set to 1. Otherwise, it is set to 0, the result of the command is an empty selection and an error is returned. This error can be intercepted by a method installed using the **ON ERR CALL** command.

# SET FIELD VALUE NULL

SET FIELD VALUE NULL ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Field where NULL value is to be attributed |

## Description

The **SET FIELD VALUE NULL** command assigns the NULL value to the field designated by the *aField* parameter.

The NULL value is used by the SQL kernel of 4D. For more information, please refer to the 4D SQL Reference manual.

**Notes:**

- It is possible to disallow the Null value for 4D fields at the Structure editor level (see the Design Reference manual).
- **SET FIELD VALUE NULL** erases the contents of object fields.

# SQL CANCEL LOAD

SQL CANCEL LOAD
Does not require any parameters

## Description

The **SQL CANCEL LOAD** command ends the current SELECT request and initializes the parameters.
This command is used to execute several SELECT requests within the same connection (i.e. the same cursor) initiated by the **SQL LOGIN** command.

## Example

In this example, two requests are executed in the same connection:

```
C_BLOB(Myblob)
C_TEXT(MyText)
SQL LOGIN("mysql";"root";"")

SQLStmt:="SELECT blob_field FROM app_testTable"
SQL EXECUTE(SQLStmt;Myblob)
While(Not(SQL End selection))
   SQL LOAD RECORD
End while

 `Resetting of cursor
SQL CANCEL LOAD

SQLStmt:="SELECT Name FROM Employee"
SQL EXECUTE(SQLStmt;MyText)
While(Not(SQL End selection))
   SQL LOAD RECORD
End while
```

## System variables and sets

If the command has been correctly executed, the system variable OK returns 1. Otherwise, it returns 0.

# SQL End selection

SQL End selection -> Function result

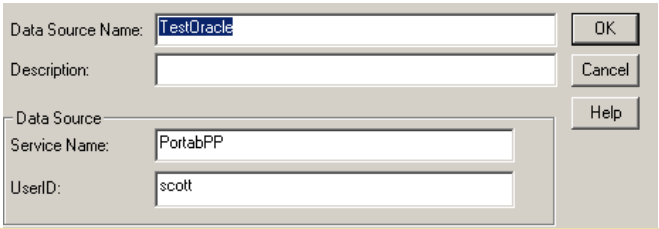
| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | Result set boundaries reached |

## Description

The **SQL End selection** command is used to determine if the boundaries of the result set have been reached.

## Example

The code below connects to an external data source (Oracle) using the following parameters:



```
C_TEXT(vName)

SQL LOGIN("TestOracle";"scott";"tiger")
If(OK=1)
   SQL EXECUTE("SELECT ename FROM emp";vName)
   While(Not(SQL End selection))
      SQL LOAD RECORD
   End while
   SQL LOGOUT
End if
```

This code will return in the 4D *vName* variable the emp names (ename) stored in the table named emp.

# SQL EXECUTE

SQL EXECUTE ( sqlStatement {; boundObj}{; boundObj2 ; ... ; boundObjN} )

| Parameter | Type | | Description |
|---|---|---|---|
| sqlStatement | Text | ⇒ | SQL command to execute |
| boundObj | Variable, Field | ⇐ | Receives result (if necessary) |

## Description

The **SQL EXECUTE** command executes an SQL command and binds the result to 4D objects (arrays, variables or fields).

A valid connection must be specified in the current process in order to execute this command.

The *sqlStatement* parameter contains the SQL command to execute. *boundObj* receives the results. Variables are bound in the column sequence order, which means that any remaining remote columns are discarded.

If 4D fields are passed as parameters in *boundObj*, the command will create records and save them automatically. 4D fields must come from the same table (a field from table 1 and a field from table 2 cannot be passed in the same call). If fields from more than one table are passed, an error is generated.

**Warning:** When you pass 4D fields in the *boundObj* parameter(s) and execute the **SELECT** command, it is always the data of the remote 4D source that is modified. If you want to retrieve data from the remote source locally, you must use intermediary local arrays and call the **INSERT** command (see example 6).

If you pass 4D arrays in the *boundObj* parameter(s), it is advisable to declare them before calling the command in order to check the type of data processed. Arrays are automatically resized when necessary.

With a 4D variable, one record is fetched at a time. The other results are ignored.

**Note:** For more information about referencing 4D expressions in SQL queries, refer to the **Overview of SQL Commands** section.

## Example 1

In this example, we will get the ename column of the emp table of the data source. The result is stored in the [Employee]Name 4D field. 4D records will be created automatically:

```
SQLStmt:="SELECT ename FROM emp"
SQL EXECUTE(SQLStmt;[Employee]Name)
SQL LOAD RECORD(SQL all records)
```

## Example 2

To check the creation of records, it is possible to include code within a transaction and to validate it only if the operation proves to be satisfactory:

```
SQL LOGIN("mysql";"root";"")
SQLStmt:="SELECT alpha_field FROM app_testTable"
START TRANSACTION
SQL EXECUTE(SQLStmt;[Table 2]Field1)
While(Not(SQL End selection))
   SQL LOAD RECORD
   ... //Place the data validation code here
End while
VALIDATE TRANSACTION //Validation of the transaction
```

## Example 3

In this example, we want to get the ename column of the emp table of the data source. The result will be stored in an *aName* array. We fetch records 10 at a time.

```
ARRAY STRING(30;aName;20)
SQLStmt:="SELECT ename FROM emp"
SQL EXECUTE(SQLStmt;aName)
While(Not(SQL End selection))
   SQL LOAD RECORD(10)
End while
```

## Example 4

In this example, we want to get the ename and job of the emp table for a specific ID (WHERE clause) of the data source. The result will be stored in the *vName* and *vJob* 4D variables. Only the first record is fetched.

```
SQLStmt:="SELECT ename, job FROM emp WHERE id = 3"
SQL EXECUTE(SQLStmt;vName;vJob)
SQL LOAD RECORD
```

## Example 5

In this example, we want to get the Blob_Field column of the Test table in the data source. The result will be stored in a BLOB variable whose value is updated each time a record is loaded.

```
C_BLOB(MyBlob)
SQL LOGIN
SQL EXECUTE("SELECT Blob_Field FROM Test";MyBlob)
While(Not(SQL End selection))
 //We look through the results
   SQL LOAD RECORD
 //The value of MyBlob is updated on each call
End while
```

## Example 6

You want to retrieve data locally from a remote 4D Server database where it is stored. To do this, you must use intermediary arrays:

```
 // Log in to the remote database
SQL LOGIN("IP:192.168.18.15:19812";"user";"password";*)
If(OK=1)
 // Starting from here all SQL requests are made on the remote database
   C_TEXT($LastName_value) // 4D variable used in the search statement
   ARRAY TEXT($a_LastName;0) // Temporary storage of remote values for LastName
   ARRAY TEXT($a_FirstName;0) // Temporary storage of remote values for FirstName
   C_BOOLEAN($UseSQL) //Choice of means for local storage of data from the remote database
 // (demo only)

   $LastName_value:="Smith" // Initialization of 4D variable

 // Associate the 4D $LastName_value variable with the first "?" in the SQL request
   SQL SET PARAMETER($LastName_value;SQL param in)

 // From the remote PERSONS table, retrieve the values of the LastName and FirstName fields
 // where "LastName = Smith" and store them in the $a_LastName and $a_FirstName arrays
   SQL EXECUTE("SELECT LastName, FirstName FROM PERSONS WHERE LastName = ?";$a_LastName;$a_FirstName)
   If(Not(SQL End selection)) // If at least one record is found

      SQL LOAD RECORD(SQL all records) // Load all the records

      $UseSQL:=True // Chooses the way to integrate the data (demo only)

      If($UseSQL) // Use SQL requests
         SQL LOGOUT // Log out from the remote database
         SQL LOGIN(SQL_INTERNAL;"user";"password") // Log in to the local database
```

```
    // Starting from here all SQL requests are made on the local database
    // Save the $a_LastName and $a_FirstName arrays in the local PERSONS table
            SQL EXECUTE("INSERT INTO PERSONS(LastName, FirstName) VALUES (:$a_LastName, :$a_FirstName);")

         Else // Using 4D commands
            For($i;1;Size of array($a_LastName))
               CREATE RECORD([PERSONS])
               [PERSONS]LastName:=$a_LastName{$i}
               [PERSONS]FirstName:=$a_FirstName{$i}
               SAVE RECORD([PERSONS])
            End for
         End if
      End if
      SQL LOGOUT // Close the connection
   End if
```

## System variables and sets

If the command has been executed correctly, the system variable OK returns 1. Otherwise, it returns 0.

# SQL EXECUTE SCRIPT

SQL EXECUTE SCRIPT ( scriptPath ; errorAction {; attribName ; attribValue} {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| scriptPath | Text | ⇒ | Complete pathname of file containing SQL script to execute |
| errorAction | Longint | ⇒ | Action to carry out in case of error during script execution |
| attribName | Text | ⇒ | Name of attribute to use |
| attribValue | Text | ⇒ | Value of attribute |

## Description

The **SQL EXECUTE SCRIPT** command is used to execute a series of SQL statements placed in the script file designated by *scriptPath*. This command can only be executed on a local machine (local 4D or stored procedure on 4D Server). It works with the current database (internal or external database).

**Note:** This command cannot be used with an external connection that is opened directly or via ODBC.

Pass the complete pathname of the text file containing the SQL statements to be executed in the *scriptPath* parameter. The pathname must be expressed using the syntax of the current system. If you pass an empty string ("") in *scriptPath*, a standard Open document dialog box will be displayed so that the user can select the script file to be executed.

**Note:** The **SQL EXPORT DATABASE** and **SQL EXPORT SELECTION** commands automatically generate this script file.

The *errorAction* parameter is used to configure the functioning of the command when an error occurs during script execution. You can pass one of the three following constants, placed in the **SQL** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| SQL On error abort | Longint | 1 | In the event of an error, 4D immediately stops script execution. |
| SQL On error confirm | Longint | 2 | In the event of an error, 4D displays a dialog box describing the error and allowing the user to interrupt or continue script execution. |
| SQL On error continue | Longint | 3 | In the event of an error, 4D ignores it and continues script execution. |

The *attribName* and *attribValue* parameters must be passed by pairs. These parameters are intended to be used to specify specific attributes for the script execution. In the current version of 4D, a single attribute can be passed in *attribName*, available via the following constant, placed in the **SQL** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| SQL use access rights | String | SQL_Use_Access_Rights | Used to restrict the access rights to be applied during execution of the SQL commands of the script. When you use this attribute, you must pass 0 or 1 in *attribValue*:<br>• *attribValue* = 1: 4D uses the access rights of the current 4D user.<br>• *attribValue* = 0 (or attribute not specified): 4D does not restrict access, the Designer rights are used. |

If the 4D log file is activated (via the selectors 28 or 45 of the **SET DATABASE PARAMETER** command), each SQL command executed will generate an entry with the following information:

- Type of SQL command
- Number of records affected by the command
- Duration of command execution
- For each error encountered:
  - the error code
  - the error text if available

If the script is executed correctly (no error occurs), the *OK* system variable is set to 1. In the event of an error, the *OK* system variable is set to 0 or not according to the *errorAction* parameter:

- If *errorAction* is SQL On error abort (value 1), *OK* is set to 0.

- If *errorAction* is SQL On error confirm (value 2), the *OK* variable is set to 0 if the user chooses to stop the operation and 1 if they choose to continue .
- If *errorAction* is SQL On error continue (value 3), the *OK* variable is always 1.

**Note:** If you use this command to execute memory-consuming actions such as massive data imports, you can consider calling the **ALTER DATABASE** SQL command in order to temporarily disable the SQL options.

# SQL EXPORT DATABASE

SQL EXPORT DATABASE ( folderPath {; numFiles {; fileLimitSize {; fieldLimitSize}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| folderPath | Text | ⇒ | Pathname of export folder or "" to display folder selection dialog box |
| numFiles | Longint | ⇒ | Maximum number of files per folder |
| fileLimitSize | Longint | ⇒ | Size limit value of export files (in KB) |
| fieldLimitSize | Longint | ⇒ | Size limit (in bytes) below which the contents of a Text, BLOB or Picture field is embedded into the main file |

## Description

The **SQL EXPORT DATABASE** command exports in SQL format all the records of all the tables in the database. In SQL, this global export operation is called "Dump".

**Note:** This command cannot be used with an external connection that has been opened directly or via ODBC.

For each table, the command generates a text file containing the SQL statements necessary for importing data into another database. This file can be used directly by the **SQL EXECUTE SCRIPT** command in order to import data into another 4D database.

The export files will be placed in a folder named "SQLExport" that is created in the destination folder designated by the *folderPath* parameter. Please note that if an "SQLExport" folder already exists at the location specified, the command will replace it without any warning message being displayed.
If you pass an empty string in this parameter, 4D displays a standard dialog box which lets the user designate the destination folder. By default, the dialog box displays the current folder of the user that opened the session ("My Documents" under Windows or "Documents" under Mac OS).

For each exported table, the command carries out the following actions:

- a subfolder with the table name is created in the destination folder.
- a text file named "Export.sql" is created in the subfolder. This file is encoded in UTF-8 with a BOM (byte-order mark). It contains SQL **INSERT** orders corresponding to the exported data. The field values are separated by colons. There may be fewer values than there are fields in the table. In this case, the remaining fields will be considered NULL.
- if the table contains BLOB, picture or text fields (texts stored externally, in other words, outside of records), by default the command creates an additional subfolder named "BLOBS" next to the "Export.sql" file and creates as many subfolders named "BlobsX" as necessary. These subfolders will store as separate files the contents of all the BLOB, picture or external text fields of the table records. The BLOB files are named "BlobXXXXX.BLOB", the text files are named "TEXTXXXXX.TXT"(where XXXXX is a unique number generated by the application). The picture files are named PICTXXXXX.ZZZZ (where XXXXX is a unique number generated by the application and ZZZZ is the extension). When possible, pictures are exported in their original native format with the extension corresponding to the picture type (.jpg, .png, etc.). If the export is not possible in the native format, the pictures are exported in the internal 4D format 4D with the .4PCT extension.
  This default behavior can be adjusted according to the size of the data contained in the field using the optional *fieldLimitSize* parameter (see below).
  **Note:** This behavior differs when you execute **SQL EXPORT DATABASE** from a 4D in remote mode. In this context, the data to be stored externally are included automatically in the "Export.sql" file.

If you pass the *numFiles* parameter, the command will create as many "BlobsX" subfolders as necessary so that each one of them does not contain more than *numFiles* BLOB, picture or external text files. By default, if the *numFiles* parameter is omitted, the command limits the number of files to 200. If you pass 0, each subfolder will contain at least one file.

The *fileLimitSize* parameter lets you set a size limit (in KB) for each "Export.sql" created on disk. Once the size of the export file being created reaches the value set in *fileLimitSize*, 4D stops writing records, closes the file and creates a new file named "ExportX.sql" (where X represents the sequence number) next to the previous one. Note that this is a theoretical limit: the actual size of the "ExportX.sql" files exceeds the value set by *fileLimitSize* because the file is only closed after the record that was being exported when the limit was reached has been completely written (the contents of the records is not divided). The minimum value accepted is 100 and the maximum value (default value) is 100,000 (100 MB).

The optional *fieldLimitSize* parameter sets a size limit below which the contents of an external BLOB, Picture or Text field will be embedded in the main "Export.sql" file rather than saved as a separate file. This purpose of this parameter is to optimize export operations by limiting the number of subfolders and files created on disk.
This parameter must be expressed in bytes. For example, if you pass 1000, any external BLOB, Picture or Text fields that

contain data with a size less than or equal to 1000 bytes are embedded into the main export file.
Note that binary field data (BLOB and Picture) that are embedded into the export file are written in hexadecimal format, in the form of X'0f20' (standard SQL hexadecimal notation, see **literal**). This format is automatically supported by the 4D SQL engine.
By default, if the *fieldLimitSize* parameter is omitted, external BLOB, Picture and Text fields are always exported as external files regardless of their size.

In the export file, there may be fewer values than there are fields in the table. In this case, the empty fields will be considered as NULL. You can also pass the NULL value in a field.

If the export has been carried out correctly, the OK variable is set to 1. Otherwise, it is set to 0.

**Note:** This command does not support Object type fields.

# SQL EXPORT SELECTION

SQL EXPORT SELECTION ( aTable ; folderPath {; numFiles {; fileLimitSize {; fieldLimitSize}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table from which to export selection |
| folderPath | Text | ⇒ | Pathname of export folder or "" to display folder selection dialog box |
| numFiles | Longint | ⇒ | Maximum number of files per folder |
| fileLimitSize | Longint | ⇒ | Maximum size of Export.sql file (in KB) |
| fieldLimitSize | Longint | ⇒ | Size limit (in bytes) below which the contents of a Text, BLOB or Picture field are embedded into the main file |

## Description

The **SQL EXPORT SELECTION** command exports in SQL format the records of the current selection of the 4D table designated by the *aTable* parameter.

This command is nearly identical to the **SQL EXPORT DATABASE** command. The file generated can be used directly by the **SQL EXECUTE SCRIPT** command in order to import data into another 4D database. The main difference between these two commands is that **SQL EXPORT SELECTION** only exports the current selection of *aTable* whereas **SQL EXPORT DATABASE** exports the entire database. Also, unlike the **SQL EXPORT DATABASE** command, this command does not work with external SQL databases. It can only be used with the main database.

Refer to the description of the **SQL EXPORT DATABASE** command for a detailed description of the functioning and parameters of these commands.

If the current selection is empty, the command does nothing. Note that in this case, the destination folder is not emptied.

If the export is carried out correctly, the *OK* variable is set to 1. Otherwise, it is set to 0.

**Note:** This command does not support Object type fields.

# SQL GET LAST ERROR

SQL GET LAST ERROR ( errCode ; errText ; errODBC ; errSQLServer )

| Parameter | Type | | Description |
|---|---|---|---|
| errCode | Longint | ⇦ | Error code |
| errText | Text | ⇦ | Error text |
| errODBC | Text | ⇦ | ODBC error code |
| errSQLServer | Longint | ⇦ | SQL server native error code |

## Description

The **SQL GET LAST ERROR** command returns information related to the last error encountered during the execution of an ODBC command. The error may come from the 4D application, the network, the ODBC source, etc.

This command must generally be called in the context of an error-handling method installed using the **ON ERR CALL** command.

- The *errCode* parameter returns the error code.
- The *errText* parameter returns the error text.

The last two parameters are only filled when the error comes from the ODBC source; otherwise, they are returned empty.

- The *errODBC* parameter returns the ODBC error code (SQL state).
- The *errSQLServer* parameter returns the SQL server native error code.

# SQL GET OPTION

SQL GET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇒ | Option number |
| value | Longint, Text | ⇐ | Option value |

## Description

The **SQL GET OPTION** command returns the current *value* of the option passed in *option*.

For more information on the different options and their associated values, refer to the description of the **SQL SET OPTION** command.

## System variables and sets

If the command was properly executed, the system variable OK is set to 1. Otherwise, it is set to 0.

# SQL LOAD RECORD

SQL LOAD RECORD {( numRecords )}

| Parameter | Type | | Description |
|---|---|---|---|
| numRecords | Longint | ⇨ | Number of records to load |

## Description

The **SQL LOAD RECORD** command retrieves one or more record(s) in 4D coming from the data source open in the current connection.

The optional *numRecords* parameter sets the number of records to retrieve:

- If you omit this parameter, the command retrieves the current record from the data source. This principle corresponds to the retrieval of data in a loop where one record is received at a time.
- If you pass an integer value in *numRecords*, the command retrieves *numRecords* records.
- If you pass the SQL All Records constant (value -1), the command retrieves all the records of the table.

**Note:** These last two settings are only useful when the retrieved data is associated with 4D arrays or fields.

## System variables and sets

If the command has been executed correctly, the system variable OK returns 1. Otherwise, it returns 0.

# SQL LOGIN

SQL LOGIN {( dataEntry ; userName ; password ; * )}

| Parameter | Type | | Description |
|---|---|---|---|
| dataEntry | String | ⇒ | Publication name of 4D database or<br>IP address of remote database or<br>Name of the data source entry in the ODBC Manager or<br>"" to display the selection dialog box |
| userName | String | ⇒ | Name of the user registered in the data source |
| password | String | ⇒ | Password of the user registered in the data source |
| * | Operator | ⇒ | Applied to Begin SQL/End SQL If omitted: do not apply (local database); if passed: apply |

## Description

The **SQL LOGIN** command allows you to connect to an SQL data source specified in the *dataEntry* parameter. It designates the target of the SQL queries executed subsequently in the current process:

- via the **SQL EXECUTE** command,
- via code placed within the *Begin SQL / End SQL* tags (if the * parameter is passed).

The SQL data source can either be:

- an external 4D Server database that you access directly,
- an external ODBC source,
- the local 4D database (internal database).

In *dataEntry*, you can pass one of the following values: an IP address, a 4D database publication name, an ODBC data source name, an empty string or the SQL_INTERNAL constant.

- **IP address**
  Syntax: **IP:<IPAddress>{:<TCPPort>}**
  In this case, the command opens a direct connection with the 4D Server database executed on the machine with the IP address specified. On the "target" machine, the SQL server must be started. If you pass a TCP port number, it must have been specified as the publication port of the SQL server in the "target" database. If you do not pass a TCP port number, the default port will be used (19812). The TCP port number of the SQL server can be modified on the "SQL" page of the Database Settings. Refer to examples 4 and 5.
  If you have enabled SSL for the "target" SQL server (option available in the Database Settings), you must add the ":ssl" keyword to the end of the IP address and TCP port number (mandatory in that case) in order for the server to be able to handle the request correctly (see example 6).

- **4D database publication name**
  Syntax: **4D:<Publication_Name>**
  In this case, the command opens a direct connection with the 4D Server database whose publication name on the network corresponds to the name specified. The network publication name of a database is set on the "Client-Server" page of the Database Settings.
  Refer to example 4.
  **Note:** The TCP port number of the target 4D SQL server (that publishes the 4D database) and the TCP port number of the SQL server of the 4D application that opens the connection must be the same.

- **valid ODBC data source name**
  Syntax: **ODBC:<My_DSN> or <My_DSN>**
  In this case, the *dataEntry* parameter contains the name of the data source as it has been set in the ODBC driver manager.
  **Notes:**
  - For compatibility with previous versions of 4D, it is possible to omit the "ODBC:" prefix. However, for better code readability, it is recommended to use this prefix.
    Refer to example 2.
  - Under Windows, the data source name is case sensitive. For example, if the data source was defined as "4D_v16", passing the value "4D_V16" will fail.

- Under Windows and Mac, the "ODBC:" prefix must be entered using uppercase letters. If you pass "odbc:", the connection will fail.

- **empty string**
  Syntax: ""
  In this case, the command displays the connection dialog box so that the data source to be connected to can be entered manually:

  This dialog box includes several pages. The TCP/IP page includes the following elements:
  - Target Name: This menu is built using two lists:
    - The list of databases that have been opened recently in direct con-nection. The mechanism for updating this list is the same as that of the 4D application, except that the folder containing the .4DLink files is named "Favorites SQL vXX" instead of "Favorites vXX".
    - The list of 4D Server applications whose SQL server is started and whose TCP port for SQL connections is the same as that of the source application. This list is dynamically updated on each new call to the **SQL LOGIN** command without the *dataEntry* parameter. If the "^" character is placed before a database name, this indicates that the connection has been made in secured mode via SSL.
  - Network Address: This area displays the IP address and possibly the TCP port of the database selected in the Target Name menu. You can also enter an IP address in this area and then click on the Connection button in order to connect to the corresponding 4D Server database. You can also specify the TCP port by entering a colon (:) followed by the port number after the address. For example: 192.168.93.105:19855
  - User Name and Password: These areas can be used to enter the con-nection identifiers.
  - The User DSN and System DSN pages display, respectively, the list of user and system ODBC data sources specified in the ODBC driver of the machine. These pages can be used to select a data source and enter the identifiers in order to open a connection with an external ODBC data source.

  If the connection is established, the OK system variable is set to 1. Otherwise, it is set to 0 and an error is generated. This error can be intercepted via an error-handling method installed by the **ON ERR CALL** command.

- **SQL_INTERNAL constant**
  Syntax: SQL_INTERNAL
  In this case, the command redirects subsequent SQL queries to the internal 4D database.

**Warning:** The prefixes used in the *dataEntry* parameter (IP, ODBC, 4D) must be written in uppercase.

*userName* contains the name of the user authorized to connect to the external data source. For example, with Oracle®, the user name can be “Scott”.

*password* contains the password of the user authorized to connect to the external data source. For example, with Oracle®, the password can be “tiger”.

**Note:** In the case of a direct connection, if you pass empty strings in the *userName* and *password* parameters, the connection will only be accepted if 4D passwords are not activated in the target database. Otherwise, the connection will be refused.

The optional * parameter can be used to change the target of the SQL code executed within the *Begin SQL/End SQL* tags. If you do not pass this parameter, the code placed within the *Begin SQL/End SQL* tags will still be sent to the internal SQL engine of 4D, without taking the configuration specified by the **SQL LOGIN** command into account. If you do pass this parameter, the SQL code executed within the *Begin SQL/End SQL* tags will be sent to the source specified in the *dataEntry* parameter.

To close the current connection and free the memory, simply execute the **SQL LOGOUT** command. All the SQL queries are then sent to the internal 4D SQL database.
If you call **SQL LOGIN** again without having explicitly closed the current connection, it will be closed automatically.

**Note:** In the case where an external connection attempt via **SQL LOGIN** fails, the internal 4D database automatically becomes the current data source.

These parameters are optional; if no parameters are passed, the command will bring up the ODBC Login dialog box that allows you to select the external data source.

The scope of this command is per process; in other words, if you want to execute two distinct connections, you must create two processes and execute each connection in each process.

**Warning:** It is not possible to open an ODBC connection in the contexts described below. These configurations lead to blocking of the application:

- connection via ODBC from the running application to itself
- connection via ODBC from a 4D application to 4D Server when a standard client/server connection is already open between these two applications.

## Example 1

This statement will bring up the ODBC Manager dialog box:

```
SQL LOGIN
```

## Example 2

Opening of a connection via the ODBC protocol with the "MyOracle" external data source. SQL queries executed via the **SQL EXECUTE** command and queries included within the **Begin SQL**/**End SQL** tags will be redirected to this connection:

```
SQL LOGIN("ODBC:MyOracle";"Scott";"tiger";*)
```

## Example 3

Open a connection with the 4D internal SQL kernel:

```
SQL LOGIN(SQL_INTERNAL;$user;$password)
```

## Example 4

Opening of a direct connection with the 4D Server application executed on the machine having the IP address 192.168.45.34 and replying on the default TCP port. The SQL queries executed via the **SQL EXECUTE** command will be redirected to this con-nection; the queries included within the **Begin SQL**/**End SQL** tags will not be redirected.

```
SQL LOGIN("IP:192.168.45.34";"John";"azerty")
```

## Example 5

Opening of a direct connection with the 4D Server application executed on the machine having the IP address 192.168.45.34 and replying on TCP port 20150. The SQL queries executed via the **SQL EXECUTE** command and the queries included within the **Begin SQL**/**End SQL** tags will be redirected to this connection.

```
SQL LOGIN("IP:192.168.45.34:20150";"John";"azerty";*)
```

## Example 6

Opening of a direct connection in SSL with the 4D Server application running on the machine with the IP address 192.168.45.34 and responding on the default TCP port. You must have enabled SSL for the SQL server on the 4D Server application:

```
SQL LOGIN("IP:192.168.45.34:19812:ssl";"Admin";"sd156") // Note the ":ssl" after of the IP address and TCP port
```

## Example 7

Opening of a direct connection with the 4D Server application which publishes, on the local network, a database whose publication name is "Accounts_DB." The TCP port used for the SQL server of both databases (set on the SQL page of the Database Settings) must be the same (19812 by default). The SQL queries executed via the **SQL EXECUTE** command will be redirected to this connection; the queries included within the **Begin SQL**/**End SQL** tags will not be redirected.

```
SQL LOGIN("4D:Accounts_DB";"John";"azerty")
```

## Example 8

This example illustrates the connection possibilities provided by the **SQL LOGIN** command:

```
ARRAY TEXT(aNames;0)
ARRAY LONGINT(aAges;0)
SQL LOGIN("ODBC:MyORACLE";"Marc";"azerty")
If(OK=1)
 `The following query will be redirected to the external ORACLE database
   SQL EXECUTE("SELECT Name, Age FROM PERSONS";aNames;aAges)
 `The following query will be sent to the local 4D database
   Begin SQL
      SELECT Name, Age
      FROM PERSONS
      INTO :aNames, :aAges;
   End SQL
 `The following SQL LOGIN command closes the current connection
 `with the external ORACLE database and opens a new connection
 `with an external MySQL database
   SQL LOGIN("ODBC:MySQL";"Jean";"qwerty";*)
   If(OK=1)
 `The following query will be redirected to the external MySQL database
      SQL EXECUTE("SELECT Name, Age FROM PERSONS";aNames;aAges)
 `The following query will also be redirected to the external MySQL database
      Begin SQL
         SELECT Name, Age
         FROM PERSONS
         INTO :aNames, :aAges;
      End SQL
      SQL LOGOUT
 `The following query will be sent to the local 4D database
      Begin SQL
         SELECT Name, Age
         FROM PERSONS
         INTO :aNames, :aAges;
      End SQL
   End if
End if
```

## System variables and sets

If the connection is successful, the system variable OK is set to 1; otherwise, it is set to

# SQL LOGOUT

SQL LOGOUT
Does not require any parameters

## Description

The **SQL LOGOUT** command closes the connection with an ODBC source that is open in the current process (if applicable). If there is no ODBC connection open, the command does nothing.

## System variables and sets

If the logout is performed properly, the system variable OK is set to 1; otherwise, it is set to 0. You can intercept this error with an error-handling method installed by the **ON ERR CALL** command.

# SQL SET OPTION

SQL SET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇒ | Number of option to set |
| value | Longint, String | ⇒ | New value of option |

## Description

The **SQL SET OPTION** command modifies the *value* of the option passed in *option*.

*option* can have one of the following values, located in the "**SQL**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| SQL asynchronous | Longint | 1 | 0 = Synchronous connection (default value), 1 (or value other than 0) = Asynchronous connection |
| SQL charset | Longint | 100 | Text encoding used for requests sent to external sources (via the SQL pass-through). The modification is carried out for the current process and the current connection.<br>Possible values: MIBEnum identifier (see note 2) or value -2 (see note 3)<br>By default: 106 (UTF-8) |
| SQL connection timeout | Longint | 5 | Maximum timeout awaiting response when executing the **SQL LOGIN** command. This value must be set before opening the connection in order to be taken into account<br>Possible values: time in seconds<br>By default: no timeout |
| SQL max data length | Longint | 3 | Maximum length of data returned |
| SQL max rows | Longint | 2 | Maximum number of rows in resulting group (used for previews) |
| SQL query timeout | Longint | 4 | Maximum timeout awaiting response when executing the **SQL EXECUTE** command.<br>Values: time in seconds<br>By default: no timeout |

**Notes:**

1. When you work with the internal SQL kernel of 4D, the SQL Asynchronous option serves no purpose due to the fact that this type of connection is always synchronous.
2. MIBEnum numbers are referenced at the following address: *http://www.iana.org/assignments/character-sets*.
3. When you pass -2 as the *value* to SQL Charset, the encoding used by the 4D SQL server is automatically adapted to the running platform (non-UTF encoding):
   - Under Windows, ISO8859-1 is used,
   - Under Mac OS, MAC-ROMAN is used.

## System variables and sets

If the command was properly executed, the system variable OK returns 1. Otherwise, it returns 0.

# SQL SET PARAMETER

SQL SET PARAMETER ( object ; paramType )

| Parameter | Type | | Description |
|---|---|---|---|
| object | 4D object | ➡ | 4D object to be used (variable, array or field) |
| paramType | Longint | ➡ | Type of parameter |

## Description

The **SQL SET PARAMETER** command allows the use of a 4D variable, array or field value in SQL requests.

**Note:** It is also possible to directly insert the name of a 4D object to be used (variable, array or field) between the << and >> characters in the text of the request (see example 1). For more information about this, please refer to the **Overview of SQL Commands** section.

- In the *object* parameter, pass the 4D object (variable, array or field) to be used in the request.
- In the *paramType* parameter, pass the SQL type of the parameter. You can pass a value or use one of the following constants, located in the "**SQL**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| SQL param in | Longint | 1 | |
| SQL param in out | Longint | 2 | Usable only in the context of an SQL stored procedure (in-out parameter defined in the stored procedure) |
| SQL param out | Longint | 4 | Usable only in the context of an SQL stored procedure (out parameter defined in the stored procedure) |

The value of the 4D object replaces the *?* character in the SQL request (standard syntax). If the request contains more than one *?* character, several calls to **SQL SET PARAMETER** will be necessary. The values of the 4D objects will be assigned sequentially in the request, in accordance with the execution order of the commands.

**Warning:** This command is used for handling *parameters* passed to the SQL request. It is not possible to use the SQL param out type to associate a 4D object with the *result* of an SQL request. SQL request results are retrieved, for example, using the *boundObj* parameter of the **SQL EXECUTE** command (see the **Overview of SQL Commands**). The **SQL SET PARAMETER** command is mainly intended for setting parameters passed to the request (SQL param in); the SQL param out and SQL param in out types are reserved for use in the context of SQL stored procedures that could return parameters.

## Example 1

This example is used to execute an SQL request which calls the associated 4D variables directly:

```
C_TEXT(MyText)
C_LONGINT(MyLongint)

SQL LOGIN("mysql";"root";"")
SQLStmt:="insert into app_testTable (alpha_field, longint_field) VALUES (<<MyText>>, <<MyLongint>>)"
For(vCounter;1;10)
   MyText:="Text"+String(vCounter)
   MyLongint:=vCounter
   SQL EXECUTE(SQLStmt)
   SQL CANCEL LOAD
End for
SQL LOGOUT
```

## Example 2

Same example as the previous one, but using the **SQL SET PARAMETER** command:

```
C_TEXT(MyText)
C_LONGINT(MyLongint)
```

```
SQL LOGIN("mysql";"root";"")
SQLStmt:="insert into app_testTable (alpha_field, longint_field) VALUES (?,?)"
For(vCounter;1;10)
   MyText:="Text"+String(vCounter)
   MyLongint:=vCounter
   SQL SET PARAMETER(MyText;SQL param in)
   SQL SET PARAMETER(MyLongint;SQL param in)
   SQL EXECUTE(SQLStmt)
   SQL CANCEL LOAD
End for
SQL LOGOUT
```

## System variables and sets

If the command has been executed correctly, the system variable OK returns 1. Otherwise, it returns 0.

# START SQL SERVER

START SQL SERVER
Does not require any parameters

## Description

The **START SQL SERVER** command launches the integrated SQL server in the 4D application where it has been executed. Once launched, the SQL server can respond to external SQL queries.

**Note:** This command does not affect the internal functioning of the 4D SQL kernel. The SQL kernal is always available for internal queries.

## System variables and sets

If the SQL server has been launched correctly, the OK system variable is set to 1. Otherwise, it is set to 0.

# STOP SQL SERVER

STOP SQL SERVER
Does not require any parameters

## Description

The **STOP SQL SERVER** command stops the integrated SQL server in the 4D application where it has been executed.

If the SQL server was launched, all the SQL connections are interrupted and the server no longer accepts any external SQL queries. If the SQL server was not launched, the command does nothing.

**Note:** This command does not affect the internal functioning of the 4D SQL kernel. The SQL kernel is always available for internal queries.

# _o_USE EXTERNAL DATABASE

_o_USE EXTERNAL DATABASE ( sourceName {; user ; password} )

| Parameter | Type | | Description |
|---|---|---|---|
| sourceName | String | ⇒ | Name of ODBC data source to connect to |
| user | String | ⇒ | User name |
| password | String | ⇒ | User password |

## Compatibility Note

This command has been replaced by the **SQL LOGIN** command since version 11.3 of 4D. It should no longer be used in your developments.

# _o_USE INTERNAL DATABASE

_o_USE INTERNAL DATABASE
Does not require any parameters

## Compatibility Note

This command has been replaced by the **SQL LOGOUT** command since version 11.3 of 4D. It should no longer be used in your developments.

# String

# Character Reference Symbols

## Introduction

The character reference symbols: **[[...]]**

These symbols are used to refer to a single character within a string. This syntax allows you to individually address the characters of a text variable, string variable, or field.

**Compatibility note:** Starting with 4D v13, you can no longer view the former Mac OS symbols in the Method editor (≤...≥).

If the character reference symbols appear on the left side of the assignment operator (*:=*), a character is assigned to the referenced position in the string. For example, if *vsName* is not an empty string, the following line sets the first character of *vsName* to uppercase:

```
If(vsName#"")
   vsName[[1]]:=Uppercase(vsName[[1]])
End if
```

Otherwise, if the character reference symbols appear within an expression, they return the character (to which they refer) as a 1-character string. For example:

```
  ` The following example tests if the last character of vtText is an At sign "@"
If(vtText#"")
   If(Character code(Substring(vtText;Length(vtText);1))=At sign)
  ` ...
   End if
End if

  ` Using the character reference syntax, you would write in a simpler manner:
If(vtText#"")
   If(Character code(vtText[[Length(vtText)]])=At sign)
  ` ...
   End if
End if
```

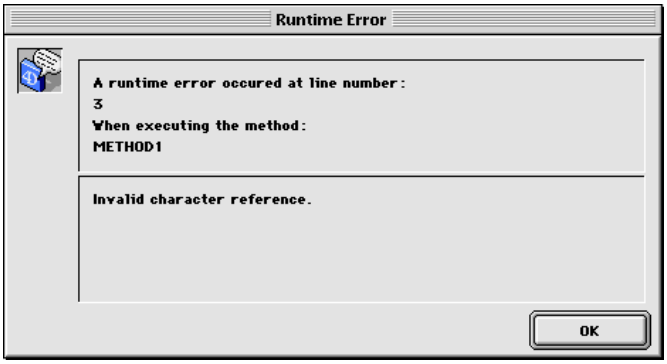
## Advanced note about invalid character reference

When you use the character reference symbols, you must address existing characters in the string in the same way you address existing elements of an array. For example if you address the 20th character of a string variable, this variable MUST contain at least 20 characters.

- Failing to do so, in interpreted mode, does not cause a syntax error.
- Failing to do so, in compiled mode (with no options), may lead to memory corruption, if, for instance, you write a character beyond the end of a string or a text.
- Failing to do so, in compiled mode, causes an error with the option Range Checking On. For example, executing the following code:

```
  ` Very bad and nasty thing to do, boo!
vsAnyText:=""
vsAnyText[[1]]:="A"
```

will trigger the Runtime Error shown here:



## Example

The following project method capitalizes the first character of each word of the text received as parameter and returns the resulting capitalized text:

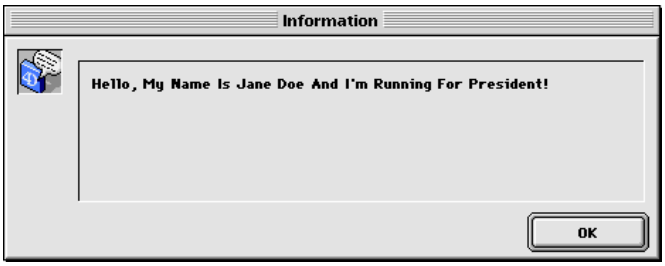
```
  ` Capitalize text project method
  ` Capitalize text ( Text ) -> Text
  ` Capitalize text ( Source text ) -> Capitalized text

$0:=$1
$vlLen:=Length($0)
If($vlLen>0)
   $0[[1]]:=Uppercase($0[[1]])
   For($vlChar;1;$vlLen-1)
      If(Position($0[[$vlChar]];" !&()-{}:;<>?/,.=+*")>0)
         $0[[$vlChar+1]]:=Uppercase($0[[$vlChar+1]])
      End if
   End for
End if
```

For example, the line:

```
ALERT(Capitalize text("hello, my name is jane doe and i'm running for president!"))
```

displays the alert shown here:



# 4D Transformation Tags

4D provides a set of transformation tags which allow you to insert references to 4D variables or expressions, or to perform different types of processing within a source text, referred to as a "template". These tags are interpreted when the source text is executed and generate an output text.

This principle is used in particular by the 4D Web server to build the **Semi-dynamic pages**.

These tags must generally be inserted as HTML type comments (*<!--#Tag Contents-->* ) in the source text. However, other comments such as *<!--Beginning of list-->* are also possible.

**Note:** An alternative $-based syntax is used in certain conditions for tags that return values, in order to make them XML-compliant. For more information, refer to the following paragraph **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL**.

The following 4D transformation tags are available:

- 4DTEXT, to insert 4D variables and expressions as text,
- 4DHTML, to insert HTML code,
- 4DEVAL, to evaluate any 4D expression
- 4DSCRIPT, to execute a 4D method,
- 4DINCLUDE, to include a page within another one,
- 4DBASE, to modify the default folder used by the 4DINCLUDE tag,
- 4DCODE, to insert blocks of 4D code,
- 4DIF, 4DELSE, 4DELSEIF and 4DENDIF, to insert conditions in the tagged code,
- 4DLOOP and 4DENDLOOP, to make loops in the tagged code.

It is possible to mix several types of tags. For example, the following HTML structure is entirely feasible:

```
<HTML> ... <BODY> <!--#4DSCRIPT/PRE_PROCESS-->          (Method call) <!--#4DIF (myvar=1)-->                (If condition)
   <!--#4DINCLUDE banner1.html-->    (Subpage insertion) <!--#4DENDIF-->                        (End if) <!--#4DIF (mtvar=2)-->
   <!--#4DINCLUDE banner2.html--> <!--#4DENDIF--> <!--#4DLOOP [TABLE]-->                (Loop on the current selection) <!--
#4DIF ([TABLE]ValNum>10)-->          (If [TABLE]ValNum>10)    <!--#4DINCLUDE subpage.html-->   (Subpage insertion) <!--
#4DELSE-->                      (Else)    <B>Value: <!--#4DTEXT [TABLE]ValNum--></B><BR>
                              (Field display) <!--#4DENDIF--> <!--#4DENDLOOP-->                   (End for) </BODY> </HTML>
```

## Executing templates

Parsing the contents of 'template' pages can be done in two ways:

- Using the **PROCESS 4D TAGS** command; this command accepts a 'template' as input, as well as (optional) parameters and returns a text resulting from the processing.
- Using 4D's integrated HTTP server: **Semi-dynamic pages** sent by means of the **WEB SEND FILE** (.htm, .html, .shtm, .shtml), **WEB SEND BLOB** (text/html type BLOB), or **WEB SEND TEXT** commands, or called using URLs. In this last case, for reasons of optimization, pages that are suffixed with ".htm" and ".html" are NOT parsed. In order to "force" the parsing of HTML pages in this case, you must add the suffix ".shtm" or ".shtml" (for example, http://www.server.com/dir/page.shtm). For more information on this point, refer to the **Semi-dynamic pages** section in the **Web Server** chapter.

## 4DTEXT

**Syntax:** *<!--#4DTEXT VarName-->* or *<!--#4DTEXT 4DExpression-->*
**Alternative syntax:** *$4DTEXT(VarName)* or *$4DTEXT(4DExpression)* (see **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL**)

The tag *<!--#4DTEXT VarName-->* allows you to insert a reference to the 4D variable or expression returning a value. For example, if you write (in an HTML page):

<P>Welcome to *<!--#4DTEXT vtSiteName-->*!</P>

The value of the 4D variable *vtSiteName* will be inserted in the HTML page when it is sent. This value is inserted as simple text, special HTML characters such as ">" are automatically escaped.

You can also insert 4D expressions using the *4DTEXT* tag. You can for example directly insert the contents of a field (*<!--#4DTEXT [tableName]fieldName-->*), an array element (*<!--#4DTEXT tabarr{1}-->*) or a method returning a value (*<!--#4DTEXT mymethod-->*). The expression conversion follows the same rules as the variable ones. Moreover, the expression must comply with 4D syntax rules.

**Note:** Executing a 4D method with *4DTEXT* from a Web request depends on the value of the "Available through 4D tags and URLs (4DACTION...)" attribute set in the Method properties. For more information about this, refer to the **Connection Security** section.

Although an expression can contain direct calls to 4D functions, this is not recommended for localization issues. For example, *<!--#4DTEXT Current date-->*, although correctly interpreted with a 4D in English will not be understood by an French version. The same applies to real numbers (the decimal separator can be different according to the language). In both cases, we strongly advise you to assign a variable through programming.

To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

In case of an evaluation error, the inserted text will appear as "*<!--#4DTEXT myvar-->* : ## error # error code".

**Notes:**

- You work with process variables.
- For security reasons, it is recommended to use this tag when processing data introduced from outside the application, in order to prevent the insertion of malicious code (see the **Usage notes** section below).
- You can display a picture field content. However, it is not possible to display the content of a picture array item.
- It is possible to display the contents of an object field by means of a 4D formula. For example, you can write *<!--#4DTEXT **OB Get**:C1224([Rect]Desc;¥"color¥")-->*.
- You will usually work with Text variables. However, you can also use BLOB variables. You just need to generate the BLOB in Text without length mode.

## 4DHTML

**Syntax:** *<!--#4DHTML VarName-->* or *<!--#4DHTML 4DExpression-->*
**Alternative syntax**: *$4DHTML(VarName)* or *$4DHTML(4DExpression)* (see **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL**)

Just like the 4DTEXT tag, this tag lets you assess a variable or 4D expression that returns a value, and insert it as an HTML expression. Unlike the 4DTEXT tag, this tag does not escape HTML special characters.

For example, here are the processing results of the 4D text variable *myvar* with the available tags:

| ***myvar* Value** | **Tags** | **Result** |
|---|---|---|
| myvar:="<B>" | *<!--#4DTEXT myvar-->* | <B> |
| myvar:="<B>" | *<!--#4DHTML myvar-->* | <B> |

To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

In case of an interpretation error, the inserted text will be "*<!--#4DHTML myvar-->* : ## error # error code".

**Notes:**

- Executing a 4D method with *4DHTML* from a Web request depends on the value of the "Available through 4D tags and URLs (4DACTION...)" attribute set in the Method properties. For more information about this, refer to the **Connection Security** section.
- For security reasons, it is recommended to use the 4DTEXT tag when processing data introduced from outside the application, in order to prevent the insertion of malicious code (see the **Usage notes** section below).

## 4DEVAL

**Syntax:** *<!--#4DEVAL VarName--> or <!--#4DEVAL 4DExpression-->*
**Alternative syntax:** *$4DEVAL(VarName)* or *$4DEVAL(4DExpression*) (see **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL**)

The 4DEVAL tag allows you to assess a variable or a 4D expression. Like the existing 4DHTML tag, 4DEVAL does not escape HTML characters when returning text. However, unlike 4DHTML or 4DTEXT, 4DEVAL allows you to execute any valid 4D statement, including assignments and expressions that do not return any value.

For example, you can execute:

```
$input:="<!--#4DEVAL a:=42-->" //assignment
$input:=$input+"<!--#4DEVAL a+1-->" //calculation
PROCESS 4D TAGS($input;$output)
 //$output = "43"
```

To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

In case of an error during interpretation, the text inserted will be in the form: "*<!--#4DEVAL expr-->*: ## error # error code".

**Notes:**

- Executing a 4D method with *4DEVAL* from a Web request requires that the "Available through 4D tags and URLs (4DACTION...)" option is set in the Method properties. For more information, refer to the **Connection Security** section.
- For security reasons, it is recommended to use the 4DTEXT tag when processing data introduced from outside the application, in order to prevent the insertion of malicious code (see the **Usage notes** section below).

## 4DSCRIPT/

**Syntax:** *<!--#4DSCRIPT/MethodName/MyParam-->*

The *4DSCRIPT* tag allows you to execute 4D methods when processing the template.. The presence of the *<!--#4DSCRIPT/MyMethod/MyParam-->* tag as an HTML comment forces the execution of the ***MyMethod*** method with the *Param* parameter as a string in *$1*.

**Note:** If the tag is called in the context of a Web process, when the page is loaded, 4D calls the **On Web Authentication Database Method** (if it exists). If it returns **True**, 4D executes the method.

The method must return text in *$0*. If the string starts with the code character 1, it is considered as HTML (the same principle is true for the *4DHTML* tag).

**Note:** The execution of a method with *4DSCRIPT* depends on the value of the "Available through 4D tags and URLs (4DACTION...)" attribute defined in the Method properties. For more information about this, refer to the **Connection Security** section.

For example, let's say that you insert the following comment "Today is *<!--#4DSCRIPT/MYMETH/MYPARAM-->*" into a semi-dynamic Web page. When loading the page, 4D calls the **On Web Authentication Database Method** (if it exists), then calls the ***MYMETH*** method and passes the string "/MYPARAM" as the parameter *$1*. The method returns text in *$0* (for example "12/31/14"); the expression "Today is *<!--#4DSCRIPT/MYMETH/MYPARAM-->*" therefore becomes "Today is 12/31/14".

The MYMETH method is as follows:

```
C_TEXT($0)¥¥This parameter must always be declared
C_TEXT($1)¥¥This parameter must always be declared
$0:=String(Current date)
```

**Warning:** You must always declare the *$0* and *$1* parameters in the called method.

**Note:** A method called by *4DSCRIPT* must not call interface elements (**DIALOG**, **ALERT**...).

As 4D executes methods in their order of appearance, it is absolutely possible to call a method that sets the value of many variables that are referenced further in the document, whichever mode you are using. You can insert as many *<!--#4DSCRIPT...-->* comments as you want in a template.

## 4DINCLUDE

**Syntax:** *<!--#4DINCLUDE Path-->*

This tag is mainly designed to allow another HTML page (indicated by the *path* parameter) to be included in an HTML page. By default, only the body of the HTML page that is specified is included, in other words, the contents found within the <body> and </body> tags (the tags themselves are not included). This lets you avoid conflicts related to meta tags present in the headers. However, if the HTML page specified does not contain <body></body> tags, the entire page is included. It is

up to you to verify the consistency of the meta tags.
The *<!--#4DINCLUDE -->* comment is very useful for tests (*<!--#4DIF-->*) or loops (*<!--#4DLOOP-->*). It is very convenient to include tags according to a criteria or randomly.
When including, regardless of the file name extension, 4D analyzes the called page and then inserts the contents (modified or not) in the page originating the *4DINCLUDE* call.

An included page with the *<!--#4DINCLUDE -->* comment is loaded in the Web server cache the same way as pages called via a URL or sent with the **WEB SEND FILE** command.

In *path*, put the path leading to the document to include. **Warning**: In the case of a *4DINCLUDE* call, the path is relative to the document being analyzed, that is, the “parent” document. Use the slash character (/) as a folder separator and the two dots (..) to go up one level (HTML syntax).

**Notes:**

- When you use the *4DINCLUDE* tag with the **PROCESS 4D TAGS** command, the default folder is the folder containing the database structure file.
- You can modify the default folder used by the *4DINCLUDE* tag in the current page, using the *<!--#4DBASE -->* tag (see below).

The number of *<!--#4DINCLUDE path-->* within a page is unlimited. However, the *<!--#4DINCLUDE path-->* calls can be made only at one level. This means that, for example, you cannot insert *<!--#4DINCLUDE mydoc3.html-->* in the mydoc2.html body page, which is called by *<!--#4DINCLUDE mydoc2-->* inserted in mydoc1.html.
Furthermore, 4D verifies that inclusions are not recursive.

In case of error, the inserted text is "*<!--#4DINCLUDE path-->* :The document cannot be opened".

**Examples**

```
<!--#4DINCLUDE subpage.html--> <!--#4DINCLUDE folder/subpage.html--> <!--#4DINCLUDE ../folder/subpage.html-->
```

## 4DBASE

**Syntax:** *<!--#4DBASE folderPath-->*

The *<!--#4DBASE -->* tag designates a working directory that is used by the *<!--#4DINCLUDE-->* tag.
When it is called in a Web page, the *<!--#4DBASE -->* tag modifies all subsequent *<!--#4DINCLUDE-->* calls on this page, until the next *<!--#4DBASE -->*, if any. If the *<!--#4DBASE -->* folder is modified from within an included file, it retrieves its original value from the parent file.

The *folderPath* parameter must contain a pathname relative to the current page and it must end with a slash (/). The designated folder must be located inside the Web folder.
Pass the *WEBFOLDER* keyword to restore the default path (relative to the page).

Thus the following code (4D v12), which must specify a relative path for each call:

```
<!--#4DINCLUDE subpage.html--> <!--#4DINCLUDE folder/subpage1.html--> <!--#4DINCLUDE folder/subpage2.html--> <!--#4DINCLUDE folder/subpage3.html--> <!--#4DINCLUDE ../folder/subpage.html-->
```

... can be rewritten using the *<!--#4DBASE -->* tag:

```
<!--#4DINCLUDE subpage.html--> <!--#4DBASE folder/--> <!--#4DINCLUDE subpage1.html--> <!--#4DINCLUDE subpage2.html--> <!--#4DINCLUDE subpage3.html--> <!--#4DBASE ../folder/--> <!--#4DINCLUDE subpage.html--> <!--#4DBASE WEBFOLDER-->
```

### Example

Setting a directory for the home page using the *<!--#4DBASE -->* tag:

```
/* Index.html */ <!--#4DIF LangFR=True-->     <!--#4DBASE FR/--> <!--#4DELSE-->     <!--#4DBASE US/--> <!--#4DENDIF--> <!--#4DINCLUDE head.html--> <!--#4DINCLUDE body.html--> <!--#4DINCLUDE footer.html-->
```

In the head.html file, the current folder is modified through *<!--#4DBASE -->*, without this changing its value in Index.html:

```
/* Head.htm */ /* the working directory here is relative to the included file (FR/ or US/) */ <!--#4DBASE Styles/--> <!--#4DINCLUDE main.css--> <!--#4DINCLUDE product.css--> <!--#4DBASE Scripts/--> <!--#4DINCLUDE main.js--> <!--#4DINCLUDE product.js-->
```

## 4DCODE

The 4DCODE tag allows you to insert a multi-line 4D code block in a template.

When a "<!--#4DCODE" sequence is detected that is followed by a space, a CR or a LF character, 4D interprets all the lines of code up to the next "-->" sequence. The code block itself can contain carriage returns, line feeds, or both; it will be interpreted sequentially by 4D.

For example, using the 4DCODE tag, you can write in a template:

```
<!--#4DCODE
//PARAMETERS initialization

$graphType:=1
If(OB Is defined:C1231($graphParameters;"graphType")) //US language only
    $graphType:=OB GET:C1224($graphParameters;"graphType")
    If($graphType=7)
        $nbSeries:=1
        If($nbValues>8)
            DELETE FROM ARRAY:C228 ($yValuesArrPtr{1}->;9;100000)
            $nbValues:=8
        End if
    End if
End if
-->
```

**Note:** In a 4DCODE tag, the 4D code must always be written using the English-US language. Therefore, 4DCODE ignores the "Use regional system settings" user preferences for the 4D language (see **Language for commands and constants**).

Here are the 4DCODE tag features:

- The **TRACE** command is supported and activates the 4D debugger, thus allowing you to debug your template code.
- Any error will display the standard error dialog that lets the user stop code execution or enter debugging mode.
- The text in between <!--#4DCODE and --> is split into lines accepting any line-ending convention (cr, lf, or crlf).
- The text is tokenized within the context of the database that called **PROCESS 4D TAGS**. This is important for recognition of project methods for example.
  **Note:** The "Available through 4D tags and URLs 4DACTION" method property is not taken into account (see also the **Note about security** below).
- Even if the text always uses English-US, it is recommended to use the token syntax (:Cxxx) for command and constant names to protect against potential problems due to commands or constants being renamed from one version of 4D to another.
  **Note:** For more information on the *:Cxxx* syntax, please refer to the **Using tokens in formulas** section.

**Note about security:** The fact that 4DCODE tags can call any of the 4D language commands or project methods could be seen as a security issue, especially when the database is available through HTTP. However, since it executes server-side code called from your own template files, the tag itself does not represent a security issue. In this context, as for any Web server, security is mainly handled at the level of remote accesses to server files.

## 4DIF, 4DELSE, 4DELSEIF and 4DENDIF

**Syntax:** *<!--#4DIF expression--> {<!--#4DELSEIF expression2-->...<!--#4DELSEIF expressionN-->} {<!--#4DELSE-->} <!--#4DENDIF-->*

Used with the *<!--#4DELSEIF-->* (optional), *<!--#4DELSE-->* (optional) and *<!--#4DENDIF-->* comments, the *<!--#4DIF expression-->* comment offers the possibility to execute portions of code conditionally.

The *expression* parameter can contain any valid 4D expression returning a Boolean value. It must be indicated within parenthesis and comply with the 4D syntax rules.

To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

The *<!--#4DIF expression-->* ... *<!--#4DENDIF-->* blocks can be nested in several levels. Like in 4D, each *<!--#4DIF expression-->* should match a *<!--#4DENDIF-->*.

In case of an interpretation error, the text "*<!--#4DIF expression-->*: A Boolean expression was expected" is inserted instead of the contents located between *<!--#4DIF -->* and *<!--#4DENDIF-->*.

Likewise, if there are not as many *<!--#4DENDIF-->* as *<!--#4DIF -->*, the text "*<!--#4DIF expression-->*: 4DENDIF expected" is inserted instead of the contents located between *<!--#4DIF -->* and *<!--#4DENDIF-->*.

Using the *<!--#4DELSEIF-->* tag, you can test an unlimited number of conditions. Only the code that follows the first condition evaluated as **True** is executed. If no conditions are true, no statement is executed (if there is no final *<!--#4DELSE-->*).
You can use a *<!--#4DELSE-->* tag after the last *<!--#4DELSEIF-->*. If all the conditions are false, the statements following the *<!--#4DELSE-->* are executed.

The two following codes are equivalent.

- Code using 4DELSE only:

```
<!--#4DIF Condition1-->   /* Condition1 is true*/ <!--#4DELSE-->     <!--#4DIF Condition2-->         /* Condition2 is true*/     <!--#4DELSE-->
      <!--#4DIF Condition3-->            /* Condition3 is true */         <!--#4DELSE-->            /*None of the conditions are true*/
   <!--#4DENDIF-->     <!--#4DENDIF--> <!--#4DENDIF-->
```

- Similar code using the 4DELSEIF tag:

```
<!--#4DIF Condition1-->      /* Condition1 is true*/ <!--#4DELSEIF Condition2-->      /* Condition2 is true*/ <!--#4DELSEIF Condition3-->     /*
Condition3 is true */ <!--#4DELSE-->     /* None of the conditions are true*/ <!--#4DENDIF-->
```

### Example 1

This example of code inserted in a static HTML page displays a different label according the vname#"" expression result:

```
<BODY> ... <!--#4DIF (vname#"")--> Names starting with <!--#4DTEXT vname-->. <!--#4DELSE--> No name has been found. <!--
#4DENDIF--> ... </BODY>
```

### Example 2

This example inserts different pages depending on which user is connected:

```
<!--#4DIF LoggedIn=False-->     <!--#4DINCLUDE Login.htm --> <!--#4DELSEIF User="Admin" -->     <!--#4DINCLUDE
AdminPanel.htm --> <!--#4DELSEIF User="Manager" -->     <!--#4DINCLUDE SalesDashboard.htm --> <!--#4DELSE-->     <!--
#4DINCLUDE ItemList.htm --> <!--#4DENDIF-->
```

## 4DLOOP and 4DENDLOOP

**Syntax:** *<!--#4DLOOP condition--> <!--#4DENDLOOP-->*

This comment allows repetition of a portion of code as long as the condition is fulfilled. The portion is delimited by *<!--#4DLOOP-->* and *<!--#4DENDLOOP-->*.

The *<!--#4DLOOP condition-->* ... *<!--#4DENDLOOP-->* blocks can be nested. Like in 4D, each *<!--#4DLOOP condition-->* should match a *<!--#4DENDLOOP-->*.

There are five kinds of conditions:

- **<!--#4DLOOP [table]-->**
  This syntax makes a loop for each record from the *table* current selection in the current process. The code portion located between the two comments is repeated for each current selection record.

**Note:** When the 4DLOOP tag is used with a table, records are loaded in Read only mode.

The following code:

```
<!--#4DLOOP [People]--> <!--#4DTEXT [People]Name--> <!--#4DTEXT [People]Surname--><BR> <!--#4DENDLOOP-->
```

... could be expressed in 4D language in the following way:

```
FIRST RECORD([People])
While(Not(End selection([People])))
   ...
   NEXT RECORD([People])
End while
```

- **<!--#4DLOOP array-->**
  This syntax makes a loop for each item array. The array current item is increased when each code portion is repeated.

**Note:** This syntax cannot be used with two dimension arrays. In this case, it is better to combine a method with nested loops.

The following code example:

```
<!--#4DLOOP arr_names--> <!--#4DTEXT arr_names{arr_names}--><BR> <!--#4DENDLOOP-->
```

... could be expressed in 4D language in the following way:

```
For($Elem;1;Size of array(arr_names))
   arr_names:=$Elem
   ...
End for
```

- **<!--#4DLOOP method-->**
  This syntax makes a loop as long as the method returns True. The method takes a Long Integer parameter type. First it is called with the value 0 to allow an initialization stage (if necessary); it is then called with the values 1,then 2, then 3 and so on, as long as it returns True.

For security reasons, within a Web process, the **On Web Authentication database method** can be called once just before the initialization stage (method execution with 0 as parameter). If the authentication is OK, the initialization stage will proceed.

**Warning:** **C_BOOLEAN**($0) and **C_LONGINT**($1) MUST be declared within the method for compilation purposes.

The following code example:

```
<!--#4DLOOP my_method--> <!--#4DTEXT var--> <BR> <!--#4DENDLOOP-->
```

... could be expressed in 4D language in the following way:

```
If(AuthenticationWebOK)
   If(my_method(0))
      $counter:=1
      While(my_method($counter))
         ...
         $counter:=$counter+1
      End while
   End if
End if
```

The *my_method* method can be as follow:

```
C_LONGINT($1)
C_BOOLEAN($0)
If($1=0)
 `Initialisation
   $0:=True
Else
   If($1<50)
      ...
      var:=...
      $0:=True
   Else
      $0:=False `Stops the loop
   End if
End if
```

- **<!--#4DLOOP 4DExpression-->**
  With this syntax, the 4DLOOP tag makes a loop as long as the 4D expression returns **True**. The expression can be any valid Boolean expression and must contain a variable part to be evaluated in each loop to avoid infinite loops.
  For example, the following code:

```
<!--#4DEVAL $i:=0--> <!--#4DLOOP ($i<4)--> <!--#4DEVAL $i--> <!--#4DEVAL $i:=$i+1--> <!--#4DENDLOOP-->
```

produces the following result:

```
0
1
2
3
```

To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

- **<!--#4DLOOP pointerArray-->**
  In this case, the 4DLOOP tag works like it does with an array: it makes a loop for each element of the array referenced by the pointer. The current array element is increased each time the portion of code is repeated.
  This syntax is useful when you pass an array pointer as a parameter to the **PROCESS 4D TAGS** command.
  Example:

```
ARRAY TEXT($array;2)
$array{1}:="hello"
$array{2}:="world"
$input:="<!--#4DEVAL $1-->"
$input:=$input+"<!--#4DLOOP $2-->"
$input:=$input+"<!--#4DEVAL $2->{$2->}--> "
$input:=$input+"<!--#4DENDLOOP-->"
PROCESS 4D TAGS($input;$output;"elements = ";->$array)
 // $output = "elements = hello world "
```

In case of an interpretation error, the text "*<!--#4DLOOP expression-->*: description" is inserted instead of the contents located between *<!--#4DLOOP -->* and *<!--#4DENDLOOP-->*.

The following messages can be displayed:

- Unexpected expression type (standard error);
- Incorrect table name (error on the table name);
- An array was expected (the variable is not an array or is a two dimension array);
- The method does not exist;
- Syntax error (when the method is executing);
- Access error (you do not have the appropriate access privileges to access the table or the method).
- 4DENDLOOP expected (the *<!--#4DENDLOOP-->* number does not match the *<!--#4DLOOP -->*).

## Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL

Several existing 4D transformation tags can be expressed using a $-based syntax:
**$4dtag (*expression*)** can be used instead of **<!--#4dtag *expression*-->**

This alternative syntax is available only for tags used to return processed values:

- 4DTEXT
- 4DHTML
- 4DEVAL

(Other tags, such as 4DIF or 4DSCRIPT, must be written with the regular syntax).

For example, you can write:

```
$4DEVAL(UserName)
```

instead of:

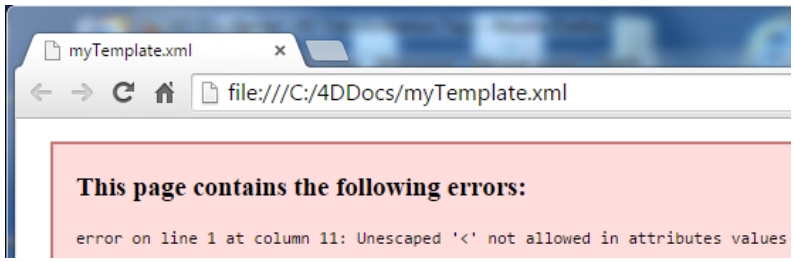
```
<!--#4DEVAL(UserName)-->
```

The main advantage of this syntax is that it allows you to **write XML-compliant templates**. Some 4D developers need to create and validate XML-based templates using standard XML parser tools. Since the "<" character is invalid in an XML

attribute value, it was not possible to use the "<!-- -->" syntax of 4D tags without breaking the document syntax. On the other hand, escaping the "<" character will prevent 4D from interpreting the tags correctly.

For example, the following code would cause an XML parsing error because of the first "<" character in the attribute value:

```
<line x1="<!--#4DEVAL $x-->" y1="<!--#4DEVAL $graphY1-->"/>
```



Using the $ syntax, the following code is validated by the parser:

```
<line x1="" y1=""/>
```

Note that *$4dtag* and *<--#4dtag -->* are not strictly equivalent: unlike *<--#4dtag -->*, *$4dtag* processing does not interpret 4D tags recursively. $ tags are always evaluated once and the result is considered as plain text.

**Note:** For more information on recursive processing, please refer to the **Recursive processing** paragraph.

The reason for this difference is to prevent malicious code injection. As explained below, it is strongly recommended to use 4DTEXT tags instead of 4DHTML tags when handling user text to protect against unwanted reinterpretation of tags: with 4DTEXT, special characters such as "<" are escaped, thus any 4D tags using the *<!--#4dtag expression -->* syntax will lose their particular meaning. However, since 4DTEXT does not escape the $ symbol, we decided to break support for recursion in order to prevent malicious injection using the *$4dtag (expression)* syntax.

The following examples show the result of processing depending on the syntax and tag used:

```
 // example 1
myName:="<!--#4DHTML QUIT 4D-->" //malicious injection
input:="My name is: <!--#4DHTML myName-->"
PROCESS 4D TAGS(input;output)
 //4D will quit!
```

```
 // example 2
myName:="<!--#4DHTML QUIT 4D-->" //malicious injection
input:="My name is: <!--#4DTEXT myName-->"
PROCESS 4D TAGS(input;output)
 //output is "My name is:  & lt;!--#4DHTML QUIT 4D-->"
```

```
 // example 3
myName:="" //malicious injection
input:="My name is: <!--#4DTEXT myName-->"
PROCESS 4D TAGS(input;output)
 //output is "My name is: ERROR: missing ')'"
```

Note that the *$4dtag* syntax supports matching pairs of enclosed quotes or parenthesis. For example, suppose that you need to evaluate the following complex (unrealistic) string:

```
String(1) + "¥"(hello)¥""
```

You can write:

```
input:="$4DEVAL( String(1)+¥"¥¥¥"(hello)¥¥¥"¥")"
PROCESS 4D TAGS(input;output)
-->output is 1"(hello)"
```

## Usage notes

### Recursive processing

4D tags are interpreted recursively: 4D always attempts to reinterpret the result of a transformation and, if a new transformation has taken place, an additional interpretation is performed, and so on until the product obtained no longer requires any further transformation. For example, given the following statement:

```
<!--#4DHTML [Mail]Letter_type-->
```

If the [Mail]Letter_type text field itself contains a tag, for example *<!--#4DSCRIPT/m_Gender-->*, this tag will be evaluated recursively after the interpretation of the 4DHTML tag.

This powerful principle meets most needs related to text transformation. Note, however, that in some cases this can also allow malicious code to be inserted. For more information about this point, refer to the following section.

### Prevention of malicious code insertion

4D transformation tags accept different types of data as parameters: text, variables, methods, command names, etc. When this data is provided by your own code, there is no risk of malicious code insertion since you control the input. However, your database code often works with data that was, at one time or another, introduced through an external source (user input, import, etc.).
In this case, it is advisable to not use transformation tags such as 4DEVAL or 4DSCRIPT, which evaluate parameters, directly with this sort of data.
In addition, according to the principle of recursion (see previous section), malicious code may itself include transformation tags. In this case, it is imperative to use the 4DTEXT tag.
Imagine, for example, a Web form field named "Name", where users must enter their name. This name is then displayed using a *<!--#4DHTML vName-->* tag in the page. If text of the "*<!--#4DEVAL **QUIT 4D**-->*" type is inserted instead of the name, interpreting this tag will cause the application to be exited.
To avoid this risk, you can just use the 4DTEXT tag systematically in this case. Since this tag escapes the special HTML characters, any malicious recursive code that may have been inserted will not be reinterpreted. To refer to the previous example, the "Name" field will contain, in this case, "*<!--#4DEVAL **QUIT 4D**-->*" which will not be transformed.

### Using the "." as decimal separator

Starting from v15 R4, 4D always uses the period character (.) as decimal separator when evaluating a numerical expression using a 4D tag (4DTEXT, 4DVAR, 4DHTML, 4DHTMLVAR, and 4DEVAL). Regional settings are now ignored.

This feature facilitates code maintenance and compatibility between 4D languages and versions.

For example, whatever the regional settings:

```
value:=10/4
input:="<!--#4DTEXT value-->"
PROCESS 4D TAGS(input;output)
 // always outputs 2.5 even if regional settings use the ',' as separator
```

**Compatibility note:** If your code evaluates numerical expressions using 4D tags with respect to the regional settings, you need to adapt it using the **String** command:

- To get *value* with a period as decimal point: *<!--#4DTEXT value-->*
- To get *value* with a decimal point based on the regional settings: *<!--#4DTEXT String(value)-->*

# Change string

Change string ( source ; newChars ; where ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String | ⇒ | Original string |
| newChars | String | ⇒ | New characters |
| where | Longint | ⇒ | Where to start the changes |
| Function result | String | ⇐ | Resulting string |

## Description

**Change string** changes a group of characters in *source* and returns the resulting string. The command overlays *source*, with the characters in *newChars*, at the character described by *where*.

If *newChars* is an empty string (""), **Change string** returns *source* unchanged. **Change string** always returns a string of the same length as *source*. If *where* is less than one or greater than the length of *source*, **Change string** returns *source*.

**Change string** is different from **Insert string** in that it overwrites characters instead of inserting them.

## Example

The following example illustrates the use of **Change string**. The results are assigned to the variable *vtResult*.

```
vtResult:=Change string("Acme";"CME";2) ` vtResult gets "ACME"
vtResult:=Change string("November";"Dec";1) ` vtResult gets "December"
```

# Char

Char ( charCode ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| charCode | Longint | ⇒ | Character code |
| Function result | String | ⇐ | Character represented by the charCode |

## Description

The **Char** command returns the character whose code is *charCode*.

Pass a UTF-16 value (included between 1 and 65535) in *charCode*.

**Tip:** In editing a method, the command **Char** is commonly used to specify characters that cannot be entered from the keyboard or that would be interpreted as an editing command in the Method editor.

## Example

The following example uses **Char** to insert a carriage return within the text of an alert message:

```
ALERT("Employees: "+String(Records in table([Employees]))+Char(Carriage return)+"Press OK to continue.")
```

# Character code

Character code ( character ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| character | String | ⇒ | Character for which you want to get the code |
| Function result | Longint | ⇐ | Character code |

## Description

The **Character code** command returns the Unicode UTF-16 code (included between 1 and 65535) of *character*.

If there is more than one character in the string, **Character code** returns only the code of the first character.

The **Char** function is the counterpart of **Character code**. It returns the character that the UTF-16 code represents.

## Example 1

Uppercase and lowercase characters are considered equal within a comparison. You can use **Character code** to differentiate between uppercase and lowercase characters. Thus, this line returns True:

```
("A"="a")
```

On the other hand, this line returns False:

```
(Character code("A")=Character code("a"))
```

## Example 2

This example returns the code of the first character of the string *"ABC"*:

```
GetCode:=Character code("ABC") ` GetCode gets 65, the character code of A
```

## Example 3

The following example tests for carriage returns and tabs:

```
For($vlChar;1;Length(vtText))
   Case of
      :(vtText[$vlChar]=Char(Carriage return))
   ` Do something
      :(vtText[$vlChar]=Char(Tab))
   ` Do something else
      :(...)
   ` ...
   End case
End for
```

When executed multiple times on large texts, this test will run faster when compiled if it is written this way:

```
For($vlChar;1;Length(vtText))
   $vlCode:=Character code(vtText[$vlChar])
   Case of
      :($vlCode=Carriage return)
   ` Do something
      :($vlCode=Tab)
   ` Do something else
      :(...)
   ` ...
```

```
    End case
End for
```

The second piece of code runs faster for two reasons: it does only one character reference by iteration and uses LongInt comparisons instead of string comparisons to test for carriage returns and tabs. Use this technique when working with common codes such as CR and TAB.

# CONVERT FROM TEXT

CONVERT FROM TEXT ( 4Dtext ; charSet ; convertedBLOB )

| Parameter | Type | | Description |
|---|---|---|---|
| 4Dtext | String | ⇨ | Text expressed in current character set of 4D |
| charSet | String, Longint | ⇨ | Name or Number of character set |
| convertedBLOB | BLOB | ⇦ | BLOB containing converted text |

## Description

The **CONVERT FROM TEXT** command can be used to convert a text expressed in the current character set of 4D to a text expressed in another character set.

In the *4Dtext* parameter, pass the text to be converted. This text is expressed in the character set of 4D. In version 11, 4D uses the Unicode character set by default.

In *charSet*, pass the character set to be used for the conversion. You can pass a string containing the standard name of the set (for example “ISO-8859-1” or “UTF-8”), or its MIBEnum identifier.

Here is a list of character sets supported by the **CONVERT FROM TEXT** and **Convert to text** commands:

| MIBEnum | Name(s) |
|---|---|
| 1017 | UTF-32 |
| 1018 | UTF-32BE |
| 1019 | UTF-32LE |
| 1015 | UTF-16 |
| 1013 | UTF-16BE |
| 1014 | UTF-16LE |
| 106 | UTF-8 |
| 1012 | UTF-7 |
| 3 | US-ASCII |
| 3 | ANSI_X3.4-1968 |
| 3 | ANSI_X3.4-1986 |

**Note:** Several rows have the same MIBEnum identifier because a character set can have more than one name (alias).

For more information about the names of character sets, please refer to the following address:
*http://www.iana.org/assignments/character-sets*

After execution of the command, the converted text will be returned in the *convertedBLOB* BLOB. This BLOB can be read by the **Convert to text** command.

## System variables and sets

If the command has been correctly executed, the OK variable is set to 1. Otherwise, it is set to 0.

# Convert to text

Convert to text ( blob ; charSet ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ➡ | BLOB containing text expressed in a specific character set |
| charSet | String, Longint | ➡ | Name or Number of BLOB character set |
| Function result | Text | ↩ | Contents of BLOB expressed in 4D character set |

## Description

The **Convert to text** command converts the text contained in the *blob* parameter and returns it in text expressed in the character set of 4D. 4D uses the UTF-16 character set by default.

In *charSet*, pass the character set of the text contained in *blob*, which will be used for the conversion. If the BLOB contains text copied from within 4D, then the BLOB's text is likely to be in the UTF-16 character set. You can pass a string providing the standard name of the character set, or one of its aliases (for example, "ISO-8859-1" or "UTF-8"), or its identifier (longint). For more information, please refer to the description of the **CONVERT FROM TEXT** command.

**Convert to text** supports Byte Order Marks (BOMs). If the character set specified is of the Unicode type (UTF-8, UTF-16 or UTF-32), 4D attempts to identify a BOM among the first bytes received. If one is detected, it is filtered out of the result and 4D uses the character set that it defines instead of the one specified.

## System variables and sets

If the command has been correctly executed, the OK variable is set to 1. Otherwise, it is set to 0.

# Delete string

Delete string ( source ; where ; numChars ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String | ➡ | String from which to delete characters |
| where | Longint | ➡ | First character to delete |
| numChars | Longint | ➡ | Number of characters to delete |
| Function result | String | ↩ | Resulting string |

## Description

**Delete string** deletes *numChars* from *source*, starting at *where*, and returns the resulting string.

**Delete string** returns the same string as *source* when:

- *source* is an empty string
- *where* is greater than the length of *source*
- *numChars* is zero (0)

If *where* is less than one, the characters are deleted from the beginning of the string.

If *where* plus *numChars* is equal to or greater than the length of *source*, the characters are deleted from *where* to the end of *source*.

## Example

The following example illustrates the use of **Delete string**. The results are assigned to the variable *vtResult*.

```
vtResult:=Delete string("Lamborghini";6;6) ` vtResult gets "Lambo"
vtResult:=Delete string("Indentation";6;2) ` vtResult gets "Indention"
vtResult:=Delete string(vtOtherVar;3;32000) ` vtResult gets the first two characters of vtOtherVar
```

# Get localized string

Get localized string ( resName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| resName | String | ⇒ | Name of resname attribute |
| Function result | String | ⇐ | Value of string designated by resName in current language |

## Description

The **Get localized string** command returns the value of the string designated by the *resName* attribute for the current language.

This command only works within an XLIFF architecture. For more information about this type of architecture, please refer to the description of XLIFF support in the *Design Reference* manual.

**Note:** The **Get database localization** command can be used to find out the language used by the application.

Pass the resource name of the string for which you want to get the translation into the current target language in *resName*.

Note that XLIFF is diacritical.

## Example

Here is an extract from an .xlf file:

```
<file source-language="en-US" target-language="fr-FR"> [...]    <trans-unit resname="Show on disk">       <source>Show on disk</source>       <target>Montrer sur le disque</target>    </trans-unit>
```

After executing the following statement:

```
$FRvalue:=Get localized string("Show on disk")
```

... if the current language is French, $FRvalue contains “Montrer sur le disque”.

## System variables and sets

If the command is executed correctly, the OK variable is set to 1. If *resName* is not found, the command returns an empty string and the OK variable is set to 0.

# GET TEXT KEYWORDS

GET TEXT KEYWORDS ( text ; arrKeywords {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| text | Text | ⇒ | Original text |
| arrKeywords | Text array | ⇐ | Array containing keywords |
| * | Operator | ⇒ | If passed = unique words |

## Description

The **GET TEXT KEYWORDS** command splits all the *text* into individual words and creates an item in the *arrKeywords* text array for each word.

4D uses the same algorithm to break up text into individual words that it does to build a **Keywords index**. It is based on the ICU library. For more information about how text is separated into words, refer to the following address: http://userguide.icu-project.org/boundaryanalysis.

**Note:** At the request of users, we introduced an exception for French and Italian: the apostrophe (') followed by either a vowel or the letter "h" is considered as a word separator. For example, the strings "L'homme" or "l'arbre" are split into "L'"+"homme" and "l'"+"arbre".

The algorithm used differs according to whether or not the **Consider only non-alphanumeric chars for keywords** option is checked in the Database settings (refer to **Database/Data storage page** in the *Design Reference* manual).

In the *text* parameter, pass the original text to be split into words. This can be styled text, in which case style tags are ignored.

For the *arrKeywords* parameter, the command fills this text array with the words extracted from the text.

If you pass the optional * parameter, the command only stores each different keyword once in *arrKeywords*. By default, if this parameter is omitted, all the words extracted from the text are stored in the array, even when they appear more than once.

This command gives you a simple way to search records containing large amounts of text with the assurance of using the same keywords as 4D. For example, imagine you have a text containing "10,000 Jean-Pierre BC45". If this text is split into the keywords "10,000" + "Jean" + "Pierre" + "BC45", then the array contains 4 elements. Then it is easy to loop through this array by programming to find records containing one or more of these keywords using the % operator (see examples).

## Example 1

In a form with a search area, users can enter one or more word(s). When a user validates this form, we look for records where the *MyField* field contains at least one of the words entered by the user.

```
 // vSearch is the variable of the search area in the form
GET TEXT KEYWORDS(vSearch;arrSearch;*)
 //* in case a user enters the same word more than once
CREATE SET([MyTable];"Totalfound")
$n:=Size of array(arrSearch)
For($i;1;$n)
   QUERY([MyTable];[MyTable]MyField % arrSearch{$i})
   CREATE SET([MyTable];"found")
   UNION("Totalfound";"found";"Totalfound")
End for
USE SET("Totalfound")
```

## Example 2

In the same form as before, we look for records where the *MyField* field contains all the words entered by the user.

```
 // vSearch is the variable of the search area in the form
GET TEXT KEYWORDS(vSearch;arrSearch;*)
$n:=Size of array(arrSearch)
QUERY([MyTable];[MyTable]MyField >=0;*)
```

```
 // initializing search = all records
For($i;1;$n)
   QUERY([MyTable];&;[MyTable]MyField % arrSearch{$i};*)
 // add criterion
End for
QUERY([MyTable]) //search
```

## Example 3

To count words in a text:

```
GET TEXT KEYWORDS(vText;arrWords) // all words
$n:=Size of array(arrWords)
GET TEXT KEYWORDS(vText;arrWords;*) // different words
$m:=Size of array(arrWords)
ALERT("This text contains "+String($n)+" separate words among "+String($m))
```

# Insert string

Insert string ( source ; what ; where ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String | ➡ | String in which to insert the other string |
| what | String | ➡ | String to insert |
| where | Longint | ➡ | Where to insert |
| Function result | String | ↩ | Resulting string |

## Description

**Insert string** inserts a string into *source* and returns the resulting string. **Insert string** inserts the string *what* before the character at position *where*.

If *what* is an empty string (""), **Insert string** returns *source* unchanged.

If *where* is greater than the length of *source*, then *what* is appended to *source*. If *where* is less than one (1), then *what* is inserted before *source*.

**Insert string** is different from **Change string** in that it inserts characters instead of overwriting them.

## Example

The following example illustrates the use of **Insert string**. The results are assigned to the variable *vtResult*.

```
vtResult:=Insert string("The tree";" green";4) ` vtResult gets "The green tree"
vtResult:=Insert string("Shut";"o";3) ` vtResult gets "Shout"
vtResult:=Insert string("Indention";"ta";6) ` vtResult gets "Indentation"
```

# Length

Length ( string ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| string | String | ⇒ | String for which to return length |
| Function result | Longint | ⇐ | Length of string |

## Description

**Length** is used to find the length of *aString*. **Length** returns the number of characters that are in *aString*.

**Note:** In Unicode mode, when you want to check whether a string contains any characters, including ignorable characters, you must use the test If(Length(vtAnyText)=0) rather than If(vtAnyText=""). If the string contains for example Char(1), which is an ignorable character, Length(vtAnyText) does return 1 but vtAnyText="" returns True.

## Example

This example illustrates the use of **Length**. The results, described in the comments, are assigned to the variable *vlResult*.

```
vlResult:=Length("Topaz") ` vlResult gets 5
vlResult:=Length("Citizen") ` vlResult gets 7
```

# Lowercase

Lowercase ( aString {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aString | String | ➡ | String to convert to lowercase |
| * | Operator | ➡ | If passed: keep accents |
| Function result | String | ⮌ | String in lowercase |

## Description

**Lowercase** takes *aString* and returns the string with all alphabetic characters in lowercase.

The optional * parameter, if passed, indicates that any accented characters present in *aString* must be returned as accented lowercase characters. By default, when this parameter is omitted, accented characters “lose” their accents after the conversion is carried out.

## Example 1

The following project method capitalizes the string or text received as parameter. For instance, Caps ("john") would return "John".

```
  ` Caps project method
  ` Caps ( String ) -> String
  ` Caps ( Any text or string ) -> Capitalized text

$0:=Lowercase($1)
If(Length($0)>0)
   $0≤1≥:=Uppercase($0≤1≥)
End if
```

## Example 2

This example compares the results obtained according to whether or not the * parameter has been passed:

```
$thestring:=Lowercase("DÉJÀ VU") ` $thestring is "deja vu"
$thestring:=Lowercase("DÉJÀ VU";*) ` $thestring is "déjà vu"
```

# Match regex

Match regex ( pattern ; aString ; start {; pos_found ; length_found}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| pattern | Text | ⇒ | Regular expression |
| aString | Text | ⇒ | String in which search will be done |
| start | Longint | ⇒ | Position in aString where search will start |
| pos_found | Longint array, Longint variable | ⇐ | Position of occurrence |
| length_found | Longint array, Longint variable | ⇐ | Length of occurrence |
| * | Operator | ⇒ | If passed: only searches at position indicated |
| Function result | Boolean | ⇒ | True = search has found an occurrence; Otherwise, False. |

Match regex ( pattern ; aString ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| pattern | Text | ⇒ | Regular expression (complete equality) |
| aString | Text | ⇒ | String in which search will be done |
| Function result | Boolean | ⇒ | True = search has found an occurrence; Otherwise, False. |

## Description

The **Match regex** command checks the conformity of a character string with respect to a set of synthesized rules by means of a meta-language called “regular expression” or “rational expression.” The regex abbreviation is commonly used to indicate these types of notations.

Pass the regular expression to search for in *pattern*. This consists of a set of characters used for describing a character string, using special characters.

Pass the string where you want to search for the regular expression in *aString*.

In *start*, pass the position at which to start the search in *aString*.

If *pos_found* and *length_found* are variables, the command returns the position and length of the occurrence in these variables. If you pass arrays, the command returns the position and length of the occurrence in the element zero of the arrays and the positions and lengths of the groups captured by the regular expression in the following elements.

The optional * parameter indicates, when it is passed, that the search must be carried out at the position specified by *start* without searching any further in the case of failure.

The command returns **True** if the search has found an occurrence.

For more information about regex, refer to the following address:
http://en.wikipedia.org/wiki/Regular_expression

For more information about the syntax of the regular expression passed in the *pattern* parameter, refer to the following address:
http://www.icu-project.org/userguide/regexp.html

## Example 1

Search for complete equality (simple syntax):
*vfound:=Match regex(pattern;mytext)*

```
QUERY BY FORMULA([Employees];Match regex(".*smith.*";[Employees]name))
```

## Example 2

Search in text by position:
*vfound:=Match regex( pattern;mytext; start; pos_found; length_found)*
Example to display all the $1 tags:

```
$start:=1
Repeat
   vfound:=Match regex("<.*>";$1;$start;pos_found;length_found)
```

```
   If(vfound)
      ALERT(Substring($1;pos_found;length_found))
      $start:=pos_found+length_found
   End if
Until(Not(vfound))
```

## Example 3

Search with support of “capture groups” via parentheses. ( ) are used to specify groups in the regexes:
*vfound:=Match regex( pattern;mytext; start; pos_found_array; length_found_array)*

```
ARRAY LONGINT(pos_found_array;0)
ARRAY LONGINT(length_found_array;0)
vfound:=Match regex("(.*)stuff(.*)";$1;1;pos_found_array;length_found_array)
If(vfound)
   $group1:=Substring($1;pos_found_array{1};length_found_array{1})
   $group2:=Substring($1;pos_found_array{2};length_found_array{2})
End if
```

## Example 4

Search limiting the comparison of the pattern to the position indicated:
Add a star to the end of one of the two previous syntaxes.

```
vfound:=Match regex("a.b";"---a-b---";1;$pos_found;$length_found)
 `returns True
vfound:=Match regex("a.b";"---a-b---";1;$pos_found;$length_found;*)
 `returns False
vfound:=Match regex("a.b";"---a-b---";4;$pos_found;$length_found;*)
 `returns True
```

**Note:** The positions and lengths returned are only meaningful in Unicode mode or if the text being worked with is of the 7-bit ASCII type.

## Error management

In the event of an error, the command generates an error that you can intercept via a method installed by the **ON ERR CALL** command.

# Num

Num ( expression {; separator} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| expression | String, Boolean, Longint | ⇒ | String for which to return the numeric form, or Boolean to return 0 or 1, or Numeric expression |
| separator | String | ⇒ | Decimal separator |
| Function result | Longint | ⇐ | Numeric form of the expression parameter |

## Description

The **Num** command returns the numeric form of the String, Boolean or numeric expression you pass in *expression*. The optional *separator* parameter designates a decimal separator for evaluating string type expressions.

**String Expressions**

If *expression* consists only of one or more alphabetic characters, **Num** returns a zero. If *expression* includes alphabetic and numeric characters, the command ignores the alphabetic characters. Thus, it transforms the string "a1b2c3" into the number 123.

There are three reserved characters that **Num** treats specially: the decimal separator as defined in the system (if the *separator* parameter is not passed), the hyphen "-", and "*e*" *or* "E". These characters are interpreted as numeric format characters.

- The decimal separator is interpreted as a decimal place and must appear embedded in a numeric string. By default, the command uses the decimal separator set by the operating system. You can modify this character using the *separator* parameter (see below).
- The hyphen causes the number or exponent to be negative. The hyphen must appear before any negative numeric characters or after the "e" for an exponent. Except for the "e" character, if a hyphen is embedded in a numeric string, the portion of the string after the hyphen is ignored. For example, **Num**("123-456") returns 123, but **Num**("-9") returns -9.
- The e or E causes any numeric characters to its right to be interpreted as the power of an exponent. The "e" must be embedded in a numeric string. Thus, **Num**("123e-2") returns 1.23.
  Note that when the string includes more than one "e", conversion might give different results under Mac OS and under Windows.

The *separator* parameter designates a custom decimal separator for evaluating the *expression*. When the string to be evaluated is expressed with a decimal separator different from the system operator, the command returns an incorrect result. The *separator* parameter can be used in this case to obtain a correct evaluation. When this parameter is passed, the command does not take the system decimal separator into account. You can pass one or more characters.

**Note:** The **GET SYSTEM FORMAT** command can be used to find out the current decimal separator as well as several other regional system parameters.

**Boolean Expressions**

If you pass a Boolean expression, **Num** returns 1 if the expression is True; otherwise, it returns *0* (zero).

**Numeric Expressions**

If you pass a numeric expression in the *expression* parameter, **Num** returns the value passed in the *expression* parameter as is. This can be useful more particularly in the case of generic programming using pointers.

## Example 1

The following example illustrates how **Num** works when passed a string argument. Each line assigns a number to the *vResult* variable. The comments describe the results:

```
vResult:=Num("ABCD") ` vResult gets 0
vResult:=Num("A1B2C3") ` vResult gets 123
vResult:=Num("123") ` vResult gets 123
vResult:=Num("123.4") ` vResult gets 123.4
vResult:=Num("-123") ` vResult gets -123
vResult:=Num("-123e2") ` vResult gets -12300
```

## Example 2

Here, *[Client]Debt* is compared with *$1000*. The **Num** command applied to these comparisons returns 1 or 0. Multiplying 1 or 0 with a string repeats the string once or returns the empty string. As a result, *[Client]Risk* gets either “Good” or “Bad”:

```
  ` If client owes less than 1000, a good risk.
  ` If client owes more than 1000, a bad risk.
[Client]Risk:=("Good"*Num([Client]Debt<1000))+("Bad"*Num([Client]Debt>=1000))
```

## Example 3

This example compares the results obtained depending on the “current” separator:

```
$thestring:="33,333.33"
$thenum:=Num($thestring)
  ` by default, $thenum equals 33,33333 on a French system
$thenum:=Num($thestring;".")
  ` $thenum will be correctly evaluated regardless of the system;
  ` for example, 33 333,33 on a French system
```

# Position

Position ( find ; aString {; start {; lengthFound}}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| find | String | ⇒ | String to find |
| aString | String | ⇒ | String in which to search |
| start | Longint | ⇒ | Position in string where search will start |
| lengthFound | Longint | ⇐ | Length of string found |
| * | Operator | ⇒ | If passed: evaluation based on character codes |
| Function result | Longint | ⇒ | Position of first occurrence |

## Description

**Position** returns the position of the first occurrence of *find* in *aString*.

If *aString* does not contain *find*, it returns a zero (0).

If **Position** locates an occurrence of *find*, it returns the position of the first character of the occurrence in *aString*.

If you ask for the position of an empty string within an empty string, **Position** returns zero (0).

By default, the search begins at the first character of *aString*. The optional *start* parameter can be used to specify the character where the search will begin in *aString*.

The *lengthFound* parameter, if passed, returns the length of the string actually found by the search. This parameter is necessary to be able to correctly manage letters that can be written using one or more characters (e.g.: æ and ae, ß and ss, etc.).
Note that when the * parameter is passed (see below), these letters are not considered as equivalent (æ # ae); in this mode, *lengthFound* is always equal to the length of *find* (if an occurrence is found).

By default, the command makes global comparisons that take linguistic particularities and letters that may be written with one or more characters (for example æ = ae) into account. On the other hand, it is not diacritical (a=A, a=à and so on) and does not take "ignorable" characters into account (Unicode specification). Ignorable characters include all characters in unicode *C0 Control* subset (U+0000 to U+001F, ascii character control set) except printable ones (U+0009 TAB, U+0010 LF, U+0011 VT, U+0012 FF and U+0013 CR).
To modify this functioning, pass the asterisk * as the last parameter. In this case, comparisons will be based on character codes. You must pass the * parameter:

- If you want to take special characters into account, used for example as delimiters (**Char**(1), etc.),
- If the evaluation of characters must be case sensitive and take accented characters into account (a#A, a#à and so on). Note that in this mode, the evaluation does not handle variations in the way words are written.

**Note:** In certain cases, using the * parameter can significantly accelerate the execution of the command.

**Warning:** You cannot use the @ wildcard character with **Position**. For example, if you pass *"abc@"* in *find*, the command will actually look for *"abc@"* and not for "abc" plus any character.

## Example 1

This example illustrates the use of **Position**. The results, described in the comments, are assigned to the variable *vlResult*.

```
vlResult:=Position("ll";"Willow") ` vlResult gets 3
vlResult:=Position(vtText1;vtText2) ` Returns first occurrence of vtText1 in vtText2
vlResult:=Position("day";"Today is the first day";1) ` vlResult gets 3
vlResult:=Position("day";"Today is the first day";4) ` vlResult gets 20
vlResult:=Position("DAY";"Today is the first day";1;*) ` vlResult gets 0

vlResult:=Position("œ";"Bœuf";1;$length) ` vlResult =2, $length = 1
```

## Example 2

In the following example, the *lengthFound* parameter can be used to search for all the occurrences of "aegis" in a text, regardless of how it is written:

```
$start:=1
Repeat
   vlResult:=Position("aegis";$text;$start;$lengthfound)
   $start:=$start+$lengthfound
Until(vlResult=0)
```

# Replace string

Replace string ( source ; oldString ; newString {; howMany}{; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String | ➡ | Original string |
| oldString | String | ➡ | Characters to replace |
| newString | String | ➡ | Replacement string (if empty string, occurrences are deleted) |
| howMany | Longint | ➡ | How many times to replace If omitted, all occurrences are replaced |
| * | Operator | ➡ | If passed: evaluation based on character codes |
| Function result | String | ⮌ | Resulting string |

## Description

**Replace string** replaces *howMany* occurrences of *oldString* in *source* with *newString*.

If *newString* is an empty string (""), **Replace string** deletes each occurrence of *oldString* in *source*.

If *howMany* is specified, **Replace string**will replace only the number of occurrences of *oldString* specified, starting at the first character of *source*. If *howMany* is not specified, then all occurrences of *oldString* are replaced.

If *oldString* is an empty string, **Replace string** returns the unchanged *source*.

By default, the command makes global comparisons that take linguistic particularities and letters that may be written with one or more characters (for example æ = ae) into account. On the other hand, it is not diacritical (a=A, a=à and so on) and does not take "ignorable" characters such as characters whose code < 9 into account (Unicode specification).

To modify this functioning, pass the asterisk * as the last parameter. In this case, comparisons will be based on character codes. You must pass the * parameter:

- If you want to replace special characters, used for example as delimiters (**Char**(1), etc.),
- If the replacement of characters must be case sensitive and take accented characters into account (a#A, a#à and so on).
  Note that in this mode, the evaluation does not handle variations in the way words are written.

**Note:** In 4D v15 R3 and higher, a significant optimization was made to the algorithm used by this command when you replace a string by another of a different length, regardless of the syntax used. This results in a considerable acceleration of processing in this context.

## Example 1

The following example illustrates the use of **Replace string**. The results, described in the comments, are assigned to the variable *vtResult*.

```
vtResult:=Replace string("Willow";" ll";"d") ` Result gets "Widow"
vtResult:=Replace string("Shout";"o";"") ` Result gets "Shut"
vtResult:=Replace string(vtOtherVar;Char(Tab);",";*) ` Replaces all tabs in vtOtherVar with commas
```

## Example 2

The following example eliminates CRs and TABs from the text in *vtResult*:

```
vtResult:=Replace string(Replace string(vtResult;Char(Carriage return);"";*);Char(Tab);"";*)
```

## Example 3

The following example illustrates the use of the * parameter in the case of a diacritical evaluation:

```
vtResult:=Replace string("Crème brûlée";"Brulee";"caramel") `Result gets "Crème caramel"
vtResult:=Replace string("Crème brûlée";"Brulee";"caramel";*) `Result gets "Crème brûlée"
```

# String

String ( expression {; format {; addTime}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| expression | Expression | ⇒ | Expression for which to return the string form (can be Real, Integer, Long Integer, Date, Time String, Text or Boolean) |
| format | String, Longint | ⇒ | Display format |
| addTime | Time | ⇒ | Time to add on if expression is a date |
| Function result | String | ⇐ | String form of the expression |

## Description

The **String** command returns the string form of the numeric, Date, Time, string or Boolean expression you pass in *expression*.

If you do not pass the optional *format* parameter, the string is returned with the appropriate default format. If you pass *format*, you can force the result string to be of a specific format.

The optional *addTime* parameter adds a time to a date in a combined format. It can only be used when the *expression* parameter is a date (see below).

**Numeric Expressions**

If *expression* is a numeric expression (Real, Integer, Long Integer), you can pass an optional string format. Following are some examples:

| Example | Result | Comments |
|---|---|---|
| String(2^15) | "32768" | Default format |
| String(2^15;"###,##0 Inhabitants") | "32,768 Inhabitants" | |
| String(1/3;"##0.00000") | "0.33333" | |
| String(1/3) | "0.3333333333333" | Default format(*) |
| String(Arctan(1)*4) | "3.14159265359" | Default format(*) |
| String(Arctan(1)*4;"##0.00") | "3.14" | |
| String(-1;"&x") | "0xFFFFFFFF" | |
| String(-1;"&$") | "$FFFFFFFF" | |
| String(0 ?+ 7;"&x") | "0x0080" | |
| String(0 ?+ 7;"&$") | "$80" | |
| String(0 ?+ 14;"&x") | "0x4000" | |
| String(0 ?+ 14;"&$") | "$4000" | |
| String(50.3;"&xml") | "50.3" | Always "." as decimal separator |
| String(Num(1=1);"True;;False") | "True" | |
| String(Num(1=2);"True;;False") | "False" | |
| String(Log(-1)) | "" | Undefined number |
| String(1/0) | "INF" | Positive infinite number |
| String(-1/0) | "-INF" | Negative infinite number |

(*) Beginning with 4D v14 R3, the algorithm for converting real values into text is based on 13 significant digits (as opposed to 15 digits in previous versions of 4D).

The format is specified in the same way as it would be for a number field on a form. See the section **Display formats** in the 4D Design Reference manual for more information about formatting numbers. You can also pass the name of a custom style in *format*. The custom style name must be preceded by the "|" character.

**Note:** The **String** function is not compatible with "Integer 64 bits" type fields in compiled mode.

**Date Expressions**

If *expression* is a Date expression, the string is returned using the default format specified in the system.
In the *format* parameter, you can pass one of the constants described below (**Date Display Formats** theme).

In this case, you can also pass a time in the *addTime* parameter. This parameter lets you combine a date with a time so that you can generate time stamps in compliance with current standards (ISO Date GMT and Date RFC 1123 constants). These formats are particularly useful in the context of XML and Web processing. The *addTime* parameter can only be used when the *expression* parameter is a date.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null date | Longint | 100 | "" instead of 0 |
| Date RFC 1123 | Longint | 10 | |
| Internal date abbreviated | Longint | 6 | Dec 29, 2006 |
| Internal date long | Longint | 5 | December 29, 2006 |
| Internal date short | Longint | 7 | 12/29/2006 |
| Internal date short special | Longint | 4 | 12/29/06 (but 12/29/1896 or 12/29/2096) |
| ISO Date | Longint | 8 | 2006-12-29T00:00:00 (deprecated) |
| ISO Date GMT | Longint | 9 | 2010-09-13T16:11:53Z |
| System date abbreviated | Longint | 2 | Sun, Dec 29, 2006 |
| System date long | Longint | 3 | Sunday, December 29, 2006 |
| System date short | Longint | 1 | 12/29/2006 |

**Note:** Formats can vary depending on system settings.

Here are a few examples of simple formats (assuming that the current date is 12/29/2006):

```
$vsResult:=String(Current date) //$vsResult gets "12/29/06"
$vsResult:=String(Current date;Internal date long) // $vsResult gets "December 29, 2006"
$vsResult:=String(Current date;ISO Date GMT) // $vsResult gets "2009-03-04T23:00:00" in France
```

**Notes for combined date/time formats:**

- The ISO Date GMT format corresponds to the ISO8601 standard, containing a date and a time expressed with respect to the time zone (GMT).

  ```
  $mydate:=String(Current date;ISO Date GMT;Current time) // returns, for instance, 2010-09-13T16:11:53Z
  ```

  Note that the "Z" character at the end indicates the GMT format.
  If you do not pass the *addTime* parameter, the command returns the date at midnight (local time) expressed in GMT time, which may cause the date to be moved forward or back depending on the local time zone:

  ```
  $mydate:=String(!13/09/2010!;ISO Date GMT) // returns 2010-09-12T22:00:00Z in France
  ```

- The ISO Date format is similar to the ISO Date GMT, except that it expresses the date and time without respect to the time zone. Note that since this format does not comply with the ISO8601 standard, its use should be reserved for very specific purposes.

  ```
  $mydate:=String(!13/09/2010!;ISO Date) // returns 2010-09-13T00:00:00 regardless of the time zone
  $mydate:=String(Current date;ISO Date;Current time) // returns 2010-09-13T18:11:53
  ```

- The Date RFC 1123 format formats a date/time combination according to the standard defined by RFC 822 and 1123. You need this format for example to set the expiration date for cookies in an HTTP header.

  ```
  $mydate:=String(Current date;Date RFC 1123;Current time) // returns, for example Fri, 10 Sep 2010 13:07:20 GMT
  ```

  The time expressed takes the time zone into account (GMT zone). If you only pass a date, the command returns the date at midnight (local time) expressed in GMT time which may cause the date to be moved forward or back depending on the local time zone:

  ```
  $mydate:=String(Current date;Date RFC 1123) // returns Thu, 09 Sep 2010 22:00:00 GMT
  ```

**Time Expressions**

If *expression* is a Time expression, the string is returned using the default **HH:MM:SS** format. In the *format* parameter, you can pass one of the following constants (thème **Time Display Formats** theme):

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null time | Longint | 100 | "" instead of 0 |
| HH MM | Longint | 2 | 01:02 |
| HH MM AM PM | Longint | 5 | 1:02 AM |
| HH MM SS | Longint | 1 | 01:02:03 |
| Hour min | Longint | 4 | 1 hour 2 minutes |
| Hour min sec | Longint | 3 | 1 hour 2 minutes 3 seconds |
| ISO time | Longint | 8 | 0000-00-00T01:02:03 |
| Min sec | Longint | 7 | 62 minutes 3 seconds |
| MM SS | Longint | 6 | 62:03 |
| System time long | Longint | 11 | 1:02:03 AM HNEC (Mac only) |
| System time long abbreviated | Longint | 10 | 1•02•03 AM (Mac only) |
| System time short | Longint | 9 | 01:02:03 |

**Notes:**

- The ISO Time format corresponds to the ISO8601 standard and contains, in theory, a date and a time. Since this format does not support combined dates/times; the date part is filled with 0s. This format expresses the local time.
- The Blank if null time constant must be added to the format; it indicates that in the case of a null value, 4D must return an empty string instead of zeros.

These examples assume that the current time is 5:30 PM and 45 seconds:

```
$vsResult:=String(Current time) ` $vsResult gets "17:30:45"
$vsResult:=String(Current time;Hour Min Sec) ` $vsResult gets "17 hours 30 minutes 45 seconds"
```

**String Expressions**

If *expression* is of the String or Text type, the command returns the same value as the one passed in the parameter. This can be useful more particularly in generic programming using pointers.
In this case, the *format* parameter, if passed, is ignored.

**Boolean Expressions**

If *expression* is of the Boolean type, the command returns the string “True” or “False” in the language of the application (for example, “Vrai” or “Faux” in a French version of 4D).
In this case, the *format* parameter, if passed, is ignored.

# Substring

Substring ( source ; firstChar {; numChars} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| source | String | ➡ | String from which to get substring |
| firstChar | Longint | ➡ | Position of first character |
| numChars | Longint | ➡ | Number of characters to get |
| Function result | String | ↩ | Substring of source |

## Description

The **Substring** command returns the portion of *source* defined by *firstChar* and *numChars*.

The *firstChar* parameter points to the first character in the string to return, and *numChars* specifies how many characters to return.

If *firstChar* plus *numChars* is greater than the number of characters in the string, or if *numChars* is not specified, **Substring** returns the last character(s) in the string, starting with the character specified by *firstChar*. If *firstChar* is greater than the number of characters in the string, **Substring** returns an empty string ("").

**Warning:** When you use this command in a multi-style context, you need to convert any Window end-of-line characters ('¥r¥n') into single ('¥r') characters in order for processing to be valid. This is due to the mechanism which normalizes 4D line endings to ensure multi-platform compatibility for texts. For more information, refer to **Automatic normalization of line endings**.

## Example 1

This example illustrates the use of **Substring**. The results, described in the comments, are assigned to the variable *vsResult*.

```
vsResult:=Substring("08/04/62";4;2) ` vsResult gets "04"
vsResult:=Substring("Emergency";1;6) ` vsResult gets "Emerge"
vsResult:=Substring(var;2) ` vsResult gets all characters except ` the first
```

## Example 2

The following project method appends the paragraphs found in the text (passed as first parameter) to a string or text array (the pointer of which is passed as second parameter):

```
  ` EXTRACT PARAGRAPHS
  ` EXTRACT PARAGRAPHS ( text ; Pointer )
  ` EXTRACT PARAGRAPHS ( Text to parse ; -> Array of ¶s )

C_TEXT($1)
C_POINTER($2)

$vlElem:=Size of array($2->)
Repeat
   $vlElem:=$vlElem+1
   INSERT IN ARRAY($2->;$vlElem)
   $vlPos:=Position(Char(Carriage return);$1)
   If($vlPos>0)
      $2->{$vlElem}:=Substring($1;1;$vlPos-1)
      $1:=Substring($1;$vlPos+1)
   Else
      $2->{$vlElem}:=$1
   End if
Until($1="")
```

# Uppercase

Uppercase ( aString {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aString | String | ⇒ | String to convert to uppercase |
| * | Operator | ⇒ | If passed: keep accents |
| Function result | String | ⇐ | String in uppercase |

## Description

**Uppercase** takes *aString* and returns the string with all alphabetic characters in uppercase.

The optional * parameter, if passed, indicates that any accented characters present in *aString* must be returned as accented uppercase characters. By default, when this parameter is omitted, accented characters “lose” their accents after the conversion is carried out.

## Example 1

This example compares the results obtained according to whether or not the * parameter has been passed:

```
$thestring:=Uppercase("hélène") ` $thestring is "HELENE"
$thestring:=Uppercase("hélène";*) ` $thestring is "HÉLÈNE"
```

## Example 2

See the example for **Lowercase**.

# _o_Convert case

_o_Convert case
Does not require any parameters

## Description

*This command is obsolete and must no longer be used*.

# _o_ISO to Mac

_o_ISO to Mac ( text ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ⇒ | Text expressed using standard Web character set |
| Function result | String | ⇐ | Text expressed using Mac OS ASCII map |

## Compatibility Note

In Unicode mode, this command does nothing (the *text* string is returned without modification). Since version 11 of 4D, this command is obsolete and its use is no longer recommended. It is recommended to convert character strings using the **CONVERT FROM TEXT** or **Convert to text** commands.

# _o_Mac to ISO

_o_Mac to ISO ( text ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ⇒ | Text expressed using Mac OS ASCII map |
| Function result | String | ⇐ | Text expressed using standard Web character set |

## Compatibility Note

In Unicode mode, this command has no effect (the *text* string is returned without modification). Since version 11 of 4D, this command is obsolete and its use is no longer recommended. It is recommended to convert character strings using the **CONVERT FROM TEXT** or **Convert to text** commands.

# _o_Mac to Win

_o_Mac to Win ( text ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ⇒ | Text expressed using Mac OS ASCII map |
| Function result | String | ⇐ | Text expressed using Windows ANSI map |

## Compatibility Note

In Unicode mode, this command has no effect (the *text* string is returned without modification). Since version 11 of 4D, this command is obsolete and its use is no longer recommended. It is recommended to convert character strings using the **Convert to text** or **CONVERT FROM TEXT** commands.

# _o_Win to Mac

_o_Win to Mac ( text ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| text | String | ➡ | Text expressed using Windows ANSI map |
| Function result | String | ⮌ | Text expressed using Macintosh ASCII map |

## Compatibility Note

In Unicode mode, this command has no effect (the *text* string is returned without modification). Since version 11 of 4D, this command is obsolete and its use is no longer recommended. It is recommended to convert character strings using the **Convert to text** or **CONVERT FROM TEXT** commands.

# Structure Access

- PAUSE INDEXES
- REGENERATE MISSING TABLE
- RELOAD EXTERNAL DATA
- RESUME INDEXES
- SET EXTERNAL DATA PATH
- SET INDEX
- Table
- Table name

# Structure Access Commands

The commands in this theme return a description of the database structure. They can be used to find out the number of tables, the number of fields in each table, the names of the tables and fields, and the type and properties of each field. Utility commands can be used to detect and regenerate missing tables in order to recover "phantom" data.

Determining the database structure is extremely useful when you are developing and using groups of project methods and forms that can be copied into different databases.

The ability to read the database structure allows you to develop and use portable code.

**Note:** You can create and modify 4D fields and tables by programming using the commands of 4D's integrated SQL kernel, like **CREATE TABLE** or **ALTER TABLE**. For more information, refer to the "**4D SQL Reference**" manual.

## Counting tables and fields

It is possible to delete 4D tables and fields. You must take this possibility into account in algorithms used for counting tables and fields. It is necessary to use algorithms combining the **Get last table number** and **Get last field number**, as well as **Is table number valid** and **Is field number valid** commands. The following is an example of this type of algorithm:

```
For($thetable;1;Get last table number)
   If(Is table number valid($thetable))
      For($thefield;1;Get last field number($thetable))
         If(Is field number valid($thetable;$thefield))
            ... `The field exists and is valid
         End if
      End for
   End if
End for
```

# CREATE INDEX

CREATE INDEX ( aTable ; fieldsArray ; indexType ; indexName {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to create an index |
| fieldsArray | Pointer array | ⇒ | Pointer(s) to field(s) to be indexed |
| indexType | Longint | ⇒ | Type of index to create: -1 = Keywords, 0 = default, 1 = Standard B-Tree, 3 = Cluster B-Tree |
| indexName | Text | ⇒ | Name of index to create |
| * | Operator | ⇒ | If passed = asynchronous indexing |

## Description

The **CREATE INDEX** command creates:

- A standard index on one or more fields (composite index) or
- A keyword index on a field.

The index is created for the *aTable* table by using one or more fields designated by the *fieldsArray* pointer array. This array contains a single row when you want to create a simple index and two or more rows when you want to create a composite index (except in the case of a keyword index). In the case of composite indexes, the order of the fields in the array is important when the index is being built.

The *indexType* parameter sets the type of index to be created. You can pass one of the following constants, found in the **Index Type** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Cluster BTree index | Longint | 3 | B-Tree type index using clusters. This type of index is optimized when the index contains few keywords, i.e. when the same values occur frequently in the data. |
| Default index type | Longint | 0 | 4D specifies the index type (excluding keywords indexes) that is the most optimized according to the contents of the field. |
| Keywords index | Longint | -1 | Permits word-by-word indexing of field contents. This type of index can only be used with fields of the Text, Alpha or Picture type. Warning: Keywords indexes cannot be composite. |
| Standard BTree index | Longint | 1 | Standard B-Tree type index. This multi-purpose index type is used in previous versions of 4D |

**Note:** A B-Tree index associated with a Text type field stores the first 1024 characters of the field (maximum). Therefore in this context, searches for strings containing more than 1024 characters will fail.

In the *indexName* parameter, you pass the name of the index to be created. Naming the index is necessary if several different types of indexes can be associated with the same field and if you want to be able to delete them individually using the **DELETE INDEX** command. If the *indexName* index already exists, the command does nothing.

The optional * parameter, when it is passed, performs indexing in asynchronous mode. In this mode, the original method continues its execution after the call from the command, regardless of whether or not the indexing is finished.

If the **CREATE INDEX** command encounters any locked records, they will not be indexed and the command will wait for them to be unlocked.

If a problem occurs during command execution (non-indexed field, attempt to create a keyword index on more than one field, etc.), an error is generated. This error can be intercepted using an error-handling method.

## Example 1

Creation of two standard indexes on the “Last Name” and “Telephone”fields of the [Customers] table:

```
ARRAY POINTER(fieldPtrArr;1)
fieldPtrArr{1}:=->[Customers]LastName
CREATE INDEX([Customers];fieldPtrArr;Standard BTree Index;"CustLNameIdx")
fieldPtrArr{1}:=->[Customers]Telephone
CREATE INDEX([Customers];fieldPtrArr;Standard BTree Index;"CustTelIdx")
```

## Example 2

Creation of a keywords index on the “Observations” field of the [Customers] table:

```
ARRAY POINTER(fieldPtrArr;1)
fieldPtrArr{1}:=->[Customers]Observations
CREATE INDEX([Customers];fieldPtrArr;Keywords Index;"CustObsIdx")
```

## Example 3

Creation of a composite index on the “City” and “Zipcode” fields of the [Customers] table:

```
ARRAY POINTER(fieldPtrArr;2)
fieldPtrArr{1}:=->[Customers]City
fieldPtrArr{2}:=->[Customers]Zipcode
CREATE INDEX([Customers];fieldPtrArr;Standard BTree Index;"CityZip")
```

# DELETE INDEX

DELETE INDEX ( fieldPtr | indexName {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr \| indexName | Pointer, String | ⇒ | Pointer to field whose indexes are to be deleted or Name of index to be deleted |
| * | Operator | ⇒ | If passed = asynchronous operation |

## Description

The **DELETE INDEX** command deletes one or more existing indexes from the database.
You can pass either a pointer to a field or the name of an index in the parameter:

- If you pass a pointer to a field (*fieldPtr*), all the indexes associated with the field will be deleted. This can consist of keyword indexes or standard indexes. However, if the field is included in one or more composite indexes, they are not deleted (you must pass an index name).
- If you pass the name of an index (*indexName*), only the designated index will be deleted. This can consist of keyword indexes, standard indexes or composite indexes.

The optional * parameter, when it is passed, performs deindexing in asynchronous mode. In this mode, the original method continues its execution after the call from the command, regardless of whether or not the index deletion is finished.

If there is no index corresponding to *fieldPtr* or *indexName*, the command does nothing.

## Example

This example illustrates both syntaxes of the command:

```
 `Deletion of all indexes related to the LastName field
DELETE INDEX(->[Customers]LastName)
 `Deletion of index named  “CityZip”
DELETE INDEX(“CityZip”)
```

# EXPORT STRUCTURE

EXPORT STRUCTURE ( xmlStructure )

| Parameter | Type | | Description |
|---|---|---|---|
| xmlStructure | Text variable | ⇦ | Export of XML definition of 4D database structure |

## Description

The **EXPORT STRUCTURE** command exports, in *xmlStructure*, the structure definition of the current 4D database in XML format. This command uses the same mechanisms as the **Export > Structure definition to XML file...** menu item found in 4D's Design mode (see **Exporting and importing structure definitions**).

In *xmlStructure*, you pass the text variable intended to store the structure definition. The exported definition includes tables, fields, indexes, and relations, as well as their attributes and any characteristics necessary for a complete description of the structure. Invisible elements are exported with the corresponding attribute. However, deleted elements are not exported.

The internal "grammar" of 4D structure definitions is documented by means of DTD files — also used for the validation of XML files. The DTD files used by 4D are grouped together in the **DTD** folder, found next to the 4D application. The **base_core.dtd** and **common.dtd** files are used for structure definitions. For more information, you can consult these files along with the comments they contain.

## Example

You want to export the current database structure in a text file:

```
C_TEXT($vTStruc)
EXPORT STRUCTURE($vTStruc)
TEXT TO DOCUMENT("myStructure.xml";$vTStruc)
```

# Field

Field ( tableNum ; fieldNum ) -> fieldPtr

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum | Longint | ⇒ | Table number |
| fieldNum | Longint | ⇒ | Field number |
| fieldPtr | Pointer | ⇐ | Field pointer |

Field ( fieldPtr ) -> fieldNum

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr | Pointer | ⇒ | Field pointer |
| fieldNum | Longint | ⇐ | Field number |

## Description

The **Field** command has two forms:

- If you pass a table number in *tableNum* and a field number in fieldNum, **Field** returns a pointer to the field.
- If you pass a field pointer in *fieldPtr*, **Field** returns the field number of the field.

## Example 1

The following example sets the *fieldPtr* variable to a pointer to the second field in the third table:

```
FieldPtr:=Field(3;2)
```

## Example 2

Passing *fieldPtr* (a pointer to the second field of a table) to **Field** returns the number 2. The following line sets *FieldNum* to 2:

```
FieldNum:=Field(FieldPtr)
```

## Example 3

The following example sets the *FieldNum* variable to the field number of [Table3]Field2:

```
FieldNum:=Field(->[Table3]Field2)
```

# Field name

Field name ( fieldPtr | tableNum {; fieldNum} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr \| tableNum | Pointer, Longint | ⇒ | Field pointer or Table number |
| fieldNum | Longint | ⇒ | Field number if a table number is passed as first parameter |
| Function result | String | ⇐ | Name of the field |

## Description

The **Field name** command returns the name of the field whose pointer you pass in *fieldPtr* or whose table and field number you pass in *tableNum* and *fieldNum*.

## Example 1

This example sets the second element of the array *FieldArray*{1} to the name of the second field in the first table. *FieldArray* is a two-dimensional array:

```
FieldArray{1}{2}:=Field name(1;2)
```

## Example 2

This example sets the second element of the array *FieldArray*{1} to the name of the field *[MyTable]MyField*. *FieldArray* is a two-dimensional array:

```
FieldArray{1}{2}:=Field name(->[MyTable]MyField)
```

## Example 3

This example displays an alert. This method passes a pointer to a field:

```
ALERT("The ID number for the field "+Field name($1)+" in the table "+Table name(Table($1))+" has to be longer than five characters.")
```

# Get external data path

Get external data path ( aField ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Text, BLOB, Picture | ⇒ | Field whose storage location you want to get |
| Function result | Text | ⇐ | Full pathname of external storage file |

## Description

The **Get external data path** command returns the full pathname of the external storage file for the data of the field passed in the *aField* parameter, for the current record. You must pass fields of the Text, BLOB or Picture type in the parameter. The command returns the pathname of the storage file even if the file does not exist or is not accessible.

More particularly, this command lets you recopy the external file.

**Note:** For more information about external storage, refer to the *Design Reference* manual.

This command returns an empty string in the following cases:

- The field is not stored outside of the data file.
- The field has a Null value (and does not contain a pathname).
- The command is executed from a remote 4D.

# GET FIELD ENTRY PROPERTIES

GET FIELD ENTRY PROPERTIES ( fieldPtr|tableNum {; fieldNum}; list ; mandatory ; nonEnterable ; nonModifiable )

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr\|tableNum | Pointer, Longint | ⇒ | Field pointer or table number |
| fieldNum | Longint | ⇒ | Field number if the table number is passed as first parameter |
| list | String | ⇐ | Associated choice list name or empty string |
| mandatory | Boolean | ⇐ | True = Mandatory, False = Optional |
| nonEnterable | Boolean | ⇐ | True = Non-enterable, False = Enterable |
| nonModifiable | Boolean | ⇐ | True = Non-modifiable, False = Modifiable |

## Description

The **GET FIELD ENTRY PROPERTIES** command returns the data entry properties for the field specified by *tableNum* and *fieldNum* or by *fieldPtr*.
You can either pass:

- table and field numbers in *tableNum* and *fieldNum*, or
- a pointer to the field in *fieldPtr*.

**Note:** This command returns the properties defined at the structure window level. Similar properties can be defined at the form level.

Once the command has been executed:

- The *list* parameter returns the choice list name associated to the field (if any). A list can be associated to the following field types: String, Text, Real, Integer, Long Integer, Date, Time and Boolean.
  If there is no choice list associated to the field or if the field type is not suitable for a choice list, an empty string is returned ("").
- The *mandatory* parameter returns True if the field is “Mandatory”; else False. The Mandatory attribute can be set for all field types, except for BLOB.
- The *nonEnterable* parameter returns True if the field is “Non-enterable”, else False. A non-enterable field can only be read, no data can be entered. The non-enterable attribute can be set for all field types, except for BLOB.
- The *nonModifiable* parameter returns True if the field is “Non-modifiable”, else False. A non-modifiable field can be entered just once and cannot be modified anymore. The Non-modifiable attribute can be set for all field types, except for BLOB.

# GET FIELD PROPERTIES

GET FIELD PROPERTIES ( fieldPtr | tableNum {; fieldNum}; fieldType {; fieldLength {; indexed {; unique {; invisible}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr \| tableNum | Pointer, Longint | ➡ | Table number or Field pointer |
| fieldNum | Longint | ➡ | Field number if Table number is passed |
| fieldType | Longint | ⬅ | Type of field |
| fieldLength | Longint | ⬅ | Length of field, if Alphanumeric |
| indexed | Boolean | ⬅ | True = Indexed, False = Non indexed |
| unique | Boolean | ⬅ | True = Unique, False = Non unique |
| invisible | Boolean | ⬅ | True = Invisible, False = Visible |

## Description

The **GET FIELD PROPERTIES** command returns information about the field specified by *fieldPtr* or by *tableNum* and *fieldNum*.

You either pass:

- the table and field numbers in *tableNum* and *fieldNum*, or
- a pointer to the field in *fieldPtr*.

After the call:

- *fieldType* returns the type of the field. The *fieldType* variable parameter can take a value provided by the following predefined constants (**Field and Variable Types** theme):

| Constant | Type | Value |
|---|---|---|
| Is alpha field | Longint | 0 |
| Is BLOB | Longint | 30 |
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is float | Longint | 35 |
| Is integer | Longint | 8 |
| Is integer 64 bits | Longint | 25 |
| Is longint | Longint | 9 |
| Is object | Longint | 38 |
| Is picture | Longint | 3 |
| Is real | Longint | 1 |
| Is subtable | Longint | 7 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |

- The *fieldLen* parameter returns the length of the field, if the field is Alphanumeric (i.e., *fieldType*=Is alpha field). The value of *fieldLen* is meaningless for the other field types.
- The *indexed* parameter returns True is the field is indexed, and False if not. The value of *indexed* is meaningful only for Alphanumeric, Integer, Long Integer, Real, Date, Time, and Boolean fields.
- The *unique* parameter returns True if the field is set to “Unique”, else False.
- The *invisible* parameter returns True if the field is set to “Invisible”, else False. The Invisible attribute can be used to hide a given field in 4D standard editor (label, charts...).

## Example 1

This example sets the variables *vType*, *vLength*, *vIndex*, *vUnique* and *vInvisible* to the properties for the third field of the first table:

```
GET FIELD PROPERTIES(1;3;vType;vLength;vIndex;vUnique;vInvisible)
```

## Example 2

This example sets the variables *vType*, *vLength*, *vIndex*, *vUnique* and *vInvisible* to the properties for the field named [Table3]Field2:

```
GET FIELD PROPERTIES(->[Table3]Field2;vType;vLength;vIndex;vUnique;vInvisible)
```

# Get last field number

Get last field number ( tableNum | tablePtr ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum \| tablePtr | Longint, Pointer | ⇒ | Table number or Pointer to table |
| Function result | Longint | ⇐ | Highest field number in table |

## Description

The **Get last field number** command returns the highest field number among the fields in the table whose number or pointer you pass in *tableNum* or *tablePtr*.

Fields are numbered in the order in which they are created. If no field has been deleted from the table, then this command returns the number of fields that the table contains. In the case of iterative loops on the field numbers of the table, you must use the **Is field number valid** command in order to check whether the field has been deleted.

## Example

The following project method builds the array *asFields*, consisting of the field names, for the table whose pointer is received as first parameter:

```
$vlTable:=Table($1)
ARRAY STRING(31;asFields;Get last field number($vlTable))
For($vlField;Size of array(asFields);1;-1)
   If(Is field number valid($vlTable;$vlField))
      asFields{$vlField}:=Field name($vlTable;$vlField)
   Else
      DELETE FROM ARRAY(asFields;$vlField)
   End if
End for
```

# Get last table number

Get last table number -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Highest table number in the database |

## Description

**Get last table number** returns the highest table number among the tables in the database. Tables are numbered in the order in which they are created. If no table has been deleted from the database, this command then returns the number of tables present in the database. In the case of repeated loops on the table numbers of the database, you must use the **Is table number valid** command in order to check that the table has not been deleted.

## Example

The following example builds an array, named asTables, with the names of tables defined in the database. This array can be used as a drop-down list (or tab control, scrollable area, and so on) to display the list of the tables, within a form:

```
ARRAY STRING(31;asTables;Get last table number)
If(Get last table number>0) `If the database does contain tables
   For($vlTables;Size of array(asTables);1;-1)
      If(Is table number valid($vlTables))
         asTables{$vlTables}:=Table name($vlTables)
      Else
         DELETE FROM ARRAY(asTables;$vlTables)
      End if
   End for
End if
```

# GET MISSING TABLE NAMES

GET MISSING TABLE NAMES ( missingTables )

| Parameter | Type | | Description |
|---|---|---|---|
| missingTables | Text array | ⇦ | Names of missing tables in the database |

## Description

The **GET MISSING TABLE NAMES** command returns the names of all the missing tables of the current database in the *missingTables* array.

Missing tables are tables whose data are present in the data file but that do not exist at the level of the current structure. This can happen when a data file is opened with different versions of the structure.

Typically, the scenario is as follows:

- The developer provides a structure containing tables A, B and C,
- The user adds the custom tables D and E, using, for example, the integrated **SQL** commands of 4D, and stores data in these tables,
- The developer provides a new version of the structure. It does not contain tables D and E.
  In this case, the user version of the database still contains data from tables D and E, but it cannot be accessed. The **GET MISSING TABLE NAMES** command will return the names "D" and "E".

Once you have identified the missing tables of the database, you can reactivate them via the **REGENERATE MISSING TABLE** command.

**Note:** The data of missing tables are erased when the data file is compacted (if the tables have not been regenerated).

# GET RELATION PROPERTIES

GET RELATION PROPERTIES ( fieldPtr|tableNum {; fieldNum}; oneTable ; oneField {; choiceField {; autoOne {; autoMany}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| fieldPtr\|tableNum | Pointer, Longint | ⇒ | Field pointer or table number |
| fieldNum | Longint | ⇒ | Field number if the table number is passed as first parameter |
| oneTable | Longint | ⇐ | One table number or 0 if no relation is defined from the field |
| oneField | Longint | ⇐ | One field number or 0 if no relation is defined from the field |
| choiceField | Longint | ⇐ | Choice field number or 0 if no choice field |
| autoOne | Boolean | ⇐ | True = Auto relate one, False = Manual relate one |
| autoMany | Boolean | ⇐ | True = Auto one to many, False = Manual one to many |

## Description

The **GET RELATION PROPERTIES** command returns the properties of the relation (if any) which starts from the source field defined by *tableNum* and *fieldNum* or by *fieldPtr*.

You can pass:

- Either table and field numbers in *tableNum* and *fieldNum*,
- Or a pointer to the field in *fieldPtr*.

Once the command has been executed:

- The *oneTable* and *oneField* parameters contain respectively the table and field number to which the relation (from the source field) is pointing. If there is no relation starting from the field, these parameters return 0.
- The *choicefield* parameter contains the choice field number (from the target table) defined within this relation. If no choice field has been set for this relation, or if no relation starts from the source field, this parameter returns 0.
- The *autoOne* and *autoMany* parameters return **True** if, respectively, the “Auto Relate One” and “Auto One to Many” boxes has been checked for this relation; otherwise, they return **False**.

**Note:** The *autoOne* and *autoMany* parameters will also return **True** if no relation starts from the source field (in this case they return non-significant values). The value of both the *oneTable* and *oneField* parameters allows you to make sure that a relation exists.

# GET TABLE PROPERTIES

GET TABLE PROPERTIES ( tablePtr|tableNum ; invisible {; trigSaveNew {; trigSaveRec {; trigDelRec {; trigLoadRec}}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| tablePtr\|tableNum | Pointer, Longint | ⇒ | Table pointer or Table number |
| invisible | Boolean | ⇐ | True = Invisible, False = Visible |
| trigSaveNew | Boolean | ⇐ | True = Trigger “On saving new record” activated; otherwise, False |
| trigSaveRec | Boolean | ⇐ | True = Trigger “On saving an existing record” activated; otherwise, False |
| trigDelRec | Boolean | ⇐ | True = Trigger “On deleting a record” activated; otherwise, False |
| trigLoadRec | Boolean | ⇐ | *** Do not use (obsolete) *** |

## Description

The **GET TABLE PROPERTIES** command returns the properties for the table passed in *tablePtr* or *tableNum*. The table number or a pointer to the table can be passed as first parameter.

Once the command has been executed:

- The *invisible* parameter returns True if the “Invisible” attribute has been set for the table, else False. The Invisible attribute allows to hide the table when using 4D standard editors (label, charts...).
- The *trigSaveNew* parameter returns True if the “On saving new record” trigger has been set for the table, else False.
- The *trigSaveRec* parameter returns True if the “On saving an existing record” trigger has been set for the table, else False.
- The *trigDelRec* parameter returns True if the “On deleting a record” trigger has been set for this table, else false.

# IMPORT STRUCTURE

IMPORT STRUCTURE ( xmlStructure )

| Parameter | Type | | Description |
|---|---|---|---|
| xmlStructure | Text | ➡ | XML definition of 4D database structure |

## Description

The **IMPORT STRUCTURE** command imports, into the current database, the XML definition of the 4D database structure passed in the *xmlStructure* parameter.

The *xmlStructure* parameter must contain a valid 4D structure definition in XML format. There are several ways to obtain a valid structure definition:

- Execute the new command,
- Select the **Export > Structure definition to XML file...** menu item found in 4D's Design mode (see **Exporting and importing structure definitions**),
- Create or modify a custom XML file based on public DTDs found in the "DTD" folder of the 4D application.

The imported structure definition is added to the structure that is already open, and is displayed in the standard Structure editor of 4D among the existing tables (if any). If an imported table has the same name as a local one, an error is generated and the import operation is aborted.

You can create a new database by importing a structure definition into an empty database.

An error is generated when the structure is in compiled and/or read only mode.

A 4D application operating in remote mode cannot call this command.

## Example

You want to import a saved structure definition into the current database:

```
$struc:=Document to text("c:¥¥4DStructures¥¥Employee.xml")
IMPORT STRUCTURE($struc)
```

# Is field number valid

Is field number valid ( tableNum | tablePtr ; fieldNum ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum \| tablePtr | Longint, Pointer | ⇒ | Table number or Pointer to table |
| fieldNum | Longint | ⇒ | Field number |
| Function result | Boolean | ⇐ | True = field exists in the table False = field does not exist in the table |

## Description

The **Is field number valid** command returns True if the field whose number is passed in the *fieldNum* parameter exists in the table whose number or pointer is passed in the *tableNum* or *tablePtr* parameter. If the field does not exist, the command returns False. Keep in mind that the command returns False if the table containing the field is in the Trash of the Explorer.

This command can be used to detect any field deletions, which create gaps in the sequence of field numbers.

## Is table number valid

Is table number valid ( tableNum ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum | Longint | ⇒ | Table number |
| Function result | Boolean | ⇐ | True = table exists in database, False = table does not exist in database |

### Description

The **Is table number valid** command returns True if the table whose number is passed in the *tableNum* parameter exists in the database and False otherwise. Keep in mind that the command returns False if the table is in the Trash of the Explorer.

This command can be used to detect any table deletions, which create gaps in the sequence of table numbers.

# PAUSE INDEXES

PAUSE INDEXES ( aTable )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table for which to pause indexes |

## Description

The **PAUSE INDEXES** command temporarily disables all the indexes of *aTable*, except for the index of the primary key.

The indexes are not physically deleted from the data (.4DIndx file) or the structure of the database (_USER_INDEXES, see **System Tables**), but they are rendered invalid and are thus no longer updated. When indexes are disabled, all the operations performed on *aTable* (queries, sorts, record additions, modifications and deletions) no longer use the indexes.

This command is mainly useful when you are importing or modifying large amounts of data in tables that have several indexes. Since 4D must update the indexes each time a record is validated, the operation could take a considerable amount of time. Disabling the indexes beforehand can significantly speed up the operation.

To resume the indexes after the operation is over, you can just call the **RESUME INDEXES** command for *aTable*.

**Note:** You can obtain a similar result by using the **CREATE INDEX** and **DELETE INDEX** commands, but you will have to call them for each index of *aTable*.

If you call the **PAUSE INDEXES** command for a table and then quit the database without having called the **RESUME INDEXES** command for this table, all this table's indexes are automatically rebuilt when the database is restarted.

**Note:** This command cannot be executed from a 4D remote.

## Example

Example of method for importing large amounts of data:

```
PAUSE INDEXES([Articles])
IMPORT DATA("HugeImport.txt") //Importing
RESUME INDEXES([Articles])
```

# REGENERATE MISSING TABLE

REGENERATE MISSING TABLE ( tableName )

| Parameter | Type | | Description |
|---|---|---|---|
| tableName | Text | ➡ | Name of missing table to be regenerated |

## Description

The **REGENERATE MISSING TABLE** command rebuilds the missing table whose name is passed in the *tableName* parameter. When a missing table is rebuilt, it becomes visible in the Structure editor and its data can once again be accessed.

Missing tables are tables whose data are present in the data file but that do not exist at the structure level. You can identify any missing tables that may be present in the application by using the **GET MISSING TABLE NAMES** command.

If the table designated by the *tableName* parameter is not a missing table of the database, the command does nothing.

## Example

This method regenerates all the missing tables that may be present in the database:

```
ARRAY TEXT($arrMissingTables;0)
GET MISSING TABLE NAMES($arrMissingTables)
$SizeArray:=Size of array($arrMissingTables)
If($SizeArray#0)
 // Fills the array with the names of all the tables in the database
   ARRAY TEXT(arrTables;Get last table number)
   If(Get last table number>0) //If there are actually tables
      For($vlTables;Size of array(arrTables);1;-1)
         If(Is table number valid($vlTables))
            arrTables{$vlTables}:=Table name($vlTables)
         Else
            DELETE FROM ARRAY(arrTables;$vlTables)
         End if
      End for
   End if
   For($i;1;$SizeArray)
      If(Find in array(arrTables;$arrMissingTables{$i})=-1)
         CONFIRM("Regenerate the table"+$arrMissingTables{$i}+"?")
         If(OK=1)
            REGENERATE MISSING TABLE($arrMissingTables{$i})
         End if
      Else
         ALERT("Impossible to regenerate table "+$arrMissingTables{$i}+" because there is already a table with this name in
the database.")
      End if
   End for
 Else
   ALERT("No tables to regenerate.")
 End if
```

# RELOAD EXTERNAL DATA

RELOAD EXTERNAL DATA ( aField )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Text, BLOB, Picture, Object | ⇒ | Field for which to set the storage location |

## Description

The **RELOAD EXTERNAL DATA** command reloads the contents in memory of an external storage file associated with a BLOB, Picture, Text or Object type field.

This command is useful when the field of a record already loaded in memory is modified on the disk by another application (external storage files for fields are always writable). For example, a picture used in a Picture field can be modified by a graphic editor then saved on disk.

You then need to reload the data using the **RELOAD EXTERNAL DATA** command to update the contents of the field if it displayed in a form.

**Note:** The **RELOAD EXTERNAL DATA** command only works on a local 4D or on 4D Server. You cannot reload a field individually with 4D in remote mode. In this context, you have to reload all the records (using the **LOAD RECORD** command for example).

# RESUME INDEXES

RESUME INDEXES ( aTable {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to resume indexes |
| * | Operator | ⇒ | If passed = asynchronous indexing |

## Description

The **RESUME INDEXES** command reactivates all the indexes of *aTable* when they have been paused previously using the **PAUSE INDEXES** command. If the indexes of *aTable* have not been paused, this command does nothing.

In most cases, executing this command triggers the rebuilding of the indexes for *aTable*.
If you pass the optional * parameter, the rebuilding of the indexes is performed in asynchronous mode. This means that the method calling the command continues its execution after this call, regardless of whether the indexing is finished or not. If you omit this parameter, the rebuilding of the indexes blocks the execution of the method until the rebuilding operation is completed.

The **RESUME INDEXES** command can only be called from 4D Server or a local 4D. If this command is executed from a remote 4D machine, the error -10513 is generated. This error can be intercepted using a method installed by the **ON ERR CALL** command.

# SET EXTERNAL DATA PATH

SET EXTERNAL DATA PATH ( aField ; path )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Text, BLOB, Picture, Object | ⇒ | Field for which to set the storage location |
| path | Text, Longint | ⇒ | Pathname and file name of external storage or<br>0 = use structure definition<br>1 = use default folder |

## Description

The **SET EXTERNAL DATA PATH** command sets or modifies, for the current record, the external storage location for the *aField* field passed as parameter.

With 4D, it is possible to store Text, BLOB, Picture and Object type fields *outside* of the data file. For a complete description of this functionality, refer to the *Design Reference* manual.

The setting defined by this command is only applied when the current record is saved on the disk. If the current record is canceled, the command does nothing. Storage parameters set in the application structure are not changed.

In *path*, you can pass either a custom pathname, or a constant designating an automatic location:

- **custom pathname to file**
  In this case, you use external storage in "custom mode." Certain 4D database functions are not available automatically in this mode (see the *Design Reference* manual). In particular, you must manage the creation or modification of the files yourself.
  You can pass either a path relative to the data file or an absolute path, which must include the name and extension of the storage file. You must use the system syntax. To set a path relative to the data file, pass "../" (Windows) or "..:" (OS X) at the start of the string. You can designate any folder, including the default folder of database external files (*databaseName*.ExternalData) - in this case, these files are included when the database is saved.
  The file designated by the *path* parameter must exist and be accessible when the command is executed. Note that if the path is invalid (file or folder missing), an error is returned only in cases where the *path* was defined as absolute. When a relative *path* has been specified, you must ensure its validity since no error is generated if the file is not found.
  If you save the external file in the same folder as the data file or one of its subfolders, 4D considers that the path specified is relative to the data file and maintains the link even when the data file folder is moved or renamed.
  Note that this means it is possible to "share" the same external file between several records. Any changes made to this external file are available in all the records. In this case, if several processes can write the same fields simultaneously, you must be careful to prevent concurrent accesses through semaphores, so as not to risk damaging the external files.

- **automatic location**
  You can designate two automatic locations using the following constants, found in the **Data File Maintenance** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Use default folder | Longint | 1 | The data of the field passed as parameter are saved in the default folder, named *databaseName*.ExternalData and placed next to the data file. In this mode, external data are managed by 4D as if they were inside the data file. |
| Use structure definition | Longint | 0 | 4D uses the parameters set in the structure for field storage (see the *Design Reference* manual). If you change from external storage to internal storage, the external file is not deleted. |

Once this command is executed, 4D automatically maintains the link between the field of the record and the file on disk. You do not need to execute the command again (except if you need to change the *path*). If 4D can no longer access the data of the field (storage file renamed or deleted, path modified, etc.), the field is empty but no error is generated.

**Note:** The **SET EXTERNAL DATA PATH** command can only be executed on a local 4D or on 4D Server. It does nothing when it is executed on a remote 4D.

## Example

You want to save an existing file in the picture field, stored outside of the data, in the database folder:

```
CREATE RECORD([Photos])
[Photos]Name:="Paris.png"
SET EXTERNAL DATA PATH([Photos]Thumbnail:Get 4D folder(Database folder)+"custom"+Folder separator+[Photos]Name)
 //"/custom/Paris.png" must exist next to structure file
SAVE RECORD([Photos])
```

# SET INDEX

SET INDEX ( aField ; index {; mode} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aField | Field | ⇒ | Field for which to create or delete the index |
| index | Boolean, Integer | ⇒ | • True=Create index, False=Delete index, or • Create an index of the type: -1=Keywords, 0=by default, 1=B-Tree standard, 3=B-Tree cluster |
| mode | Longint | ⇒ | Obsolete (parameter ignored) |
| * | | ⇒ | Asynchronous indexing if * is passed |

## Description

**Compatibility note:** This command is kept only for compatibility reasons. We now recommend using the **CREATE INDEX** and **DELETE INDEX** commands to manage indexes through programming.

The **SET INDEX** accepts two syntaxes:

- If you pass a Boolean in the*index* parameter, the command creates or removes the index for the field you pass in *aField*.
- If you pass an integer in the *index* parameter, the command creates an index of the type specified.

**index = Boolean**
To index the field, pass True in *index*. The command creates an index of the default type. If the index already exists, the call has no effect.
If you pass False in *index*, the command will delete all the standard indexes (i.e., non-composite and non-keyword) that are associated with the field. If the index does not exist, the call has no effect.

**index = Integer**
In this case, the command creates an index of the type specified for *aField*. You can pass one of the following constants, found in the "**Index Type**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Cluster BTree Index | Longint | 3 | B-Tree type index using clusters. This type of index is optimized when the index contains few keywords, i.e. when the same values occur frequently in the data. |
| Default Index Type | Longint | 0 | 4D specifies the index type (excluding keywords indexes) that is the most optimized according to the contents of the field. |
| Keywords Index | Longint | -1 | Permits word-by-word indexing of field contents. This type of index can only be used with fields of the Text or Alpha type. |
| Standard BTree Index | Longint | 1 | Standard B-Tree type index. This multi-purpose index type is used in previous versions of 4D |

**Note:** A B-Tree index associated with a Text type field stores the first 1024 characters of the field (maximum). Therefore in this context, searches for strings containing more than 1024 characters will fail.

**SET INDEX** will not index locked records; it will wait until the record becomes unlocked.

Starting with version 11, the *mode* parameter no longer serves any purpose and will be ignored if it is passed.

The optional * parameter indicates an asynchronous (simultaneous) indexing. Asynchronous indexing allows the execution of the calling method to continue immediately, whether or not indexing is completed. However, execution will halt at any command that requires the index.

**Notes:**

- Indexes created by this command do not have names. They cannot be deleted by the **DELETE INDEX** command using the syntax based on the name.
- This command cannot be used to create or delete composite indexes.
- This command cannot be used to delete a keywords index created by the **CREATE INDEX** command.

## Example 1

The following example indexes the field *[Customers]ID*:

```
UNLOAD RECORD([Customers])
SET INDEX([Customers]ID;True)
```

## Example 2

You want to index the *[Customers]Name* field in asynchronous mode:

```
SET INDEX([Customers]Name;True;*)
```

## Example 3

Creation of a keywords index:

```
SET INDEX([Books]Summary;Keywords Index)
```

# Table

Table ( tableNum | aPtr ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum \| aPtr | Longint, Pointer | ⇒ | Table number, or Table pointer, or Field pointer |
| Function result | Longint, Pointer | ⇐ | Table pointer, if a Table number is passed |
| | | | Table number, if a Table pointer is passed |
| | | | Table number, if a Field pointer is passed |

## Description

The **Table** command has three forms:

- If you pass a table number in *tableNum*, **Table** returns a pointer to the table.
- If you pass a table pointer in *aPtr*, **Table** returns the table number of the table.
- If you pass a field pointer in *aPtr*, **Table** returns the table number of the field.

## Example 1

This example sets the *tablePtr* variable to a pointer to the third table of the database:

```
TablePtr:=Table(3)
```

## Example 2

Passing *tablePtr* (a pointer to the third table) to **Table** returns the number 3. The following line sets *TableNum* to 3:

```
TableNum:=Table(TablePtr)
```

## Example 3

This example sets the *tableNum* variable to the table number of *[Table3]*:

```
TableNum:=Table(->[Table3])
```

## Example 4

This example sets the *tableNum* variable to the table number of the table to which the *[Table3]Field1* field belongs:

```
TableNum:=Table(->[Table3]Field1)
```

# Table name

Table name ( tableNum | tablePtr ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| tableNum \| tablePtr | Longint, Pointer | ⇒ | Table number or Table pointer |
| Function result | String | ⇐ | Name of the table |

## Description

The **Table name** command returns the name of the table whose number or pointer you pass in *tableNum* or *tablePtr*.

## Example

The following is an example of a generic method that displays the records of a table. The reference to the table is passed as a pointer to the table. The **Table name** command is used to include the name of the table in the title bar for the window:

```
  ` SHOW CURRENT SELECTION Project method
  ` SHOW CURRENT SELECTION ( Pointer )
  ` SHOW CURRENT SELECTION (->[Table])

SET WINDOW TITLE("Records for "+Table name($1)) `Sets the window title
DISPLAY SELECTION($1->) `Displays the selection
```

# Styled Text

The "**Styled Text**" theme contains the language commands used for managing and modifying multi-style text areas, also known as *rich text areas*.

You declare a rich text area by enabling its "Multi-style" option in the Property List (see **GET DATA SOURCE LIST** in the *Design Reference* manual). You can use the **OBJECT Is styled text** command of the "**Objects (Forms)**" theme to find out whether or not a text area is in multi-style mode.

## 4D Write Pro areas

Most commands of the "**Styled Text**" theme support 4D Write Pro areas. For more information about this point, refer to the **Using commands from the Styled Text theme** section in the 4D Write Pro Reference manual.

## Text object management commands

The commands that can be used to manipulate text objects by programming do not take any style tags integrated into the text into account. They act upon displayed text so they function as in previous versions of 4D. This concerns the following commands:

- **User Interface** theme
  **HIGHLIGHT TEXT**
  **GET HIGHLIGHT**

Note that when you use these commands with commands that manipulate character strings, it is necessary to filter the formatting characters using the **ST Get plain text** command:

```
HIGHLIGHT TEXT([Products]Notes;1;Length(ST Get plain text([Products]Notes))+1)
```

- **Objects (Forms)** theme
  The commands that can be used to modify the style of objects (for example, **OBJECT SET FONT**) apply to the whole object and not to the selection.
  Note that if the object does not have the focus when the command is executed, the modification is applied simultaneously to the object (the text area) and to its associated variable. If the object does have the focus, the modification is carried out on the object but not on the associated variable. The modification is only applied to the variable when the object loses the focus. Keep this principle in mind when programming text areas.

If the "Store with default style tags" option is checked for the object, the use of these commands will cause a modification of the tags saved with each object.

### Interaction of generic commands with multi-style areas

Starting with 4D v14, a new way of interacting has been defined between generic commands such as **OBJECT SET RGB COLORS** or **OBJECT SET FONT STYLE** and multi-style text areas.

In previous versions of 4D, executing one of these commands modified the contents of any custom style tags inserted in the area. From now on, only default properties are affected by these commands (as well as any properties saved by means of default tags). Custom style tags remain as they are.

For example, given a multi-style area where default tags were saved:

The plain text of the area is as follows:

```
<span style="text-align:left;font-family:'Segoe UI';font-size:9pt;color:#009900">This is the word <span
style="color:#D81E05">red</span></span>
```

If you execute the following code:

```
OBJECT SET COLOR(*;"myArea";-(Blue+(256*Yellow)))
```

With 4D v14, the red color remains:

**4D v14 and higher**

```
<span style="text-align:left;font-
family:'Segoe UI';font-
size:9pt;color:#0000FF">This is the word
<span style="color:#D81E05">red</span>
</span>
```

**prior versions**

```
<span style="font-family:'Segoe UI';font-size:9pt;text-
align:left;font-weight:normal;font-style:normal;text-
decoration:none;color:#0000FF;"><span style="background-
color:#FFFFFF">This is the word red</span></span>
```

The following generic commands are concerned:

**OBJECT SET RGB COLORS**
**OBJECT SET COLOR**
**OBJECT SET FONT**
**OBJECT SET FONT STYLE**
**OBJECT SET FONT SIZE**

In the context of multi-style areas, generic commands should be used to set default styles only. To manage styles during database execution, we recommend using the commands of the "**Styled Text**" theme.

## Get edited text command

When it is used with a rich text area, the **Get edited text** command (**Form Events** theme) returns the text of the current area including any style tags.

To retrieve the "plain" text (text without tags) being edited, you must use the **ST Get plain text** command:

```
ST Get plain text(Get edited text)
```

## Query and order by commands

Queries and sorts carried out among multi-style objects take into account any style tags saved in the object. If a style modification has been made within a word, searching for the word will not be successful.

To be able to carry out valid searches and sorts, you must use the **ST Get plain text** command. For example:

```
QUERY BY FORMULA([MyTable];ST Get plain text([MyTable]MyFieldStyle)="very well")
```

## Automatic normalization of line endings

In order to ensure greater multi-platform compatibility of texts handled in the database, beginning with v14, 4D automatically normalizes line endings so that they occupy a single character: '¥r' (carriage return). This normalization is carried out at the level of form objects (variables or fields) hosting plain or multi-style text. Line endings that are not native, or that use a mix of several characters (for example '¥r¥n'), are considered as a single '¥r'.

Note that in compliance with the XML standard (multi-style text format), the multi-style text commands also normalize line endings for text variables that are not associated with objects.

This principle makes it easier to use multi-style text commands or commands such as **HIGHLIGHT TEXT** in a multi-platform context. However, you must take this into account in your processing when you work with texts from heterogeneous sources.

## Supported tags

### Dynamic tags

You can use the following tags in 4D multi-style text areas.

#### 4D Expression

This tag inserts a 4D expression (expression, method, field, variable, command, etc.) in the text. The expression is tokenized and evaluated:

- when the expression is inserted
- when the object is loaded
- when the **ST COMPUTE EXPRESSIONS** command is executed
- when the **ST FREEZE EXPRESSIONS** command is executed, if the second * parameter is passed.

The evaluated value of the expression is not saved in the  tag, only its reference is.

**Note:** To ensure that expressions will be evaluated correctly regardless of the 4D language or version used, we recommend using the *token* syntax for elements whose name might vary between different versions (commands, tables, fields, constants). For example, to insert the **Current time** command, enter '**Current time:C178**'. For more information about this, refer to **Using tokens in formulas**.

#### URL

<a href="*url*">Visible label</a>

This tag inserts a URL in the text. Example:

```
<span><a href="http://www.4d.com/">4D Web Site</a></span>
```

#### User link

Click here

"User links" look the same as URLs, but when you click them, they do not automatically open the source. You can pass any string you want as reference, and it is up to the developer to program any custom actions that occur when it is clicked. This means you can create links which are not URLs but references to files, 4D methods, and so on, that you can open or execute when they are clicked. The **ST Get content type** command detects if a user link has been clicked.

User links are defined using the **ST SET TEXT** command. For example:

```
ST SET TEXT(txtVar;"This is a user link: <span style=¥"-d4-ref-user:'UserLink'¥">User Label</span>";$start;$end)
```

#### Custom tags

You can now insert any tag in plain text, for example <img src="http://doc.4d.com/pictures/ja.png">. It is stored in the code of the plain text without being interpreted or displayed. This is particularly useful in the context of e-mails in HTML format and including pictures for example.

### Style tags

This paragraph lists the attributes of <SPAN> tags that are supported by 4D in rich text areas. You can use these tags to implement custom style handling. Only the tags listed below are supported by 4D for style variations.

#### Font name

<SPAN STYLE="font-family: DESDEMONA"> ... </SPAN>

#### Font size

<SPAN STYLE="font-size: 20pt"> ... </SPAN>

#### Font style

- **Bold**
  <SPAN STYLE="font-weight: bold"> ... </SPAN>
- **Italic or normal**
  <SPAN STYLE="font-style: italic"> ... </SPAN>
  <SPAN STYLE="font-style: normal"> ... </SPAN>
- **Underline**
  <SPAN STYLE="text-decoration: underline"> ... </SPAN>
- **Strikethrough**
  <SPAN STYLE="text-decoration:line-through">...</SPAN>
  **Note :** The "strikethrough" style is not supported under Mac OS, but this tag can still be managed by programming.

### Font colors

<SPAN STYLE="color:green"> ... </SPAN>
or
<SPAN STYLE="color:#006CCC">...</SPAN>

### Background colors (Windows only)

<SPAN STYLE="background-color:green"> ... </SPAN>
or
<SPAN STYLE="background-color:#006CCC">...</SPAN>

**Note:** Under Mac OS, this attribute is ignored. It is removed when the object is modified.

### Color values

For font color and background color attributes, the color value can be either the hexadecimal code for an RGB color, or the name of one of the 16 HTML colors defined for standard CSS by the W3C:

| Color | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Name | Aqua | Black | Blue | Fuchsia | Gray | Green | Lime | Maroon |
| RGB | #00FFFF | #000000 | #0000FF | #FF00FF | #808080 | #008000 | #00FF00 | #800000 |
| Color | | | | | | | | |
| Name | Navy | Olive | Purple | Red | Silver | Teal | White | Yellow |
| RGB | #000080 | #808000 | #800080 | #FF0000 | #C0C0C0 | #008080 | #FFFFFF | #FFFF00 |

# ST COMPUTE EXPRESSIONS

ST COMPUTE EXPRESSIONS ( {* ;} object {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or<br>Field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST COMPUTE EXPRESSIONS** command updates the dynamic 4D expressions found in the styled text field or variable designated by the *object* parameter.

For more information about 4D expressions used in multi-style text areas, refer to the description of the **ST INSERT EXPRESSION** command.

The command re-evaluates the result of expressions found in the *object* based on the current context and displays the result obtained. For example, if the expression inserted is the time, the value will be modified each time the **ST COMPUTE EXPRESSIONS** command is called. Expressions are also computed:

- when they are inserted
- when the object is loaded
- when they are "frozen" using the **ST FREEZE EXPRESSIONS** command, if the second * parameter is passed.

**ST COMPUTE EXPRESSIONS** does not modify styled text (containing *span* tags) but only plain text displayed in *object*. The values computed are not stored in the styled text, only their reference is stored there.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

It is not necessary for the *object* to have the focus; however, the object must be included in a form, or else the **ST COMPUTE EXPRESSIONS** command has no effect.

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags or references that may be present. Note that a reference is equivalent to a single character.

- If you pass *startSel* and *endSel*, **ST COMPUTE EXPRESSIONS** only updates the expressions located within this selection.
- If you only pass *startSel* or if the value of *endSel*is greater than the total number of characters in object, all the expressions between *startSel* and the end of the text are computed.
- If you omit *startSel* and *endSel*, all the expressions included in the user selection of the *object* are computed.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

## Example

You want to update the references included in the selection of text:

```
ST COMPUTE EXPRESSIONS(*;"myText";ST Start highlight;ST End highlight)
```

# ST FREEZE EXPRESSIONS

ST FREEZE EXPRESSIONS ( {* ;} object {; startSel {; endSel}}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |
| * | Operator | ⇒ | If passed = update expressions before freezing them |

## Description

The **ST FREEZE EXPRESSIONS** command "freezes" the contents of expressions found in the styled text field or variable designated by the *object* parameter. This action converts dynamic expressions into static text and removes the associated references from the *object*.

For more information about 4D expressions used in multi-style text areas, refer to the description of the **ST INSERT EXPRESSION** command.

The **ST FREEZE EXPRESSIONS** command stores the computed value of an expression at a given time. This operation is necessary particularly before each use of the *object* outside of a multi-style area (exports, storage in a disk file, printing, etc.) since only the reference of the expression is kept in the area itself.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags or references that may be present.

- If you pass *startSel* and *endSel*, **ST FREEZE EXPRESSIONS** only freezes the expressions located within this selection.
- If you only pass *startSel* or if the value of *endSel* is greater than the total number of characters in the *object*, all the expressions between *startSel* and the end of the text are frozen.
- If you omit *startSel* and *endSel*, all the expressions included in the user selection of the *object* are frozen.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters.
These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel*is 0), the command does nothing and the *OK* variable is set to 0.

By default, expressions are not re-evaluated before they are frozen. If you want the expression to be recomputed and then frozen, you can pass the second * parameter.

## Example

You want to insert the current time at the start of the text and then freeze it before saving the record:

```
 //Inserting the time at the start of the text
ST INSERT EXPRESSION(*;StyledText_t;"Current time";1)
 //We freeze the expression
ST FREEZE EXPRESSIONS(*;"StyledText_t";1)
```

# ST GET ATTRIBUTES

ST GET ATTRIBUTES ( {* ;} object ; startSel ; endSel ; attribName ; attribValue {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| startSel | Longint | ⇒ | Start of text selection |
| endSel | Longint | ⇒ | End of text selection |
| attribName | Longint | ⇒ | Attribute to get |
| attribValue | Variable | ⇐ | Current value of attribute |

## Description

The **ST GET ATTRIBUTES** command is used to recover the current value of a style attribute in a selection of text of the form object(s) designated by *object*.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns information about the object being edited; however, when the object does not have the focus, the command returns information about the data source (field or variable) of the object.
If you omit the * parameter, this indicates that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference instead of a string and during execution, the command returns information about this field or variable.

The *startSel* and *endSel* parameters are used to designate the text selection of the object from which the style attribute is to be read. Pass the position of the first character of the selection in *startSel* and the position plus one of the last character of the selection in *endSel*. You can pass 0 in *endSel* to designate automatically the last character of the text (pass 1 in *startSel* to designate the first character of the text).
If the values of *startSel* and *endSel* are equal or if *startSel* is greater than *endSel* (except if *endSel* value is 0, see above), an error is returned.
The *startSel* and *endSel* values do not take any style tags already present in the area into account. They are evaluated on the basis of raw text (text from which style tags have been filtered).

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

Pass the name of the attribute to get in the *attribName* parameter and pass a variable which must recover the current value of the attribute in the *attribValue* parameter. To specify the *attribName* parameter, you must use one of the constants of the **Multistyle Text Attributes** theme.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute background color | Longint | 8 | *attribValue*=Hexadecimal values or HTML color names (Windows only) |
| Attribute bold style | Longint | 1 | *attribValue*=0: remove bold attribute from selection<br>*attribValue*=1: apply bold attribute to selection |
| Attribute font name | Longint | 5 | *attribValue*=Font family name (string) |
| Attribute italic style | Longint | 2 | *attribValue*=0: remove italic attribute from selection<br>*attribValue*=1: apply italic attribute to selection |
| Attribute strikethrough style | Longint | 3 | *attribValue*=0: remove strikethrough attribute from selection<br>*attribValue*=1: apply strikethrough attribute to selection |
| Attribute text color | Longint | 7 | *attribValue*=Hexadecimal values or HTML color names |
| Attribute text size | Longint | 6 | *attribValue*=Number of points (number) |
| Attribute underline style | Longint | 4 | *attribValue*=0: remove underline attribute from selection<br>*attribValue*=1: apply underline attribute to selection |

You can pass as many attribute/value pairs as you want.

If the value of the *attribName* attribute is the same for all of the selection, it is returned in *attribValue*. If this value is different or if *object* does not contain SPAN tags, the following values are returned:

| attribName | attribValue if attribute heterogenous in selection or no SPAN tags |
|---|---|
| Attribute background color | FFFFFFFF |
| Attribute bold style | 2 |
| Attribute font name | "" (empty string) |
| Attribute italic style | 2 |
| Attribute strikethrough style | 2 |
| Attribute text color | FFFFFFFF |
| Attribute text size | -1 |
| Attribute underline style | 2 |

## Example

Given a [Table_1]StyledText field displayed in a form. The object has the Multistyle property and is named "StyledText_t". You want to get the highlighted text as well as the status of the Bold style attribute. You can proceed in two different ways depending on whether you use the object name or the field reference.

- Using the object name:

```
$text:=ST Get text(*;"StyledText_t";ST Start highlight;ST End highlight)
ST GET ATTRIBUTES(*;"StyledText_t";ST Start highlight;ST End highlight;Attribute bold style;$bold)
```

- Using the field name:

```
GET HIGHLIGHT([Table_1]StyledText;$Begin_l;$End_l)
$text:=ST Get text([Table_1]StyledText;$Begin_l;$End_l)
ST GET ATTRIBUTES([Table_1]StyledText;$Begin_l;$End_l;Attribute bold style;$bold)
```

## System variables and sets

After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

# ST Get content type

ST Get content type ( {* ;} object {; startSel {; endSel {; startBlock {; endBlock}}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |
| startBlock | Longint | ⇐ | Start position of first type of selection |
| endBlock | Longint | ⇐ | End position of first type of selection |
| Function result | Longint | ⇐ | Type of content |

## Description

The **ST Get content type** command returns the type of content found in the styled text field or variable designated by the *object* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns the information of the object being edited; if the object does not have the focus, the command returns the information of the object's data source (variable or field).
If you omit the * parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string. During execution, the command returns the information of the variable or field.

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags that may be present.

- If you pass *startSel* and *endSel*, **ST Get content type** evaluates the contents within this selection.
- If you only pass *startSel* or if the value of *endSel*is greater than the total number of characters in *object*, the contents between *startSel* and the end of the text is evaluated.
- If you omit *startSel* and *endSel*, the contents within the current text selection is evaluated.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

The optional *startBlock* and *endBlock* parameters retrieve the position of the first and last character of the first homogenous block identified in the object or the selection of the object. For example, if the selection contains an expression and then plain text, *startBlock* and *endBlock* will return the limits of the expression. You can make a loop to process all the blocks of the selection.

This command returns a value designating the type of contents identified. You can compare this value with the following constants, found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST Expression type | Longint | 2 | Selection contains only an expression reference |
| ST Mixed type | Longint | 3 | Selection contains at least two different types of contents |
| ST Picture type | Longint | 6 | Selection contains only a picture (4D Write Pro areas only) |
| ST Plain type | Longint | 0 | Selection contains text and no references |
| ST Unknown tag type | Longint | 4 | Selection contains only an unknown tag type |
| ST URL type | Longint | 1 | Selection contains only a URL reference |
| ST User type | Longint | 5 | Selection contains only a custom reference |

## Example

You want to display context-menu commands based on the type of contents selected in the area.

```
Case of
   :(Form event=On Clicked)
 //we retrieve the selection
      GET HIGHLIGHT(*;"myText";startSel;endSel)
      If(Contextual click & (Macintosh control down=False)) //calls the context menu
         If(startSel=endSel) // no contents selected
 //we enable only certain commands
            DISABLE MENU ITEM(<>menu_STYLEDTEXT;2)
            DISABLE MENU ITEM(<>menu_STYLEDTEXT;4)
            ENABLE MENU ITEM(<>menu_STYLEDTEXT;6)
            ...
         Else // we get the content type
            CT_Texttype:=ST Get content type(*;"myText";startSel;endSel)
            Case of // processing of different types
               :(CT_Texttype=ST URL type)
                  DISABLE MENU ITEM(<>menu_STYLEDTEXT;6)
                  ENABLE MENU ITEM(<>menu_STYLEDTEXT;7)
                  ...
               :(CT_Texttype=ST Expression type)
                  DISABLE MENU ITEM(<>menu_STYLEDTEXT;6)
                  DISABLE MENU ITEM(<>menu_STYLEDTEXT;7)
                  ...
               Else
                  ENABLE MENU ITEM(<>menu_STYLEDTEXT;6)
                  DISABLE MENU ITEM(<>menu_STYLEDTEXT;7)
                  ...
            End case
         End if
         GET MOUSE($xCoord;$yCoord;$ButtonState)
         $AlphaVar:=Dynamic pop up menu(<>menu_STYLEDTEXT;"";$xCoord;$yCoord)
         startSel:=-3
         endSel:=-3
      End if
      ...
   End if
```

# ST Get expression

ST Get expression ( {* ;} object {; startSel {; endSel}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |
| Function result | Text | ⇐ | Expression label |

## Description

The **ST Get expression** command returns the first expression found in the current selection of the styled text field or variable designated by the *object* parameter.

The command returns the label of the expression as it was inserted into the object (for example "mymethod" or "[table1]field1"). The current value of the expression is not returned.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns the information of the object being edited; if the object does not have the focus, the command returns the information of the object's data source (variable or field).
If you omit the * parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string. During execution, the command returns the information of the variable or field.

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags that may be present.

- If you pass *startSel* and *endSel*, **ST Get expression** looks for the expression within this selection.
- If you only pass *startSel* or if the value of *endSel* is greater than the total number of characters in *object*, the command looks for the expression between *startSel* and the end of the text.
- If you omit *startSel* and *endSel*, the command looks for the expression within the current text selection.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

If there is no expression found in the selection, the command returns an empty string.

## Example 1

When there is a double-click event, you check that there is in fact an expression, and if so, you display a dialog where you have retrieved its values so that the user can modify them:

```
Case of
   :(Form event=On Double Clicked)
      GET HIGHLIGHT(*;"StyledText_t";startSel;endSel)
      If(ST Get content type(*;"StyledText_t";startSel;endSel)=ST Expression type)
         vExpression:=ST Get expression(*;"StyledText_t";startSel;endSel)
         $winRef:=Open form window("Dial_InsertExpr";Movable form dialog box;Horizontally centered;Vertically centered;*)
         DIALOG("Dial_InsertExpr")
         If(OK=1)
```

```
            ST INSERT EXPRESSION(*;"StyledText_t";vExpression;startSel;endSel)
            HIGHLIGHT TEXT(*;"StyledText_t";startSel;endSel)
         End if
      End if
End case
```

## Example 2

You want to execute a 4D method when a user link is clicked:

```
Case of
   :(Form event=On Clicked)
 //we retrieve the selection
      HIGHLIGHT TEXT(*;"myText";startSel;endSel)
      If(startSel#endSel) //there is selected content
 //we get the content type
         $CT_type:=ST Get content type(*;"myText";startSel;endSel)
         If($CT_type=ST User type) //this is a user link
            MyMethod //we execute a 4D method
         End if
      End if
End case
```

# ST GET OPTIONS

ST GET OPTIONS ( {* ;} object ; option ; value {; option2 ; value2 ; ... ; optionN ; valueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| option | Longint | ⇒ | Option to get |
| value | Longint | ⇐ | Current value of option |

## Description

The **ST GET OPTIONS** command gets the current value of one or more operating options for the styled text field or variable designated by the *object* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns the information of the object being edited; if the object does not have the focus, the command returns the information of the object's data source (variable or field).
If you omit the * parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string. During execution, the command returns the information of the variable or field.

Pass the code of the option to get in the *option* parameter. The command returns the current value of this option in *value*.
For both these parameters, you can use the following constants, found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST Expressions display mode | Longint | 1 | The *value* parameter can contain ST Values or ST References |
| ST References | Longint | 1 | Display source strings of expressions |
| ST Values | Longint | 0 | Display computed values of expressions |

# ST Get plain text

ST Get plain text ( {* ;} object {; refMode} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| refMode | Longint | ⇒ | Mode for handling references found in the text |
| Function result | Text | ⇐ | Text without tags |

## Description

The **ST Get plain text** command removes any style tags from the text variable or field designated by the * and *object* parameters and returns the plain text.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns information about the object being edited; however, when the object does not have the focus, the command returns information about the data source (field or variable) of the object.
If you omit the * parameter, this indicates that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference instead of a string and during execution, the command returns information about this field or variable.

The optional *refMode* parameter indicates the way that references found in *object* must be returned. In *refMode*, pass one of the following constants, found in the "**Multistyle Text**" theme (you can pass a single constant or a combination):

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST 4D Expressions as sources | Longint | 2 | The original string of 4D expression references is returned |
| ST 4D Expressions as values | Longint | 1 | 4D expression references are returned in their evaluated form (default functioning in forms) |
| ST References as spaces | Longint | 0 | Each reference is returned as a non-breaking space character (default operation, used by other commands) |
| ST Tags as plain text | Longint | 64 | The label of the tag is returned in plain text. For example for the tag '<img src="test.jpg" alt="picture">my picture</img>', the plain text is "my picture" (default functioning in forms) |
| ST Tags as XML code | Longint | 128 | The XML code of the tag is returned in plain text. For example for the tag '<img src="test.jpg" alt="picture">my picture</img>', the plain text is '<img src="test.jpg" alt="picture">my picture</img>' |
| ST Text displayed with 4D Expression sources | Longint | 86 | Returns the text as it is shown in the forms with the original string of the 4D expressions.<br>Corresponds a predefined combination of constants 2+4+16+64. |
| ST Text displayed with 4D Expression values | Longint | 85 | Returns the text as it is shown in the forms with the 4D expressions in their evaluated form.<br>Corresponds to a predefined combination of constants 1+4+16+64. |
| ST URL as labels | Longint | 4 | The visible label of URLs is returned, for example "Visit our Web site" (default functioning in forms) |
| ST URL as links | Longint | 8 | The link is returned, for example "http://www.4d.com" |
| ST User links as labels | Longint | 16 | The visible label of the user link is returned (default functioning in forms) |
| ST User links as links | Longint | 32 | The contents of the user link is returned |

**Note:** Since plain text remains the same regardless of the values passed in the *refMode* parameter, the optional *refMode* parameter is only useful when the text contains references.

## Example 1

You are looking for the text "very nice" among the values of a multistyle text field. The value was stored in the following form: "The weather is very nice **today**".

```
QUERY BY FORMULA([Comments];ST Get plain text([Comments]Weather)="@very nice@")
```

**Note:** In this context, the following statement will not give the desired result because the text is saved with style tags:

```
QUERY([Comments];[Comments]Weather="@very nice@")
```

## Example 2

Given the following text placed in the multi-style area entitled "MyArea":

```
<span>It is now <span style="-d4-ref:'Current time:C178'"> </span> <a href="http://www.4d.com">Go to the 4D site</a> or
<span style="-d4-ref-user:'openW'">Open a window</span></span>
```

This text is displayed:

If you execute the following code:

```
$txt :=ST Get plain text(*;"myArea";ST References as spaces)
 // $txt = "It is now    or "  (spaces)
$txt :=ST Get plain text(*;"myArea";ST 4D Expressions as values)
 // $txt = "It is now 15:48:19  or  "
$txt :=ST Get plain text(*;"myArea";ST 4D Expressions as sources)
 // $txt = "It is now Current time  or  "
$txt :=ST Get plain text(*;"myArea";ST URL as links)
 //$txt = "It is now   http://www.4d.com or  "
$txt :=ST Get plain text(*;"myArea";ST Text displayed with 4D Expression values)
 //$txt = "It is now 15:48:19 Go to the 4D site or Open a window"
$txt :=ST Get plain text(*;"myArea";ST Text displayed with 4D Expression sources)
 //$txt = "It is now Current time Go to 4D site or Open a window"
$txt :=ST Get plain text(*;"myArea";ST User links as labels)
 //$txt = "It is now    or Open a window"
$txt :=ST Get plain text(*;"myArea";ST User links as links)
 //$txt = "It is now    or openW"
```

## System variables and sets

After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

# ST Get text

ST Get text ( {* ;} object {; startSel {; endSel}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Text field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |
| Function result | Text | ⇐ | Text including style tags |

## Description

The **ST Get text** command returns the styled text found in the text field or variable designated by the *object* parameter.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns information about the object being edited; however, when the object does not have the focus, the command returns information about the data source (field or variable) of the object.
If you omit the * parameter, this indicates that the *object* parameter is a field or a variable. In this case, you pass a field or variable reference instead of a string and during execution, the command returns information about this field or variable.

The command returns the text with any style tags that are associated with it, which means, for example, that you can copy and paste text while keeping its style.

The optional *startSel* and *endSel* parameters let you designate a selection of text in object. The *startSel* and *endSel* values give a selection of plain text, without taking any style tags found in the text into account.

- If you omit *startSel* and *endSel*, **ST Get text** returns all the text contained in *object*,
- If you pass *startSel* and *endSel*, **ST Get text** returns the selection of text set by these limits.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

If the values of *startSel* and *endSel* are equal or if *startSel* is greater than *endSel*, an error is returned.

## System variables and sets

After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

# ST GET URL

ST GET URL ( {* ;} object ; urlText ; urlAddress {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| urlText | Text | ⇐ | Visible text of URL |
| urlAddress | Text | ⇐ | URL address |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST GET URL** command returns the text label and address of the first URL detected in the styled text field or variable designated by the *object* parameter.

The text label and address are returned in the *urlText* and *urlAddress* parameters. If the selection does not contain a URL, empty strings are returned in these parameters.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). During execution, if the object has the focus, the command returns the information of the object being edited; if the object does not have the focus, the command returns the information of the object's data source (variable or field).
If you omit the * parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string. During execution, the command returns the information of the variable or field.

The optional *startSel* and *endSel* parameters designate a selection of text in object. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags that may be present.

- If you pass *startSel* and *endSel*, **ST GET URL** looks for the URL within this selection.
- If you only pass *startSel* or if the value of *endSel* is greater than the total number of characters in *object*, the command looks for the URL between *startSel* and the end of the text.
- If you omit *startSel* and *endSel*, the command looks for the URL within the current text selection.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

## Example

When there is a double-click event, you check that there is in fact an URL, and if so, you display a dialog where you have retrieved its values so that the user can modify them:

```
Case of
   :(Form event=On Double Clicked)
      GET HIGHLIGHT(*;"StyledText_t";startSel;endSel)
      If(ST Get content type(*;"StyledText_t";startSel;endSel)=ST URL type) //URL
         ST GET URL(*;"StyledText_t";vTitle;vURL;startSel;endSel)
         $winRef:=Open form window("Dial_InsertURL";Movable form dialog box;Horizontally centered;Vertically centered;*)
         SET WINDOW TITLE("URL settings")
         DIALOG("Dial_InsertURL")
         If(OK=1)
```

```
            ST INSERT URL(*;"StyledText_t";vTitle;vURL;startSel;endSel)
            HIGHLIGHT TEXT(*;"StyledText_t";startSel;startSel+1)
         End if
      End if
End case
```

# ST INSERT EXPRESSION

ST INSERT EXPRESSION ( {* ;} object ; expression {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| expression | Text | ⇒ | Expression and (optional) format to insert |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST INSERT EXPRESSION** command inserts a reference to the *expression* in the styled text field or variable designated by the *object* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *expression* parameter, you pass the 4D expression to evaluate in the *object*. A valid 4D expression is a string returning a value. *expression* can be a field, a variable, a 4D command, a statement returning a value, a project method, and so on.

The expression must be placed in quotation marks ("").

**Note:** The *expression* parameter cannot be a Picture type variable.

If *expression* returns a value containing carriage returns and tabs, 4D formats the text according to the object hosting the expression; carriage return characters are interpreted as line breaks.

You can format the expression by including formatting information in the *expression* parameter. In this case, the parameter must be in the form:

```
"String(value:format)"
```

... where *value* contains the expression itself and *format* contains the format to apply. The *format* parameter can have the following values:

- for numbers: any number display format (existing or not), for example "###,##".
- for dates: a number designating an existing date format. You can use the constants of the "**Date Display Formats**" theme, for example System date short .
- for times: a number designating an existing time format. You can use the constants of the "**Time Display Formats**" theme, for example System time short .

For example:

```
"String([Table_1]Field_1;System date short)"
```

By default, the expression **values** are displayed in the multi-style text areas. You can force the display of the **references** instead using the **ST SET OPTIONS** command.

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags that may be present.

- If you only pass *startSel*, the result of the expression is inserted at the specified location.
- If you omit *startSel* and *endSel*, the result of the expression is inserted at the location of the cursor.
- If you pass *startSel* and *endSel*, **ST INSERT EXPRESSION** replaces the text in this selection with the result of the *expression*. If the value of *endSel* is greater than the total number of characters in the object, all the characters between *startSel* and the end of the text are replaced by the result of the *expression*.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

## Example

You want to replace the highlighted text with the result of a project method:

```
ST INSERT EXPRESSION(*;"myText";"MyMethod";ST Start highlight;ST End highlight)
```

# ST INSERT URL

ST INSERT URL ( {* ;} object ; urlText ; urlAddress {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| urlText | Text | ⇒ | Visible text of URL |
| urlAddress | Text | ⇒ | URL address |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST INSERT URL** command inserts a URL link in the styled text field or variable designated by the *object* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

In the *urlText* parameter, pass the visible text of the URL, as it should appear in the object. For example, text labels such as "4D Web Site" or "Follow this link for more information" can be used. You can also use the address itself, for instance "http://www.4d.com".

In the *urlAddress* parameter, pass the complete address you want the browser page to connect to, for example "http://www.4D.com".

The optional *startSel* and *endSel* parameters designate a selection of text in *object*. The *startSel* and *endSel* values express a plain text selection, without taking into account any style tags that may be present.

- If you only pass *startSel*, *urlText* is inserted at the specified location.
- If you omit *startSel* and *endSel*, *urlText* is inserted at the location of the cursor.
- If you pass *startSel* and *endSel*, **ST INSERT URL** replaces the text in this selection with the *urlText*. If the value of *endSel* is greater than the total number of characters in the object, all the characters between *startSel* and the end of the text are replaced with the *urlText*.

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except when *endSel* is 0), the command does nothing and the *OK* variable is set to 0.

Once the link is inserted, it is active: using **Ctrl+click** (Windows) or **Command+click** (OS X) on its label opens a page of the default browser at the address specified in the *urlAddress* parameter.

## Example

You want to insert a link to the 4D Web site to replace the text selected in the object:

```
vTitle:="4D Web Site"
vURL:="http://www.4d.com/"
ST INSERT URL(*;"myText";vTitle;vURL;ST Start highlight;ST End highlight)
```

# ST SET ATTRIBUTES

ST SET ATTRIBUTES ( {* ;} object ; startSel ; endSel ; attribName ; attribValue {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Text field or variable (if * is omitted) |
| startSel | Longint | ⇒ | Start of new text selection |
| endSel | Longint | ⇒ | End of new text selection |
| attribName | String | ⇒ | Attribute to set |
| attribValue | String, Longint | ⇒ | New value of attribute |

## Description

The **ST SET ATTRIBUTES** command can be used to modify one or more style attributes in the form object(s) designated by *object*.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, when the object has the focus, the command only applies to the object being edited and not to its data source (field or variable). The changes are only transferred to the source (and to any other objects using this same source) when the object being edited is validated either by losing the focus or with the **Enter** key. When the object does not have the focus, the command applies directly to the data source and the changes are immediately transferred to any other objects using the same source.
If you omit the * parameter, this indicates that the *object* parameter is a field or variable and you pass a field or variable reference instead of a string. The command applies directly to the field or variable and changes are immediately transferred to all the objects using this source, including the object with the focus.

**Note:** You can only use style attributes with Text type fields. Since Alpha type fields have a preset length, adding style tags would lead to a loss of data.

The definition of an attribute is carried out via the insertion or modification of HTML style tags within the text (for more information about this point, refer to the *Design Reference* manual). Note that **ST SET ATTRIBUTES** inserts style tags in all cases, even if the *object* designates text objects of the form that do not have the Multistyle property.

The *startSel* and *endSel* parameters can be used to designate the selection of text to which to apply the style modification(s) within the *object*. In *startSel*, you pass the position of the first character to be modified and in *endSel*, you pass the position of the last character to be modified plus one (the last character passed is not included in the modification). You can pass 0 in *endSel* to designate automatically the last character of the text (pass 1 in *startSel* to designate the first character of the text).
If the value of *endSel* is greater than the number of characters in the object, all the characters between *startSel* and the end of the text are modified. If *startSel* is greater than *endSel* (except when *endSel* value is 0, see above), the command does nothing and the OK variable is set to 0.
The *startSel* and *endSel* values do not take any style tags already present in the area into account. They are evaluated on the basis of raw text (text where style tags have been filtered).

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

In *attribName* and *attribValue*, pass the name and the value, respectively, of the attribute to be modified. You can pass as many attribute/value pairs as you want. To specify the *attribName* parameter, use the predefined constants placed in the

**Multistyle Text Attributes** theme. The value passed in the *attribValue* parameter depends on the *attribName* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute background color | Longint | 8 | *attribValue*=Hexadecimal values or HTML color names (Windows only) |
| Attribute bold style | Longint | 1 | *attribValue*=0: remove bold attribute from selection<br>*attribValue*=1: apply bold attribute to selection |
| Attribute font name | Longint | 5 | *attribValue*=Font family name (string) |
| Attribute italic style | Longint | 2 | *attribValue*=0: remove italic attribute from selection<br>*attribValue*=1: apply italic attribute to selection |
| Attribute strikethrough style | Longint | 3 | *attribValue*=0: remove strikethrough attribute from selection<br>*attribValue*=1: apply strikethrough attribute to selection |
| Attribute text color | Longint | 7 | *attribValue*=Hexadecimal values or HTML color names |
| Attribute text size | Longint | 6 | *attribValue*=Number of points (number) |
| Attribute underline style | Longint | 4 | *attribValue*=0: remove underline attribute from selection<br>*attribValue*=1: apply underline attribute to selection |

**Colors**

If you pass the Attribute text color or Attribute background color constants in *attribName*, you must pass a string containing either an HTML color name or a hexadecimal color value in *attribValue*:

| HTML color name | Hexa value |
|---|---|
| Aqua | #00FFFF |
| Black | #000000 |
| Blue | #0000FF |
| Fuchsia | #FF00FF |
| Gray | #808080 |
| Green | #008000 |
| Lime | #00FF00 |
| Maroon | #800000 |
| Navy | #000080 |
| Olive | #808000 |
| Purple | #800080 |
| Red | #FF0000 |
| Silver | #C0C0C0 |
| Teal | #008080 |
| White | #FFFFFF |
| Yellow | #FFFF00 |

## Example

In this example, we modify the size and color of the text as well as the bold and underline attributes of the characters 2 to 4 of the field:

```
ST SET ATTRIBUTES([MyTable]MyField;2;5;Attribute font name;"Arial";Attribute text size;10;Attribute underline style;1;Attribute bold style;1;Attribute text color;"Blue")
```

## System variables and sets

After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

# ST SET OPTIONS

ST SET OPTIONS ( {* ;} object ; option ; value {; option2 ; value2 ; ... ; optionN ; valueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a field or variable |
| object | Form object | ⇒ | Object name (if * is specified) or Field or variable (if * is omitted) |
| option | Longint | ⇒ | Option to set |
| value | Longint | ⇒ | New value of option |

## Description

The **ST SET OPTIONS** command modifies one or more operating options for the styled text field or variable designated by the *object* parameter.

Passing the optional * parameter indicates that the *object* parameter is an object name (string). If you do not pass this parameter, it indicates that the *object* parameter is a field or variable. In this case, you pass a field or variable reference instead of a string (field or variable object only).

Pass the code of the option to modify in *option* and its new value in *value*.

The *option* parameter supports the following constant found in the "**Multistyle Text**" theme:

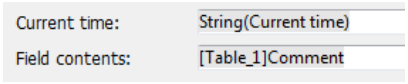
| Constant | Type | Value | Comment |
|---|---|---|---|
| ST Expressions display mode | Longint | 1 | The *value* parameter can contain ST Values or ST References |

In the *value* parameter, you can pass one of the following constants:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST References | Longint | 1 | Display source strings of expressions |
| ST Values | Longint | 0 | Display computed values of expressions |

Display of values:

Display of expressions:



## Example

The following code lets you switch the display mode of the area:

```
ST GET OPTIONS(*;"StyledText_t";ST Expressions display mode;$exprValue)
If($exprValue=1)
   ST SET OPTIONS(*;"StyledText_t";ST Expressions display mode;ST Values)
Else
   ST SET OPTIONS(*;"StyledText_t";ST Expressions display mode;ST References)
End if
```

# ST SET PLAIN TEXT

ST SET PLAIN TEXT ( {* ;} object ; newText {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Variable or field (if * is omitted) |
| newText | Text | ⇒ | Text to insert |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST SET PLAIN TEXT** command inserts the text passed in the *newText* parameter into the styled text field or variable designated by the *object* parameter. This command only applies to the plain text of the*object* parameter, without modifying any style tags that it contains.

Unlike the **ST SET TEXT** command, **ST SET PLAIN TEXT** only inserts plain text. You must not pass text with style tags  in *newText* must not have any style tags. If it contains the <, > or & characters, they are considered as standard characters and converted into HTML entities:

- '&' is converted to &
- '<' is converted to <
- '>' is converted to >

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, when the object has the focus, the command only applies to the object being edited and not to its data source (field or variable). The changes are only transferred to the source (and to any other objects using this same source) when the object being edited is validated either by losing the focus or with the **Enter** key. When the object does not have the focus, the command applies directly to the data source and the changes are immediately transferred to any other objects using the same source.
If you omit the * parameter, this indicates that the *object* parameter is a field or variable and you pass a field or variable reference instead of a string. The command applies directly to the field or variable and changes are immediately transferred to all the objects using this source, including the object with the focus.

In *newText*, pass the plain text to be inserted.

The optional *startSel* and *endSel* parameters let you designate a selection of text in *object*. The *startSel* and *endSel* values give a selection of plain text, without taking any style tags found in the text into account. The action of the command varies according to the optional *startSel* and *endSel* parameters:

- If you omit *startSel* and *endSel*, **ST SET PLAIN TEXT** replaces all the text of the *object* by *newText*,
- If you only pass *startSel* or if the values of *startSel* and *endSel* are equal, **ST SET PLAIN TEXT** inserts the *newText* text into *object* beginning at *startSel*,
- If you pass both *startSel* and *endSel*, **ST SET PLAIN TEXT** replaces the plain text set by these limits with the *newText* text.
- You can pass 0 in *endSel* to designate automatically the last character of the text (pass 1 in *startSel* to designate the first character of the text).

4D provides predefined constants that you can use to automatically designate the limits of the selection in the *startSel* and *endSel* parameters. These constants are available in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a field or variable reference, the command is applied to all the text of the object.

The style of the first character replaced will be used for all of the *newText* text.

If *startSel* is greater than *endSel* (except when *endSel* value is 0, see above), the text is not modified and the OK variable is set to 0.

## Example

Given the following rich text (multi-style) variable:

Please remember that the **X company has made a commitment** to you.

You want to insert company names that are stored in a text field. These names can contain, for example, the "&" character. In this case, you will need to use the **ST SET PLAIN TEXT** command:

```
ST SET PLAIN TEXT(myStyledText;[Company]Name;33;34)
```

Here is the result:

Please remember that the **Smith & Jones company has made a commitment** to you.

Here is the plain text contained in the variable:

```
Please remember that the <SPAN STYLE="font-weight:bold"> Smith &amp;amp; Jones </SPAN> <SPAN STYLE="font-weight:bold">company has made a commitment</SPAN> to you.
```

You can see that the inserted text was enclosed within an additional pair of style tags. These tags correspond to the style of the characters before they were inserted. This mechanism is a way of guaranteeing the correct display of rich text fields in all cases.

**Note:** If you had used the **ST SET TEXT** command in this case, 4D would not have inserted anything because the presence of the non-encoded "&" character would prevent the interpretation of the style tags found in the variable. For more information, refer to the description of this command.

## System variables and sets

After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

# ST SET TEXT

ST SET TEXT ( {* ;} object ; newText {; startSel {; endSel}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable or a field |
| object | Form object | ⇒ | Object name (if * is specified) or Text field or variable (if * is omitted) |
| newText | Text | ⇒ | Text to insert |
| startSel | Longint | ⇒ | Start of selection |
| endSel | Longint | ⇒ | End of selection |

## Description

The **ST SET TEXT** command inserts the text passed in the *newText* parameter into the styled text field or variable designated by the *object* parameter. This command only applies to the plain text of the object parameter, without modifying any style tags that it contains. It can be used to modify, by programming, styled text displayed on screen.

If you pass the optional * parameter, this indicates that the *object* parameter is an object name (string). During execution, when the object has the focus, the command only applies to the object being edited and not to its data source (field or variable). The changes are only transferred to the source (and to any other objects using this same source) when the object being edited is validated either by losing the focus or with the **Enter** key. When the object does not have the focus, the command applies directly to the data source and the changes are immediately transferred to any other objects using the same source.
If you omit the * parameter, this indicates that the *object* parameter is a field or variable and you pass a field or variable reference instead of a string. The command applies directly to the field or variable and changes are immediately transferred to all the objects using this source, including the object with the focus.

In *newText*, pass the text to be inserted. The **ST SET TEXT** command is intended for working with rich text (multistyle) containing  type tags. In all other cases (more particularly, when working with plain text that contains the <, > or & characters), you must use the **ST SET PLAIN TEXT** command. If you pass plain text containing the <, > or & characters to the **ST SET TEXT** command, it does nothing. This is necessary behavior because if you insert a string such as "a<b" directly into rich text, it will distort the internal analysis of the  tags. In this case, "<" characters must be encoded beforehand as "<", which can be done using the **ST SET PLAIN TEXT** command (see also the example of this command).

The optional *startSel* and *endSel* parameters let you designate a selection of text in *object*. The *startSel* and *endSel* values give a selection of plain text, without taking any style tags found in the text into account. The action of the command varies according to the optional *startSel* and *endSel* parameters:

- If you omit *startSel* and *endSel*, **ST SET TEXT** replaces all the text of the *object* by *newText*,
- If you only pass *startSel* or if the values of *startSel* and *endSel* are equal, **ST SET TEXT** inserts the *newText* text into object beginning at *startSel*,
- If you pass both *startSel* and *endSel*, **ST SET TEXT** replaces the plain text set by these limits with the *newText* text.
- You can pass 0 in *endSel* to designate automatically the last character of the text (pass 1 in *startSel* to designate the first character of the text).

4D provides predefined constants so that you can designate the selection limits automatically in the *startSel* and *endSel* parameters. These constants are found in the "**Multistyle Text**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |

(*) You must pass an object name in *object* to be able to use this constant. If you pass a reference to a field or variable, the command is applied to all the text of the object.

**Note:** If *startSel* is greater than *endSel* (except if *endSel* value is 0, see above), the text is not modified and the OK variable is set to 0.

## System variables and sets

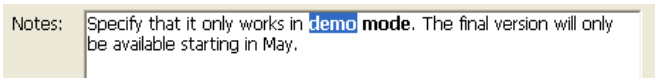
After this command is executed, the OK variable is set to 1 if no error occurred; otherwise, it is set to 0. This is the case more particularly when style tags are not evaluated properly (incorrect or missing tags).

In the case of an error, the variable is not changed. When an error occurs on a variable when text is being evaluated, 4D transforms the text into plain text; as a result, the <, > and & characters are converted into HTML entities.

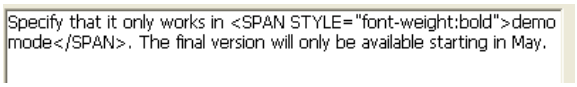
## Example 1

You want to replace the styled text selected by the user with the contents of a variable.

Here is the selected text:



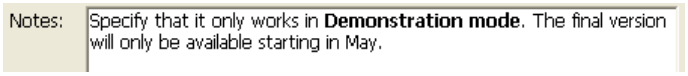
The following contents are stored in the field:

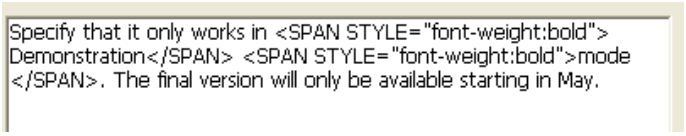


After executing this code:

```
vtempo:="Demonstration"
GET HIGHLIGHT([Products]Notes;vStart;vEnd)
ST SET TEXT([Products]Notes;vtemp;vStart;vEnd)
```

The field and its contents are as follows:





## Example 2

Refer to the example of the **ST SET PLAIN TEXT** command.

# Subrecords

- Get subrecord key
- *_o_ALL SUBRECORDS*
- *_o_APPLY TO SUBSELECTION*
- *_o_Before subselection*
- *_o_CREATE SUBRECORD*
- *_o_DELETE SUBRECORD*
- *_o_End subselection*
- *_o_FIRST SUBRECORD*
- *_o_LAST SUBRECORD*
- *_o_NEXT SUBRECORD*
- *_o_ORDER SUBRECORDS BY*
- *_o_PREVIOUS SUBRECORD*
- *_o_QUERY SUBRECORDS*
- *_o_Records in subselection*

# Get subrecord key

Get subrecord key ( idField ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| idField | Field | ➡ | "Subtable Relation" or "Longint" type field of a former subtable relation |
| Function result | Longint | ⮌ | Internal key of relation |

## Description

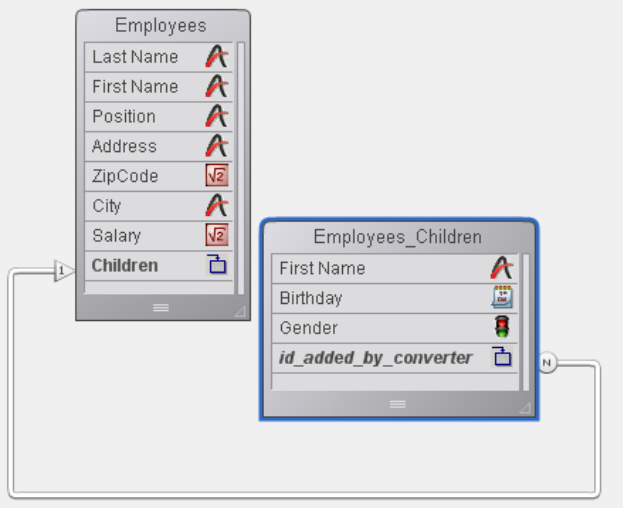
The **Get subrecord key** command facilitates the migration of 4D code using converted subtables to standard code for working with tables.

**Reminder:** Beginning with version 11 of 4D, subtables are not supported. When a older database is converted, any existing subtables are transformed into standard tables that are linked with the original tables by an automatic relation. The former subtable becomes the Many table and the original table is the One table. In the One table, the former subtable field is transformed into a special field of the "Subtable Relation" type and in the Many field, a special "Subtable Relation" type field is added named “id_added_by_converter”.

This allows converted databases to function but we strongly recommend that you replace any subtable mechanisms in your converted databases by those used for standard tables.

The first step in this process consists in deleting the special automatic relations, which permanently disables the mechanisms inherited from subtables. After this you need to rewrite the associated code. The **Get subrecord key** command accompanies this rewriting by returning the internal ID used by the relation. This internal ID makes the actual relation unnecessary and you can then work with the selection of the former subtable even when the relation is no longer present.

Let's look for example at the following converted structure:



In 4D, the following code still works but it must be updated:

```
ALL SUBRECORDS([Employees]Children)
$total:=Records in subselection([Employees]Children)
vFirstnames:=""
For($i;1;$total)
   vFirstnames:=vFirstnames+[Employees]Children'FirstName+" "
   NEXT SUBRECORD([Employees]Children)
End for
```

You can now replace this code with:

```
QUERY([Employees_Children];[Employees_Children]id_added_by_converter=Get subrecord key([Employees]Children))
$total:=Records in selection([Employees_Children])
vFirstnames:=""
For($i;1;$total)
   vFirstnames:=vFirstnames+[Employees_Children]FirstName+" "
   NEXT RECORD(Employees_Children)
End for
```

**Note: Get subrecord key** returns 0 if there is no current recorded loaded when it is executed.

The second piece of code has the advantage of using standard 4D commands and it works the same way whether the relation is present or not. When you remove the relation, the command simply returns the key value stored in the Longint field.

In the *idField* parameter, the command accepts either a field of the Subtable Relation type (if the relation still exists) or of the Longint type (if the relation has been removed). In any other case, an error is generated.

This lets you write the transition code. During the final stage of upgrading the application, you can remove the calls to this command.

## Assigning values to the id_added_by_converter field

Starting with 4D v14 R3, you can assign a value to the "id_added_by_converter" field. Previously, this value could only be assigned by 4D itself, which forced developers to use obsolete commands such as **_o_CREATE SUBRECORD** to be able to add records into converted subtables.

Thanks to this possibility, you can convert former databases containing subtables progressively: at first, you can keep the special "Subtable relation", while adding or modifying related records as if they were standard ones. Then, once all your methods are up to date, you can replace this special relation with a standard one, without having to change your code.

For example, with the structure above you can write:

```
CREATE RECORD([Employees])
[Employees]LastName:="Jones"
CREATE RECORD([Employees_Children])
[Employees_Children]FirstName:="Natacha"
[Employees_Children]BirthDate:=!12/24/2013!
[Employees_Children]id_added_by_converter:=Get subrecord key([Employees]Children)
SAVE RECORD([Employees_Children])
SAVE RECORD([Employees]
```

This code will work with either a special relation or a standard one.

# _o_ALL SUBRECORDS

_o_ALL SUBRECORDS ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable in which to select all subrecords |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_APPLY TO SUBSELECTION

_o_APPLY TO SUBSELECTION ( subtable ; statement )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable to which to apply the formula |
| statement | Statement | ⇒ | One line of code or a method |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_Before subselection

_o_Before subselection ( subtable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable for which to test if subrecord pointer is before the first selected subrecord |
| Function result | Boolean | ⇐ | Yes (TRUE) or No (FALSE) |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_CREATE SUBRECORD

_o_CREATE SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable for which to create a new subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_DELETE SUBRECORD

_o_DELETE SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable from which to delete the current subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_End subselection

_o_End subselection ( subtable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable for which to test if subrecord pointer is after the last selected subrecord |
| Function result | Boolean | ⇐ | Yes (TRUE) or No (FALSE) |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_FIRST SUBRECORD

_o_FIRST SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇨ | Subtable in which to move to the first selected subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_LAST SUBRECORD

_o_LAST SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable in which to move to the last selected subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_NEXT SUBRECORD

_o_NEXT SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇨ | Subtable in which to move to the next selected subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

## _o_ORDER SUBRECORDS BY

_o_ORDER SUBRECORDS BY ( subtable ; subfield {; > or <}{; subfield2 ; > or <2 ; ... ; subfieldN ; > or <N} )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable by which to order the selected subrecords |
| subfield | Subfield | ⇒ | Subfield on which to order by for each level |
| > or < | Operator | ⇒ | Ordering direction for each level: > to order in ascending order or < to order in descending order |

### Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_PREVIOUS SUBRECORD

_o_PREVIOUS SUBRECORD ( subtable )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable in which to move to the previous selected subrecord |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_QUERY SUBRECORDS

_o_QUERY SUBRECORDS ( subtable ; queryFormula )

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable to search |
| queryFormula | Boolean | ⇒ | Query formula |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# _o_Records in subselection

_o_Records in subselection ( subtable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| subtable | Subtable | ⇒ | Subtable for which to count number of subrecords |
| Function result | Longint | ⇒ | Number of subrecords in current subselection |

## Compatibility note

Subtables are no longer supported starting with version 11 of 4D. A compatibility mechanism ensures the functioning of this command in converted databases; however, it is strongly recommended to replace any subtables with standard related tables.

# SVG

- Overview of SVG commands
- SVG EXPORT TO PICTURE
- SVG Find element ID by coordinates
- SVG Find element IDs by rect
- SVG GET ATTRIBUTE
- SVG SET ATTRIBUTE
- SVG SHOW ELEMENT

## Overview of SVG commands

---

SVG (Scalable Vector Graphics) is an XML-based file format (.svg extension) that is used to describe vector graphics. SVG is most commonly used for publishing statistical or cartographic data.

These files can be viewed in Web browsers either natively or via plug-ins. 4D includes an SVG rendering engine that allows you to display SVG files in picture field or variables. The **SVG EXPORT TO PICTURE** command can be used to generate a picture in 4D on the basis of an SVG description. Also note that the **GRAPH** command makes use of the integrated SVG engine of 4D.

For more information about this format, please refer to the following address: http://www.w3.org/Graphics/SVG/.

# SVG EXPORT TO PICTURE

SVG EXPORT TO PICTURE ( elementRef ; pictVar {; exportType} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | Root XML element reference |
| pictVar | Picture | ⇒ | Picture variable to receive XML tree (SVG picture) |
| exportType | Longint | ⇒ | 0 = Do not store data source, 1 = Copy data source, 2 = Own data source (default) |

## Description

The **SVG EXPORT TO PICTURE** command saves an SVG format picture contained in an XML tree in the picture field or variable indicated by the *pictVar* parameter.

**Note:** For more information about the SVG format, refer to the **Overview of XML Utilities Commands** section.

Pass the root XML element reference that contains the SVG picture in *elementRef*.

Pass the name of the 4D picture field or variable that will contain the SVG picture in *pictVar*. The picture is exported in its native format (XML description) and is redrawn via the SVG rendering engine when it is displayed.

The optional *exportType* parameter specifies the way the XML data source is to be handled by the command. You can pass one of the following constants, found in the "**XML**" theme, in this parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Copy XML data source | Longint | 1 | 4D keeps a copy of the DOM tree with the picture, which means the picture can be saved in a picture field of the database and then redisplayed or exported at any time. |
| Get XML data source | Longint | 0 | 4D only reads the XML data source; it is not kept with the picture. This noticeably increases command execution speed; however, because the DOM tree is not kept, it is not possible to store or export the picture. |
| Own XML data source | Longint | 2 | 4D exports the DOM tree with the picture. The picture can be stored or exported and command execution is fast. However, the *elementRef* XML reference can then no longer be used by other 4D commands. This is the default mode for exporting when the *exportType* parameter is omitted. |

## Example

The following example can be used to display "Hello World" in a 4D picture:

```
C_PICTURE(vpict)
$svg:=DOM Create XML Ref("svg";"http://www.w3.org/2000/svg")
$ref:=DOM Create XML element($svg;"text";"font-size";26;"fill";"red")
DOM SET XML ATTRIBUTE($ref;"y";"1em")
DOM SET XML ELEMENT VALUE($ref;"Hello World")
SVG EXPORT TO PICTURE($svg;vpict;Copy XML data source)
DOM CLOSE XML($svg)
```

# SVG Find element ID by coordinates

SVG Find element ID by coordinates ( {* ;} pictureObject ; x ; y ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, pictureObject is an object name (string) If omitted, pictureObject is a field or variable |
| pictureObject | Picture | ⇒ | Object name (if * specified) or Field or Variable (if * omitted) |
| x | Longint | ⇒ | X coordinate in pixels |
| y | Longint | ⇒ | Y coordinate in pixels |
| Function result | String | ⇐ | ID of element found at the location X, Y |

## Description

The **SVG Find element ID by coordinates** command returns the ID ("id" or "xml:id" attribute) of the XML element found at the location set by the coordinates (x,y) in the SVG picture designated by the *pictureObject* parameter. This command can be used more particularly to create interactive graphic interfaces using SVG objects.

**Note:** For more information about the SVG format, refer to the **Overview of XML Utilities Commands** section.

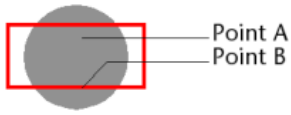
If you pass the optional * parameter, you indicate that the *pictureObject* parameter is an object name (string). If you do not pass this parameter, you indicate that the *pictureObject* parameter is a field or variable. In this case, you do not pass a string but a field or variable reference (field or variable object only).

Note that it is not mandatory for the picture to be displayed in a form. In this case, the "object name" type syntax is not valid and you must pass a field or variable name.

The coordinates passed in the *x* and *y* parameters must be expressed in pixels relative to the top left corner of the picture (0,0). In the context of a picture displayed in a form, you can use the values returned by the MouseX and MouseY system variables. These variables are updated in the On Clicked, On Double Clicked and On Mouse Up form events, as well as in the On Mouse Enter and On Mouse Move form events.

**Note:** In the picture coordinate system, MouseX and MouseY always specify the same point of the picture, regardless of the picture display format (except in the case of the "Replicated" format), even when the picture has been scrolled or zoomed.

The point taken into account is the first point reached. For example, in the case below, the command will return the ID of the circle if the coordinates of point A are passed and that of the rectangle if the coordinates of point B are passed:



When the coordinates correspond to superimposed or composite objects, the command returns the ID of the first object having a valid ID attribute by going back, if necessary, among the parent elements.

The command returns an empty string if:

- the root is reached without an "id" attribute having been found,
- the coordinates point does not belong to any object,
- the "id" attribute is an empty string.

**Note:** This command cannot detect objects whose opacity value ("fill-opacity" attribute) is less than 0.01.

## System variables and sets

If *pictureObject* does not contain a valid SVG picture, the command returns an empty string and the OK system variable is set to 0. Otherwise, if the command has been executed correctly, the OK system variable is set to 1.

# SVG Find element IDs by rect

SVG Find element IDs by rect ( {* ;} pictureObject ; x ; y ; width ; height ; arrIDs ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, pictureObject is an object name (string) If omitted, pictureObject is a variable |
| pictureObject | Picture | ⇒ | Object name (if * specified) or Field or variable (if * omitted) |
| x | Longint | ⇒ | Horizontal coordinate of top left corner of selection rectangle |
| y | Longint | ⇒ | Vertical coordinate of top left corner of selection rectangle |
| width | Longint | ⇒ | Width of selection rectangle |
| height | Longint | ⇒ | Height of selection rectangle |
| arrIDs | Text array | ⇐ | IDs of elements whose bounding rectangle intersects with the selection rectangle |
| Function result | Boolean | ⇐ | True = at least one element is found |

## Description

The **SVG Find element IDs by rect** command fills the Text or Alpha *arrIDs* array with the IDs ("id" or "xml:id" attribute) of the XML elements whose bounding rectangle intersects with the selection rectangle at the location specified by the *x* and *y* parameters.

The command returns True if at least one element is found (in other words if the *arrIDs* array is not empty), and False otherwise.

This command can be used in particular to manage interactive graphic interfaces.

If you pass the optional * parameter, you indicate that the *pictureObject* parameter is an object name (string). If you do not pass this parameter, you indicate that the *pictureObject* parameter is a field or a variable. In this case, you pass a field or variable reference (object field or variable only) instead of a string.

If you are working with a picture field or variable, the command uses the original picture, corresponding to the data source. However, if you are working with a form object, the command uses the current picture, that may have been modified via the **SVG SET ATTRIBUTE** command and that is kept with the properties of the form object.

The coordinates passed in the *x* and *y* parameters must be expressed in pixels in relation to the top left corner of the picture (0,0). You can use the values returned by the MouseX and MouseY **System Variables**. These variables are updated in the On Clicked and On Double Clicked form events as well as the in the On Mouse Enter and On Mouse Move form events.

**Note:** In the system of picture coordinates, [x;y] always specifies the same point, regardless of the picture display format, apart from the "Replicated" format.

All elements whose bounding rectangle intersects with the selection rectangle are taken into account, even those that are under other elements.

# SVG GET ATTRIBUTE

SVG GET ATTRIBUTE ( {* ;} pictureObject ; element_ID ; attribName ; attribValue )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, pictureObject is an object name (string) If omitted, pictureObject is a variable |
| pictureObject | Picture | ⇒ | Object name (if * specified) or Variable or field (if * omitted) |
| element_ID | Text | ⇒ | ID of element whose attribute value you want to get |
| attribName | String | ⇒ | Attribute whose value you want to get |
| attribValue | String, Longint | ⇐ | Current value of attribute |

## Description

The **SVG GET ATTRIBUTE** command is used to get the current value of the *attribName* attribute in an object or an SVG picture.

If you pass the optional * parameter, you indicate that the *pictureObject* parameter is an object name (string). In this case, the command returns the value of the attribute for the rendered image attached to the object. This value may have been modified by **SVG SET ATTRIBUTE** for example.
If you do not pass the * parameter, you indicate that the *pictureObject* parameter is a variable or a field. Therefore, you pass a variable (object variable only) or field reference instead of a string. In this case, the command returns the value of the attribute for the initial rendered image (corresponding to the data source of the variable).

**Note:** This principle also applies to the **SVG Find element ID by coordinates** command.

The *element_ID* parameter is used to set the ID ("id" or "xml:id" attribute) of the element whose attribute value you want to get.

For more information about SVG attributes, please refer to the description of the **SVG SET ATTRIBUTE** command. Here is a list of 4D attributes reserved and dedicated to animation:

| Attributes | Access | Comments |
|---|---|---|
| 4D-text | read/write | Replaces/reads the contents of the text node. Can be used with 'text' 'tspan' and 'textArea' elements. |
| 4D-bringToFront | write | If 'true', move node in front of sibling nodes. Can only be used with the **SVG SET ATTRIBUTE** command. |
| 4D-isOfClass-{IDENT [[S\|COMMA] IDENT]*} | read | Returns 'true' if inherited class attribute of node contains all class name(s); otherwise, returns 'false'. Returns for example true for "4D-isOfClass-land" if the inherited class of the node is "land department01"). |
| 4D-enableD2D | read/write | If 'false', disables Direct2D for the SVG rendering engine. In fact, SVG filters are not rendered in Direct2D but they are in GDI/GDIPlus. This option lets you use SVG filters even when the database is in Direct2D. Note that this option is only taken into account when a picture has already been loaded into the *pictureObject*. However, since this option is applied globally to the engine, you only need to set it once per session (for example with a simple SVG loaded in memory from a text variable when the database is started). |

# SVG SET ATTRIBUTE

SVG SET ATTRIBUTE ( {* ;} pictureObject ; element_ID ; attribName ; attribValue {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} {; *})

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, pictureObject is an object name (string) If omitted, pictureObject is a variable |
| pictureObject | Picture | ⇒ | Object name (if * specified) or Variable or field (if * omitted) |
| element_ID | Text | ⇒ | ID of element where one or more attributes are set |
| attribName | String | ⇒ | Attribute to be specified |
| attribValue | String, Longint | ⇒ | New value of attribute |
| * | Operator | ⇒ | If passed = modify internal DOM tree of SVG image (variable only) |

## Description

The **SVG SET ATTRIBUTE** command is used to modify the value of an existing attribute in the SVG rendering tree of a displayed image or in the internal DOM tree of an image.

If you pass the optional * parameter, you indicate that the *pictureObject* parameter is an object name (string). In this case, the command applies to the parameters of the rendered image attached to the object (note that the parameters and therefore the rendered image of the object are only created if the **SVG SET ATTRIBUTE** command is called at least once). If you do not pass the * parameter, you indicate that the *pictureObject* parameter is a variable or a field. Therefore, you pass a variable (object variable only) or field reference instead of a string. In this case, the command applies to the rendered images of all the objects that use the variable or the field.

By default, modifications made by this command apply only to the rendered images; they are not stored in the data source (internal DOM tree) and are lost when the picture is erased by programming or when the form is closed. However, you can transfer these changes into the internal DOM tree of the image when the *pictureObject* parameter references a variable: you just need to pass the second * as the last parameter. This lets you keep the modifications made on the fly.

**Notes:**

- Transferring modifications into the internal DOM tree is not possible when the *pictureObject* parameter references an object.
- To be able to transfer modifications, the SVG variable must have been created from a DOM document (with **DOM EXPORT TO VAR**). If the SVG variable was created from a file, when you pass the second * parameter, the command does nothing and an error is generated because, in this case, the data source does not contain a modifiable DOM document.
- To change the data source of an SVG image, you can also use the **XML DOM** commands or the **MissingRef** provided by 4D.

The *element_ID* parameter is used to specify the ID ("id" or "xml:id" attribute) of the element whose attribute(s) you want to modify.

In the *attribName* and *attribValue* parameters, pass, respectively, the attribute to set and its value (as variables, fields or literal values). You can pass as many attribute/value pairs as you want.

The **SVG SET ATTRIBUTE** command is used to modify (but not to add or delete) most of the SVG attributes, such as, for instance, 'fill', 'opacity', 'font-family', and so on. For a complete definition of the SVG attributes, please refer to the reference documents available on the Internet, for example: http://www.w3.org/TR/SVG11/attindex.html. The rendered image is updated immediately; the modifications are transferred on to the child elements for inherited styles.

Note that for technical reasons, the attributes of certain elements as well as certain attributes cannot be modified. The following table lists the elements that can be modified, and those that cannot, as well as the attributes that cannot be modified:

**Elements whose attributes can be modified**

| | |
|---|---|
| svg | Restrictions :<br>- "width" and "height" cannot be modified(1)<br>- "viewBox" can only be modified if "width" and "height" are specified in the original document |
| g | |
| defs | |
| use | |
| filter | Restriction: fe_xxx child elements cannot be modified |
| circle | |
| ellipse | |
| line | |
| polyline | |
| polygon | |
| path | |
| rect | |
| text, tspan, textArea | The specific "4d-text" attribute is used to modify the text of a "text", "tspan" or "textArea" element (see the example) |
| Image | |

**Elements whose attributes cannot be modified**

| | |
|---|---|
| linearGradient, radialGradient, Stop, solidColor, marker, symbol, clipPath, filter et les éléments commençant par fe, style, pattern | This group designates all the elements that can be referenced or contained in an element that can be referenced. This means that it is not possible, for example, to redefine the attributes of a gradient (but it is possible to change the gradient used). Similarly, to change a black color marker to a red marker, it is necessary to define both markers in the SVG document (one black and one red) and to select one of them. It is not possible either for example to modify the color of a rectangle if its parent is a symbol or marker element |

**Attributes that cannot be modified**

| | |
|---|---|
| id or xml:id | |
| lang or xml:lang | |
| class or xml:class | |
| width, height | Concerns the attributes of the 'svg' element only(1) |

(1) These attributes cannot be modified because they define and structure the resulting image. The *width* and *height* attributes of the *svg* element are used to define the initial dimensions of the picture in 4D and these dimensions must remain constant after the picture is created (it is however possible to modify the dimensions of the resulting picture with the **TRANSFORM PICTURE** command of 4D).

You can also refer to the description of the **SVG GET ATTRIBUTE** command to see the list of 4D attributes that are reserved and dedicated to animation.

If you attempt to modify the attribute of an element that is not supported or one of its child elements, the command does nothing and no error is generated.

If the command is not executed in the context of a form or if an invalid *pictureObject* is passed, the *OK* variable is set to 0. If the command has been executed correctly, it is set to 1.

## Example

Modification of the contents of a Text type element:

```
SVG SET ATTRIBUTE(*;picture_object_name;text_element_ID;"4d-text";"This is a text")
```

**Note:** There is no namespace in order that the attribute could be used in a CSS style sheet without risk of conflict.

# SVG SHOW ELEMENT

SVG SHOW ELEMENT ( {* ;} pictureObject ; id {; margin} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, pictureObject is an object name (string) If omitted, pictureObject is a variable |
| pictureObject | Picture | ⇒ | Object name (if * specified) or Variable or field (if * omitted) |
| id | Text | ⇒ | ID attribute of element to display |
| margin | Longint | ⇒ | Margin of visibility (in pixels by default) |

## Description

The **SVG SHOW ELEMENT** command moves the *pictureObject* SVG document in order to show the element whose "id" attribute is specified by the *id* parameter.

If you pass the optional * parameter, you indicate that the *pictureObject* parameter is an object name (string). In this case, the command applies to the rendered picture attached to the object. If you do not pass this parameter, you indicate that the *pictureObject* parameter is a field or a variable and you pass a variable (object variable only) or field reference instead of a string. In this case, the command applies to the rendered pictures of all the objects that use the variable (but not the initial rendered picture).

The command moves the SVG document so that all of the object, whose limits are defined by its bounding rectangle, is visible. The *margin* parameter is used to configure the amplitude of the movement by specifying the distance that must separate the object displayed from the borders of the document. In other words, the bounding rectangle will be increased by *margin* pixels in width and in height. By default, the movement value is 4 pixels.

This command only takes effect in "top left" display mode (with scrollbars).

If this command is not executed in the context of a form or if an invalid *pictureObject* is passed, the *OK* variable is set to 0. If the command is executed correctly, it is set to 1.

# System Documents

## Introduction

All the documents and applications you use on your computer are stored as **files** on the hard disk(s) **connected** to or **mounted** on your machine, or floppy disk(s) or other similar permanent storage devices. Within 4D, we use the terms **file** or **document** to refer to these documents and applications. However, most commands in this theme use the term "document" because most of the time you will use them to access documents (rather than application or system files) on disk.

A hard disk can be formatted as one or several partitions, each of which is called a **volume**. It does not matter if two volumes are physically present on the same hard disk; at the 4D First level, you will usually treat these volumes as separate and equal entities.

A volume can be located on a hard disk physically connected to your machine or mounted over the network through a file sharing protocol such as TCP/IP, AFP ou SMB (Macintosh). Whatever the case, when using the System Documents commands at the 4D level, you treat all these volumes in the same way (unless you know what you are doing and use Plug-ins to extend the capability of your application in that domain).

Each volume has a **volume name**. On Windows, volumes are designated by a letter followed by a colon. Usually C: and D: are used to designate the volumes you use for booting your system (unless you configure your PC otherwise). Then the letters E: through Z: are used for the additional volumes connected or mounted to your PC (DVD drives, additional drives, network drives, and so on). On Macintosh, volumes have natural names; these are the names you see on the desktop at the Finder level.

Normally, you classify your documents into **folders**, which themselves can contain other folders. It is not a good idea to accumulate hundreds or thousands of files at the same level of a volume; it is messy and it slows down your system. On Windows, a folder is (or was) called a **directory**. Folders have always been called so on the Macintosh.

To uniquely identify a document, you need to know the name of the volume and the name(s) of the folder(s) where the document is located as well as the name of the document itself. If you concatenate all these names, you get the **pathname** to the document. Within this pathname, folder names are separated by a special character called the **folder separator** symbol. On Windows, this character is the backslash (*¥)*; on Macintosh it is the colon (*:*).

Let's look at an example. You have a document **Important Memo** located in the **Memos** folder, which is located in the **Documents** folder, which is located in the **Current Work** folder.

On Windows, if the whole thing is located on the C: drive (volume), the pathname of the document is:

C:¥Current Work¥Documents¥Memos¥Important Memo.TXT

**Note:** The ¥ character is also used by the method editor of 4D to designate escape sequences. In order to avoid any interpretation problems, the editor automatically transforms pathnames such as C:¥Disk into C:¥¥Disk. For more information, refer to the paragraph below titled “Specifying Document names or Document pathnames”.

On Macintosh, if the whole thing is located on the disk (volume) **Internal Drive**, the pathname of the document is:

**Internal Drive:Current Work:Documents:Memos:Important Memo**

On Windows, the name of the document is suffixed with *.TXT*; we will see why in the next section.

Whatever the platform, the full pathname of a document can be expressed as follows:

VolName DirSep { DirName DirSep { DirName DirSep { ... } } } DocName

All the documents (files) located on volumes have several characteristics, usually called **attributes** or **properties**: the **name** of the document itself, the **type** and the **creator**.

## DocRef: Document reference number

A document is **open in read/write mode**, **open in read-only mode** or **closed**. Using the built-in 4D commands, a document can be opened in read/write mode by only one process at a time. One process can open several documents, several processes can open multiple documents, you can open the same document in read-only mode as many times as necessary, but you cannot open the same document in read/write mode twice at a time.

You open a document with the **Open document**, **Create document** and **Append document** commands. The **Create document** and **Append document** commands automatically open documents in read/write mode. Only the **Open document** command lets you choose the opening mode. Once a document is open, you can read and write characters from

and to the document (see the **RECEIVE PACKET** and **SEND PACKET** commands). When you are finished with the document, you usually close it using the **CLOSE DOCUMENT** command.

All open documents are referred to using the **DocRef** expression returned by the **Open document**, **Create document** and **Append document** commands. A DocRef uniquely identifies an open document. It is formally an expression of the Time type. All commands working with open documents expect DocRef as a parameter. If you pass an incorrect DocRef to one of these commands, a file manager error occurs.

**Note:** When it is called from a preemptive process, a *DocRef* reference can only be used from this preemptive process. When it is called from a cooperative process, a *DocRef* reference can be used from any other cooperative process.

## Handling I/O errors

When you access (open, close, delete, rename, copy) documents, when you change the properties of a document or when you read and write characters in a document, I/O errors may occur. A document might not be found; it may be locked; it may be already open in write mode. You can catch these errors with an error-handling method installed with **ON ERR CALL**. Most of the errors that can occur while using system documents are described in the section **OS File Manager Errors (-124 -> -33)**.

## The Document system variable

The commands **Open document**, **Create document**, **Append document** and **Select document** enable you to access a document using the standard Open or Save file dialog boxes. When you access a document through a standard dialog, 4D returns the full pathname of the document in the *Document* system variable. This system variable has to be distinguished from the *document* parameter that appears in the parameter list of the commands.

## Specifying Document names or Document pathnames

Most of the routines of this section expecting a document name accept both a name or a pathname to the document (except when signaled otherwise). If you pass a name, the command looks for the document within the folder of the database. If you pass a pathname, it must be valid.

If you pass a wrong name or a wrong pathname, the command generates a file manager error that you can intercept using an **ON ERR CALL** method.

### Entering Windows pathnames and escape sequences

The method editor of 4D allows the use of escape sequences. An escape sequence is a set of characters that are used to replace a “special” character. The sequence begins with a backslash ¥, followed by a character. For example, *¥t* is the escape sequence for the Tab character.

The ¥ character is also used as the separator in pathnames under Windows. In general, 4D will correctly interpret Windows pathnames that are entered in the method editor by replacing single backslashes *¥* with double backslashes *¥¥*. For example, **C:¥Folder** will become **C:¥¥Folder**.

However, if you write **C:¥MyDocuments¥New**, 4D will display **C:¥¥MyDocuments¥New**. In this case, the second ¥is incorrectly interpreted as *¥N* (an existing escape sequence). You must therefore enter a double *¥¥* when you want to insert a backslash before a character that is used in one of the escape sequences recognized by 4D.

The following escape sequences are recognized by 4D:

| Escape sequence | Character replaced |
|---|---|
| ¥n | LF (New line) |
| ¥t | HT (Horizontal tab) |
| ¥r | CR (Carriage return) |
| ¥¥ | ¥ (Backslash) |
| ¥" | " (Quotes) |

## Absolute or relative pathname

Most commands for managing 4D documents and folders accept either relative or absolute pathnames:

- **Relative pathnames** define a location with respect to a folder located on disk. In 4D, a relative pathname is usually expressed with respect to the database folder, i.e. the folder containing the structure file. Relative pathnames are

especially useful when deploying applications in heterogenous environments.
- **Absolute pathnames** define a location with respect to the root of the volume and so they do not depend on the current location of the database folder.

To determine whether a pathname passed to a command must be interpreted as absolute or relative, 4D applies a specific algorithm on each platform.

### Under Windows

If the parameter contains only two characters **and** if the second one is a ':',
**or** if the text contains ':' and '¥' as the second and third character,
**or** if the text starts with "¥¥",
then the pathname is **absolute**.

In all other cases, the pathname is **relative**.

Examples with the **CREATE FOLDER** command:

```
CREATE FOLDER("lundi") // relative path
CREATE FOLDER("¥Monday") // relative path
CREATE FOLDER("¥Monday¥Tuesday") // relative path
CREATE FOLDER("c:") // absolute path
CREATE FOLDER("d:¥Monday") // absolute path
CREATE FOLDER("¥¥srv-Internal¥temp") // absolute path
```

### Under Mac OS

If the text starts with a folder separator ':',
**or** if does not contain any,
then the path is **relative**.

In all other cases, it is **absolute**.

Examples with the **CREATE FOLDER** command:

```
CREATE FOLDER("Monday") // relative path
CREATE FOLDER("macintosh hd:") // absolute path
CREATE FOLDER("Monday:Tuesday") // absolute path (a volume must be called Monday)
CREATE FOLDER(":Monday:Tuesday") // relative path
```

## Useful Project Methods when handling documents on disk

**• Detecting on which platform you're running**

Although 4D provides commands, such as **MAP FILE TYPES**, for eliminating coding variations due to platform specificities, once you start to work at a lower level when handling documents on disk (such as programmatically obtaining pathnames), you need to know if you are running on a Macintosh or a Windows platform.

The ***On Windows*** project method listed here tells whether your database is running on Windows:

```
//On Windows Project Method
//On Windows -> Boolean
//On Windows -> True if on Windows

C_BOOLEAN($0)
C_LONGINT($vlPlatform;$vlSystem;$vlMachine)

PLATFORM PROPERTIES($vlPlatform;$vlSystem;$vlMachine)
$0:=($vlPlatform=Windows)
```

**• Extracting the file name from a long name**

Once you have obtained the long name (pathname + file name) of a document, you may need to extract the file name of the document from that long name in order, for example, to display it in the title of a window. The ***Long name to file name*** project method does this on both Windows and Macintosh.

```
//Long name to file name Project Method
//Long name to file name ( String ) -> String
//Long name to file name ( Long file name ) -> File name
```

```
C_TEXT($1;$0)
C_LONGINT($viLen;$viPos;$viChar;$viDirSymbol)

$viDirSymbol:=Character code(Folder separator)
$viLen:=Length($1)
$viPos:=0
For($viChar;$viLen;1;-1)
   If(Character code($1≤$viChar≥)=$viDirSymbol)
      $viPos:=$viChar
      $viChar:=0
   End if
End for
If($viPos>0)
   $0:=Substring($1;$viPos+1)
Else
   $0:=$1
End if
If(<>vbDebugOn) //Set this variable to True or False in the On Startup database method
   If($0="")
      TRACE
   End if
End if
```

**• Extracting the pathname from a long name**

Once you have obtained the long name (pathname + file name) of a document, you may need to extract the pathname of the directory where the document is located from that long name; for instance, you may want to save additional documents at the same location. The ***Long name to path name*** project method does this on both Windows and Macintosh.

```
 //Long name to path name Project Name
 //Long name to path name ( String ) -> String
 //Long name to path name ( Long file name ) -> Path name

C_TEXT($1;$0)
C_LONGINT($viLen;$viPos;$viChar;$viDirSymbol)

$viDirSymbol:=Character code(Folder separator)
$viLen:=Length($1)
$viPos:=0
For($viChar;$viLen;1;-1)
   If(Character code($1≤$viChar≥)=$viDirSymbol)
      $viPos:=$viChar
      $viChar:=0
   End if
End for
If($viPos>0)
   $0:=Substring($1;1;$viPos)
Else
   $0:=$1
End if
If(<>vbDebugOn) //Set this variable to True or False in the On Startup database method
   If($0="")
      TRACE
   End if
End if
```

# Append document

Append document ( document {; fileType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname or Empty string for standard file dialog box |
| fileType | String | ⇒ | List of types of documents to be screened, or "*" to not screen the documents |
| Function result | DocRef | ⇐ | Document reference number |

## Description

The **Append document** command does the same as thing as **Open document**: it opens a document on disk.

The only difference is that **Append document** sets the file position at the end of the document while **Open document** sets its at the beginning of the document.

Refer to **Open document** for more details about using **Append document**.

## Example

The following example opens an existing document called Note, appends the string “and so long” and a carriage return onto the end of the document, and closes the document. If the document already contained the string “Good-bye”, the document would now contain the string “Good-bye and so long”, followed by a carriage return:

```
C_TIME(vhDocRef)
vhDocRef:=Append document("Note.txt") ` Open Note document
SEND PACKET(vhDocRef;" and so long"+Char(13)) ` Append a string
CLOSE DOCUMENT(vhDocRef) ` Close the document
```

# CLOSE DOCUMENT

CLOSE DOCUMENT ( docRef )

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ➡ | Document reference number |

## Description

**CLOSE DOCUMENT** closes the document specified by *docRef*.

Closing a document is the only way to ensure that the data written to a file is saved. You must close all the documents you open with the commands **Open document**, **Create document** or **Append document**.

## Example

The following example lets the user create a new document, writes the string “Hello” into it, and closes the document:

```
C_TIME(vhDocRef)
vhDocRef:=Create document("")
If(OK=1)
   SEND PACKET(vhDocRef;"Hello") ` Write one word into the document
   CLOSE DOCUMENT(vhDocRef) ` Close the document
End if
```

# Convert path POSIX to system

Convert path POSIX to system ( posixPath {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| posixPath | Text | ⇒ | POSIX pathname |
| * | Operator | ⇒ | Encoding option |
| Function result | Text | ⇐ | Pathname expressed in system syntax |

## Description

The **Convert path POSIX to system** command converts a pathname expressed with the POSIX (Unix) syntax into a pathname expressed with the system syntax.

Pass the complete pathname of a file or folder in the *posixPath* parameter, expressed with the POSIX syntax. This path must be absolute (it must begin with the "/" character). You must pass a disk path; it is not possible to pass a network path (beginning, for example, with ftp://ftp.mysite.fr).

The command returns the complete pathname of the file or folder expressed in the current system syntax.

The optional * parameters can be used to indicate whether the *posixPath* parameter is encoded. If this is the case, you must pass this parameter, otherwise the conversion will not be valid. The command returns the pathname without encoding.

## Example 1

Examples under Mac OS:

```
$path:=Convert path POSIX to system("/Volumes/machd/file 2.txt")
 //returns "machd:file 2.txt"
$path:=Convert path POSIX to system("/Volumes/machd/file%202.txt";*)
 //returns "machd:file 2.txt"
$path:=Convert path POSIX to system("/file 2.txt")
 //returns "machd:file 2.txt" if machd is the startup disk
```

## Example 2

Examples under Windows:

```
$path:=Convert path POSIX to system("c:/docs/file 2.txt")
 //returns "c:¥¥docs¥¥file 2.txt"
$path:=Convert path POSIX to system("c:/docs/file%202.txt";*)
 //returns "c:¥¥docs¥¥file 2.txt"
```

# Convert path system to POSIX

Convert path system to POSIX ( systemPath {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| systemPath | Text | ⇒ | Relative or absolute pathname expressed in system syntax |
| * | Operator | ⇒ | Encoding option |
| Function result | Text | ⇐ | Chemin d'accès absolu exprimé en syntaxe POSIX |

## Description

The **Convert path system to POSIX** command converts a pathname expressed with the system syntax as a pathname expressed with the POSIX (Unix) syntax.

Pass the pathname for a file or folder in the *systemPath* parameter, expressed with the system syntax (Mac OS or Windows). This path may be absolute or relative to the database folder (folder containing the database structure file). It is not mandatory that the elements of the path actually exist on the disk at the time the command is executed (the command does not test the validity of the pathname).

The command returns the complete pathname of the file or folder expressed in the POSIX syntax. The command always returns an absolute pathname, regardless of the type of path passed in *systemPath*. If you passed a relative pathname in *systemPath*, 4D completes the value returned by adding the pathname of the database folder.

The optional * parameter can be used to specify the encoding of the POSIX path. By default, **Convert path system to POSIX** does not encode the special characters of the POSIX path. If you pass the * parameter, the special characters are translated (for example, "My folder" becomes "My%20folder").

## Example 1

Examples under OS X

```
$path:=Convert path system to POSIX("machd:file 2.txt")
 //machd is the startup disk
 //returns "/file 2.txt"
$path:=Convert path system to POSIX("disk2:file 2.txt")
 //disk2 is an additional disk (not the startup)
 //returns "/Volumes/disk2/file 2.txt"
$path:=Convert path system to POSIX("machd:file 2.txt";*)
 //returns "/file%202.txt"
$path:=Convert path system to POSIX(":resources:images") //relative path
 //returns "/User/mark/Documents/videodatabase/resources/images"
$path:=Convert path system to POSIX("resources:images") //absolute path
 //returns "/resources/images"
```

## Example 2

Example under Windows

```
$path:=Convert path system to POSIX("c:¥docs¥file 2.txt")
 `returns "c:/docs/file 2.txt"
$path:=Convert path system to POSIX("¥¥srv¥tempo¥file.txt")
 `returns "//srv/tempo/file.txt"
```

# COPY DOCUMENT

COPY DOCUMENT ( sourceName ; destinationName {; newName} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| sourceName | String | ➡ | Pathname of file or folder to be copied |
| destinationName | String | ➡ | Name or pathname of copied file or folder |
| newName | String | ➡ | New name of copied file or folder |
| * | Operator | ➡ | Override existing document if any |

## Description

The **COPY DOCUMENT** command copies the file or folder specified by *sourceName* to the location specified by *destinationName* and, optionally, renames it.

- **Copying files**
  In this case, the *sourceName* parameter can contain:
  - either a complete file pathname expressed with respect to the root of the volume,
  - or a pathname relative to the database folder.

  The *destinationName* parameter can contain several types of locations:
  - a complete file pathname expressed with respect to the root of the volume: the file is copied to this location
  - a file name or file pathname relative to the database folder: the file is copied into the database folder (the subfolders must already exist)
  - a complete folder pathname or a pathname relative to the database folder (*destinationName* must end with the folder separator for the platform): the file is copied into the designated folder. These folders must already exist on the disk; they are not created.

  An error is generated if there is already a document named *destinationName* unless you specify the optional * parameter which, in this case, instructs **COPY DOCUMENT** to delete and override the existing document in the destination location.

- **Copying folders**
  To indicate that you are designating a folder, the strings passed in *sourceName* and *destinationName* must end with a folder separator for the platform. For example, under Windows "C:¥¥Element¥¥" designates a folder and "C:¥¥Element" designates a file.
  To copy a folder, pass its complete pathname in *sourceName*. This folder must already exist on the disk. When a folder is set in the *sourceName* parameter, a folder must also be designated in the *destinationName* parameter. You must pass the complete folder pathname (where each element must already exist on the disk)
  If a folder with the same name as the one designated by the *sourceName* parameter already exists at the location set by the *destinationName* parameter and it is not empty, 4D checks its contents before copying the items. An error is generated when a file with the same name already exists, unless you have passed the optional * parameter which, in this case, indicates to the command to delete and replace the file in the destination location. .

Note that you can pass a file in the *sourceName* parameter and a folder in the *destinationName* parameter, in order to copy a file into a folder.

The optional *newName* parameter, when it is passed, renames the document copied to its destination location (file or folder). When it is passed in the context of copying a file, this parameter replaces the name (if any) passed in the *destinationName* parameter.

## Example 1

The following example duplicates a document in its own folder:

```
COPY DOCUMENT("C:¥¥FOLDER¥¥DocName";"C:¥¥FOLDER¥¥DocName2")
```

## Example 2

The following example copies a document to the database folder (provided **C:¥¥FOLDER** is not the database folder):

```
COPY DOCUMENT("C:¥¥FOLDER¥¥DocName";"DocName")
```

## Example 3

The following example copies a document from one volume to another one:

```
COPY DOCUMENT("C:¥¥FOLDER¥¥DocName";"F:¥¥Archives¥¥DocName.OLD")
```

## Example 4

The following example duplicates a document in its own folder overriding an already existing copy:

```
COPY DOCUMENT("C:¥¥FOLDER¥¥DocName";"C:¥¥FOLDER¥¥DocName2";*)
```

## Example 5

Copying a file into a specific folder while keeping the same name:

```
COPY DOCUMENT("C:¥¥Projects¥¥DocName";"C:¥¥Projects¥¥")
```

## Example 6

Copying a file into a specific folder while keeping the same name and overriding the existing document:

```
COPY DOCUMENT("C:¥¥Projects¥¥DocName";"C:¥¥Projects¥¥"; *)
```

## Example 7

Copying a folder into another folder (both folders must already be present on the disk):

```
COPY DOCUMENT("C:¥¥Projects¥¥";"C¥¥Archives¥¥2011¥¥")
```

## Example 8

The following examples create different files and folders in the database folder (examples under Windows). In each case, the "folder2" folder must exist:

```
COPY DOCUMENT("folder1¥¥name1";"folder2¥¥")
 //creates the "folder2/name1" file

COPY DOCUMENT("folder1¥¥name1";"folder2¥¥" ; "new")
 //creates the "folder2/new" file

COPY DOCUMENT("folder1¥¥name1";"folder2¥¥name2")
 //creates the "folder2/name2" file

COPY DOCUMENT("folder1¥¥name1";"folder2¥¥name2";"new")
 //creates the "folder2/new" file (name2 is ignored)

COPY DOCUMENT("folder1¥¥" ; "folder2¥¥")
 //creates the "folder2/folder1/" folder

COPY DOCUMENT("folder1¥¥" ; "folder2¥¥" ; "new")
 //creates the "folder2/new/" folder
```

# CREATE ALIAS

CREATE ALIAS ( targetPath ; aliasPath )

| Parameter | Type | | Description |
|---|---|---|---|
| targetPath | String | ⇒ | Name or access path of the alias/shortcut target |
| aliasPath | String | ⇒ | Name or full pathname for the alias or shortcut |

## Description

The **CREATE ALIAS** command creates an alias (named “shortcut” under Windows) for the target file or folder passed in *targetPath*. The name and location are defined by the *targetPath* parameter.

An alias can be made for any kind of document or folder. The alias icon will be the same as the target item. The icon contains a small arrow at the bottom left side. Under Mac OS, the icon name is also displayed in italics characters.

This command does not assign a name by default, the name has to be passed in the *aliasPath* parameter. If just a name is passed in this parameter, the alias is created in the current working folder (usually the folder containing the structure file).

**Note:** Under Windows, the shortcuts are designated by a “.LNK” extension (invisible). If this extension is not passed, it is automatically added by the command.

If an empty string is passed in the *targetPath*, the command does nothing.

## Example

Your database generates text files called “Report Number” sorted in the database folder. The user would like to create shortcuts to these reports and to store them at a convenient location:

```
  `Method CREATE_REPORT
C_TEXT($vtRport)
C_STRING(250;$vtpath)
C_STRING(80;$vaname)
C_TIME(vDoc)
C_INTEGER($ReportNber)

$vTReport:=... `Create report
$ReportNber:=... `Compute the report number
$vaName:="Report"+String($ReportNber)+".txt" `File name
vDoc:=Create document($vaName)
If(OK=1)
   SEND PACKET(vDoc;$vTReport)
   CLOSE DOCUMENT(vDoc)
 `Add the alias
   CONFIRM("Create an alias for this report?")
   If(OK=1)
      $vtPath:=Select folder("Where do you want the alias to be created?")
      If(OK=1)
         CREATE ALIAS($vaName;$vtPath+$vaName)
         If(OK=1)
            SHOW ON DISK($vtPath+$vaName)
 `Show the alias location
         End if
      End if
   End if
End if
```

## System variables and sets

The OK system variable is set to 1 if the command execution was successful; otherwise it is set to 0.

# Create document

Create document ( document {; fileType} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname or Empty string for standard file dialog box |
| fileType | String | ⇒ | List of types of documents to be screened, or "*" to not screen the documents |
| Function result | DocRef | ⇐ | Document reference number |

## Description

The**Create document** command creates a new document and returns its document reference number.

Pass the name or full pathname of the new document in *document*. If *document* already exists on the disk, it is overwritten. However, if *document* is locked or already open, an error is generated.

If you pass an empty string in *document*, the Save As dialog box appears and you can then enter the name of the document you want to create. If you cancel the dialog, no document is created; **Create document** returns a null DocRef and sets the OK variable to 0.

If the document is correctly created and opened, **Create document** returns its document reference number and sets the OK variable to 1. The system variable Document is updated and returns the complete access path of the created document.

Whether or not you use the Save As dialog box, **Create document** creates a .TXT (Windows) or TEXT (Macintosh) document by default. If you want to create another type of document, pass the *fileType* parameter.

In the *fileType* parameter, pass the type(s) of file(s) that can be selected in the opening dialog box. You can pass a list of several types separated by a ; (semi-colon). For each type set, an item will be added to the menu used for choosing the type in the dialog box.

Under Mac OS, you can pass either a standard Mac OS type (TEXT, APPL, etc.), or a UTI (Uniform Type Identifier) type. UTIs are defined by Apple in order to meet standardization needs for file types. For example, "public.text" is the UTI type of text type files. For more information about UTIs, refer to the following address: https://developer.apple.com/library/mac/#documentation/Miscellaneous/Reference/UTIRef/Articles/System-DeclaredUniformTypeIdentifiers.html.

Under Windows, you can also pass a standard Mac OS file type — 4D makes the correspondence internally — or file extensions (.txt, .exe, etc.). Note that under Windows, the user can “force” the display of all file types by entering *.* in the dialog box. However, in this case, 4D will carry out an additional check of the selected file types: if the user selects an unauthorized file type, the command returns an error.

If you do not want to restrict the displayed files to one or more types, pass the "*" (star) string or ".*" in *fileType*.

On Windows you pass a Windows file extension or Macintosh file type mapped through the **MAP FILE TYPES** mechanism. If you want to create a document without an extension, a document containing several extensions, or a document containing an extension with more than three characters, do not use the *type* parameters and pass the full name in *document* (see example2).

Once you have created and opened a document, you can write and read the document using the **RECEIVE PACKET** and **SEND PACKET** commands that you can combine with the **Get document position** and **SET DOCUMENT POSITION** commands in order to directly access any part of the document.

Do not forget to eventually call **CLOSE DOCUMENT** for the document.

## Example 1

The following example creates and opens a new document called Note, writes the string “Hello” into it, and closes the document:

```
C_TIME(vhDoc)
vhDoc:=Create document("Note.txt") ` Create new document called Note
If(OK=1)
   SEND PACKET(vhDoc;"Hello") ` Write one word in the document
   CLOSE DOCUMENT(vhDoc) ` Close the document
End if
```

## Example 2

The following example creates documents with non-standard extensions under Windows:

```
$vtMyDoc:=Create document("Doc.ext1.ext2") `Several extensions
$vtMyDoc:=Create document("Doc.shtml") `Long extension
$vtMyDoc:=Create document("Doc.") `No extension (the period "." is mandatory)
```

## System variables and sets

If the document has been created correctly, the system variable OK is set to 1 and the system variable Document contains the full pathname and the name of *document*.

# CREATE FOLDER

CREATE FOLDER ( folderPath {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| folderPath | String | ⇒ | Pathname to new folder to create |
| * | Operator | ⇒ | Create folder hierarchy |

## Description

The **CREATE FOLDER** command creates a folder according to the pathname you pass in *folderPath*.

If you pass a name in *folderPath*, the folder is created in the database folder.

In *folderPath*, you can also pass a folder hierarchy starting from the root of the volume or from the database folder (in this case, the string must end with a folder separator).
If you omit the * parameter, an error is generated and no folder is created if any one of the intermediary folders does not exist.
If you pass the * parameter, **CREATE FOLDER** recreates the folder hierarchy if necessary and no error is generated. In this case, you can also pass a document pathname in *folderPath*. The document name is then ignored but the folder hierarchy specified in *folderPath* is created recursively

## Example 1

The following example creates the “Archives” folder in the folder of the database:

```
CREATE FOLDER("Archives")
```

## Example 2

The following example creates the Archives folder in the folder of the database, then it creates the “January” and “February” subfolders:

```
CREATE FOLDER("Archives")
CREATE FOLDER("Archives¥¥January")
CREATE FOLDER("Archives¥¥February")
```

## Example 3

The following example creates the “Archives” folder at the root level of the C volume:

```
CREATE FOLDER("C:¥¥Archives")
```

## Example 4

Creation of the "C:¥Archives¥2011¥January¥" folder hierarchy:

```
CREATE FOLDER("C:¥¥Archives¥¥2011¥¥January¥¥";*)
```

## Example 5

Creation of the "¥February¥" subfolder in the existing "C:¥Archives¥" folder:

```
CREATE FOLDER("C:¥¥Archives¥¥2011¥¥February¥¥Doc.txt";*)
 // the "Doc.txt" file is ignored
```

# DELETE DOCUMENT

DELETE DOCUMENT ( document )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname |

## Description

The **DELETE DOCUMENT** command deletes the document whose name you pass in *document*.

If the document name or the entered path name is incorrect, an error is generated. This is also the case if you try to delete an open document.

**DELETE DOCUMENT** doesn't accept an empty string argument for *document*. If an empty string is used, the Open File dialog box is not displayed and an error is generated.

**WARNING: DELETE DOCUMENT** can delete any file on a disk. This includes documents created with other applications as well as the applications themselves. **DELETE DOCUMENT** should be used with extreme caution. Deleting a document is a permanent operation and cannot be undone.

## Example 1

The following example deletes the document named Note:

```
DELETE DOCUMENT("Note") ` Delete the document
```

## Example 2

See example for the **APPEND DATA TO PASTEBOARD** command.

## System variables and sets

Deleting a document sets the OK system variable to 1. If **DELETE DOCUMENT** can't delete the document, the OK system variable is set to 0.

# DELETE FOLDER

DELETE FOLDER ( folder {; deleteOption} )

| Parameter | Type | | Description |
|---|---|---|---|
| folder | String | ⇒ | Name or full path of the folder to be deleted |
| deleteOption | Longint | ⇒ | Folder deletion option |

## Description

The **DELETE FOLDER** command deletes the folder whose name or full path has been passed in *folder*.

By default, for security reasons, if you omit the *deleteOption* parameter, **DELETE FOLDER** only allows empty folders to be deleted. If you want the command to be able to delete non-empty folders, you must use the *deleteOption* parameter. In *deleteOption*, you can pass one of the following constants, found in the "**System Documents**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Delete only if empty | Longint | 0 | Deletes folder only when it is empty |
| Delete with contents | Longint | 1 | Deletes folder along with everything it contains |

- When Delete only if empty (0) is passed or if you omit the *deleteOption* parameter:
  - The folder specified in the *folder* parameter is only deleted if it is empty; otherwise, the command does nothing and an error -47 (The file is already open, or the folder is not empty) is generated.
  - If the folder specified does not exist , the error -120 (Tried to access a file by using a pathname that specifies a non existing directory) is generated.

- When Delete with contents (1) is passed:
  - The folder along with all of its contents are deleted.
    **Warning:** Even when this folder and/or its contents are locked or set to read-only, if the current user has suitable access rights, they are still deleted.
  - If this folder, or any of the files it contains, cannot be deleted, deletion is aborted as soon as the first inaccessible element is detected, and an error(*) is returned. In this case, the folder may be only partially deleted. When deletion is aborted, you can use **GET LAST ERROR STACK** command to retrieve the name and path of the offending file.
  - If the folder specified does not exist, the command does nothing and no error is returned.

    (*) under Windows: -54 (Attempt to open locked file for writing)
    under OS X: -45 (The file is locked or the pathname is not correct)

You can intercept these errors using a method installed by the **ON ERR CALL** command.

# Document creator

Document creator ( document ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname |
| Function result | String | ⇐ | Empty string (Windows) or File Creator (Mac OS) |

## Description

The **Document creator** command returns the creator of the document whose name or pathname you pass in *document*.

On Windows, **Document creator** returns an empty string.

# DOCUMENT LIST

DOCUMENT LIST ( pathname ; documents {; options} )

| Parameter | Type | | Description |
|---|---|---|---|
| pathname | String | ⇒ | Pathname to volume, directory or folder |
| documents | Text array | ⇐ | Names of the documents present at this location |
| options | Longint | ⇒ | Options for building list |

## Description

The **DOCUMENT LIST** command populates the Text array *documents* with the names of the documents located at the location you pass in *pathname*.

**Note:** You must pass an absolute pathname in the *pathname* parameter.

By default, if you omit the *options* parameter, only the names of documents are returned in the *documents* array. You can modify this by passing, in the *options* parameter, one or more of the following constants, found in the **System Documents** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Absolute path | Longint | 2 | The *documents* array contains absolute pathnames |
| Ignore invisible | Longint | 8 | Invisible documents are not listed |
| Posix path | Longint | 4 | The *documents* array contains Posix format pathnames |
| Recursive parsing | Longint | 1 | The *documents* array contains all files and subfolders of the specified folder |

**Notes:**

- With the Recursive parsing option in relative mode (option 1 only), the paths of documents located in subfolders begin with the ":" or "¥" characters depending on the platform.
- With the Posix path option in relative mode (option 4 only), paths do not start with "/".
- With the Posix path option in absolute mode (option 4 + 2), paths always begin with "/".

If there are no documents at the specified location, the command returns an empty array. If the pathname you pass in *pathname* is invalid, **DOCUMENT LIST** generates a file manager error that you can intercept using an **ON ERR CALL** method.

## Example 1

List of all documents in a folder (default syntax):

```
DOCUMENT LIST("C:¥¥";arrFiles)
```

-> arrFiles:
Text1.txt
Text2.txt

## Example 2

List of all documents in a folder in absolute mode:

```
DOCUMENT LIST("C:¥¥";arrFiles; Absolute path)
```

-> arrFiles:
C:¥Text1.txt
C:¥Text2.txt

## Example 3

List of all documents in recursive (relative) mode:

```
DOCUMENT LIST("C:¥¥";arrFiles;Recursive parsing)
```

-> arrFiles:
Text1.txt
Text2.txt
¥Folder1¥Text3.txt
¥Folder1¥Text4.txt
¥Folder2¥Text5.txt
¥Folder2¥Folder3¥Picture1.png

## Example 4

List of all documents in recursive absolute mode:

```
DOCUMENT LIST("C:¥¥MyFolder¥¥";arrFiles;Recursive parsing+Absolute path)
```

-> arrFiles:
C:¥MyFolder¥MyText1.txt
C:¥MyFolder¥MyText2.txt
C:¥MyFolder¥Folder1¥MyText3.txt
C:¥MyFolder¥Folder1¥MyText4.txt
C:¥MyFolder¥Folder2¥MyText5.txt
C:¥MyFolder¥Folder2¥Folder3¥MyPicture1.png

## Example 5

List of all documents in recursive Posix (relative) mode:

```
DOCUMENT LIST("C:¥¥MyFolder¥¥";arrFiles;Recursive parsing+Posix path)
```

-> arrFiles:
MyText1.txt
MyText2.txt
Folder1/MyText3.txt
Folder1/MyText4.txt
Folder2/MyText5.txt
Folder2/Folder3/MyPicture1.png

# Document to text

Document to text ( fileName {; charSet {; breakMode}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ➡ | Document name or Pathname to document |
| charSet | Text, Longint | ➡ | Name or Number of character set |
| breakMode | Longint | ➡ | Processing mode for line breaks |
| Function result | Text | ⬅ | Text from the document |

## Description

The **Document to text** command lets you retrieve the contents of a file directly on disk in a 4D text variable or text field.

In *fileName*, pass the name or pathname of the file to be read. The file must exist on the disk, otherwise an error is generated. You can pass:

- just the file name, for example "myFile.txt": in this case, the file must be located next to the structure file of the application.
- a pathname relative to the structure file of the application, for example "¥¥docs¥¥myFile.txt" under Windows or ":docs:myFile.txt" under OS X.
- an absolute pathname, for example "c:¥¥app¥¥docs¥¥myFile.txt" under Windows or "MacHD:docs:myFile.txt" under OS X.

In *charSet*, you pass the character set to be used for reading the contents. You can pass a string containing the standard set name (for example “ISO-8859-1” or “UTF-8”) or its MIBEnum ID (longint). For more information about the list of character sets supported by 4D, refer to the description of the **CONVERT FROM TEXT** command.

If the document contains a Byte Order Mark (BOM), 4D uses the character set that it has set instead of the one specified in *charSet* (this parameter is then ignored).

If the document does not contain a BOM and if the *charSet* parameter is omitted, by default 4D uses the following character sets:

- under Windows: ANSI
- under OS X: MacRoman

In *breakMode*, you can pass a longint indicating the processing to apply to end-of-line characters in the document. You can pass one of the following constants, found in the "**System Documents**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Document unchanged | Longint | 0 | No processing |
| Document with CR | Longint | 3 | Line breaks are converted to OS X format: CR (carriage return) |
| Document with CRLF | Longint | 2 | Line breaks are converted to Windows format: CRLF (carriage return + line feed) |
| Document with LF | Longint | 4 | Line breaks are converted to Unix format: LF (line feed) |
| Document with native format | Longint | 1 | (Default) Line breaks are converted to the native format of the operating system: CR (carriage return) under OS X, CRLF (carriage return + line feed) under Windows |

By default, when you omit the *breakMode* parameter, line breaks are processed in native mode (1).

**Note:** This command does not modify the OK variable. In case of failure, an error is generated that you can intercept using a method installed by the **ON ERR CALL** command.

## Example

Given the following text document (fields are separated by tabs):

```
id    name    price    vat
3    4D Tags    99    19.6
```

When you execute this code:

```
$Text:=Document to text("products.txt")
```

... you get:

```
// $Text = "id¥tname¥tprice¥tvat¥r¥n3¥t4D Tags¥t99 ¥t19.6"
// ¥t = tab
// ¥r = CR
```

# Document type

Document type ( document ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name |
| Function result | String | ⇐ | Windows file extension (1 to 3-character string) or Mac OS file type (4-character string) |

## Description

The **Document type** command returns the extension or the type of the document whose name or pathname you pass in *document*.

On Windows, **Document type** returns the file extension of the document (i.e. *'DOC'* for a Microsoft Word document, *'EXE'* for an executable file, and so on) or the corresponding Mac OS-based 4 characters file type if this latter has been mapped with its equivalent Windows file extension by 4D (i.e. *'TEXT'* for the *'TXT'* file extension) or by a prior call to **MAP FILE TYPES**.

On Macintosh, **Document type** returns, if specified, the 4-characters file type of the document (i.e. *'TEXT'* for a Text document, *'APPL'* for a double-clickable application and so on).

### Compatibility Note

The use of Mac OS file types is obsolete under Mac OS X. Like Windows, file identification is now based on the suffix of its name (see the **System Documents** section). For compatibility's sake, it nevertheless remains possible to read the Mac OS type of documents when it has been specified using **MAP FILE TYPES**.

# FOLDER LIST

FOLDER LIST ( pathname ; directories )

| Parameter | Type | | Description |
|---|---|---|---|
| pathname | String | ⇒ | Pathname to volume, directory or folder |
| directories | String array | ⇐ | Names of the directories present at this location |

## Description

The **FOLDER LIST** command populates the Text or String array *directories* with the names of the folders located at the pathname you pass in *pathname*.

**Note:** The *pathname* parameter only accepts absolute pathnames.

If there are no folders at the specified location, the command returns an empty array. If the pathname you pass in *pathname* is invalid, **FOLDER LIST** generate a file manager error that you can intercept using an **ON ERR CALL** method.

# GET DOCUMENT ICON

GET DOCUMENT ICON ( docPath ; icon {; size} )

| Parameter | Type | | Description |
|---|---|---|---|
| docPath | String | ➡ | Name or path of document to get icon, or Empty string for standard Open File dialog box |
| icon | Picture | ➡ | Picture variable or field |
| size | Longint | ➡ | Size of the returned picture (in pixels) |

## Description

The **GET DOCUMENT ICON** command returns, in the 4D picture variable or field *icon*, the icon of the document whose name or complete pathname is passed in *docPath*. *docPath* can specify a file of any type (executable, document, shortcut or alias, etc.) or a folder.

*docPath* contains the full pathname of the document. You can also pass the document name only or a relative pathname, in this case the document must be placed in the database current working directory (usually, the folder containing the database structure file).
If you pass an empty string in *docPath*, the standard Open File dialog box appears. The user can then select the file to read. Once the dialog box is validated, the Document system variable contains the full pathname to the selected file.

Pass a 4D picture field or variable in *icon*. After the command is executed, this parameter contains the icon of the file (PICT format).

The optional *size* parameter sets the dimensions in pixels of the returned icon. This value actually represents the side length of the square including the icon. Icons are usually defined in 32x32 pixels (“large icons”) or 16x16 pixels (“small icons”). If you pass 0 or omit this parameter, the largest available icon is returned.

# Get document position

Get document position ( docRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ⇒ | Document reference number |
| Function result | Real | ⇐ | File position (expressed in bytes) from the beginning of the file |

## Description

This command operates only on a document that is currently open whose document reference number you pass in *docRef*.

**Get document position** returns the position, starting from the beginning of the document, where the next read (**RECEIVE PACKET**) or write (**SEND PACKET**) will occur.

# GET DOCUMENT PROPERTIES

GET DOCUMENT PROPERTIES ( document ; locked ; invisible ; created on ; created at ; modified on ; modified at )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name |
| locked | Boolean | ⇐ | Locked (True) or unlocked (False) |
| invisible | Boolean | ⇐ | Invisible (True) or visible (False) |
| created on | Date | ⇐ | Creation date |
| created at | Time | ⇐ | Creation time |
| modified on | Date | ⇐ | Last modification date |
| modified at | Time | ⇐ | Last modification time |

## Description

The **GET DOCUMENT PROPERTIES** command returns information about the document whose name or pathname you pass in *document*.

After the call:

- *locked* returns True if the document is locked. A locked document cannot be modified.
- *invisible* returns True if the document is hidden.
- *created on* and *created at* return the date and time when the document was created.
- *modified on* and *modified at* return the date and time when the document modified for the last time.

## Example

You have created a documentation database and you would like to export all the records you created in the database to documents on disk. Because the database is regularly updated you want to write an export algorithm that create or recreate each document on disk if the document does not exist or if the corresponding record has been modified after the document was saved for the last time. Consequently, you need to compare the date and time of modification of a document (if it exists) with its corresponding record. For illustrating this example, we use the table whose definition is shown below:

Rather than saving both a date and time values into each record, you can save a “time stamp” value which expresses the number of seconds elapsed between an arbitrary anterior date and time (in this example we use Jan, 1st 1995 at 00:00:00) and the date and time when the record was saved.

In our example, the field *[Documents]Creation Stamp* holds the time stamp when the record was first created and the field *[Documents]Modification Stamp* holds the time stamp when the record was last modified.

The ***Time stamp*** project method listed below calculates the time stamp for a specific date and time or for the current date and time if no parameters are passed:

```
[ ` Time stamp Project Method
  ` Time stamp { ( date ; Time ) } -> Long
  ` Time stamp { ( date ; Time ) } -> Number of seconds since Jan, 1st 1995

C_DATE($1;$vdDate)
C_TIME($2;$vhTime)
C_LONGINT($0)

If(Count parameters=0)
   $vdDate:=Current date
   $vhTime:=Current time
Else
```

```
   $vdDate:=$1
   $vhTime:=$2
End if
$0:=(($vdDate-!01/01/95!)*86400)+$vhTime
```

**Note:** Using this method, you can encode dates and times from the *01/01/95* at *00:00:00* to the *01/19/2063* at *03:14:07* which cover the long integer range *0* to *2^31* minus one.

Conversely, the ***Time stamp to date*** and ***Time stamp to time*** project methods listed below allow extracting the date and the time stored into a time stamp:

```
 ` Time stamp to date Project Method
 ` Time stamp to date ( Long ) -> Date
 ` Time stamp to date ( Time stamp ) -> Extracted date

C_DATE($0)
C_LONGINT($1)

$0:=!01/01/95!+($1¥86400)

 ` Time stamp to time Project Method
 ` Time stamp to time ( Long ) -> Date
 ` Time stamp to time ( Time stamp ) -> Extracted time

C_TIME($0)
C_LONGINT($1)

$0:=Time(Time string(†00:00:00†+($1%86400)))
```

For ensuring that the records have their time stamps correctly updated no matter the way they are created or modified, we just need to enforce that rule using the trigger of the table *[Documents]*:

```
 // Trigger for table [Documents]
Case of
   :(Trigger event=Save New Record Event)
      [Documents]Creation Stamp:=Time stamp
      [Documents]Modification Stamp:=Time stamp
   :(Trigger event=Save Existing Record Event)
      [Documents]Modification Stamp:=Time stamp
End case
```

Once this is implemented in the database, we have all we need to write the project method ***CREATE DOCUMENTATION*** listed below. We use of **GET DOCUMENT PROPERTIES** and **SET DOCUMENT PROPERTIES** for handling the date and time of creation and modification of the documents.

```
 ` CREATE DOCUMENTATION Project Method

C_STRING(255;$vsPath;$vsDocPathName;$vsDocName)
C_LONGINT($vlDoc)
C_BOOLEAN($vbOnWindows;$vbDoIt;$vbLocked;$vbInvisible)
C_TIME($vhDocRef;$vhCreatedAt;$vhModifiedAt)
C_DATE($vdCreatedOn;$vdModifiedOn)

If(Application type=4D Client)
 ` If we are running 4D Client, save the documents
 ` locally on the Client machine where 4D Client is located
   $vsPath:=Long name to path name(Application file)
Else
 ` Otherwise, save the documents where the data file is located
   $vsPath:=Long name to path name(Data file)
End if
 ` Save the documents in a directory we arbitrarily name "Documentation"
$vsPath:=$vsPath+"Documentation"+Char(Directory symbol)
 ` If this directory does not exist, create it
If(Test path name($vsPath)#Is a folder)
   CREATE FOLDER($vsPath)
End if
 ` Establish the list of the already existing documents
 ` because we'll have to delete the obsolete ones, in other words,
```

```
  ` the documents whose corresponding records have been deleted.
ARRAY STRING(255;$asDocument;0)
DOCUMENT LIST($vsPath;$asDocument)

```

# Get document size

Get document size ( document {; *} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String, DocRef | ⇒ | Document reference number or Document name |
| * | Operator | ⇒ | On Mac OS only: - if omitted, size of data fork - if specified, size of resource fork |
| Function result | Real | ⇐ | Size (expressed in bytes) of the document |

## Description

The **Get document size** command returns the size, expressed in bytes, of a document.

If the document is open, you pass its document reference number in *document*.

If the document is not open, you pass its name or pathname in *document*.

On Macintosh, if you do not pass the optional * parameter, the size of the data fork is returned. If you do pass the * parameter, the size of the resource fork is returned.

# Get localized document path

Get localized document path ( relativePath ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| relativePath | Text | ⇒ | Relative pathname of document for which we want to obtain localized version |
| Function result | Text | ⇐ | Absolute pathname of localized document |

## Description

The **Get localized document path** command returns the complete (absolute) pathname of a document designated by *relativePath* and located in a xxx.lproj folder.

This command must be used within a multi-language application architecture based on the presence of a **Resources** folder and *xxx.lproj* subfolders (where xxx represents a language). With this architecture, 4D automatically supports localized files of the .xliff type as well as pictures, but you may need to use the same mechanism for other types of files.

Pass the relative pathname of the document to be searched for in *relativePath*. The path entered must be relative to the first level of the "xxx.lproj" folder of the database. The command will return a complete pathname using the "xxx.lproj" folder corresponding to the current language of the database.

**Note:** The current language is either set automatically by 4D according to the contents of the **Resources** folder (see the **Get database localization** command), or via the **SET DATABASE LOCALIZATION** command).

You can express the contents of the *relativePath* parameter using a system or a POSIX syntax. For example:

- xsl/log.xsl (POSIX syntax: can be used under Mac OS or Windows)
- xsllog.xsl (Windows only)
- xsl:log.xsl (Mac OS only)

The absolute pathname returned by the command is always expressed in the system syntax.

**4D Server:** In remote mode, the command returns the path of the **Resources** folder on the client machine if the command is called from a client process.

4D looks for the file while respecting a sequence that allows all the cases of multi-language applications to be processed. At each step, 4D checks for the presence of *relativePath* in the folder corresponding to the language and returns the complete path when it succeeds. If *relativePath* is not found or if the folder does not exist, 4D passes to the next step. Here are the folders for each of the different search stages:

*Current language (e.g.: fr-ca)*
*Current language without region (e.g.: fr)*
*Language loaded by default on startup (e.g.: es-ga)*
*Language loaded by default on startup without region (e.g.: es)*
*First .lproj folder found (e.g.: en.lproj)*
*First level of Resources folder*

If *relativePath* is not found in any of these locations, the command returns an empty string.

## Example

For the purpose of transforming an XML or HTML file, you want to use a "log.xsl" transformation file. This file differs depending on the current language. You therefore want to know which "log.xsl" file path to use.
Here are the contents of the Resources folder:

To use a .xsl file adapted to the current language, you simply need to pass:

```
$myxsl:=Get localized document path("xsl/log.xsl")
```

If the current language is, for example, French Canadian (fr-ca), the command returns:

- under Windows: C:¥users¥…¥…¥…¥resources¥fr_ca.lproj¥xsl¥log.xsl
- under Mac OS: "HardDisk:users:…:…:…:resources:fr_ca.lproj:xsl:log.xsl"

# MAP FILE TYPES

MAP FILE TYPES ( macOS ; windows ; context )

| Parameter | Type | | Description |
|---|---|---|---|
| macOS | String | ⇒ | Mac OS file type (4-character string) |
| windows | String | ⇒ | Windows file extension |
| context | String | ⇒ | String displayed in List of Types drop-down list of the Windows file dialog boxes |

## Description

**MAP FILE TYPES** lets you associate a Windows file extension with a Macintosh file type.

You need to call this routine only once to establish a mapping for an entire worksession with a database. Once the call has been made, the commands **Create document**, **Append document**, and **Open resource file** while running on Windows will automatically substitute the Windows file extension for the Macintosh file type you actually pass as a parameter to the routine.

In the *macOS* parameter you pass a 4-character Macintosh file type. If you do not pass a 4-character string, the command does nothing and generates an error.

In the *windows* parameter you pass a 1- to X-character Windows file extension. If you do not pass a 1 to 3-character string, the command does nothing and generates an error.

In the *context* parameter you pass the string that will be displayed in the List Files of Type drop-down list of the Windows Open File dialog box. The context string is limited to 32 characters; additional characters are ignored.

**IMPORTANT:** Once you have mapped a Windows file extension to a Macintosh file type, you cannot change or delete this mapping within a single work session. If you need to change a mapping while developing and debugging a 4D application, reopen the database and remap the file extension.

## Example

The following line of 4D code (that could be part of the **Startup** database method) maps the Macintosh MS-Word file type *"WDBN"* to the Windows file extension *".DOC"*:

```
MAP FILE TYPES("WDBN";"DOC";"Word documents")
```

Once the call above has been made, the following code will display only Word documents in the Open file dialog on Windows and Macintosh:

```
$DocRef:=Open document("";"WDBN")
If(OK=1)
   ...
End if
```

# MOVE DOCUMENT

MOVE DOCUMENT ( srcPathname ; dstPathname )

| Parameter | Type | | Description |
|---|---|---|---|
| srcPathname | String | ➡ | Full pathname to existing document |
| dstPathname | String | ➡ | Destination pathname |

## Description

The **MOVE DOCUMENT** command moves or renames a document.

You specify the full pathname to the document in *srcPathname* and the new name and/or new location for the document in *dstPathname*.

**Warning:** Using **MOVE DOCUMENT**, you can move a document from and to any directory on the same volume. If you want to move a document between two distinct volumes, use **COPY DOCUMENT** to "move" the document then delete the original copy of the document using **DELETE DOCUMENT**.

## Example 1

The following example renames the document *DocName*:

```
MOVE DOCUMENT("C:¥¥FOLDER¥¥DocName";"C:¥¥FOLDER¥¥NewDocName")
```

## Example 2

The following example moves and renames the document *DocName*:

```
MOVE DOCUMENT("C:¥¥FOLDER1¥¥DocName";"C:¥¥FOLDER2¥¥NewDocName")
```

## Example 3

The following example moves the document *DocName*:

```
MOVE DOCUMENT("C:¥¥FOLDER1¥¥DocName";"C:¥¥FOLDER2¥¥DocName")
```

**Note:** In the last two examples, the destination folder *"C:¥¥FOLDER2"* must exist. The **MOVE DOCUMENT** command only moves a document; it does not create folders.

# Open document

Open document ( document {; fileType}{; mode} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname or Empty string for standard file dialog box |
| fileType | String | ⇒ | List of types of documents to be screened, or "*" to not screen the documents |
| mode | Longint | ⇒ | Document's opening mode |
| Function result | DocRef | ⇐ | Document reference number |

## Description

The **Open document** command opens the document whose name or pathname you pass in *document*.

If you pass an empty string in *document*, the Open File dialog box is presented, and you then select the document to be open. If you cancel the dialog, no document is opened; **Open document** returns a null DocRef and sets the OK variable to 0.

- If the document is correctly opened, **Open document** returns its document reference number and sets the OK variable to 1.
- If the document is already open in Read mode and the *mode* parameter is omitted, **Open document** opens the document in Read/Write mode by default and sets the OK variable to 1.
- If the document is already open in Read/Write mode and you try to open it in Write mode, an error (-43) is generated. However, you can open it in Read only mode, then the OK variable is set to 1.
- If the document does not exist, an error is generated.

In the *fileType* parameter, pass the type(s) of file(s) that can be selected in the opening dialog box. You can pass a list of several types separated by a ; (semi-colon). For each type set, an item will be added to the menu used for choosing the type in the dialog box.

Under Mac OS, you can pass either a standard Mac OS type (TEXT, APPL, etc.), or a UTI (Uniform Type Identifier) type. UTIs are defined by Apple in order to meet standardization needs for file types. For example, "public.text" is the UTI type of text type files. For more information about UTIs, refer to the following address: https://developer.apple.com/library/mac/#documentation/FileManagement/Conceptual/understanding_utis/understand_utis_intro/understand_utis_intro.html.

Under Windows, you can also pass a standard Mac OS file type — 4D makes the correspondence internally — or file extensions (.txt, .exe, etc.). Note that under Windows, the user can "force" the display of all file types by entering *.* in the dialog box. However, in this case, 4D will carry out an additional check of the selected file types: if the user selects an unauthorized file type, the command returns an error.

If you do not want to restrict the displayed files to one or more types, pass the "*" (star) string or ".*" in *fileType*.

The optional *mode* parameter allows you to define how *document* is to be opened. Four different open file modes are possible. 4D offers the following predefined constants, located in the "**System Documents**" theme:

| Constant | Type | Value |
|---|---|---|
| Get Pathname | Longint | 3 |
| Read and Write | Longint | 0 |
| Read Mode | Longint | 2 |
| Write Mode | Longint | 1 |

If a document is open, **Open document** initially sets the file position at the beginning of the document while **Append document** sets it at the end of the document.

Once you have opened a document, you can read and write in the document using the **RECEIVE PACKET** and **SEND PACKET** commands that you can combine with the **Get document position** and **SET DOCUMENT POSITION** commands in order to directly access any part of the document.

Do not forget to eventually call **CLOSE DOCUMENT** for the document.

## Example 1

The following example opens an existing document called Note, writes the string "Good-bye" into it, and closes the document. If the document already contains the string "Hello", this string would be overwritten:

```
C_TIME(vhDoc)
vhDoc:=Open document("Note.txt";Read and Write) ` Open a document called Note
If(OK=1)
   SEND PACKET(vhDoc;"Good-bye") ` Write one word into the document
   CLOSE DOCUMENT(vhDoc) ` Close the document
End if
```

## Example 2

You can read a document even if it is already open in write mode:

```
vDoc:=Open document("PassFile";"TEXT") ` The file is open
 ` Before the file is closed, it is possible to consult it in read-only mode:
vRef:=Open document("PassFile";"TEXT";Read Mode)
```

## System variables and sets

If the document is correctly opened, the OK system variable is set to 1; otherwise, it is set to 0. After the call, the Document system variable contains the full name of the document.
If you call **Open document** with a mode of 3, the function returns ?00:00:00? (no document reference). The document is not opened but the Document and OK system variables are updated:

- OK is equal to 1.
- Document contains the full pathname and the name of *document*.

**Note:** If you pass an empty string in *document*, an open file dialog box appears. If the user chooses a document and clicks the OK button, *document* is set to the path of the document the user selected and OK is set to 1. If the user clicked the Cancel button, OK is set to 0.

# RESOLVE ALIAS

RESOLVE ALIAS ( aliasPath ; targetPath )

| Parameter | Type | | Description |
|---|---|---|---|
| aliasPath | String | ⇒ | Name or access path of the alias/shortcut |
| targetPath | String | ⇐ | Name or access path of the alias/shortcut target |

## Description

The **RESOLVE ALIAS** command returns the full path to the target file or folder of the alias (named shortcut under Windows).

The full path to the alias is passed in *aliasPath*.

Once the command has been executed, the *targetPath* variable contains the full path to the target file or folder of the alias and the OK system variable is set to 1.

If the path passed in *aliasPath* corresponds to a file and not an alias, *targetPath* returns the path of the file and the OK system variable is set to 0.

## System variables and sets

If *aliasPath* does specify an alias/shortcut, the OK system variable is set to 1. If *aliasPath* specifies a standard file, the OK system variable is set to 0.

# Select document

Select document ( directory ; fileTypes ; title ; options {; selected} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| directory | Text, Longint | ⇒ | • Directory access path to display by default in the document selection dialog box, or<br>• Empty string to display default user folder (“My documents” under Windows, “Documents” under Mac OS), or<br>• Number of the memorized access path |
| fileTypes | Text | ⇒ | List of types of documents to filter, or "*" to not filter documents |
| title | Text | ⇒ | Title of the selection dialog box |
| options | Longint | ⇒ | Selection option(s) |
| selected | Text array | ⇐ | Array containing the list of access paths + names of selected files |
| Function result | String | ⇐ | Name of selected file (first file of the list in case of multiple selection) |

## Description

The **Select document** command displays a standard open document dialog box which allows the user to set one or more files and returns the name and/or full access path of the selected file(s).

The *directory* parameter indicates the folder whose contents are initially displayed in the open document dialog box. You can pass three types of values:

- a text containing the full access path of the folder to display.
- an empty string ("") to display the default user folder for the current opeerating system (“My documents” under Windows, “Documents” under Mac OS).
- a number of the memorized access path (from 1 to 32000) to display the associated folder.
  As such, you can store in memory the access path of the folder opened when the user clicked the selection button, in other words, the folder selected by the user. During the first call of an arbitrary number (for example, 5) the command displays the default user folder of the operating system (equivalent of passing an empty string). The user could also browse folders on the hard disk. When the user clicks on the selection button, the access path is memorized and associated with number 5. During future calls to number 5, the memorized access path will be used by default. If a new location is selected, path number 5 is updated.
  This mechanism lets you memorize up to 32,000 access paths. Under Windows, each path is kept for the session only. Under Mac OS, the paths are kept by the system and remain stored from one session to the next.

**Note:** This mechanism is the same as the one used by the **Select folder** command. The numbers of the memorized pathnames are shared by both commands.

Pass the type(s) of file(s) that can be selected in the open file dialog box in the *fileTypes* parameter. You can pass a list of several types separated by a ; (semi-colon). For each type defined, a row will be added in the type choice menu of the dialog box.

- Under Mac OS, you can pass either a standard Mac OS type (TEXT, APPL, etc.), or a UTI (Uniform Type Identifier) type. UTI types have been defined by Apple in order to meet requirements concerning the standardization of file types. For example, "public.text" is the UTI type of text type files. For more information about UTIs, please refer to the following address: Uniform Type Identifiers Overview on developer.apple.com.
- Under Windows, you can also pass a standard Mac OS type file — 4D performs the conversion internally — or the file extensions (.txt, .exe, etc.). Please note that under Windows, the user can “force” the display of all document types by entering *.* in the dialog box. However, in this case, 4D will perform an additional verification of the types of files selected: if the user selects an unauthorized file type, the command returns an error.

If you do not want to restrict the files displayed to one or more types, pass the "*" (star) or ".*" string in *fileTypes*.

Pass the label that must appear in the dialog box in the *title* parameter. By default, if you pass an empty string, the label “Open” is displayed.

The *options* parameter allows you to specify advanced functions that are allowed in an open file dialog box. 4D provides the following pre-defined constants in the **System Documents** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Alias selection | Longint | 8 | Authorizes the selection of shortcuts (Windows) or aliases (Mac OS) as document. By default, if this constant is not used, when an alias or shortcut is selected, the command will return the access path of the targeted element. When you pass the constant, the command returns the path of the alias or shortcut itself. |
| File name entry | Longint | 32 | Allows user to enter a file name in a 'Save as' dialog box. No file is saved and it is up to the developer to create a file in response to this action (the Document system variable is updated). In this context, the *directory* parameter may contain the path to a file instead of a directory. The file name will be used as the suggested file name in the Save as text field. The parent directory will be used as default path. |
| Multiple files | Longint | 1 | Authorizes the simultaneous selection of several files using the key combinations **Shift+click** (adjacent selection) and **Ctrl+click** (Windows) or **Command+click** (Mac OS). In this case, the *selected* parameter, if passed, contains the list of all selected files. By default, if this constant is not used, the command will not allow the selection of multiple files. |
| Package open | Longint | 2 | (Mac OS only): Authorizes the opening of packages as folders and thus the viewing /selection of their contents. By default, if this constant is not used, the command will not allow the opening of packages. |
| Package selection | Longint | 4 | (Mac OS only): Authorizes the selection of packages as entities. By default, if this constant is not used, the command will not allow the selection of software packages as such. |
| Use sheet window | Longint | 16 | (Mac OS only): Displays the selection dialog box in the form of a sheet window (this option is ignored under Windows). Sheet windows are specific to the Mac OS X interface which have graphic animation (for more information, refer to the **Window Types** section). By default, if this constant is not used, the command will display a standard dialog box. |

If you do not want to use an option, pass 0 in the *options* parameter.

The optional *selected* parameter allows you to get the full access path (access path + name) of every file selected by the user. The command creates, sizes and fills the array according to the user selection. This parameter is useful when the Multiple files option is used or when you want to find out the access path of the selected file (simply take the name of the file returned by the command from the value of the array). If no file is selected, the array is returned empty.

**Note:** Under Mac OS, a selected package is considered as a folder. The pathname returned in the *selected* array includes a final ":" character. For example: **Disk:Applications:4D:4D v11.4:US:4D Volume Desktop.app:**

The command returns the name (name + extension under Windows) of the selected file. If several files are selected, the command returns the name of the first file in the list of selected files. The list of files can be obtained in the *selected* parameter. If no file is selected, the command returns an empty string.

## Example 1

This example is used to specify a 4D data file:

```
C_LONGINT($platform)
PLATFORM PROPERTIES($platform)
If($platform=Windows)
   $DocType:=".4DD"
Else
   $DocType:="com.4d.4d.data-file" `UTI type
End if
$Options:=Alias selection+Package open+Use sheet window
$Doc:=Select document("";$DocType;"Select the data file";$Options)
```

## Example 2

Creation of a custom document by user:

```
$doc:=Select document(System folder(Documents folder)+"Report.pdf";"pdf";"Report name:";File name entry)
If(OK=1)
   BLOB TO DOCUMENT(Document;$blob) // $blob contains document to record
End if
```

## System variables and sets

If the command has been correctly executed and a valid document was selected, the system variable OK is set to 1 and the system variable Document will contain the full access path of the selected file.
If no file was selected (for example, if the user clicked on the **Cancel** button in the open file dialog box), the system variable OK is set to 0 and the system variable Document will be empty.

# Select folder

Select folder ( {message }{;}{ defaultPath {; options}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| message | String | ⇒ | Title of the window |
| defaultPath | String, Longint | ⇒ | • Default pathname or • Empty string to display the default user folder (“My documents” under Windows, “Documents” under Mac OS), or • Number of memorized pathname |
| options | Longint | ⇒ | Selection option(s)under Mac OS |
| Function result | String | ⇐ | Access path to the selected folder |

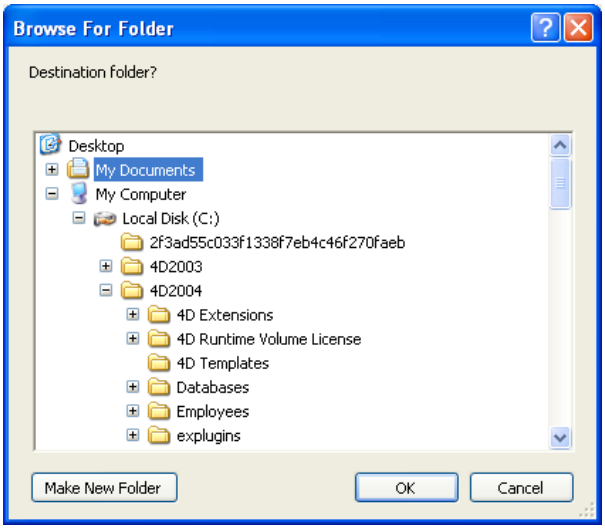
## Description

The **Select folder** command displays a dialog box that allows you to manually select a folder and then retrieve the complete access path to that folder. The optional *defaultPath* parameter can be used to designate the location of a folder that will be initially displayed in the folder selection dialog box.

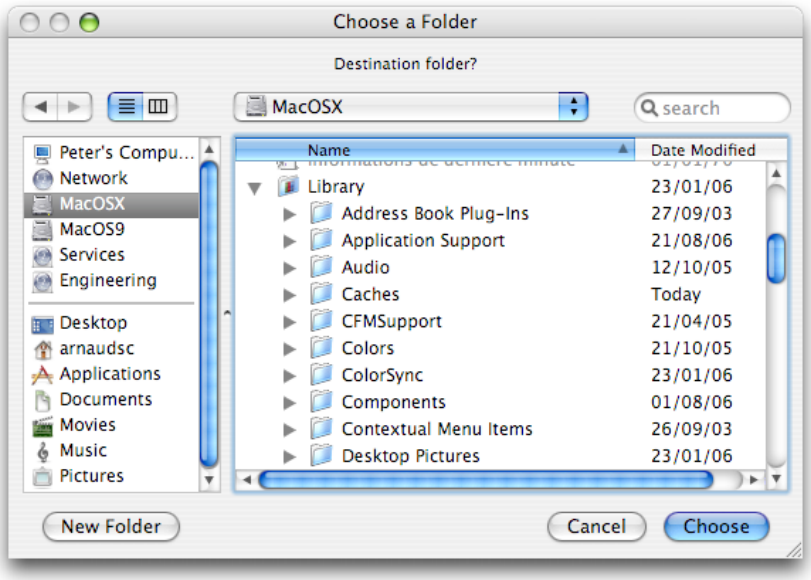
**Note:** This command does not modify 4D’s current folder.

The **Select folder** command displays a standard dialog box to browse through the workstation’s volumes and folders. The optional parameter *message* allows you to display a message in the dialog box. In the following examples, the message is "Destination folder?":

**Windows**



**Mac OS**



You can use the *defaultPath* parameter to provide a default folder location in the folder selection dialog box. You can pass three types of values in this parameter:

- The pathname of a valid folder using the syntax of the current platform.
- An empty string ("") to display the default user folder of the system ("My documents" under Windows, "Documents" under Mac OS).
- The number of a memorized pathname (from 1 to 32,000) to display the associated folder. This means that you can store in memory the pathname of the folder that is open when the user clicks on the selection button; in other words, the folder chosen by the user. When calling a random number (for instance, 5) the command displays the default user folder of the system (equivalent to passing an empty string). The user may then browse among the folders on their harddisk. When the user clicks on the selection button, the pathname is memorized and associated with the number 5. When the number 5 is called subsequently, the memorized pathnname will be used by default. If a new location is selected, the path number 5 will be updated, and so on.
  This mechanism can be used to memorize up to 32,000 pathnames. Under Windows, each path is only kept during the session. Under Mac OS, the paths remain memorized from one session to the next. If the pathname is incorrect, the *defaultPath* parameter is ignored.

**Note:** This mechanism is identical to the one used by the **Select document** command. The numbers of memorized pathnames are shared between both these commands.

The *options* parameter lets you benefit from additional functions under Mac OS. In this parameter, you can pass one of the following constants, found in the **System Documents** theme:

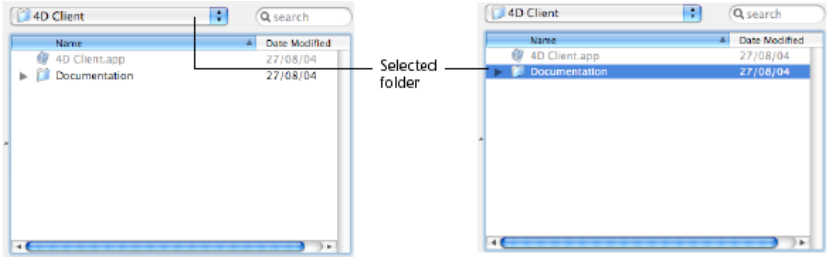
| Constant | Type | Value | Comment |
|---|---|---|---|
| Package open | Longint | 2 | (Mac OS only): Authorizes the opening of packages as folders and thus the viewing /selection of their contents. By default, if this constant is not used, the command will not allow the opening of packages. |
| Use sheet window | Longint | 16 | (Mac OS only): Displays the selection dialog box in the form of a sheet window (this option is ignored under Windows). Sheet windows are specific to the Mac OS X interface which have graphic animation (for more information, refer to the **DISPLAY SELECTION** section). By default, if this constant is not used, the command will display a standard dialog box. |

You can pass a single constant or a combination of both. These options are only taken into account under Mac OS. Under Windows, the *options* parameter is ignored if it is passed.

The user selects a folder and then clicks the **OK** button (on Windows) or the **Select** button (on Mac OS). The access path to the folder is then returned by the function.

- On Windows, the access path is returned in the following format:
  "C:¥Folder1¥Folder2¥SelectedFolder¥"
- On Mac OS, the access path is returned in the following format:
  "Hard Disk:Folder1:Folder2:SelectedFolder:"

**Note:** On Mac OS, depending on whether or not the name of the folder is selected in the dialog box, the access path that is returned to you may be different.



**4D Server:** This function allows you to view the volumes connected to the client workstations. It is not possible to call this function from a stored procedure.

If the user validates the dialog box, the **OK** system variable is set to 1. If the user clicks the **Cancel** button, the **OK** system variable is set to 0 and the function returns an empty string.

**Note:** On Windows, if the user selected some incorrect elements, such as "Workstation", "Trash can", and so on, the **OK** system variable is set to 0, even if the user validates the dialog box.

## Example

The following example allows you to select the folder in which the pictures in the picture library will be stored:

```
$PictFolder:=Select folder("Select a folder for your pictures.")
PICTURE LIBRARY LIST(pictRefs;pictNames)
For($n;1;Size of array(pictNames))
   GET PICTURE FROM LIBRARY(pictRefs{$n};$vStoredPict)
   WRITE PICTURE FILE($PictFolder+pictNames{$n};$vStoredPict)
End for
```

# SET DOCUMENT CREATOR

SET DOCUMENT CREATOR ( document ; fileCreator )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname |
| fileCreator | String | ⇒ | Mac OS file creator (4-character string) or empty string (Windows) |

## Description

The **SET DOCUMENT CREATOR** command sets the creator of the document whose name or pathname you pass in *document*.

You pass the new creator of the document in *fileCreator*.

This command does nothing on Windows.

See discussion about file creators in **System Documents**.

# SET DOCUMENT POSITION

SET DOCUMENT POSITION ( docRef ; offset {; anchor} )

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ⇒ | Document reference number |
| offset | Real | ⇒ | File position (expressed in bytes) |
| anchor | Longint | ⇒ | 1 = In relation to the beginning of the file 2 = In relation to the end of the file 3 = In relation to current position |

## Description

This command operates only on a document currently open whose document reference number you pass in *docRef*.

**SET DOCUMENT POSITION** sets the position you pass in *offset* where the next read (**RECEIVE PACKET**) or write (**SEND PACKET**) will occur.

If you omit the optional *anchor* parameter, the position is relative to the beginning of the document. If you do specify the *anchor* parameter, you pass one of the values listed above.

Depending on the anchor you can pass positive or negative values in *offset*.

# SET DOCUMENT PROPERTIES

SET DOCUMENT PROPERTIES ( document ; locked ; invisible ; created on ; created at ; modified on ; modified at )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or Full document pathname |
| locked | Boolean | ⇒ | Locked (True) or Unlocked (False) |
| invisible | Boolean | ⇒ | Invisible (True) or Visible (False) |
| created on | Date | ⇒ | Creation date |
| created at | Time | ⇒ | Creation time |
| modified on | Date | ⇒ | Last modification date |
| modified at | Time | ⇒ | Last modification time |

## Description

The **SET DOCUMENT PROPERTIES** command changes the information about the document whose name or pathname you pass in *document*.

Before the call:

- Pass True in *locked* to lock the document. A locked document cannot be modified. Pass False in *locked* to unlock a document.
- Pass True in *invisible* to hide the document. Pass False in *invisible* to make the document visible in the desktop windows.
- Pass the document creation date and time in *created on* and *created at*.
- Pass the document last modification date and time in *modified on* and *modified at*.

The dates and times of creation and last modification are managed by the file manager of your system each time you create or access a document. Using this command, you can change those properties for special purpose. See example for the command **GET DOCUMENT PROPERTIES**.

# SET DOCUMENT SIZE

SET DOCUMENT SIZE ( docRef ; size )

| Parameter | Type | | Description |
|---|---|---|---|
| docRef | DocRef | ⇒ | Document reference number |
| size | Real | ⇒ | New size expressed in bytes |

## Description

The **SET DOCUMENT SIZE** command sets the size of a document to the number of bytes you pass in *size*.

If the document is open, you pass its document reference number in *docRef*.

On Macintosh, the size of the document's data fork is changed.

# SET DOCUMENT TYPE

SET DOCUMENT TYPE ( document ; fileType )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document name or full document pathname |
| fileType | String | ⇒ | Windows file extension or Mac OS file type (4-character string) |

## Description

The **SET DOCUMENT TYPE** command sets the type of the document whose name or pathname you pass in *document*.

You pass the new type of the document in *fileType*.

See the discussion of file types in **System Documents** and **Document type**.

On Windows, this command modifies the file extension and therefore the value of *document*. For example, the instruction:

```
SET DOCUMENT TYPE("C:¥¥Docs¥¥Invoice.asc";"TEXT")
```

renames the file "Invoice.asc" to "Invoice.txt". In 4D, the Macintosh "TEXT" type corresponds to the Windows "txt" type.

If the type has no equivalent provided by 4D, you will have to pass the extension. For example, the following instruction renames the file "Invoice.asc" to "Invoice.zip":

```
SET DOCUMENT TYPE("C:¥¥Docs¥¥Invoice.asc";"zip")
```

# SHOW ON DISK

SHOW ON DISK ( pathname {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| pathname | String | ⇒ | Pathname of item to show |
| * | | ⇒ | If the item is a folder, show its contents |

## Description

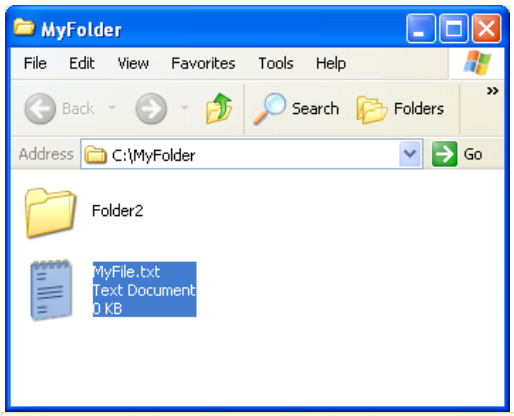
The **SHOW ON DISK** command displays the file or folder whose pathname was passed in the *pathname* parameter in a standard window of the operating system.
In a user interface, this command lets you designate the location of a specific file or folder.

By default, if *pathname* designates a folder, the command displays the level of the folder itself. If you pass the optional * parameter, the command opens the folder and displays its contents in the window. If *pathname* designates a file, the * parameter is ignored.

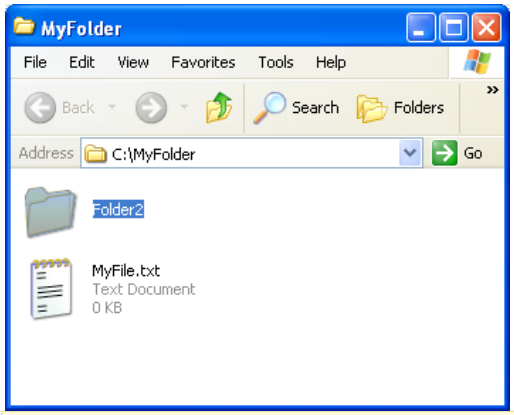
## Example

The following examples illustrate the operation of this command:

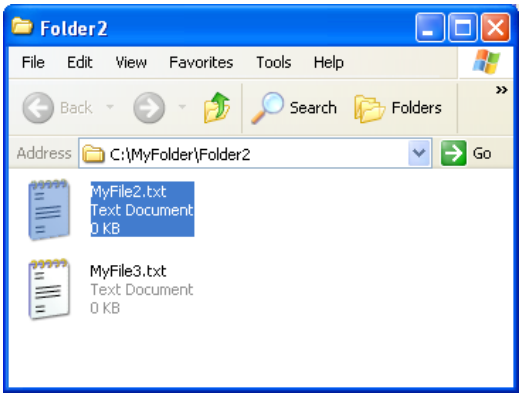
```
SHOW ON DISK("c:¥¥MyFolder¥¥MyFile.txt") ` Displays the designated file
```



```
SHOW ON DISK("c:¥¥MyFolder¥¥Folder2") ` Displays the designated folder
```



```
SHOW ON DISK("c:¥¥MyFolder¥¥Folder2";*) ` Displays the contents of the designated folder
```



## System variables and sets

The system variable OK is set to 1 if the command is executed correctly.

# Test path name

Test path name ( pathname ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| pathname | String | ⇒ | Pathname to directory, folder or document |
| Function result | Longint | ⇐ | 1, pathname refers to an existing document 0, pathname refers to an existing directory or folder <0, invalid pathname, OS file manager error code |

## Description

The **Test path name** function checks if a document or folder whose name or pathname you pass in *pathname* is present on the disk. You can pass either a relative or absolute pathname, expressed in the syntax of the current system.

If a document is found, **Test path name** returns 1. If a folder found, **Test path name** returns 0.

The following predefined constants are provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Is a document | Longint | 1 |
| Is a folder | Longint | 0 |

If no document nor folder is found, **Test path name** returns a negative value (i.e. -43 for File not found).

## Example

The following tests if the document “Journal” is present in the folder of the database, then creates it if it was not found:

```
If(Test path name("Journal")#Is a document)
   $vhDocRef:=Create document("Journal")
   If(OK=1)
      CLOSE DOCUMENT($vhDocRef)
   End if
End if
```

# TEXT TO DOCUMENT

TEXT TO DOCUMENT ( fileName ; text {; charSet {; breakMode}} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ➡ | Document name or Pathname to document |
| text | Text | ➡ | Text to store in the document |
| charSet | Text, Longint | ➡ | Name or Number of character set |
| breakMode | Longint | ➡ | Processing mode for line breaks |

## Description

The **TEXT TO DOCUMENT** command lets you write the *text* directly to a disk file.

In *fileName*, pass the name or pathname of the file to be written. If this file does not exist, it is created. When this file already exists on the disk, its prior contents are erased, except if it is already open, in which case, its contents are locked and an error is generated. In *fileName*, you can pass:

- just the file name, for example "myFile.txt": in this case, the file is placed next to the structure file of the application.
- a pathname relative to the structure file of the application, for example "¥¥docs¥¥myFile.txt" under Windows or ":docs:myFile.txt" under OS X.
- an absolute pathname, for example "c:¥¥app¥¥docs¥¥myFile.txt" under Windows or "MacHD:docs:myFile.txt" under OS X..

If you want the user to be able to indicate the name or location of the document, use the **Open document** or **Create document** commands, as well as the **Document** system variable.

**Note:** By default, documents generated by this command do not have an extension. You must pass an extension in *fileName*. You can also use the **SET DOCUMENT TYPE** command.

In *text*, pass the text to write to the disk. It can be a literal constant ("my text"), or a 4D text field or variable.

In *charSet*, you pass the character set to be used to write the document. You can pass a string containing the standard set name (for example “ISO-8859-1” or “UTF-8”) or its MIBEnum ID (longint). For more information about the list of character sets supported by 4D, refer to the description of the **CONVERT FROM TEXT** command. If a Byte Order Mark (BOM) exists for the character set, 4D inserts it into the document. If you do not specify a character set, by default 4D uses the "UTF_8" character set and a BOM.

In *breakMode*, you can pass a longint indicating the processing to apply to end-of-line characters before saving them in the file. You can pass one of the following constants, found in the "**System Documents**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Document unchanged | Longint | 0 | No processing |
| Document with CR | Longint | 3 | Line breaks are converted to OS X format: CR (carriage return) |
| Document with CRLF | Longint | 2 | Line breaks are converted to Windows format: CRLF (carriage return + line feed) |
| Document with LF | Longint | 4 | Line breaks are converted to Unix format: LF (line feed) |
| Document with native format | Longint | 1 | (Default) Line breaks are converted to the native format of the operating system: CR (carriage return) under OS X, CRLF (carriage return + line feed) under Windows |

By default, when you omit the *breakMode* parameter, line breaks are processed in native mode (1).

**Note:** This command does not modify the OK variable. In case of failure, an error is generated that you can intercept using a method installed by the **ON ERR CALL** command.

## Example 1

Here are some typical examples of using this command:

```
TEXT TO DOCUMENT("myTest.txt";"This is a test")
TEXT TO DOCUMENT("myTest.xml";"This is a test")
```

## Example 2

Example allowing the user to indicate the location of the file to create:

```
$MyTextVar:="This is a test"
ON ERR CALL("IO ERROR HANDLER")
$vhDocRef :=Create document("")
 // Store document with the ".txt" extension
 // In this case, the .txt extension is always added to the name; it is not possible to change it
If(OK=1) // If document has been created successfully
   CLOSE DOCUMENT($vhDocRef) //Closes the document
   TEXT TO DOCUMENT(Document;$MyTextVar )
 // We write the document
Else
 // Error management
End if
```

# VOLUME ATTRIBUTES

VOLUME ATTRIBUTES ( volume ; size ; used ; free )

| Parameter | Type | | Description |
|---|---|---|---|
| volume | String | ⇒ | Volume name |
| size | Real | ⇐ | Volume size expressed in bytes |
| used | Real | ⇐ | Used space expressed in bytes |
| free | Real | ⇐ | Free space expressed in bytes |

## Description

The **VOLUME ATTRIBUTES** command returns, expressed in bytes, the size, the used space and the free space for the volume whose name you pass in *volume*.

**Note:** If *volume* indicates a non-mounted remote volume, the OK variable is set to 0 and the three parameters return -1.

## Example

Your application includes some batch operations running the night or the week-end that store huge temporary files on disk. To make this process as automatic and flexible as possible, you write a routine that will automatically find the first volume whose free space is sufficient for your temporary files. You might write the following project method:

```
  ` Find volume for space Project Method
  ` Find volume for space ( Real ) -> String
  ` Find volume for space ( Space needed in bytes ) -> Volume name or Empty string

C_STRING(31;$0)
C_STRING(255;$vsDocName)
C_LONGINT($vlNbVolumes;$vlVolume)
C_REAL($1;$vlSize;$vlUsed;$vlFree)
C_TIME($vhDocRef)

  ` Initialize function result
$0:=""
  ` Protect all I/O operations with an error interruption method
ON ERR CALL("ERROR METHOD")
  ` Get the list of the volumes
ARRAY STRING(31;$asVolumes;0)
gError:=0
VOLUME LIST($asVolumes)
If(gError=0)
  ` If running on windows, skip the (usual) two floppy drives
   If(On Windows)
      $vlVolume:=Find in array($asVolumes;"A:¥¥")
      If($vlVolume>0)
         DELETE FROM ARRAY($asVolumes;$vlVolume)
      End if
      $vlVolume:=Find in array($asVolumes;"B:¥¥")
      If($vlVolume>0)
         DELETE FROM ARRAY($asVolumes;$vlVolume)
      End if
   End if
   $vlNbVolumes:=Size of array($asVolumes)
  ` For each volume
   For($vlVolume;1;$vlNbVolumes)
  ` Get the size, used space and free space
      gError:=0
      VOLUME ATTRIBUTES($asVolumes{$vlVolume};$vlSize;$vlUsed;$vlFree)
      If(gError=0)
  ` Is the free space large enough (plus an extra 32K) ?
         If($vlFree>=($1+32768))
  ` If so, check if the volume is unlocked...
            $vsDocName:=$asVolumes{$vlVolume}+Char(Directory symbol)+"XYZ"+String(Random)+".TXT"
```

```
            $vhDocRef:=Create document($vsDocName)
            If(OK=1)
               CLOSE DOCUMENT($vhDocRef)
               DELETE DOCUMENT($vsDocName)
 ` If everything's fine, return the name of the volume
               $0:=$asVolumes{$vlVolume}
               $vlVolume:=$vlNbVolumes+1
            End if
         End if
      End if
   End for
End if
ON ERR CALL("")
```

Once this project method is added to your application, you can for instance write:

```
$vsVolume:=Find volume for space(100*1024*1024)
If($vsVolume#"")
 ` Continue
Else
   ALERT("A volume with at least 100 MB of free space is required!")
End if
```

# VOLUME LIST

VOLUME LIST ( volumes )

| Parameter | Type | | Description |
|---|---|---|---|
| volumes | String array | ⇦ | Names of the volumes currently mounted |

## Description

The **VOLUME LIST** command populates the text array *volumes* with the names of the volumes currently defined (Windows) or mounted (Macintosh) on your machine.

- On Macintosh, it returns the list of the volumes visible at the Finder level. Only the names of the volumes are returned (for example "MacHD", "BootCamp", etc.).
- On Windows, it returns the list of the volumes currently defined whether or not each volume is physically present (i.e. the volume **E:¥** will be returned whether or not a CD or DVD is actually present in the drive). The names of the volumes are followed by the folder separator character ("C:¥").

## Example

Using a scrollable area named *atVolumes* you want to display the list of the volumes defined or mounted on your machine, you write:

```
Case of
   :(Form event=On Load)
      ARRAY TEXT(atVolumes;0)
      VOLUME LIST(atVolumes)

   //...
End case
```

# System Environment

- Count screens
- Current client authentication
- Current machine
- Current machine owner
- FONT LIST
- FONT STYLE LIST
- Gestalt
- GET SYSTEM FORMAT
- LOG EVENT
- Menu bar height
- Menu bar screen
- OPEN COLOR PICKER
- OPEN FONT PICKER
- PLATFORM PROPERTIES
- SCREEN COORDINATES
- SCREEN DEPTH
- Screen height
- Screen width
- Select RGB Color
- SET RECENT FONTS
- SET SCREEN DEPTH
- System folder
- Temporary folder
- *_o_Font name*
- *_o_Font number*

# Count screens

Count screens -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of monitors |

## Description

The **Count screens** command returns the number of screen monitors connected to your machine.

# Current client authentication

Current client authentication {( domain ; protocol )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| domain | Text | ⇐ | Domain name |
| protocol | Text | ⇐ | "Kerberos", "NTLM", or empty string |
| Function result | Text | ⇒ | Session user login returned by Windows |

## Description

The **Current client authentication** command asks the Windows Active Directory server to authenticate the current client and, if successful, returns the Windows login name for this client (session identifier). If the authentication failed, an empty string is returned.

This command can only be used in the context of an SSO implementation on Windows with 4D Server. For more information, please refer to the **Single Sign On (SSO) on Windows** section.

Usually, both the client and the server must be managed by the same Active Directory. However, different configurations can be supported, as described in the **Requirements for SSO** section.

The returned login string must be passed to your 4D identification module to grant access rights to the client based upon the Windows session login; if you managed to remove the 4D Server login dialog by setting a "Default user", you can implement an interface where the user does not need to reenter any IDs (see example).

Optionally, the command can return two text parameters:

- *domain*: name of domain to which the client belongs.
- *protocol*: name of protocol used by Windows to authenticate the user. It can be "Kerberos" or "NTLM", depending on available resources. If the authentication failed, an empty string ("") is returned.

These parameters can be used to accept or reject connections if you want to filter access with regard to the domain or protocol.

### Authentication security level

The security level of the authentication (i.e., how much you can trust the user login) depends on how the user has actually been identified. The value(s) returned in the **Current client authentication** command parameters will allow you to find out what the login (if any) is based on, and thus the security level:

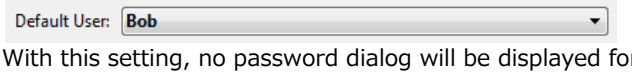
| Login | Domain | Protocol | Comments |
|---|---|---|---|
| Empty | Empty | Empty | Command was unable to get authentication information about the logged user |
| Filled | Empty | NTLM | ID returned is the local one, which has been defined on the local computer |
| Filled | Filled | NTLM | ID returned has been authenticated using the NTLM protocol in the Domain returned in the *domain* parameter. In this case, you must check the Domain to increase the security level. Since some architectures have a Domain forest, you need to make sure that the Domain where the user was authenticated was the expected one. |
| Filled | Filled | Kerberos | ID returned has been authenticated with the Kerberos protocol in the expected Domain. This configuration provides the highest level of security. |

For more information on these requirements, please refer to the paragraph.

## Example

In your 4D Server database, you have designed an access control system based on 4D's users and groups feature. You want to configure your application so that 4D remote users on Windows connect directly to 4D Server (no password dialog box is displayed), but while being logged with their actual rights:

1. In the "Security" page of the Database Settings dialog box, designate a user as the "default user":



With this setting, no password dialog will be displayed for a remote 4D that connects to the server; all clients being logged as "Bob".

2. In the On Server Open Connection database method, add the following code to check user authentication from the Active Directory:

```
 //On Server Open Connection database method
C_LONGINT($0;$1;$2;$3)
$login:=Current client authentication($domain;$protocol)
If($login #"") //a login was returned
 //call your custom authentication method
   $0:=CheckCredentials($login)
 //should return 0 in case of success or -1 for error
Else
   $0:=-1 //reject the connection
End if
```

**Note:** This example shows a basic scenario that must be adapted to your solutions. The 4D user custom authentication method (***CheckCredentials*** in the above example) could be based on one of the following implementations:

- replicate the Active directory names in the 4D user and group names, for an automatic mapping,
- map returned information to a custom [users] table,
- use LDAP features to get user credentials.

# Current machine

Current machine -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ➲ | Network name of the machine |

## Description

The **Current machine** command returns the name of the machine as set in the network parameters of the operating system.

## Example

Even if you are not running with the Client/Server version of the 4D environment, your application can include some network services that require your machine to be correctly configured. In the **On Startup database method** of your application, you write:

```
If((Current machine="")|(Current machine owner=""))
   ` Display a dialog box asking the user to setup the Network identity of his or her machine
End if
```

# Current machine owner

Current machine owner -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | String | Network name of machine owner |

## Description

The **Current machine owner** command returns the owner name of your machine, as set in the current user account on the machine.

## Example

See example for the **Current machine** command.

# FONT LIST

FONT LIST ( fonts {; listType | *} )

| Parameter | Type | | Description |
|---|---|---|---|
| fonts | Text array | ⇐ | Array of font names |
| listType \| * | Longint, Operator | ⇒ | Font type list to return or * to return font names under OS X |

## Description

The **FONT LIST** command populates the *fonts* text array with the names of scalable fonts available on your system.

The *listType* parameter lets you designate the type of font list you want to get. To do so, you can pass one of the following constants in the *listType* parameter, available in the "**Font Type List**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Favorite fonts | Longint | 1 | *fonts* contains the list of favorite fonts.<br>- Under Windows: list of active font family names.<br>- Under OS X: list of font family names found in the control panel, entitled "Favorites" in English, "Favoris" in French, "Favoriten" in German, and so on . This collection may be blank if the user has not added any favorite fonts. |
| Recent fonts | Longint | 2 | *fonts* contains the list of recent fonts (the ones used during the 4D session). This list is used in particular by multi-style text areas. |
| System fonts | Longint | 0 | *fonts* contains the list of all the system fonts. Default option when *listType* is omitted. |

Under OS X, when you pass the optional * parameter, the command populates the *fonts* array with the names of the fonts themselves, and not with the names of the font families. The default operation simplifies programmed management of rich text areas, which use font families. If you pass the * parameter, font names, for example, "Arial bold", "Arial italic", "Arial narrow italic," are returned instead of families, such as "Arial", "Arial black" or "Arial narrow".
Under Windows, the * parameter has no effect. The command still returns the font families.

**Note:** Under OS X, if you use the result of this command with the **ST SET ATTRIBUTES**, you must not pass the * parameter.

### About scalable fonts

This command returns only scalable fonts. Using non-scalable fonts (i.e. bitmap fonts) to design interfaces is not recommended since they are based on an outdated technology and suffer from limitations regarding size variations. They are not supported in cutting-edge features of 4D such as 4D Write Pro areas .

Under OS X, this principle has been in effect since OS X 10.4 (*QuickDraw* bitmap fonts are obsolete beginning with this version).

Under Windows, this principle is applied beginning with 4D v15 R4. In order to help developers select only modern fonts for their interfaces, only "trueType" or "openType" scalable fonts are listed. For example, "ASI_Mono", "MS Sans Serif" and "System" fonts are no longer available. In addition, GDI names are also ignored; only DirectWrite font family names are supported. For example, "Arial Black" or "Segoe UI Black" font families are not in the list; only "Arial" and "Segoe" are returned.

**Compatibility notes for Windows:**

- Bitmap fonts can still be used in your 4D forms (except in 4D Write Pro areas). They are just removed from the list returned by this command. However, to ensure compatibility with future versions of 4D and Windows, we recommend using only DirectWrite font families.
- Since bitmap fonts are filtered from the *fonts* parameter on Windows, the resulting list is different in 4D v15 R4 applications and higher, compared to previous releases. Please make sure to adapt your code if you were using this command to select a non-scalable font.

## Example 1

In a form, you want a drop-down list that displays a list of the fonts available on your system. The method of the drop-down list is as follows:

```
Case of
   :(Form event=On Load)
      ARRAY TEXT(asFont;0)
      FONT LIST(asFont)
   ...

End case
```

## Example 2

You want to get a list of recent fonts:

```
FONT LIST($arrFonts;Recent fonts)
```

# FONT STYLE LIST

FONT STYLE LIST ( fontFamily ; fontStyleList ; fontNameList )

| Parameter | Type | | Description |
|---|---|---|---|
| fontFamily | Text | ⇒ | Name of font family |
| fontStyleList | Text array | ⇐ | List of font styles supported by the font family |
| fontNameList | Text array | ⇐ | List of complete font names supported by the font family |

## Description

The **FONT STYLE LIST** command returns the list of font styles and the list of complete font names supported by the font family defined in the *fontFamily* parameter. This command allows you to design interfaces handling fonts and font styles, particularly in the context of 4D Write Pro areas (see **4D Write Pro Reference**).

In *fontFamily*, pass the name of the font family for which you want to know the supported font styles and names.

In *fontStyleList*, you pass a text array to be filled with the list of font styles supported by the *fontFamily*. Styles are returned using their localized names (i.e. an "Italic" element will be returned as "Itálico" on a Spanish system), so that you can build a localized "Style" pop-up menu, for example.

In *fontNameList*, you pass a text array to be filled with the complete list of font names supported by the *fontFamily*. Unlike the *fontStyleList* array, the *fontNameList* array returns non-localized values, i.e. font names based upon the system identification. Thus, font names will be independent from the system language. Elements of this array are strings intended to be used with the wk font 4D Write Pro attribute of the **WP SET ATTRIBUTES** command. Using this feature, 4D Write Pro documents can store font names and then be opened on machines using any system language without font issues.

If the *fontFamily* is not found on the machine, arrays are returned empty. To get the list of font families available on the machine, use the **FONT LIST** command.

## Example

You want to select styles of the "Verdana" font family (if available):

```
ARRAY TEXT($aTfonts;0)
ARRAY TEXT($aTStyles;0)
ARRAY TEXT($aTnames;0)
C_LONGINT($numStyle)

FONT LIST($aTfonts)
$numStyle:=Find in array($aTfonts;"Verdana")
If($numStyle#0)
   FONT STYLE LIST($aTfont{$numStyle};$aTStyles;$aTnames)
End if

 //For example, resulting arrays are:
 //$aTStyles{1}="Normal"
 //$aTStyles{1}="Italic"
 //$aTStyles{1}="Bold"
 //$aTStyles{1}="Bold Italic"

 // $aTnames{1}="Verdana"
 // $aTnames{1}="Verdana Italic"
 // $aTnames{1}="Verdana Bold"
 // $aTnames{1}="Verdana Bold Italic"
```

# Gestalt

Gestalt ( selector ; value ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| selector | String | ⇨ | 4-character gestalt selector |
| value | Longint | ⇦ | Gestalt result |
| Function result | Longint | ↩ | Error code result |

## Description

The **Gestalt** command returns in *value* a numeric value that denotes the characteristics of your system hardware and software, depending on the selector you pass in *selector*.

If the requested information is obtained, **Gestalt** returns 0 in *function result*; otherwise, it returns the error -5550. If the selector is unknown, **Gestalt** returns the error -5551.

**Important:** The Gestalt Manager is part of Mac OS. On Windows, some of the selectors are also implemented, but the usefulness of this command is limited.

For more information about the selectors that you can pass to Gestalt, refer to the Apple Developer documentation related to the Gestalt Manager, available on-line at the following address:
http://developer.apple.com/documentation/Carbon/Reference/Gestalt_Manager/index.html

## Example

Using version 10.4.11 of Mac OS, the following code displays the alert “You're running system version 0x1049”:

```
$vlErrCode:=Gestalt("sysv";$vlInfo)
If($vlErrCode=0)
   ALERT("You're running system version "+String($vlInfo;"&x"))
End if
```

# GET SYSTEM FORMAT

GET SYSTEM FORMAT ( format ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| format | Longint | ⇨ | System format to be retrieved |
| value | String | ⇦ | Value of format defined in the system |

## Description

The **GET SYSTEM FORMAT** command returns the current value of several regional parameters defined in the operating system. This command can be used to build “automatic” custom formats based on the system preferences.

In the *format* parameter, pass the type of parameter whose value you want to know. The result is returned directly by the system in the *value* parameter as a character string. In *format*, you must pass one of the following constants of the **System Format** theme. Below is a description of these constants:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Currency symbol | Longint | 2 | Currency symbol (e.g.: “$”) |
| Date separator | Longint | 13 | Separator used in date formats (e.g.: “/”) |
| Decimal separator | Longint | 0 | Decimal separator (e.g.: “.”) |
| Short date day position | Longint | 15 | Position of the day in the short date format: “1” = left, “2” = middle, “3” = right |
| Short date month position | Longint | 16 | Position of the month in the short date format: “1” = left, “2” = middle, “3” = right |
| Short date year position | Longint | 17 | Position of the year in the short date format: “1” = left, “2” = middle, “3” = right |
| System date long pattern | Longint | 8 | Long date display format in the form “dddd MMMM yyyy” |
| System date medium pattern | Longint | 7 | Medium date display format in the form “dddd MMMM yyyy” |
| System date short pattern | Longint | 6 | Short date display format in the form “dddd MMMM yyyy” |
| System time AM label | Longint | 18 | Additional label for a time before noon in 12-hour formats (e.g.: “Morning”) |
| System time long pattern | Longint | 5 | Long time display format in the form “HH:MM:SS” |
| System time medium pattern | Longint | 4 | Medium time display format in the form “HH:MM:SS” |
| System time PM label | Longint | 19 | Additional label for a time after noon in 12-hour formats (e.g.: “Afternoon”) |
| System time short pattern | Longint | 3 | Short time display format in the form “HH:MM:SS” |
| Thousand separator | Longint | 1 | Thousand separator (e.g.: “,”) |
| Time separator | Longint | 14 | Separator used in time formats (e.g.: “:”) |

## Example

On a check that is filled in mechanically, the amounts written are generally prefixed by “*” characters in order to prevent fraud. If the standard system display format for currency is “$ 5,422.33”, the format for checks should be of the type “$***5432.33”: no comma after the thousand digit and no space between the $ symbol and the first number. The format to be used with the **String** function must be “$*******.**”. To build it via programming, it is necessary to know the currency symbol and the decimal separator:

```
GET SYSTEM FORMAT(Currency symbol;$vCurrSymb)
GET SYSTEM FORMAT(Decimal separator;$vDecSep)
$MyFormat:="###"+$vCurrSymb+"*******"+$vDecSep+"**"
$Result:=String(amount;$MyFormat)
```

# LOG EVENT

LOG EVENT ( {outputType ;} message {; importance} )

| Parameter | Type | | Description |
|---|---|---|---|
| outputType | Longint | ➡ | Message output type |
| message | String | ➡ | Contents of the message |
| importance | Longint | ➡ | Message's importance level |

## Description

The **LOG EVENT** command sets up a customized system for recording internal events that occur during the use of your application.

Pass the custom information to be noted according to the event in *message*.

The optional *outputType* parameter specifies the output channel taken by the *message*. You can pass one of the following constants, located in the "**Log Events**" theme, in this parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Into 4D commands log | Longint | 3 | Indicates to 4D to record the *message* in the 4D commands log file, if this file has been activated. The 4D commands log file can be enabled using the **SET DATABASE PARAMETER** command (selector 34).<br>**Note:** 4D log files are grouped together in the **Logs** folder, which is created next to the database structure file (see the **Get 4D folder** command). |
| Into 4D debug message | Longint | 1 | Indicates to 4D to send the *message* to the system debugging environment. The result depends on the platform:<br>• Under Mac OS: the command sends the message to the Console<br>• Under Windows: the command sends the message as a debug message. To be able to read this message, you must have Microsoft Visual Studio or the DebugView utility for Windows (http://technet.microsoft.com/en-us/sysinternals/bb896647.aspx) |
| Into 4D diagnostic log | Longint | 5 | Indicates to 4D to record the *message* in the 4D diagnostic file, if this file has been enabled.<br>The diagnostic log file can be enabled using the **SET DATABASE PARAMETER** command (selector 79). |
| Into 4D request log | Longint | 2 | Indicates to 4D to record the *message* in the 4D requests log, if this file has been activated |
| Into Windows log events | Longint | 0 | Indicates to 4D to send the *message* to the "Log events" of Windows. This log receives and stores messages coming from running applications. In this case, you can attribute a level of importance to *message* via the optional *importance* parameter (see below).<br>**Notes:**<br>• For this feature to be available, the Windows Log Events service must be running.<br>• Under Mac OS, the command does nothing with this output type |

If you do not pass the *outputType* parameter, the value 0 (Into Windows log events) is used by default.

If you have defined the *outputType* parameter as Into Windows log events, you can attribute a level of importance to *message*, via the optional *importance* parameter which helps you to read and understand the log events. There are three levels of importance: Information, Warning, and Error.
4D provides you with the following predefined constants, placed in the "**Log Events**" category:

| Constant | Type | Value |
|---|---|---|
| Error message | Longint | 2 |
| Information message | Longint | 0 |
| Warning message | Longint | 1 |

If you don’t pass anything in *importance* or pass an incorrect value, the default value (0) is used.

## Example

If you want to have keep track of when your database is opened under Windows, you could write the following line of code in the **On Startup database method**:

```
LOG EVENT(Into Windows log events;"The Invoice database was opened.")
```

Each time the database is opened, this information will be written in Windows’ log events and its level of importance will be 0.

# Menu bar height

Menu bar height -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Height (expressed in pixels) of menu bar (returns zero if menu bar is hidden) |

## Description

**Menu bar height** returns the height of the menu bar, expressed in pixels.

If the menu bar is hidden, the command returns 0.

# Menu bar screen

Menu bar screen -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of screen where menu bar is located |

## Description

**Menu bar screen** returns the number of the screen where the menu bar is located.

**Windows note:** On Windows, **Menu bar screen** usually returns 1.

# OPEN COLOR PICKER

OPEN COLOR PICKER {( textOrBackground )}

| Parameter | Type | | Description |
|---|---|---|---|
| textOrBackground | Longint | ⇒ | 0 or omitted = text color, 1 = text background color |

## Description

The **OPEN COLOR PICKER** command displays the system color picker dialog box.

**Note:** This is a modal dialog box under Windows but not under OS X.

When the user selects a color and validates the dialog box, this color is applied to the current text selection in the object with the focus, if the "Allow Font/Color Picker" property is checked for this object (see the *Design Reference* manual).

If you pass 0 in the *textOrBackground* parameter or omit this parameter, the selected color is applied to the text. If you pass 1 in *textOrBackground*, this color is applied to the text background.

If the color was changed, the On After Edit form event is generated for the object.

# OPEN FONT PICKER

OPEN FONT PICKER
Does not require any parameters

## Description

The **OPEN FONT PICKER** command displays the system font picker dialog box.

**Note:** This is a modal dialog box under Windows but not under OS X.

When the user selects a font and/or a style and validates the dialog box, the changes are applied to the current text selection in the object with the focus, if the "Allow Font/Color Picker" property is checked for this object (see the *Design Reference* manual). Otherwise, the command does nothing.

If the font was changed, the On After Edit form event is generated for the object .

## Example

In a form, you want to add a button to display the font picker in order to allow users to modify the font or style of a Text variable area. Make sure that:

- the Text variable has the "Allow font/color picker" property checked .
- the "Focusable" property for the button has been unchecked.

Here is the button code:

```
Case of
   :(Form event=On Clicked)
      GOTO OBJECT(textVar) //gives the variable the focus
      OPEN FONT PICKER
End case
```

# PLATFORM PROPERTIES

PLATFORM PROPERTIES ( platform {; system {; processor {; language}}} )

| Parameter | Type | | Description |
|---|---|---|---|
| platform | Longint | ⇐ | 2 = Mac OS, 3 = Windows |
| system | Longint | ⇐ | Depends on the version you are running |
| processor | Longint | ⇐ | Processor family |
| language | Longint | ⇐ | Depends on the system you are using |

## Description

The **PLATFORM PROPERTIES** command returns information about the type of operating system you are running, the version and the language of the operating system, and the processor installed on your machine.

**PLATFORM PROPERTIES** returns environment information in the *platform*, *system*, *processor* and *language* parameters.

*platform* indicates the operating system used. This parameter returns one the following predefined constants:

| Constant | Type | Value |
|---|---|---|
| Mac OS | Longint | 2 |
| Windows | Longint | 3 |

The information returned in *system* depends on the version of 4D you are running.

### Macintosh version

If you are running a Mac OS version of 4D, the *system* parameter returns a 32-bit (Long Integer) value, for which the high level word is unused and the low level word is structured like this:

- The high byte contains the major version number,
- The low byte is composed of two nibbles (4 bits each). The high nibble is the major update version number and the low nibble is the minor update version. Example: System 9.0.4 is coded as *$0904*, so you receive the decimal value *2308*.

**Note:** In 4D, you can extract these values using the % (modulo) and ¥ (integer division) **Numeric Operators** or the **Bitwise Operators**.

Use the following formula to find out the Mac OS main version number:

```
PLATFORM PROPERTIES($vlPlatform;$vlSystem)
$vlResult:=$vlSystem¥256
 //If $vlResult = 16 --> you are under Mac OS 10.x
 //If $vlResult # 16 --> you are under another Mac OS version
```

### Windows version

If you are running the Windows version of 4D, the *system* parameter returns a 32-bit (Long Integer) value, the bits and bytes of which are structured as follows:

If the high level bit is set to 0, it means you are running Windows NT, Windows 2000, Windows XP or Windows Vista. If the bit is set to 1, it means you are running a version of Windows that is too old.

**Note:** The high level bit fixes the sign of the long integer value. Therefore, in 4D, you just need to test the value returned by *system*; if it is negative, you are using an obsolete version of Windows. You can also use the **Bitwise Operators**.

The low byte gives the major Windows version number:

- If it returns 4, you are running Windows NT 4. If it returns 5, you are running Windows 2000, Windows Server 2003 or Windows XP (the sign of the value tells whether or not you are running NT/2000).
- If it returns 6, you are running Windows Vista, Windows Seven, or Windows 8.1.
- If it returns 10, you are running Windows 10. Note that in this case, the *system* parameter is also 10.

The next low byte gives the minor Windows version number.

**Note:** In 4D, you can extract these values using the % (modulo) and ¥ (integer division) **Numeric Operators** or the **Bitwise Operators**.

The *processor* parameter indicates the microprocessor "family" of the machine. Two values can be returned, available in the form of constants:

| Constant | Type | Value |
|---|---|---|
| Intel compatible | Longint | 586 |
| Power PC | Longint | 406 |

The combination of the *platform* and *processor* parameters can be used for example to know without ambiguity whether the machine used is of the “MacIntel” type (*platform=Mac OS* and *processor=Intel Compatible*).
The *language* parameter is used to find out the current language of the system on which the database is running. Here is a list of the codes that can be returned in this parameter, as well as their meanings:

| Code | Language |
|---|---|
| 1 | Arabic |
| 2 | Bulgarian |
| 3 | Catalan |
| 4 | Chinese |
| 5 | Czech |
| 6 | Danish |
| 7 | German |
| 8 | Greek |
| 9 | English |
| 10 | Spanish |
| 11 | Finnish |
| 12 | French |
| 13 | Hebrew |
| 14 | Hungarian |
| 15 | Icelandic |
| 16 | Italian |
| 17 | Japanese |
| 18 | Korean |
| 19 | Dutch |
| 20 | Norwegian |
| 21 | Polish |
| 22 | Portuguese |
| 24 | Romanian |
| 25 | Russian |
| 26 | Croatian |
| 26 | Serbian |
| 27 | Slovak |
| 28 | Albanian |
| 29 | Swedish |
| 30 | Thai |
| 31 | Turkish |
| 33 | Indonesian |
| 34 | Ukrainian |
| 35 | Belarusian |
| 36 | Slovenian |
| 37 | Estonian |
| 38 | Latvian |
| 39 | Lithuanian |
| 41 | Farsi |
| 42 | Vietnamese |
| 45 | Basque |
| 54 | Afrikaans |
| 56 | Faeroese |

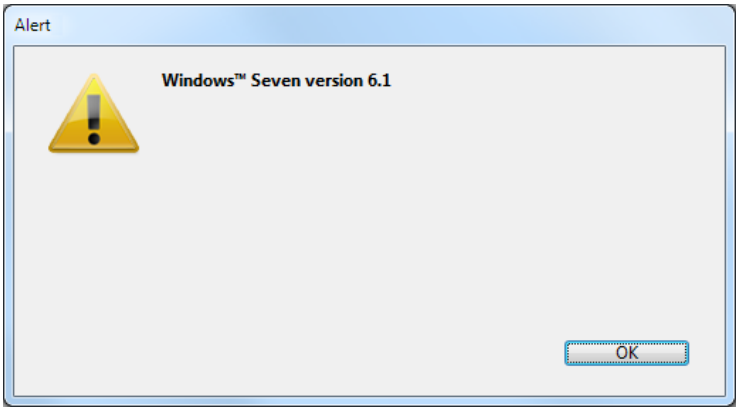
**Note:** If the command is not able to identify the system language, the value 9 (English) is returned.

## Example

The following project method displays an alert box showing the OS software you are using:

```
 //SHOW OS VERSION project method
PLATFORM PROPERTIES($vlPlatform;$vlSystem;$vlMachine)
If(($vlPlatform<2)|($vlPlatform>3))
   $vsPlatformOS:=""
Else
   If($vlPlatform=Windows)
      $vsPlatformOS:=""
      If($vlSystem<0)
         $vsPlatformOS:="Windows version too old"
      Else
         $winMajVers:=$vlSystem%256
         $winMinVers:=($vlSystem¥256)%256
         Case of
            :($winMajVers=4)
               $vsPlatformOS:="Windows™ NT"
            :($winMajVers=5)
               Case of
                  :($winMinVers=0)
                     $vsPlatformOS:="Windows™ 2000"
                  :($winMinVers=1)
                     $vsPlatformOS:="Windows™ XP"
                  :($winMinVers=2)
                     $vsPlatformOS:="Windows™ 2003"
                  Else
                     $vsPlatformOS:="Windows (undetermined version)"
               End case
            :($winMajVers=6)
               Case of
                  :($winMinVers=0)
                     $vsPlatformOS:="Windows™ Vista"
                  :($winMinVers=1)
                     $vsPlatformOS:="Windows™ Seven"
                  :($winMinVers=3)
                     $vsPlatformOS:="Windows™ 8.1"
                  Else
                     $vsPlatformOS:="Windows (undetermined version)"
               End case
            :($winMajVers=10) //$vlSystem=10 also
               $vsPlatformOS:="Windows™ 10"
         End case
      End if
      $vsPlatformOS:=$vsPlatformOS+" version "+String($winMajVers)+"."+String($winMinVers)
   Else
      $vsPlatformOS:="OS X version "
      If(($vlSystem¥256)=16)
         $vsPlatformOS:=$vsPlatformOS+"10"
      Else
         $vsPlatformOS:=$vsPlatformOS+String($vlSystem¥256)
      End if
      $vsPlatformOS:=$vsPlatformOS+"."+String(($vlSystem¥16)%16)+
        (("."+String($vlSystem%16))*Num(($vlSystem%16)#0))
   End if
End if
ALERT($vsPlatformOS)
```

On Windows, you get an alert box similar to this:



On Mac OS, you get an alert box similar to this:

# SCREEN COORDINATES

SCREEN COORDINATES ( left ; top ; right ; bottom {; screen} )

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇦ | Global left coordinate of screen area |
| top | Longint | ⇦ | Global top coordinate of screen area |
| right | Longint | ⇦ | Global right coordinate of screen area |
| bottom | Longint | ⇦ | Global bottom coordinate of screen area |
| screen | Longint | ⇨ | Screen number, or main screen if omitted |

## Description

The **SCREEN COORDINATES** command returns in *left*, *top*, *right,* and *bottom* the global coordinates of the screen specified by *screen*.

If you omit the *screen* parameter, the command returns the coordinates of the main screen.

# SCREEN DEPTH

SCREEN DEPTH ( depth ; color {; screen} )

| Parameter | Type | | Description |
|---|---|---|---|
| depth | Longint | ⇦ | Depth of the screen (number of colors = 2 ^ depth) |
| color | Longint | ⇦ | 1 = Color screen, 0 = Black and white or Gray scale |
| screen | Longint | ⇨ | Screen number, or main screen if omitted |

## Description

The **SCREEN DEPTH** command returns in *depth* and *color* information about the monitor.

The depth of the screen is returned in *depth*. The depth of the screen is the exponent of the power of 2 expressing the number of colors displayed on your monitor. For example, if your monitor is set for 256 colors (2^8), the depth of your screen is 8.

The following predefined constants are provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Black and white | Longint | 0 |
| Four colors | Longint | 2 |
| Millions of colors 24 bit | Longint | 24 |
| Millions of colors 32 bit | Longint | 32 |
| Sixteen colors | Longint | 4 |
| Thousands of colors | Longint | 16 |
| Two fifty six colors | Longint | 8 |

If the monitor is set to display in color, *1* is returned in *color*. If the monitor is set to display in gray scale, *0* is returned in *color*. Note that this value is significant on the Macintosh platform.

The following predefined constants are provided by 4D:

| Constant | Type | Value |
|---|---|---|
| Is color | Longint | 1 |
| Is gray scale | Longint | 0 |

The optional parameter *screen* specifies the monitor for which you want to get information. If you omit the *screen* parameter, the command returns the depth of the main screen.

## Example

Your application displays many color graphics. Somewhere in your database, you could write:

```
SCREEN DEPTH($vlDepth;$vlColor)
If($vlDepth<8)
   ALERT("The forms will look better if the monitor"+" was set to display 256 colors or more.")
End if
```

# Screen height

Screen height {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Windows: height of application window, or height of screen if * is specified Macintosh: height of main screen |
| Function result | Longint | ⇐ | Height expressed in pixels |

## Description

On Windows, **Screen height** returns the height of 4D application window (MDI window). If you specify the optional * parameter, the function returns the height of the screen.

On Macintosh, **Screen height** returns the height of the main screen, the screen where the menu bar is located.

# Screen width

Screen width {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Windows: width of application window, or width of screen if * is specified Macintosh: width of main screen |
| Function result | Longint | ⇐ | Width expressed in pixels |

## Description

On Windows, **Screen width** returns the width of 4D application window (MDI window). If you specify the optional * parameter, the function returns the width of the screen.

On Macintosh, **Screen width** returns the width of the main screen, the screen where the menu bar is located.

# Select RGB Color

Select RGB Color {( defaultColor {; message} )} -> Function result

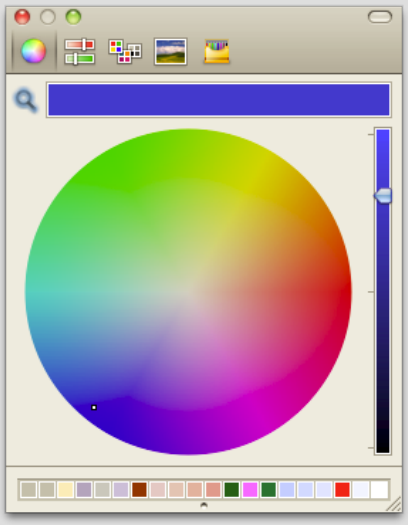
| Parameter | Type | | Description |
|---|---|---|---|
| defaultColor | Longint | ⇒ | Preselected RGB color |
| message | Alpha | ⇒ | Title of selection window |
| Function result | Longint | ⇐ | RGB color |

## Description

The **Select RGB Color** command displays the system color selection window and returns the RGB value of the color selected by the user.

The system color selection window appears as follows:

**Macintosh**



**Windows**

The optional *defaultColor* parameter preselects a color in the window. This parameter can be used, for example, to restore by default the last color set by the user. Pass an RGB-format color value in this parameter (for more information, refer to the description of the **OBJECT SET RGB COLORS** command). You can use one of the constants in the **SET RGB COLORS** theme. If the *defaultColor* parameter is omitted or if you pass 0, the color black is selected when the dialog box is opened.

The optional *message* parameter customizes the title of the system window. By default, if this parameter is omitted, the title “Colors” is displayed.

The effect of validating this dialog box differs depending on the platform:

- Under Windows, when the user clicks on **OK**, the command returns the value of the color selected in RGB format and the system variable *OK* is set to 1. If the user cancels the dialog box, the command returns -1 and the system variable *OK* is set to 0.
- Under Mac OS, you can only close this dialog box by clicking on the close box or by pressing on the **Esc** key. In both cases, the system variable *OK* is set to 1, regardless of the user actions in the window. The command returns the value of the color selected in RGB format. If the user did not select a color, the value returned is the one passed in *defaultColor* (if any) or 0 if *defaultColor* is not passed.

**Note:** This command must not be executed on the server machine nor within a Web process.

# SET RECENT FONTS

SET RECENT FONTS ( fontsArray )

| Parameter | Type | | Description |
|---|---|---|---|
| fontsArray | Text array | ➡ | Array of font names |

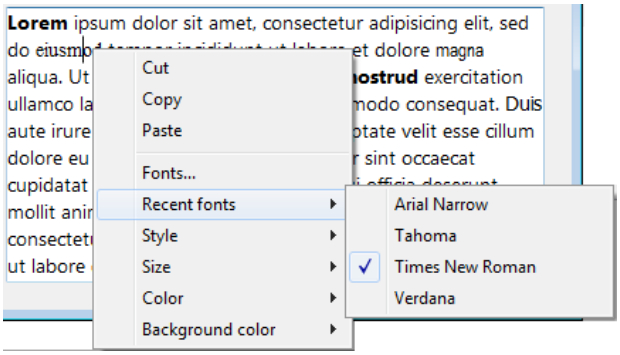
## Description

The **SET RECENT FONTS** command modifies the list of fonts displayed in the context menu of the "recent fonts".

This menu contains the names of the last fonts selected during the session. It is used in particular by **Programming Notes** areas.

## Example

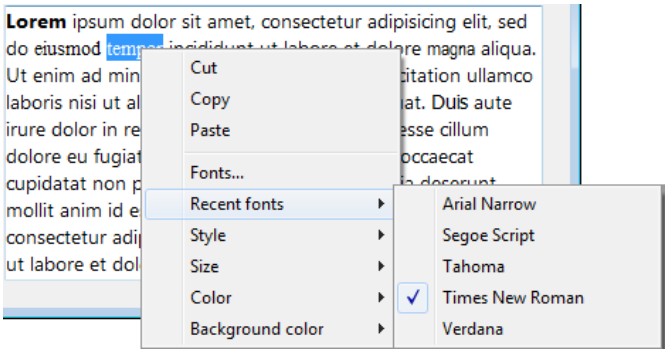
You want to add a font to the menu of recent fonts:



You execute the following code:

```
ARRAY TEXT($arrRecent;0)
FONT LIST($arrRecent;2)
APPEND TO ARRAY($arrRecent;"Segoe Script")
APPEND TO ARRAY($arrRecent)
```

Then the menu contains:



# SET SCREEN DEPTH

SET SCREEN DEPTH ( depth {; color {; screen}} )

| Parameter | Type | | Description |
|---|---|---|---|
| depth | Longint | ⇒ | Depth of the screen (number of colors = 2 ^ Screen depth) |
| color | Longint | ⇒ | 1 = Color, 0 = Gray Scale |
| screen | Longint | ⇒ | Screen number, or main screen if omitted |

## Description

**SET SCREEN DEPTH** changes the depth and color/gray scale settings of the screen whose number you pass in *screen*. If you omit this parameter, the command is applied to the main screen.

For details about the values you pass in *color* and *depth*, see the description of the command **SCREEN DEPTH**.

# System folder

System folder {( type )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| type | Longint | ⇒ | Type of system folder |
| Function result | String | ⇐ | Pathname to a system folder |

## Description

The **System folder** command returns the pathname to a particular folder of the operating system or to the active Windows or Mac OS System folder itself.

You pass in the optional *type* parameter a value indicating the type of system folder. 4D provides you with the following predefined constants, placed in the "**System Folder**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Applications or program files | Longint | 16 | |
| Desktop | Longint | 15 | |
| Documents folder | Longint | 17 | "Documents" folder of user |
| Favorites Win | Longint | 14 | |
| Fonts | Longint | 1 | |
| Start menu Win_all | Longint | 8 | |
| Start menu Win_user | Longint | 9 | |
| Startup Win_all | Longint | 4 | |
| Startup Win_user | Longint | 5 | |
| System | Longint | 0 | |
| System Win | Longint | 12 | |
| System32 Win | Longint | 13 | |
| User preferences_all | Longint | 2 | |
| User preferences_user | Longint | 3 | |

**Notes:**

- The constants suffixed **Win** can be used on Windows only. When they are used on Mac OS, **System folder** will return an empty string.
- The pathnames to some system folders can specific to the current user. Constants 2 to 9 allow you to choose whether you want to obtain the pathname to a folder which is shared by all users, or customized for the current user.

If you omit the *type* parameter, the function will return the pathname to active System folder (= constant System).

# Temporary folder

Temporary folder -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | | Pathname to temporary folder |

## Description

The **Temporary folder** command returns the pathname to the current temporary folder set by your system.

## Example

See example for the **APPEND DATA TO PASTEBOARD** command.

# _o_Font name

_o_Font name ( fontNumber ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| fontNumber | Longint | ⇒ | Font number for which to return the font name |
| Function result | String | ⇐ | Font name |

## Description

*This command is obsolete and must no longer be used beginning with 4D v14. It is kept for compatibility reasons but it will not be supported in future versions of the program.*

# _o_Font number

_o_Font number ( fontName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| fontName | String | ⇒ | Font name for which to return the font number |
| Function result | Longint | ⇒ | Font number |

## Description

*This command is obsolete and must no longer be used beginning with 4D v14. It is kept for compatibility reasons but it will not be supported in future versions of the program.*

# Table

- Current default table
- Current form table
- DEFAULT TABLE
- NO DEFAULT TABLE

# Current default table

Current default table -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Pointer | Pointer to the default table |

## Description

**Current default table** returns a pointer to the table that has been passed to the last call to **DEFAULT TABLE** for the current process.

## Example

Provided a default table has been set, the following line of code sets the window title to the name of the current default table:

```
SET WINDOW TITLE(Table name(Current default table))
```

# Current form table

Current form table -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Pointer | Pointer to the table of the currently displayed form |

## Description

The **Current form table** command returns the pointer to the table of the form being displayed or printed in the current process.

The function returns **Nil** in the following cases:

- There is no form being displayed or printed in the current process,
- The current form is a project form.

If there are several windows open for the current process (which means that the window opened last is the current active window), the command returns the pointer to the table of the form displayed in the active window.

If the currently displayed form is the Detail form for a subform area, you are in data entry and you double-clicked on a record or a subrecord of a double-clickable subform area. In this case, the command returns:

- The pointer to the table shown in the subform area, if the subform displays a table.
- A non-significant pointer, if the subform area displays a subtable.

## Example

Throughout your application, you use the following convention when displaying a record:
If the variable *vsCurrentRecord* is present in a form, it displays “New Record” if you are working with a new record. If you are working with the 56th record of a selection composed of 5200 records, it displays “56 of 5200”.

To do so, use the object method to create the variable *vsCurrentRecord*, then copy and paste it into all of your forms:

```
  ` vsCurrentRecord non-enterable variable object method
Case of
   :(Form event=On Load)
      C_STRING(31;vsCurrentRecord)
      C_POINTER($vpParentTable)
      C_LONGINT($vlRecordNum)
      $vpParentTable:=Current form table
      $vlRecordNum:=Record number($vpParentTable->)
      Case of
         :($vlRecordNum=-3)
            vsCurrentRecord:="New Record"
         :($vlRecordNum=-1)
            vsCurrentRecord:="No Record"
         :($vlRecordNum>=0)
            vsCurrentRecord:=String(Selected record number($vpParentTable->))+" of "+
            String(Records in selection($vpParentTable->))
      End case
End case
```

# DEFAULT TABLE

DEFAULT TABLE ( aTable )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table to set as the default |

## Description

**Tip:** Although using **DEFAULT TABLE** and omitting the table name may make the code easier to read, many programmers find that using this command actually causes more problems and confusion than it is worth. In particular, note that **DEFAULT TABLE** takes priority when you use, for example, the **DIALOG** command with a project form and there is a default table form with the same name.

**DEFAULT TABLE** sets *aTable* as the default table for the current process.

There is no default table for a process until the **DEFAULT TABLE** command is executed. After a default table has been set, any command that omits the *table* parameter will operate on the default table. For example, consider this command:

```
FORM SET INPUT([Table];"form")
```

If the default table is first set to [Table], the same command could be written this way:

```
FORM SET INPUT("form")
```

One reason for setting the default table is to create code that is not table specific. Doing this allows the same code to operate on different tables. You can also use pointers to tables to write code that is not table specific. For more information about this technique, see the description of the **Table name** command.

**DEFAULT TABLE** does not allow the omission of table names when referring to fields. For example:

```
[My Table]My Field:="A string" ` Good
```

could not be written as:

```
DEFAULT TABLE([My Table])
My Field:="A string" ` WRONG
```

because a default table had been set. However, you can omit the table name when referring to fields in the table method, form, and objects that belong to the table.

In 4D, all tables are "open" and ready for use. **DEFAULT TABLE** does not open a table, set a current table, or prepare the table for input or output. **DEFAULT TABLE** is simply a programming convenience to reduce the amount of typing and make the code easier to read.

## Example

The following example first shows code without the **DEFAULT TABLE** command. It then shows the same code, with **DEFAULT TABLE**. The code is a loop commonly used to add new records to a database. The **FORM SET INPUT** and **ADD RECORD** commands both require a table as the first parameter:

```
FORM SET INPUT([Customers];"Add Recs")
Repeat
   ADD RECORD([Customers])
Until(OK=0)
```

Specifying the default table results in this code:

```
DEFAULT TABLE([Customers])
FORM SET INPUT("Add Recs")
Repeat
   ADD RECORD
Until(OK=0)
```

# NO DEFAULT TABLE

NO DEFAULT TABLE
Does not require any parameters

## Description

The **NO DEFAULT TABLE** command is used to cancel the effect of the **DEFAULT TABLE** command. After this command is executed, there is no longer any default table defined for the process.
This command will have no effect if the **DEFAULT TABLE** command has not been called beforehand.

This command concerns the use of project forms (forms not linked with tables): most of the commands related to forms (apart from user forms) accept an optional *aTable* parameter as their first parameter. For example, this is the case with the **FORM GET PARAMETER**, **Open form window** or **DIALOG** commands. Since a project form and table form can have the same name, this parameter can be used to determine the form to be used: pass the *aTable* parameter when you want to target the table form and omit it in the case of a project form.

In a database containing a project form named “TheForm” and a table form with the same name for the [Table1] table:

```
DIALOG([Table1];"TheForm") `4D uses the table form
DIALOG("TheForm") `4D uses the project form
```

However, this principle is null and void if the **DEFAULT TABLE** command is executed when the database contains a project form and a table form with the same name. In fact, in this case 4D will use the table form by default, even if the *aTable* parameter is not passed. In order to guarantee the use of project forms, simply use the **NO DEFAULT TABLE** command.

## Example

In a database containing a project form named “TheForm” and a table form with the same name for the [Table1] table:

```
DEFAULT TABLE([Table1])
DIALOG("TheForm") `4D uses the table form
NO DEFAULT TABLE
DIALOG("TheForm") `4D uses the project form
```

# Tools

# BASE64 DECODE

BASE64 DECODE ( {encodedText ;} blob )

| Parameter | Type | | Description |
|---|---|---|---|
| encodedText | Text | ⇒ | Text containing BLOB encoded in Base64 format |
| blob | BLOB | ⇒ | BLOB encoded in Base64 format |
| | | ⇐ | Decoded BLOB |

## Description

The **BASE64 DECODE** command allows you to decode the BLOB coded in Base64 format passed in the *encodedText* or *blob* parameter.

If you pass the *encodedText* parameter, the command decodes its contents and returns it in the *blob* parameter. It must contain a BLOB encoded in Base64 format. In this case, the initial contents of the *blob* parameter are ignored by the command.
If you omit the *encodedText* parameter, the command directly modifies the BLOB passed in the *blob* parameter.

The command does not verify the contents of the *encodedText* or *blob* parameter. You must verify that the data passed is actually coded in Base64 format, otherwise the result will be incorrect.

## Example

This example lets you transfer a picture via a BLOB:

```
C_BLOB($sourceBlob)
C_PICTURE($mypicture)
$mypicture:=[people]photo
PICTURE TO BLOB($mypicture;$sourceBlob;".JPG")
C_TEXT($base64Text)
BASE64 ENCODE($sourceBlob;$base64Text) //Encoding of text
 // the binary is now available as character strings in $base64Text

C_TEXT($base64Text)
C_BLOB($targetBlob)
BASE64 DECODE($base64Text;$targetBlob) //Decoding of text
 // the binary encoded in base 64 is now available as a BLOB in $blobTarget
```

# BASE64 ENCODE

BASE64 ENCODE ( blob {; encodedText} )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB to encode in Base64 format |
| | | ⇐ | BLOB encoded in Base64 format |
| encodedText | Text | ⇐ | Result of BLOB encoded in Base64 format |

## Description

The **BASE64 ENCODE** command encodes the BLOB passed in the *blob* parameter in Base64 format.

If you pass the *encodedText* parameter, it receives the encoded contents of the *blob* as text at the end of command execution. In this case, the *blob* parameter itself is not modified by the command.
If you omit the *encodedText* parameter, the command directly modifies the BLOB passed as a parameter.

Base64 encoding modifies 8-bit coded data so that they do not keep more than 7 useful bits. This encoding is required, for example, for handling BLOBs using XML.

# Choose

Choose ( criterion ; value {; value2 ; ... ; valueN} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| criterion | Boolean, Integer | ⇒ | Value to test |
| value | Expression | ⇒ | Possible values |
| Function result | Expression | ⇐ | Value of criterion |

## Description

The **Choose** command returns one of the values passed in the *value1*, *value2*, etc. parameters depending on the value of the *criterion* parameter.

You can pass either a Boolean or Number type in the *criterion* parameter:

- If *criterion* is a Boolean, **Choose** returns *value1* if the Boolean equals True and *value2* if the Boolean equals False. In this case, the command expects exactly three parameters: *criterion*, *value1* and *value2*.
- If *criterion* is an integer, **Choose** returns the value whose position corresponds to *criterion*. Be careful, numbering of the values begins with 0 (the position of *value1* is thus 0). In this case, the command expects at least two parameters: *criterion* and *value1*.

The command accepts all types of data for the *value* parameter(s), except for pictures, pointers, BLOBS and arrays. Nevertheless, you need to make sure that all the values passed are of the same type, 4D will not carry out any verification on this point.

If no *value* corresponds to *criterion*, **Choose** returns a "null" value with respect to the type of the *value* parameter (for example, 0 for a Number type, "" for a String type, and so on).

This command can be used to generate concise code that replaces tests of the "Case of" type that take up several lines (see example 2). It is also very useful in places where formulas can be executed: query editor, application of a formula, quick report editor, column calculated in a listbox, and so on.

## Example 1

Here is an example of the typical use of this command with a Boolean type criterion:

```
vTitle:=Choose([Person]Masculine;"Mr";"Ms")
```

This code is strictly equivalent to:

```
If([Person]Masculine)
   vTitle:="Mr"
Else
   vTitle:="Ms"
End if
```

## Example 2

Here is an example of the typical use of this command with a Number type criterion:

```
vStatus:=Choose([Person]Status;"Single";"Married";"Widowed";"Divorced")
```

This code is strictly equivalent to:

```
Case of
   :([Person]Status=0)
      vStatus:="Single"
   :([Person]Status=1)
      vStatus:="Married"
   :([Person]Status=2)
      vStatus:="Widowed"
```

```
    :([Person]Status=3)
       vStatus:="Divorced"
End case
```

# Generate digest

Generate digest ( param ; algorithm ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| param | BLOB, Text variable | ➡ | Blob or text for which to get digest key |
| algorithm | Longint | ➡ | Algorithm used to return key:<br>0 = MD5 Digest, 1 = SHA1 Digest, 2 = 4D digest |
| Function result | Text | ⬅ | Value of digest key |

## Description

The **Generate digest** command returns the digest key of a BLOB or text after application of an encryption algorithm.

In 4D, the following algorithms are available: **MD5** (*Message Digest 5*)**, SHA-1** (*Secure Hash 1*) and **4D** (internal algorithm). These algorithms are different hash functions:

- MD5 is a series of 16 bytes returned as a string of 32 hexadecimal characters.
- SHA-1 is a series of 20 bytes returned as a string of 40 hexadecimal characters.
- 4D designates the internal algorithm used by 4D to encrypt user passwords. This algorithm is particularly useful in the context of the **On 4D Mobile Authentication database method** when you want to use your own list of users.

The value returned for the same object is the same on all the platforms (Mac/Windows, 32 or 64 bits). The calculation is performed based on the representation in UTF-8 of the text passed in the parameter.

**Note:** If you use the command with an empty text/BLOB, it does not return void but returns the following value: "d41d8cd98f00b204e9800998ecf8427e" (MD5) or "da39a3ee5e6b4b0d3255bfef95601890afd80709" (SHA-1).

Pass a Text or BLOB field or variable in the *param* parameter. The **Generate digest** function returns the digest key as a string.

In the *algorithm* parameter, pass a value designating which hash function to use. Use one of the following constants, found in the **Digest Type** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D digest | Longint | 2 | Use internal algorithm of 4D |
| MD5 digest | Longint | 0 | Use the MD5 algorithm |
| SHA1 digest | Longint | 1 | Use the SHA-1algorithm |

If the calculation of the digest key is not performed correctly, the function generates an error that you can intercept using the **ON ERR CALL** command and the function returns an empty string.

## Example 1

This example compares two documents using the MD5 algorithm:

```
PLATFORM PROPERTIES($Platf;$Syst;$vlMachine)
 // Open the first document as read-only
$Same:=True
$vhDocRef1:=Open document("";"*";Read Mode))
If(OK=1) // If a document is selected
   DOCUMENT TO BLOB(Document;$FirstBlob) // Load document
   If(OK=1)
      If($Platf=Mac OS)
         DOCUMENT TO BLOB(Document;$FirstBlobRF;*)
 // Under Mac OS, load resource fork
         $MD5_1RF:=Generate digest($FirstBlobRF;MD5 digest)
      End if

 // Open the second document as read-only
      $vhDocRef2:=Open document("";"*";Read Mode))
      If(OK=1)
         DOCUMENT TO BLOB(Document;$SecondBlob)
         If(OK=1)
```

```
            If($Platf=Mac OS)
               DOCUMENT TO BLOB(Document;$SecondBlobRF;*)
               $MD5_2RF:=Generate digest($SecondBlobRF;MD5 digest)
               If($MD5_1RF#$MD5_2RF) // Compare digests
                  $Same:=False
               End if
            End if
            $MD5_1:=Generate digest($FirstBlob;MD5 digest)
            $MD5_2:=Generate digest($SecondBlob;MD5 digest)
            If(($MD5_1#$MD5_2)|($Same=False))
               ALERT("These two documents are different.")
            End if
         End if
      End if
   End if
End if
```

## Example 2

These examples illustrate how to retrieve the digest key of a text:

```
$key1:=Generate digest("The quick brown fox jumps over the lazy dog.";MD5 digest)
 // $key1 is "e4d909c290d0fb1ca068ffaddf22cbd0"
$key2:=Generate digest("The quick brown fox jumps over the lazy dog.";SHA1 digest)
 // $key2 is "408d94384216f890ff7a0c3528e8bed1e0b01621"
```

## Example 3

This example only accepts the "admin" user with the password "123" that does not match a 4D user:

```
 //On REST Authentication database method
C_TEXT($1;$2)
C_BOOLEAN($0;$3)
 //$1: user
 //$2: password
 //$3: digest mode
If($1="admin")
   If($3)
      $0:=($2=Generate digest("123";4D digest))
   Else
      $0:=($2="123")
   End if
Else
   $0:=False
End if
```

# Generate UUID

Generate UUID -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | String | ➲ | New UUID as non-canonical text (32 characters) |

## Description

The **Generate UUID** returns a new 32-character UUID identifier in non-canonical form.

An UUID is a 16-byte number (128 bits). It contains 32 hexadecimal characters. It can be expressed either in non-canonical form (series of 32 letters [A-F, a-f] and/or numbers [0-9], for example 550e8400e29b41d4a716446655440000) or in canonical form (groups of 8,4,4,4,12, for example 550e8400-e29b-41d4-a716-446655440000).

In 4D, UUID numbers can be stored in fields. For more information, please refer to the section of the *Design Reference* manual.

## Example

Generation of a UUID in a variable:

```
C_TEXT(MyUUID)
MyUUID:=Generate UUID
```

# GET ACTIVITY SNAPSHOT

GET ACTIVITY SNAPSHOT ( arrActivities | arrUUID ; arrStart ; arrDuration ; arrInfo {; arrDetails}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| arrActivities \| arrUUID | Object array, Text array | ⇦ | Complete description of operations (object array) or Operation UUIDs (text array) |
| arrStart | Text array | ⇦ | Operation start times |
| arrDuration | Longint array | ⇦ | Operation durations in seconds |
| arrInfo | Text array | ⇦ | Description |
| arrDetails | Object array | ⇦ | Details of context and sub-operations (if any) |
| * | Operator | ⇨ | If passed = Get server activity |

## Description

The **GET ACTIVITY SNAPSHOT** command returns a single or several arrays describing operations in progress on the 4D data. These operations usually display a progress window.

This command is used to get a snapshot of the *x* operations that are most time-consuming and/or run most frequently, such as cache writing or the execution of formulas.

**Note:** The information returned by the **GET ACTIVITY SNAPSHOT** command is the same as that displayed on the "Real Time Monitor" (RTM) page of the 4D Server administration window (see *4D Server Reference Guide*).

By default, **GET ACTIVITY SNAPSHOT** processes operations performed locally (with 4D single-user, 4D Server or 4D in remote mode). However, with 4D in remote mode, you can also get a snapshot of operations performed on the server: you just need to pass the asterisk (*) as the last parameter. In this case, the server data is recovered locally.
The * parameter is ignored when the command is executed on 4D Server or 4D single-user.

The **GET ACTIVITY SNAPSHOT** command accepts two syntaxes:

- syntax using only an object array.
- syntax using several arrays.

### First syntax: GET ACTIVITY SNAPSHOT ( arrActivities {; *})

With this syntax, all the operations are returned in a structured form in the 4D object array (*arrActivities*). Each element of the array is an object built as follows:

```
[
    {
        "message":"xxx",
        "maxValue":12321,
        "currentValue":63212,
        "interruptible:0,
        "remote":0,
        "uuid":"deadbeef",
        "taskId":xxx,
        "startTime":"2014-03-20 13:37:00:123",
        "duration":92132,
        "dbContextInfo":{
            "task_id": xxx,
            "user_name": Jean,
            "host_name": HAL,
            "task_name": "CreateIndexLocal",
            "client_uid": "DE4DB33F33F"
            "user4d_id ": 1,
            "client_version ": 123456
        },
        "dbOperationDetails":{
            table: "myTable"
            field: "Field_1"
        },
        "subOperations":[
            {"message":"xxx",
            ...}
```

```
            ]
        },
        {...}
    ]
```

Here is a description of each property returned:

- *message* (text): label of operation
- *maxValue* (number): number of iterations set for the operation (-1 if non-iterative operation)
- *currentValue* (number): current iteration
- *interruptible* (number): operation can be interrupted by user (0=true, 1=false)
- *remote* (number): operation paired between client and server (0=true, 1=false)
- *uuid* (text): UUID identifier of operation
- *taskId* (number): Internal identifier of the process at the origin of the operation
- *startTime* (text): start time of operation in the "yyyy:mm:dd hh:mm:ss:mls" format
- *duration* (number): duration of operation in milliseconds
- *dbContextInfo* (objet): information concerning operations handled by the database engine. Contains the following properties:
  - *host_name* (string): name of host that launched the operation
  - *user_name* (string): name of 4D user whose session launched the operation
  - *task_name* (string): name of process that launched the operation
  - *task_id* (num): ID number of process that launched the operation
  - *client_uid* (string): optional, uuid of client that launched the operation
  - *is_remote_context* (boolean, 0 or 1): optional, indicates whether the database operation was launched by a client (value 1) or by the server through a stored procedure (value 0)
  - *user4d_id* (num): ID number of the current 4D user on the client side
  - *client_version* (string): four digits representing the version of the 4D engine of the application, as returned by the **Application version** command.

  **Note:** client_uid and is_remote_context are only available in client/server mode. client_uid is only returned when the database operation was started on a client machine.
- *dbOperationDetails* (object): property returned only when the operation calls the database engine (this is the case, for instance, for queries and sorts). This is an object containing specific information related to the operation itself. The properties available depend on the type of database operation performed. More specifically, these properties include:
  - table (string): name of table involved in the operation
  - field (string): name of field involved in the operation
  - queryPlan (string): query plan defined for the operation
  - ...
- *subOperations* (array): array of objects containing sub-operations of the current operation (if any). The structure of each sub-element is identical to the one in the main object. If the current operation does not have any sub-operations, then *subOperations* is empty.

### Second syntax: GET ACTIVITY SNAPSHOT ( arrUUID ; arrStart ; arrDuration ; arrInfo {;arrSubOp} {; *})

With this syntax, all the operations are returned in several synchronized arrays (each operation causes an element to be added to all of the arrays). The following arrays are returned:

- *arrUUID*: contains the UUIDs for each operation (corresponds to the *uuid* property of the *arrActivities* object in the previous syntax).
- *arrStart*: contains the start times for each operation (corresponds to the *startTime* property of the *arrActivities* object).
- *arrDuration*: contains the durations of each operation in milliseconds (corresponds to the *duration* property of the *arrActivities* object).
- *arrInfo* : contains the labels describing each operation (corresponds to the *message* property of the *arrActivities* object).
- *arrDetails* (optional): each element of this array is an object containing the following properties:
  - *"dbContextInfo"* (object): see above
  - *"dbOperationDetails"* (object): see above
  - "subOperations". The value of this property is an object array containing all the sub-operations for the current operation. If the current operation does not have any sub-operations, the value of the *subOperations* property is an empty array (corresponds to the *subOperations* property of the *arrActivities* object)

## Example

This method, executed in a separate process on 4D or 4D Server, provides a snapshot of the operations that are underway:

```
ARRAY TEXT(arrUUID;0)
ARRAY TEXT(arrStart;0)
ARRAY LONGINT(arrDuration;0)
ARRAY TEXT(arrInfo;0)

Repeat
   GET ACTIVITY SNAPSHOT(arrUUID;arrStart;arrDuration;arrInfo)
   If(Size of array(arrUUID)>0)
      TRACE // calling of debugger
   End if
Until(False) // Infinite loop
```

You get arrays such as:

| Expression | Value |
|---|---|
| arrUUID | 6 elements |
| arrUUID | 0 |
| arrUUID{0} | "" |
| arrUUID{1} | "1858EB64D281A7429E2012CEEE78499A" |
| arrUUID{2} | "07BBF193B1C0184EA26F1D4235A89CE6" |
| arrUUID{3} | "AE18AFA9426B424FBFB1575554751E05" |
| arrUUID{4} | "715C5B028868E44BAC4062AB0B507601" |
| arrUUID{5} | "BEF371C7CFF45946A6B5FE3488692BD4" |
| arrUUID{6} | "5C51ED352AF1344AA3895D8236D9EC25" |
| arrStart | 6 elements |
| arrStart | 0 |
| arrStart{0} | "" |
| arrStart{1} | "12/3/2013 - 11:32:34" |
| arrStart{2} | "12/3/2013 - 11:32:35" |
| arrStart{3} | "12/3/2013 - 11:32:34" |
| arrStart{4} | "12/3/2013 - 11:32:34" |
| arrStart{5} | "12/3/2013 - 11:32:34" |
| arrStart{6} | "12/3/2013 - 11:32:35" |
| arrDuration | 6 elements |
| arrDuration | 0 |
| arrDuration{0} | 0 |
| arrDuration{1} | 5747 |
| arrDuration{2} | 5388 |
| arrDuration{3} | 5752 |
| arrDuration{4} | 5653 |
| arrDuration{5} | 5959 |
| arrDuration{6} | 5466 |
| arrInfo | 6 elements |
| arrInfo | 0 |
| arrInfo{0} | "" |
| arrInfo{1} | "Array to selection: 9 of 100" |
| arrInfo{2} | "Loading data" |
| arrInfo{3} | "Array to selection: 7 of 100" |
| arrInfo{4} | "Sequential searching on Companies: 11 of 98167 records" |
| arrInfo{5} | "Deleting records: 6 of 10" |
| arrInfo{6} | "Sequential searching on Companies: 13 of 98167 records" |

# GET MACRO PARAMETER

GET MACRO PARAMETER ( selector ; textParam )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ⇨ | Selection to use |
| textParam | Text | ⇦ | Returned text |

## Description

The **GET MACRO PARAMETER** command returns, in the *paramText* parameter, all or part of the text of the method from which it was called.

The *selector* parameter can be used to set the type of information to be returned. You can pass one of the following constants, added to the "**4D Environment**" theme:

| Constant | Type | Value |
|---|---|---|
| Full method text | Longint | 1 |
| Highlighted method text | Longint | 2 |

If you pass Full method text in *selector*, all of the text of the method will be returned in *paramText*. If you pass Highlighted method text in *selector*, only the text selected in the method will be returned in *paramText*.

## Example

Refer to the example of the **SET MACRO PARAMETER** command.

# LAUNCH EXTERNAL PROCESS

LAUNCH EXTERNAL PROCESS ( fileName {; inputStream {; outputStream {; errorStream}}}{; pid} )

| Parameter | Type | | Description |
|---|---|---|---|
| fileName | String | ⇒ | File path and arguments of file to launch |
| inputStream | String, BLOB | ⇒ | Input stream (stdin) |
| outputStream | String, BLOB | ⇐ | Output stream (stdout) |
| errorStream | String, BLOB | ⇐ | Error stream (stderr) |
| pid | Longint | ⇐ | Unique identifier for external process |

## Description

The **LAUNCH EXTERNAL PROCESS** command launches an external process from 4D under Mac OS X and Windows.

Under Mac OS X, this command provides access to any executable application that can be launched from the Terminal.

Pass the fixed file path of the application to execute, as well as any required arguments (if necessary), in the *fileName* parameter.

Under Mac OS X, you can also pass the application name only; 4D will then use the **PATH** environment variable to locate the executable.

**Warning:** This command can only launch executable applications; it cannot execute instructions that are part of the shell (command interpreter). For example, under Mac OS it is not possible to use this command to execute the *echo* instruction or indirections.

The *inputStream* parameter (optional) contains the *stdin* of the external process. Once the command has been executed, the *outputStream* and *errorStream* parameters (if passed) return respectively the *stdout* and *stderr* of the external process. You can use BLOB parameters instead of strings if you are working with binary data (such as pictures).

**Note:** If you use the *_4D_OPTION_BLOCKING_EXTERNAL_PROCESS* environment variable via the **SET ENVIRONMENT VARIABLE** command (asynchronous execution), the *outputStream* and *errorStream* parameters are not returned.

When passed, the *pid* parameter (longint) returns the system level ID for the process created to launch the command, regardless of the *_4D_OPTION_BLOCKING_EXTERNAL_PROCESS* option status. With this information, it is easier to interact with a created external process thereafter, e.g. to stop it. If the process launch fails, the *pid* parameter is not returned.

## Examples under Mac OS X

The following examples use the Mac OS X Terminal available in the Application/Utilities folder.

1. To change permissions for a file (*chmod* is the Mac OS X command used to modify file access):

```
LAUNCH EXTERNAL PROCESS("chmod +x /folder/myfile.txt")
```

2. To edit a text file (*cat* is the Mac OS X command used to edit files). In this example, the full access path of the command is passed:

```
C_TEXT(input;output)
input:=""
LAUNCH EXTERNAL PROCESS("/bin/cat /folder/myfile.txt";input;output)
```

3. To get the contents of the "Users" folder (*ls -l* is the Mac OS X equivalent of the *dir* command in DOS):

```
C_TEXT($In;$Out)
LAUNCH EXTERNAL PROCESS("/bin/ls -l /Users";$In;$Out)
```

4. To launch an independent "graphic" application, it is preferable to use the *open* system command (in this case, the **LAUNCH EXTERNAL PROCESS** statement has the same effect as double-clicking the application):

```
LAUNCH EXTERNAL PROCESS("open /Applications/Calculator.app")
```

## Examples under Windows

5. To open NotePad:

```
LAUNCH EXTERNAL PROCESS("C:¥¥WINDOWS¥¥notepad.exe")
```

6. To open Notepad and open a specific document:

```
LAUNCH EXTERNAL PROCESS("C:¥¥WINDOWS¥¥notepad.exe C:¥¥Docs¥¥new folder¥¥res.txt")
```

7. To launch the Microsoft® Word® application and open a specific document (note the use of the two ""):

```
$mydoc:="C:¥¥Program Files¥¥Microsoft Office¥¥Office10¥¥WINWORD.EXE ¥"C:¥¥Documents and
Settings¥¥Mark¥¥Desktop¥¥MyDocs¥¥New folder¥¥test.xml¥""
LAUNCH EXTERNAL PROCESS($mydoc;$tIn;$tOut)
```

8. To execute a Perl script (requires ActivePerl):

```
C_TEXT($input;$output)
SET ENVIRONMENT VARIABLE("myvariable";"value")
LAUNCH EXTERNAL PROCESS("D:¥¥Perl¥¥bin¥¥perl.exe D:¥¥Perl¥¥eg¥¥cgi¥¥env.pl";$input;$output)
```

9. To launch a command with the current directory and without displaying the console:

```
SET ENVIRONMENT VARIABLE("_4D_OPTION_CURRENT_DIRECTORY";"C:¥¥4D_VCS")
SET ENVIRONMENT VARIABLE("_4D_OPTION_HIDE_CONSOLE";"true")
LAUNCH EXTERNAL PROCESS("mycommand")
```

10. To allow the user to open an external document on Windows:

```
$docname:=Select document("";"*.*";"Choose the file to open";0)
If(OK=1)
   SET ENVIRONMENT VARIABLE("_4D_OPTION_HIDE_CONSOLE";"true")
   LAUNCH EXTERNAL PROCESS("cmd.exe /C start ¥"¥" ¥""+$docname+"¥"")
End if
```

11. The following examples request the process list on Windows:

```
C_LONGINT($pid)
C_TEXT($stdin;$stdout;$stderr)

LAUNCH EXTERNAL PROCESS("tasklist";$pid) //gets PID only
LAUNCH EXTERNAL PROCESS("tasklist";$stdin;$stdout;$stderr;$pid) //gets all information
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise (file not found, insufficient memory, etc.), it is set to 0.

# OPEN URL

OPEN URL ( path {; appName}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| path | String | ⇒ | Path of document or URL to open |
| appName | String | ⇒ | Name of application to use |
| * | Operator | ⇒ | If specified = URL is not translated, If omitted = URL is translated |

## Description

The **OPEN URL** command opens the file or URL passed in the *path* parameter with the application indicated in *appName* (if any).

The *path* parameter can contain either a standard URL or a file pathname. The command accepts colons (':') under OS X, slashes ('¥') under Windows or a Posix URL beginning with file://.

If the *appName* parameter is omitted, 4D first attempts to interpret the *path* parameter as a file pathname. If this is the case, 4D will request the system to open the file using the most suitable application (for example, a browser for .html files, Word for .doc files, etc.). The * parameter is ignored in this case.
If the *path* parameter contains a standard URL (mailto:, news:, http:, etc. protocols), 4D starts the default Web browser and accesses the URL. If there is no browser on the volumes connected to the computer, this command has no effect.

When the *appName* parameter is passed, the command interrogates the system. If an application with this name is installed, it is started and the command requests it to open the specified URL or document.
Under Windows, the mechanism for recognizing the application name is the same as the one used by the "Run" command of the Start menu. For example, you could pass:

- "iexplore" to start the Internet Explorer.
- "chrome" to start Chrome (if installed)
- "winword" to start MS Word (if installed)

**Note:** You will find the list of applications installed in the *registry* at the following key:
HKEY_LOCAL_MACHINE¥SOFTWARE¥Microsoft¥Windows¥CurrentVersion¥App Paths

Under OS X, the mechanism uses the Finder which automatically indexes all the applications installed. It can recognize any .app application by means of its package name (with or without the .app suffix). For example, you could pass:

- "safari"
- "FireFox"
- "TextEdit"

When the *appName* application is not found, no error is returned; the command is run as if this parameter had not been specified.

4D automatically encodes the URL's special characters. If you pass the * character, 4D will not translate the URL's special characters. This option allows you to access and to send URLs of the type: "*http://www.server.net/page.htm?q=something*".

**Note:** This command does not work when called from a Web process.

## Example 1

The following examples illustrate different types of strings that are accepted as URLs by the command:

```
OPEN URL("http://www.4d.com")
OPEN URL("file://C:/Users/Laurent/Documents/pending.htm")
OPEN URL("C:¥¥Users¥¥Laurent¥¥Documents¥¥pending.htm")
OPEN URL("mailto:jean_martin@4d.fr")
```

## Example 2

This example can be used to launch the most suitable application:

```
$file:=Select document("";"";0)
If(OK=1)
   OPEN URL(Document)
End if
```

## Example 3

The *appName* parameter lets you open the same text file using different applications:

```
OPEN URL("C:¥¥temp¥¥cookies.txt") //open the file with Notepad
OPEN URL("C:¥¥temp¥¥cookies.txt";"winword") //open the file with MS Word (if installed)
OPEN URL("C:¥¥temp¥¥cookies.txt";"excel") //open the file with MS Excel (if installed)
```

# PROCESS 4D TAGS

PROCESS 4D TAGS ( inputTemplate ; outputResult {; param}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| inputTemplate | Text, BLOB | ➡ | Data containing tags to process |
| outputResult | Text, BLOB | ⬅ | Result from template execution |
| param | Text, Number, Date, Time, Pointer | ➡ | Parameter(s) passed to template being executed |

## Description

The **PROCESS 4D TAGS** command causes the processing of 4D transformation tags contained in the *inputTemplate* parameter (field or variable of the BLOB or Text type) while (optionally) inserting value(s) using the *param* parameters and returns the result in *outputResult*. For a complete description of these tags, refer to the **4D Transformation Tags** section.

This command lets you execute a "template" type text containing tags and references to 4D expressions and/or variables, and to produce a result depending on the execution context and/or the values passed as parameters.
For example, you can use this command to generate and save HTML pages based on **semi-dynamic pages** containing 4D transformation tags (without it being necessary for 4D's Web server to be started). You can use it to send e-mail messages in HTML format that contain processing of and/or references to data contained in the database via the 4D Internet Commands. It is possible to process any type of data based on text, such as XML, SVG or multi-style text.

Pass the data containing the tags to be processed in the *inputTemplate* parameter. This parameter can be a field or variable of the BLOB or Text type. The Text type is usually sufficient (parameters can receive up to 2 GB of text).

**Compatibility note**: Beginning with version 12 of 4D, when you use BLOB type parameters, the command automatically considers that the character set used for BLOBs is MacRoman. For better efficiency, it is strongly recommended to use Text type parameters for which processing is carried out in Unicode mode.

All the transformation tags of 4D are supported (*4DTEXT*, *4DHTML, 4DSCRIPT*, *4DLOOP*, *4DEVAL*, etc.).

**Note:** When using the *4DINCLUDE* tag outside the framework of the Web server (Web process):

- with 4D in local mode or 4D Server, the default folder is the folder containing the database structure file,
- with 4D in remote mode, the default folder is the folder containing the 4D application.

The **PROCESS 4D TAGS** command supports an indefinite number of *param* parameters that can be inserted into the executed code. As with project methods, these parameters can contain scalar values of varied types (text, date, time, longint, real, etc.). You can also use arrays, by means of array pointers. Inside the code processed by the 4D tags, these parameters can be accessed by means of standard arguments ($1, $2, etc.), just like in 4D methods 4D (see example).
A dedicated set of local variables is defined in the execution context of the **PROCESS 4D TAGS** command. These variables can be written or read during processing.

**Compatibility note:** In previous versions of 4D, local variables defined in the calling context could be accessed in the **PROCESS 4D TAGS** execution context in interpreted mode. Beginning with 4D v14 R4, this is not the case anymore.

After command execution, the *outputResult* parameter receives the execution result of the *inputTemplate* parameter, along with the result of the processing of any 4D tags that it contains, when applicable. If *inputTemplate* does not contain any 4D tags, the contents of *outputResult* is identical to that of *inputTemplate*.
The *outputResult* parameter may be a field or a variable, but it must be of the same type as that of the *inputTemplate* parameter.

**Note:** This command never calls the **On Web Authentication database method**.

## Example 1

This example loads a 'template' type document, processes the tags it contains and then stores it:

```
C_BLOB($Blob_x)
C_BLOB($blob_out)
C_TEXT($inputText_t)
C_TEXT($outputText_t)

DOCUMENT TO BLOB("mytemplate.txt";$Blob_x)
$inputText_t:=BLOB to text($Blob_x;UTF8 text without length)
```

```
PROCESS 4D TAGS($inputText_t;$outputText_t)
TEXT TO BLOB($outputText_t;$blob_out;UTF8 text without length)
BLOB TO DOCUMENT($document;$blob_out)
```

## Example 2

This example generates a text using data of the arrays:

```
ARRAY TEXT($array;2)
$array{1}:="hello"
$array{2}:="world"
$input:="<!--#4DEVAL $1-->"
$input:=$input+"<!--#4DLOOP $2-->"
$input:=$input+"<!--#4DEVAL $2->{$2->}--> "
$input:=$input+"<!--#4DENDLOOP-->"
PROCESS 4D TAGS($input;$output;"elements = ";->$array)
 // $output = "elements = hello world"
```

# SET ENVIRONMENT VARIABLE

SET ENVIRONMENT VARIABLE ( varName ; varValue )

| Parameter | Type | | Description |
|---|---|---|---|
| varName | String | ⇒ | Variable name to set |
| varValue | String | ⇒ | Value of the variable or "" to reset default value |

## Description

The **SET ENVIRONMENT VARIABLE** command allows you to set the value of an environment variable under Mac OS X and Windows. It is meant to be used with the **LAUNCH EXTERNAL PROCESS** command. It also works with the **PHP Execute** command.

Pass the name of the variable to define in *varName* and its value in *varValue*.

- To get the general list of environment variables and possible values, please refer to the technical documentation of your operating system.
- To see the list of environment variables available with the **LAUNCH EXTERNAL PROCESS** command, please refer to the documentation for this command. Note that three specific environment variables are available for use in this context:
  *_4D_OPTION_CURRENT_DIRECTORY*: Used to set the current directory of the external process to be launched. In *varValue*, you must pass the pathname of the directory (HFS type syntax on Mac OS and DOS on Windows).
  *_4D_OPTION_HIDE_CONSOLE* (Windows only): Used to hide the window of the DOS console. You must pass "true" in *varValue* to hide the console or "false" to display it.
  *_4D_OPTION_BLOCKING_EXTERNAL_PROCESS*: Used to execute the external process in asynchronous mode, in other words, non-blocking for other applications. You must pass "false" in *varValue* to set an asynchronous execution or "true" to set a synchronous execution (no default value can be set for this variable).
  These variables are valid in the current process for the next call to **LAUNCH EXTERNAL PROCESS**.

## Example

Refer to examples of the **LAUNCH EXTERNAL PROCESS** command.

# SET MACRO PARAMETER

SET MACRO PARAMETER ( selector ; textParam )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ➡ | Selection to use |
| textParam | Text | ➡ | Text sent |

## Description

The **SET MACRO PARAMETER** command inserts the *paramText* text into the method from which it has been called.

If text has been selected in the method, the *selector* parameter can be used to set whether the *paramText* text must replace all of the method text or only the selected text. In selector, you can pass one of the following constants, added to the "**4D Environment**" theme:

| Constant | Type | Value |
|---|---|---|
| Full method text | Longint | 1 |
| Highlighted method text | Longint | 2 |

If no text has been selected, *paramText* is inserted into the method.

## Note

In order for the **GET MACRO PARAMETER** and **SET MACRO PARAMETER** commands to work correctly, the new "version" attribute must be declared in the macro itself. The "version" attribute must be declared as follows:

```
<macro name="MyMacro" version="2">
--- Text of macro ---
</macro>
```

## Example

This macro builds a new text that will be returned to the calling method:

```
C_TEXT($input_text)
C_TEXT($output_text)
GET MACRO PARAMETER(Highlighted method text;$input_text)
 `Suppose that the selected text is a table, i.e.  "[Customers]"
$output_text:=""
$output_text:=$output_text+Command name(47)+"("+$input_text+")" ` Select all ([Customers])
$output_text:=$output_text+"$i:="+Command name(76)+"("+$input_text+")" ` $i:=Records in selection([Customers])
SET MACRO PARAMETER(Highlighted method text;$output_text)
 `Replaces the selected text by the new code
```

# Transactions

- Using Transactions
- Suspending transactions
- Active transaction
- CANCEL TRANSACTION
- In transaction
- RESUME TRANSACTION
- START TRANSACTION
- SUSPEND TRANSACTION
- Transaction level
- VALIDATE TRANSACTION

# Using Transactions

Transactions are a series of related data modifications made to a database within a process. A transaction is not saved to a database permanently until the transaction is validated. If a transaction is not completed, either because it is canceled or because of some outside event, the modifications are not saved.

During a transaction, all changes made to the database data within a process are stored locally in a temporary buffer. If the transaction is accepted with **VALIDATE TRANSACTION**, the changes are saved permanently. If the transaction is canceled with **CANCEL TRANSACTION**, the changes are not saved. In all cases, neither the current selection nor the current record are modified by the transaction management commands.

4D supports nested transactions, i.e. transactions on several hierarchical levels. The number of subtransactions allowed is unlimited. The **Transaction level** command can be used to find out the current transaction level where the code is executed.

When you use nested transactions, the result of each subtransaction depends on the validation or cancellation of the higher-level transaction. If the higher-level transaction is validated, the results of the subtransactions are confirmed (validation or cancellation). On the other hand, if the higher-level transaction is cancelled, all the subtransactions are cancelled, regardless of their respective results.

**Note:** For compatibility, nested transactions are disabled by default in databases converted from versions prior to v11 (see **Compatibility page**).

4D includes a feature allowing you to suspend and resume transactions within your 4D code. When a transaction is *suspended*, you can execute operations independently from the transaction itself and then *resume* the transaction to validate or cancel it as usual. When the transaction is suspended, you can, more particularly:

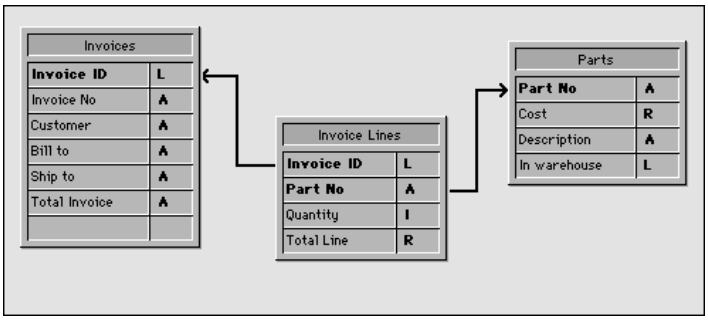
- create or modify records outside of the transaction (for example to increment an invoice number counter),
- start, suspend and/or close other transactions.

For more information about this point, refer to **Suspending transactions**.

## Transaction Examples

In this example, the database is a simple invoicing system. The invoice lines are stored in a table called [Invoice Lines], which is related to the table [Invoices] by means of a relation between the fields [Invoices]Invoice ID and [Invoice Lines]Invoice ID. When an invoice is added, a unique ID is calculated, using the **Sequence number** command. The relation between [Invoices] and [Invoice Lines] is an automatic Relate Many relation. The Auto assign related value in subform check box is checked.

The relation between [Invoice Lines] and [Parts] is manual.



When a user enters an invoice, the following actions are executed:

- Add a record in the table [Invoices].
- Add several records in the table [Invoice Lines].
- Update the [Parts]In Warehouse field of each part listed in the invoice.

This example is a typical situation in which you need to use a transaction. You must be sure that you can save all these records during the operation or that you will be able to cancel the transaction if a record cannot be added or updated. In other words, you must save related data.

If you do not use a transaction, you cannot guarantee the logical data integrity of your database. For example, if one record of the [Parts] records is locked, you will not be able to update the quantity stored in the field [Parts]In Warehouse.

Therefore, this field will become logically incorrect. The sum of the parts sold and the parts remaining in the warehouse will not be equal to the original quantity entered in the record. You can avoid such a situation by using transactions.

There are several ways of performing data entry using transactions:

1. You can handle the transactions yourself by using the transaction commands **START TRANSACTION**, **VALIDATE TRANSACTION** and **CANCEL TRANSACTION**. You can write, for example:

```
READ WRITE([Invoice Lines])
READ WRITE([Parts])
FORM SET INPUT([Invoices];"Input")
Repeat
   START TRANSACTION
   ADD RECORD([Invoices])
   If(OK=1)
      VALIDATE TRANSACTION
   Else
      CANCEL TRANSACTION
   End if
Until(OK=0)
READ ONLY(*)
```

2. To reduce record locking while performing the data entry, you can also choose to manage transactions from within the form method and access the tables in **READ WRITE** only when it becomes necessary.

You perform the data entry using the input form for [Invoices], which contains the related table [Invoice Lines] in a subform. The form has two buttons: *bCancel* and *bOK*, both of which are no action buttons.
The adding loop becomes:

```
READ WRITE([Invoice Lines])
READ ONLY([Parts])
FORM SET INPUT([Invoices];"Input")
Repeat
   ADD RECORD([Invoices])
Until(bOK=0)
READ ONLY([Invoice Lines])
```

Note that the [Parts] table is now in read-only access mode during data entry. Read/write access will be available only if the data entry is validated.

The transaction is started in the [Invoices] input form method listed here:

```
Case of
   :(Form event=On Load)
      START TRANSACTION
      [Invoices]Invoice ID:=Sequence number([Invoices]Invoice ID)
   Else
      [Invoices]Total Invoice:=Sum([Invoice Lines]Total line)
End case
```

If you click the *bCancel* button, the data entry as well as the transaction must be canceled.
Here is the object method of the *bCancel* button:

```
Case of
   :(Form event=On Clicked)
      CANCEL TRANSACTION
      CANCEL
End case
```

If you click the *bValidate* button, the data entry must be accepted and the transaction must be validated. Here is the object method of the *bOK* button:

```
Case of
   :(Form event=On Clicked)
      $NbLines:=Records in selection([Invoice Lines])
      READ WRITE([Parts]) ` Switch to Read/Write access for the [Parts] table
      FIRST RECORD([Invoice Lines]) ` Start at the first line
      $ValidTrans:=True ` Assume everything will be OK
      For($Line;1;$NbLines) ` For each line
         RELATE ONE([Invoice Lines]Part No)
```

```
            OK:=1 ` Assume you want to continue
            While(Locked([Parts]) & (OK=1)) ` Try getting the record in Read/Write access
               CONFIRM("The Part "+[Invoice Lines]Part No+" is in use. Wait?")
               If(OK=1)
                  DELAY PROCESS(Current process;60)
                  LOAD RECORD([Parts])
               End if
            End while
            If(OK=1)
   ` Update quantity in the warehouse
               [Parts]In Warehouse:=[Parts]In Warehouse-[Invoice Lines]Quantity
               SAVE RECORD([Parts]) ` Save the record
            Else
               $Line:=$NbLines+1 ` Leave the loop
               $ValidTrans:=False
            End if
            NEXT RECORD([Invoice Lines]) ` Go next line
         End for
         READ ONLY([Parts]) ` Set the table state to read only
         If($ValidTrans)
            SAVE RECORD([Invoices]) ` Save the Invoices record
            VALIDATE TRANSACTION ` Validate all database modifications
         Else
            CANCEL TRANSACTION ` Cancel everything
         End if
         CANCEL ` Leave the form
   End case
```

In this code, we call the **CANCEL** command regardless of the button clicked. The new record is not validated by a call to **ACCEPT**, but by the **SAVE RECORD** command. In addition, note that **SAVE RECORD** is called just before the **VALIDATE TRANSACTION** command. Therefore, saving the [Invoices] record is actually a part of the transaction. Calling the **ACCEPT** command would also validate the record, but in this case the transaction would be validated before the [Invoices] record was saved. In other words, the record would be saved outside the transaction.

Depending on your needs, you can customize your database, as shown in these examples. In the last example, the handling of locked records in the [Parts] table could be developed further.

# Suspending transactions

## Principle

Suspending a transaction is useful when you need to perform, from within a transaction, certain operations that do not need to be executed under the control of this transaction. For example, imagine the case where a customer places an order, thus within a transaction, and also updates their address. Next the customer changes their mind and cancels the order. The transaction is cancelled, but you do not want the address change to be reverted. This is a typical example where suspending the transaction is useful. Three commands are used to suspend and resume transactions:

- **SUSPEND TRANSACTION**: pauses current transaction. Any updated or added records remain locked.
- **RESUME TRANSACTION**: reactivates a suspended transaction.
- **Active transaction**: returns **False** if the transaction is suspended or if there is no current transaction, and **True** if it is started or resumed.

## Example

This example illustrates the need for a suspended transaction. In an Invoices database, we want to get a new invoice number during a transaction. This number is computed and stored in a [Settings] table. In a multi-user environment, concurrent accesses must be protected; however, because of the transaction, the [Settings] table could be locked by another user even though this data is independent from the main transaction. In this case, you can suspend the transaction when accessing the table.

```
 //Standard method that creates an invoice
START TRANSACTION
...
CREATE RECORD([Invoices])
[Invoices]InvoiceID:=GetInvoiceNum //call the method to get an available number
...
SAVE RECORD([Invoices])
VALIDATE TRANSACTION
```

The ***GetInvoiceNum*** method suspends the transaction before executing. Note that this code will work even when the method is called from outside of a transaction:

```
 //GetInvoiceNum project method
 //GetInvoiceNum -> Next available invoice number
C_LONGINT($0)
SUSPEND TRANSACTION
ALL RECORDS([Settings])
If(Locked([Settings])) //multi-user access
   While(Locked([Settings]))
      MESSAGE("Waiting for locked Settings record")
      DELAY PROCESS(Current process;30)
      LOAD RECORD([Settings])
   End while
End if
[Settings]InvoiceNum:=[Settings]InvoiceNum+1
$0:=[Settings]InvoiceNum
SAVE RECORD([Settings])
UNLOAD RECORD([Settings])
RESUME TRANSACTION
```

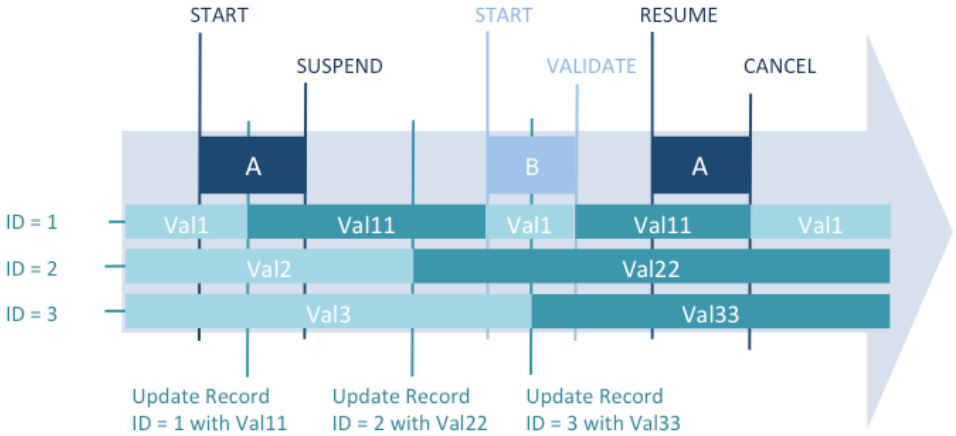
## Detailed operation

### How does a suspended transaction work?

When a transaction is suspended, the following principles are implemented:

- You can access records that were added or modified during the transaction, and you cannot see any records that were deleted during the transaction.
- You can create, save, delete, or modify records outside the transaction.
- You can start a new transaction, but within this included transaction you will not be able to see any records or record values that were added or modified during the suspended transaction. In fact, this new transaction is totally independent from the suspended one, similar to a transaction of another process, and since the suspended transaction could later be resumed or canceled, any added or modified records are automatically hidden for the new transaction. As soon as you commit or cancel the new transaction, you can see these records again.
- Any records that are modified, deleted or added within the suspended transaction remain locked for other processes. If you try to modify or delete these records outside the transaction or in a new transaction, an error is generated.

These implementations are summarized in the following graphic:



*Values edited during transaction A (ID1 record gets Val11) are not available in a new transaction (B) created during the "suspended" period. Values edited during the "suspended" period (ID2 record gets Val22 and ID3 record gets Val33) are saved even after transaction A is cancelled.*

Specific features have been added to handle errors:

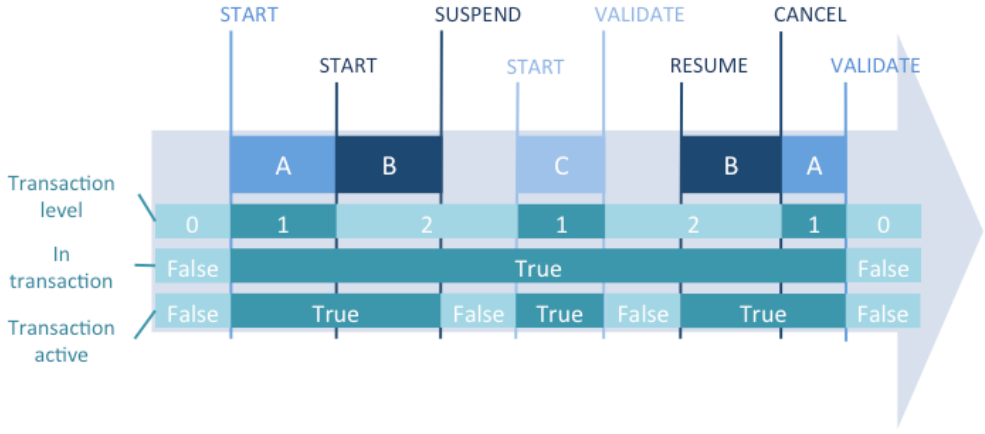
- The current record of each table becomes temporarily locked if it is modified during the transaction and is automatically unlocked when the transaction is resumed. This mechanism is important to prevent unwanted saves on parts of the transaction.
- If you execute an invalid sequence such as *start transaction / suspend transaction / start transaction / resume transaction*, an error is generated. This mechanism prevents developers from forgetting to commit or cancel any included transactions before resuming the suspended transaction.

### Suspended transactions and process status

The existing **In transaction** command returns **True** when a transaction has been started, even if it is suspended. To find out whether the current transaction is suspended, you need to use the new **Transaction active** command, which returns **False** in this case.

Both commands, however, also return **False** if no transaction has been started. You may then need to use the existing **Transaction level** command, which returns 0 in this context (no transaction started).

The following graphic illustrates the various transaction contexts and the corresponding values returned by the transaction commands:



# Active transaction

Active transaction -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | Returns False if the current transaction is suspended |

## Description

The **Active transaction** command returns **True** if the current process is in transaction, and this transaction is not suspended. It returns **False** if there is no current transaction, or if the current transaction is suspended. A transaction can be suspended using the **SUSPEND TRANSACTION** command.

Since the command will also return **False** if the current process is not in transaction, you may need to check using the **In transaction** command to know whether the process is in transaction.

For more information, please refer to **Suspending transactions**.

## Description

You want to know the current transaction status:

```
If(In transaction)
   If(Not(Active transaction))
      ALERT("The current transaction is suspended")
   Else
      ALERT("The current transaction is active")
   End if
Else
   ALERT("We are not in transaction")
End if
```

# CANCEL TRANSACTION

CANCEL TRANSACTION

Does not require any parameters

## Description

**CANCEL TRANSACTION** cancels the transaction that was started with **START TRANSACTION** of the corresponding level in the current process. **CANCEL TRANSACTION** cancels the operations executed on the data and stored during the transaction.

**Note: CANCEL TRANSACTION** does not have an effect on any changes made in the current records that were not saved - they remain displayed after the command is executed.

# In transaction

In transaction -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Returns TRUE if current process is in transaction |

## Description

The **In transaction** command returns **TRUE** if the current process is in a transaction, otherwise it returns **FALSE**.

## Example

If you perform a multi-record operation (adding, modifying, or deleting records), you may encounter locked records. In this case, if you have to maintain data integrity, you must be in transaction so you can “roll-back” the whole operation and leave the database untouched.

If you perform the operation from within a trigger or from a subroutine (that can be called while in transaction or not), you can use **In transaction** to check whether or not the current process method or the caller method started a transaction. If a transaction was not started, you do not even start the operation, because you already know that you will not be able to roll it back if it fails.

# RESUME TRANSACTION

RESUME TRANSACTION
Does not require any parameters

## Description

The **RESUME TRANSACTION** command resumes the transaction that was paused using **SUSPEND TRANSACTION** at the corresponding level in the current process. Any operations that are executed after this command are carried out under transaction control (except when several suspended transactions are nested).

For more information, please refer to **Suspending transactions**.

# START TRANSACTION

START TRANSACTION
Does not require any parameters

## Description

**START TRANSACTION** starts a transaction in the current process. All changes to the data (records) of the database within the transaction are stored temporarily until the transaction is accepted (validated) or canceled.

Beginning with version 11 of 4D, you can nest several transactions (sub-transactions). Each transaction or sub-transaction must eventually be cancelled or validated. Note that if the main transaction is cancelled, all the sub-transactions are cancelled as well, regardless of their result.

# SUSPEND TRANSACTION

SUSPEND TRANSACTION
Does not require any parameters

## Description

The **SUSPEND TRANSACTION** command pauses the current transaction in the current process. You can then handle data in other parts of the database, for example, without it being included in the transaction, and while preserving the transaction context untouched. Any records that have been updated or added in the transaction are locked until the transaction is resumed using the **RESUME TRANSACTION** command.

For more information, please refer to the **Suspending transactions** section.

# Transaction level

Transaction level -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Current transaction level (0 if no transaction has been started) |

## Description

The **Transaction level** command returns the current transaction level for the process. This command takes all the transactions of the current process into account, regardless of whether they were started via the 4D language or via SQL.

# VALIDATE TRANSACTION

VALIDATE TRANSACTION
Does not require any parameters

## Description

**VALIDATE TRANSACTION** accepts the transaction that was started with **START TRANSACTION** of the corresponding level in the current process. The command saves the changes to the data of the database that occurred during the transaction.

Starting with version 11 of 4D, you can nest several transactions (sub-transactions). If the main transaction is cancelled, all the sub-transactions are cancelled, even if they have been validated individually using this command.

## System variables and sets

The system variable OK is set to 1 if the transaction has been validated correctly; otherwise, it is set to 0.

Note that when OK is set to 0, the transaction is automatically cancelled internally (equivalent to **CANCEL TRANSACTION**). Consequently, you must not explicitly call **CANCEL TRANSACTION** if OK=0, particularly in the context of nested transactions, because the cancellation will then be applied to the higher level transaction.

# Triggers

- Triggers
- Trigger event
- Trigger level
- TRIGGER PROPERTIES

# Triggers

A Trigger is a method attached to a table. It is a property of a table. You do not call triggers; they are automatically invoked by the 4D database engine each time you manipulate table records (add, delete and modify). You can write very simple triggers, and then make them more sophisticated.

Triggers can prevent “illegal” operations on the records of your database. They are a very powerful tool for restricting operations on a table, as well as preventing accidental data loss or tampering. For example, in an invoicing system, you can prevent anyone from adding an invoice without specifying the customer to whom the invoice is billed.

## Activating and Creating a Trigger

By default, when you create a table in the Design Environment, it has no trigger.

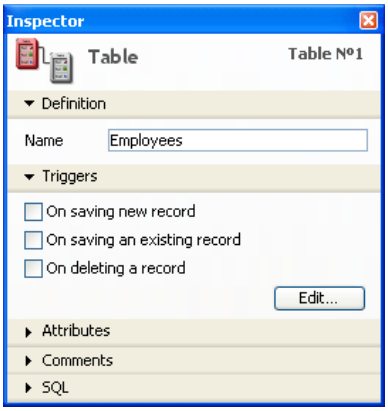
To use a trigger for a table, you need to:

- Activate the trigger and tell 4D when it has to be invoked.
- Write the code for the trigger.

Activating a trigger that is not yet written or writing a trigger without activating it will not affect the operations performed on a table.

### 1. Activating a Trigger

To activate a trigger for a table, you must select one of the **Triggers** options (database events) for the table in the Inspector window of the structure:



***On saving an existing record***

If this option is selected, the trigger will be invoked each time a record of the table is modified.
This happens when:

- Modifying a record in data entry (Design environment, **MODIFY RECORD** command or the SQL **UPDATE** command).
- Saving an already existing record using **SAVE RECORD**.
- Calling any other commands that save existing records (i.e., **ARRAY TO SELECTION**, **APPLY TO SELECTION**, etc.).
- Using a Plug-in that calls the **SAVE RECORD** command.

**Note:** For optimization reasons, the trigger is not called when the record is saved by the user or via the **SAVE RECORD** command if no field in the table has been modified in the record. If you want to "force" the calling of the trigger in this case, you can simply assign a field to itself:

```
[thetable]thefield:=[thetable]thefield
```

***On deleting a record***

If this option is selected, the trigger will be invoked each time a record of the table is deleted.
This happens when:

- Deleting a record (Design environment or calling **DELETE RECORD**, **DELETE SELECTION** or the SQL **DELETE** command).
- Performing any operation that provokes deletion of related records through the deletion control options of a relation.
- Using a Plug-in that calls the **DELETE RECORD** command.

**Note:** The **TRUNCATE TABLE** command does NOT call the trigger.

***On saving a new record***

If this option is selected, the trigger will be invoked each time a record is added to the table.
This happens when:

- Adding a record in data entry (Design environment, **ADD RECORD** command or the SQL **INSERT** command).
- Creating and saving a record with **CREATE RECORD** and **SAVE RECORD**. Note that the trigger is invoked at the moment you call **SAVE RECORD**, not when it is created.
- Importing records (Design environment or using an import command).
- Calling any other commands that create and/or save new records (i.e., **ARRAY TO SELECTION**, **SAVE RELATED ONE**, etc.).
- Using a Plug-in that calls the **CREATE RECORD** and **SAVE RECORD** commands.

### 2. Creating a Trigger

To create a trigger for a table, use the **Explorer** Window, click on the **Edit...** button in the Inspector window of the structure, or press Alt (on Windows) or Option (Macintosh) and double-click on the table title in the Structure window. For more information, see the 4D Design Reference manual.

## Database Events

A trigger can be invoked for one of the three **database events** described above. Within the trigger, you detect which event is occurring by calling the **Trigger event** function. This function returns a numeric value that denotes the database event.

Typically, you write a trigger with a **Case of** structure on the result returned by **Trigger event**. You can use the constants of the **_o_LAST SUBRECORD** theme:

```
 //  Trigger for [anyTable]
C_LONGINT($0)
$0:=0 // Assume the database request will be granted
Case of
   :(Trigger event=On Saving New Record Event)
 // Perform appropriate actions for the saving of a newly created record
   :(Trigger event=On Saving Existing Record Event)
 // Perform appropriate actions for the saving of an already existing record
   :(Trigger event=On Deleting Record Event)
 // Perform appropriate actions for the deletion of a record
End case
```

## Triggers are Functions

A trigger has two purposes:

- Performing actions on the record just before it is saved or deleted.
- Granting or rejecting a database operation.

### 1. Performing Actions

Each time a record is saved (added or modified) to a *[Documents]* table, you want to “mark” the record with a time stamp for creation and another one for the most recent modification. You can write the following trigger:

```
 // Trigger for table [Documents]
Case of
   :(Trigger event=On Saving New Record Event)
      [Documents]Creation Stamp:=Time stamp
      [Documents]Modification Stamp:=Time stamp
   :(Trigger event=On Saving Existing Record Event)
      [Documents]Modification Stamp:=Time stamp
End case
```

**Note**: The *Time stamp* function used in this example is a small project method that returns the number of seconds elapsed since a fixed date was chosen arbitrarily.

After this trigger has been written and activated, no matter what way you add or modify a record to the *[Documents]* table (data entry, import, project method, 4D plug-in), the fields *[Documents]Creation Stamp* and *[Documents]Modification Stamp* will automatically be assigned by the trigger before the record is eventually written to the disk.

**Note**: See the example for the **GET DOCUMENT PROPERTIES** command for a complete study of this example.

### 2. Granting or rejecting the database operation

To grant or reject a database operation, the trigger must return a **trigger error code** in the *$0* function result.

### Example

Let's take the case of an *[Employees]* table. During data entry, you enforce a rule on the field *[Employees]Social Security Number*. When you click the validation button, you check the field using the object method of the button:

```
 // bAccept button object method
If(Good SS number([Employees]SS number))
   ACCEPT
Else
   BEEP
   ALERT("Enter a Social Security Number then click OK again.")
End if
```

If the field value is valid, you accept the data entry; if the field value is not valid, you display an alert and you stay in data entry.

If you also create *[Employees]* records programmatically, the following piece of code would be programmatically valid, but would violate the rule expressed in the previous object method:

```
 // Extract from a project method
 // ...
CREATE RECORD([Employees])
[Employees]Name:="DOE"
SAVE RECORD([Employees]) // <-- DB rule violation! The SS number has not been assigned!
 // ...
```

Using a trigger for the *[Employees]*table, you can enforce the *[Employees]SS number* rule at all the levels of the database. The trigger would look like this:

```
 // Trigger for [Employees]
$0:=0
$dbEvent:=Trigger event
Case of
   :(($dbEvent=On Saving New Record Event)|($dbEvent=On Saving Existing Record Event))
      If(Not(Good SS number([Employees]SS number)))
         $0:=-15050
      Else
 // ...
      End if
 // ...
End case
```

Once this trigger is written and activated, the line **SAVE RECORD** ([Employees]) will generate a database engine error -15050, and the record will NOT be saved.

Similarly, if a 4D Plug-in attempted to save an *[Employees]* record with an invalid social security number, the trigger will generate the same error and the record will not be saved.

The trigger guarantees that nobody (user, database designer, plug-in) can violate the social security number rule, either deliberately or accidentally.

Note that even if you do not have a trigger for a table, you can get database engine errors while attempting to save or delete a record. For example, if you attempt to save a record with a duplicated value in a unique indexed field, the error -9998 is returned.

Therefore, triggers returning errors add new database engine errors to your application:

- 4D manages the "regular" errors: unique index, relational data control, and so on.
- Using triggers, you manage the custom errors unique to your application.

**Important**: You can return an error code value of your choice. However, do NOT use error codes already taken by the 4D database engine. We strongly recommend that you use error codes between -32000 and -15000. We reserve error codes above -15000 for the database engine.

At the process level, you handle trigger errors the same way you handle database engine errors:

- You can let 4D display the standard error dialog box, then the method is halted.
- You can use an error-handling method installed using **ON ERR CALL** and recover the error the appropriate way.

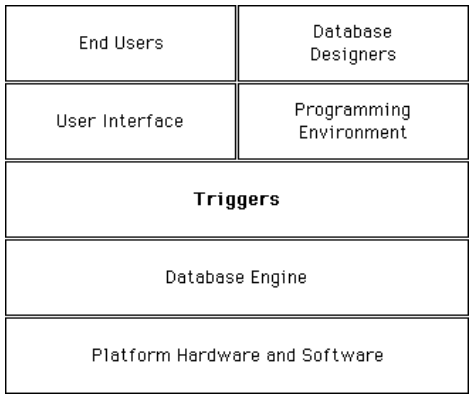
**Notes**:

- During data entry, if a trigger error is returned while attempting to validate or delete a record, the error is handled like a unique indexed error. The error dialog is displayed, and you stay in data entry. Even if you only use a database in the Design environment (not in the Application environment), you have the benefit of using triggers.
- When an error is generated by a trigger within the framework of a command acting on a selection of records (like **DELETE SELECTION**), the execution of the command is immediately stopped, without the selection having necessarily been completely processed. This case requires appropriate handling by the developer, based, for instance, on the temporary preservation of the selection, the processing and elimination of the error before trigger execution, etc.

Even when a trigger returns no error (*$0:=0*), this does not mean that a database operation will be successful—a unique index violation may occur. If the operation is the update of a record, the record may be locked, an I/O error may occur, and so on. The checking is done after the execution of the trigger. However, at the higher level of the executing process, errors returned by the database engine or a trigger are the same—a trigger error is a database engine error.

## Triggers and the 4D Architecture

Triggers execute at the database engine level. This is summarized in the following diagram:



Triggers are executed on the machine where the database engine is actually located. This is obvious with a 4D single-user version. On 4D Server, triggers are executed within the acting process on the server machine (in the "twinned" process of the process that set off the trigger), not on the client machine.

When a trigger is invoked, it executes within the context of the process that attempts the database operation. This process, which invokes the trigger execution, is called the **invoking process**.
The elements included in this context differ according to whether the database is executed with 4D in local mode or with 4D Server :

- With 4D in local mode, the trigger works with the current selections, current records, table read/write states, record locking operations, etc., of the invoking process.
- With 4D Server, only the context of the database of the invoking client process is preserved (locked records and transactional states). 4D Server also (and only) guarantees that the current record of the table of the trigger is correctly positioned. The other elements of the context (current selections for example) are those of the trigger process.

Be careful about using other database or language objects of the 4D environment, because a trigger may execute on a machine other than that of the invoking process—this is the case with 4D Server!

- **Interprocess variables**: A trigger has access to the interprocess variables of the machine where it executes. With 4D Server, it can access a machine other than that of the invoking process.
- **Process variables**: Each trigger has its own table of process variables. A trigger has no access to the process variables of the invoking process.
- **Local variables**: You can use local variables in a trigger. Their scope is the trigger execution; they are created/deleted at each execution.

- **Semaphores**: A trigger can test or set global semaphores as well as local semaphores (on the machine where it executes). However, a trigger must execute quickly, so you must be very careful when testing or setting semaphores from within triggers.
- **Sets and Named selections**: If you use a set or a named selection from within a trigger, you work on the machine where the trigger executes. In client/server mode, "process" sets and named selections (whose names do not begin with a $ nor with <>) that are created on the client machine are visible in a trigger.
- **User Interface**: Do NOT use user interface elements in a trigger (no alerts, no messages, no dialog boxes). Accordingly, you should limit any tracing of triggers in the **Debugging** window. Remember that in Client/Server, triggers execute on the 4D Server machine. An alert message on the server machine does not help a user on a client machine. Let the invoking process handle the user interface.

Note that if you use 4D's password system, you can execute the **Current user** command in the trigger in order, for example, to save the name of the user at the origin of the trigger call in a journaled table, including in client-server mode.

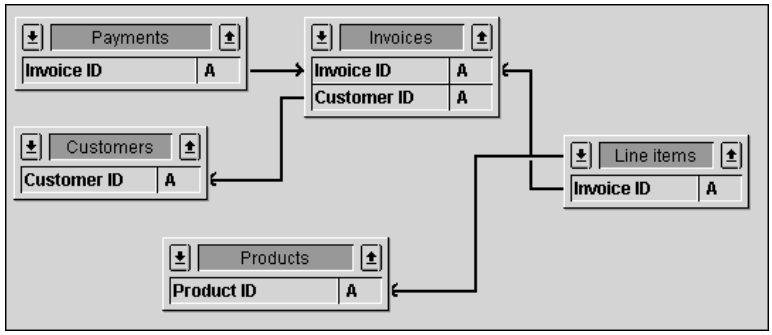
## Triggers and Transactions

Transactions must be handled at the invoking process level. They must not be managed at the trigger level. During one trigger execution, if you have to add, modify or delete multiple records (see the following case study), you must first use the **In transaction** command from within the trigger to test if the invoking process is currently in transaction. If this is not the case, the trigger may potentially encounter a locked record. Therefore, if the invoking process is not in transaction, do not even start the operations on the records. Just return an error in *$0* in order to signal to the invoking process that the database operation it is trying to perform must be executed in a transaction. Otherwise, if locked records are met, the invoking process will have no means to roll back the actions of the trigger.

**Note**: In order to optimize the combined operation of triggers and transactions, 4D does not call triggers after the execution of **VALIDATE TRANSACTION**. This prevents the triggers from being executed twice.

## Cascading Triggers

Given the following example structure:



**Note**: The tables have been collapsed; they have more fields than shown here.

Let's say that the database "authorizes" the deletion of an invoice. We can examine how such an operation would be handled at the trigger level (because you could also perform deletions at the process level).

In order to maintain the relational integrity of the data, deleting an invoice requires the following actions to be performed in the trigger for [Invoices]:

- In the [Customer] record, decrement the Gross Sales field by the amount of the invoice.
- Delete all the [Line Items] records related to the invoice.
- This also implies that the [Line Items] trigger decrements the Quantity Sold field of the [Products] record related to the line item to be deleted.
- Delete all the [Payments] records related to the deleted invoice.

First, the trigger for [Invoices] must perform these actions only if the invoking process is in transaction, so that a roll-back is possible if a locked record is met.

Second, the trigger for [Line Items] is **cascading** with the trigger for [Invoices]. The [Line Items] trigger executes "within" the execution of the [Invoices] trigger, because the deletion of the list items are consequent to a call to **DELETE SELECTION** from within the [Invoices] trigger.

Consider that all tables in this example have triggers activated for all database events. The cascade of triggers will be:

- [Invoices] trigger is invoked because the invoking process deletes an invoice
  - [Customers] trigger is invoked because the [Invoices] trigger updates the Gross Sales field
  - [Line Items] trigger is invoked because the [Invoices] trigger deletes a line item (repeated)

        - [Products] trigger is invoked because the [Line Items] trigger updates the Quantity Sold field
    - [Payments] trigger is invoked because the [Invoices] trigger deletes a payment (repeated)

In this cascade relationship, the [Invoices] trigger is said to be executing at level 1, the [Customers], [Line Items], and [Payments] triggers at level 2, and the [Products] trigger at level 3.

From within the triggers, you can use the **Trigger level** command to detect the level at which a trigger is executed. In addition, you can use the **TRIGGER PROPERTIES** command to get information about the other levels.

For example, if a [Products] record is being deleted at a process level, the [Products] trigger would be executed at level 1, not at level 3.

Using **Trigger level** and **TRIGGER PROPERTIES**, you can detect the cause of an action. In our example, an invoice is deleted at a process level. If we delete a [Customers] record at a process level, then the [Customers] trigger should attempt to delete all the invoices related to that customer. This means that the [Invoices] trigger will be invoked as above, but for another reason. From within the [Invoices] trigger, you can detect if it executed at level 1 or 2. If it did execute at level 2, you can then check whether or not it is because the [Customers] record is deleted. If this is the case, you do not even need to bother updating the Gross Sales field.

# Trigger event

Trigger event -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Longint | 0 Outside any trigger execution cycle 1 Saving a new record 2 Saving an existing record 3 Deleting a record |

## Description

Called from within a trigger, the **Trigger event** command returns a numeric value that denotes the type of the database event, in other words, the reason why the trigger has been invoked.

The following predefined constants are provided in the **Trigger Events** theme:

| Constant | Type | Value |
|---|---|---|
| On Deleting Record Event | Longint | 3 |
| On Saving Existing Record Event | Longint | 2 |
| On Saving New Record Event | Longint | 1 |

Within a trigger, if you perform database operations on multiple records, you may encounter conditions (usually locked records) that will make the trigger unable to perform correctly. An example of this situation is updating multiple records in a [Products] table when a record is being added to an [Invoices] table. At this point, you must stop attempting database operations, and return a database error so the invoking process will know that its database request cannot be performed. Then the invoking process must be able to cancel, during the transaction, the incomplete database operations performed by the trigger. When this type of situation occurs, you need to know from within the trigger if you are in transaction even before attempting anything. To do so, use the command **In transaction**.

When cascading trigger calls, 4D has no limit other than the available memory. To optimize trigger execution, you may want to write the code of your triggers depending not only on the database event, but also on the level of the call when triggers are cascaded. For example, during a deletion database event for the [Invoices] table, you may want to skip the update of the [Customers] Gross Sales field if the deletion of the [Invoices] record is part of the deletion of **all** the invoices related to a [Customers] record being deleted. To do so, use the commands **Trigger level** and **TRIGGER PROPERTIES**.

## Example

You use the **Trigger event** command to structure your triggers as follows:

```
 // Trigger for [anyTable]
C_LONGINT($0)
$0:=0 // Assume the database request will be granted
Case of
   :(Trigger event=On Saving New Record Event)
 // Perform appropriate action for the saving of a newly created record
   :(Trigger event=On Saving Existing Record Event)
 // Perform appropriate actions for the saving of an already existing record
   :(Trigger event=On Deleting Record Event)
 // Perform appropriate actions for the deletion of a record
End case
```

# Trigger level

Trigger level -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Level of trigger execution (0 if outside any trigger execution cycle) |

## Description

The **Trigger level** command returns the execution level of the trigger.

For more information on execution levels, see the topic **Cascading Triggers**.

# TRIGGER PROPERTIES

TRIGGER PROPERTIES ( triggerLevel ; dbEvent ; tableNum ; recordNum )

| Parameter | Type | | Description |
|---|---|---|---|
| triggerLevel | Longint | ⇒ | Trigger execution cycle level |
| dbEvent | Longint | ⇐ | Database event |
| tableNum | Longint | ⇐ | Involved table number |
| recordNum | Longint | ⇐ | Involved record number |

## Description

The **TRIGGER PROPERTIES** command returns information about the trigger execution level you pass in *triggerLevel*. You use this command in conjunction with **Trigger level** to perform different actions depending on the cascading of trigger execution levels. For more information, see **Triggers**.

If you pass a non-existing trigger execution level, the command returns 0 (zero) in all parameters.

The nature of the database event for the trigger execution level is returned in *dbEvent*. The following predefined constants are provided in the **Trigger Events** theme:

| Constant | Type | Value |
|---|---|---|
| On Deleting Record Event | Longint | 3 |
| On Saving Existing Record Event | Longint | 2 |
| On Saving New Record Event | Longint | 1 |

The table number and record number for the record involved by the database event for the trigger execution level are returned in *tableNum* and *recordNum*.

# User Forms

- Overview of user forms
- CREATE USER FORM
- DELETE USER FORM
- EDIT FORM
- LIST USER FORMS

# Overview of user forms

In 4D, developers can offer users the possibility of creating or modifying customized forms. These “User forms” can then be used like any other 4D form.

## Introduction

User forms are based on standard 4D forms created by the developer in the Design environment (called “source” or “developer” forms) where the **Editable by user** property has been applied in the Form editor. A simplified Form editor (called using the **EDIT FORM** command) allows users to modify the form appearance, add graphic objects (using a library of specific objects), hide elements, etc.— the developer can control of authorized actions.

User forms can be used in two different ways:

- The user modifies the “source” form and adapts it to his or her needs using the **EDIT FORM** command. The user form is kept locally and is automatically used instead of the original form.
  This behavior responds to a developer’s need to set parameters for dialog boxes while on site; for example, to add a company logo in forms, hide unnecessary fields, etc.
- The “source” file acts as a basic template that users can freely duplicate and make as many copies as necessary using the **CREATE USER FORM** command. Each copy can be set freely (content, name, etc.) using the **EDIT FORM** command. However, the name of each user form must be unique. The **FORM SET INPUT** and **FORM SET OUTPUT** commands then let you specify the user form to be used in each process.

  This behavior lets developers build, for example, customized reports for users.

## Storing and managing user forms

User form mechanisms work with both compiled and interpreted databases, with 4D in local mode, 4D Server or 4D Desktop. In client/server mode, user modified forms are available on all machines.

4D automatically handles changes in forms. When a form is set as **Editable by user**, it is locked in the Design environment. The developer must explicitly click on the icon to unlock it in order to be able to access form objects. This operation makes related user forms obsolete, which must also be regenerated. When a “source” form is deleted, the related user forms are also deleted.

User forms are stored in a separate file with a .4DA extension, placed next to the main structure file (.4DB/.4DC). This file is called “user structure file”. The behavior of this file is transparent: 4D uses a user form when it exists (the **LIST USER FORMS** command allows finding valid user forms at any time). It is also in this file that the **FORM SET INPUT** and **FORM SET OUTPUT** commands look for the user forms. When a user form is obsolete, it is deleted and 4D uses the source form by default.

In client/server, the .4DA file is broadcast on client machines following the same rules as the main structure file.

This principle also allows keeping user forms non-obsolete in case of a structure file update by the developer.

## Error codes

Specific error codes may be returned when using user form management commands. These codes, located from -9750 to -9759, are described in the **Database Engine Errors (-10602 -> 4004)** section.

## User forms and project forms

User form mechanisms are no longer compatible with project forms. The commands of the “User Forms” theme can therefore not be used with project forms.

# CREATE USER FORM

CREATE USER FORM ( aTable ; form ; userForm )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Source form table |
| form | String | ⇒ | Source table form name |
| userForm | String | ⇒ | Name of new user form |

## Description

The **CREATE USER FORM** command duplicates the 4D table *form* whose table and name are passed as parameters and creates a new user form named *userForm*.

Once created, the *userForm* form can be modified using the **EDIT FORM** command. This command allows you to create X user forms (for example, various report forms) from a single source form.

## System variables and sets

The OK variable returns 1 if the operation is executed properly; otherwise, it returns 0.

## Error management

An error is generated if:

- *form* is already a user form,
- the name of *userForm* is the same as the name of the source form or an existing user form,
- the user cannot access the form because they do not have the proper access rights.

You can intercept these errors with the error-handling method installed by the **ON ERR CALL** command.

# DELETE USER FORM

DELETE USER FORM ( aTable ; form ; userForm )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | User form table |
| form | String | ➡ | Source table form name |
| userForm | String | ➡ | User form name |

## Description

The **DELETE USER FORM** command allows you to remove the user form set using the *aTable*, *form* and *userForm* parameters.

## System variables and sets

If the user form is properly removed, the OK variable returns 1. Otherwise, OK is set to 0.

## Error management

An error is generated if:

- the user form does not exist or *userForm* contains an empty string (-9757),
- the user does not have the proper access to remove the user form.
  You can intercept this error with the error-handling method installed by the **ON ERR CALL** command.

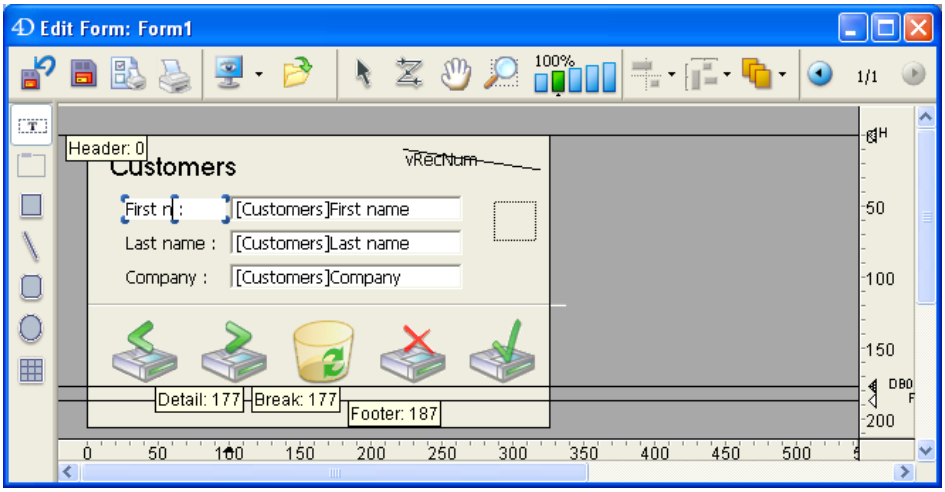
# EDIT FORM

EDIT FORM ( aTable ; form {; userForm {; library}} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table of form to modify |
| form | String | ➡ | Name of table form to modify |
| userForm | String | ➡ | Name of the user form to modify |
| library | String | ➡ | Full pathname of usable object library |

## Description

The **EDIT FORM** command opens the table form set using the a*Table*, *form* and the optional *userForm* parameters in the User form editor:



**Note:** The window of the editor opens only if it is the first window of the processs. In other words, usually you will need to open a new process to display the editor.

If you pass an empty string in the *userForm* parameter and if there is not a user form already linked to *form*, the source form is displayed in the editor. The modified form is then copied in the user structure file (.4DA) and will be used as a *form* replacement.

If a user form was already generated from *form* using this command, the user form is displayed in the editor. If you want to start from the source form, you must first delete the user form using the **DELETE USER FORM** command.

The *userForm* parameter sets a user form (created using the **CREATE USER FORM** command) to modify. In this case, the form is displayed in the editor.

In the optional *library* parameter, pass the full access path of the object library that the user will be authorized to use to customize the form. When used with the User form editor, object libraries will allow you to paste objects with their graphic properties and automatic actions. Objects with methods do not appear in the library. Be careful, it is up to the developer to make sure that the addition of library objects is compatible with the user form (and its objects) in terms of names, variables and types.

In client/server mode, the library must be found in the **Resources** folder of the database, at the same level as the **Plugins** folder, so that it is available for all client machines. If the library is valid, it is opened with the form window.

For more information on object libraries, refer to the Design Reference manual of the 4D documentation.

## Example

In this example, the user can choose a library then modify a dialog form:

```
MAP FILE TYPES("4DLB";"4IL";"4D Library")
$vALib:=Select document(1;"4DLB";"Please select a library";0)
If(OK=1)
  `A library was chosen
   $vALibPath:=Document
Else
   $vALibPath:=""
```

```
End if

EDIT FORM([Dialogs];"Welcome";"Lib_Logos.4il")
If(OK=1)
 `Display of modified form
   DIALOG([Dialogs];"Welcome")
End if
```

## System variables and sets

If the user stores the changes made to the form, the OK variable is set to 1. In case of error, OK is set to 0.

## Error management

An error is generated if:

- the form has not been declared editable by the user in the Design environment or if it does not exist,
- the form is already open and being modified in another process,
- the user cannot access the form because they do not have the proper access rights.
  You can intercept this error with the error-handling method installed by the **ON ERR CALL** command.

# LIST USER FORMS

LIST USER FORMS ( aTable ; form ; userFormArray )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇨ | Source form table |
| form | String | ⇨ | Source table form name |
| userFormArray | String array | ⇦ | Names of user forms coming from the source form |

## Description

The **LIST USER FORMS** command fills the *userFormArray* array with the names of user forms coming from the developer form (table form) set in the *table* and *form* parameters.

If the user form was created directly using the **EDIT FORM** command, the only item that *userFormArray* contains is an empty string ("").

The array is empty if there are no user forms for the specified developer form.

# User Interface

- BEEP
- Caps lock down
- Focus object
- GET FIELD TITLES
- GET MOUSE
- GET TABLE TITLES
- HIDE MENU BAR
- Macintosh command down
- Macintosh control down
- Macintosh option down
- PLAY
- Pop up menu
- POST CLICK
- POST EVENT
- POST KEY
- REDRAW
- SET ABOUT
- SET CURSOR
- SET FIELD TITLES
- SET TABLE TITLES
- Shift down
- SHOW MENU BAR
- Windows Alt down
- Windows Ctrl down
- *_o_Get platform interface*
- *_o_INVERT BACKGROUND*
- *_o_SET PLATFORM INTERFACE*

# BEEP

BEEP
Does not require any parameters

## Description

The **BEEP** command causes the PC or Macintosh to generate a beep. Your computer (on Windows or Macintosh) can emit a sound other than a beep, depending on the sound chosen in the Sound control panel.

**Warning:** Do not call **BEEP** from within a Web connection process, because the beep will be produced on the 4D Web server machine and not on the client Web browser machine.

## Example

In the following example, if no records are found by the query, a beep is emitted and an alert is displayed:

```
QUERY([Customers];[Customers]Name=$vsNameToLookFor)
If(Records in selection([Customers])=0)
   BEEP
   ALERT("There is no Customer with such a name.")
End if
```

# Caps lock down

Caps lock down -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | State of the Caps Lock key |

## Description

**Caps lock down** returns TRUE if the Caps Lock key is pressed.

## Example

See example for the **Shift down** command.

# Focus object

Focus object -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Pointer | Pointer to the object having the focus |

## Compatibility Note

This command is kept only for compatibility reasons. Starting with version 12 of 4D, it is recommended to use the **OBJECT Get pointer** command.

## Description

**Focus object** returns a pointer to the object having the focus in the current form. If no object has the focus, the command returns **Nil**. You can use **Focus object** to perform an action on a form area without having to know which object is currently selected. Be sure to test that the object is the correct data type, using **Type**, before performing an action on it.

**Note:** When it is used with a list box, the **Focus object** function returns a pointer to the list box or the column of the list box depending on the context. For more information, please refer to the **Managing List Box Objects** section.

This command cannot be used with fields in subforms.

**Note:** This command is to be used only in a data entry context; otherwise it will return errors.

## Example

The following example is an object method for a button. The object method changes the data in the current object to uppercase. The object must be a text or string data type (type 0 or 24):

```
$vp :=Focus object ` Save the pointer to the last area
Case of
   :(Nil($pointer)) ` No object has the focus
      ...
   :((Type($vp->)=Is alpha field)|(Type($vp->)=Is string var)) ` If it is a string or text area
      $vp->:=Uppercase($vp->) ` Change the area to uppercase
End case
```

# GET FIELD TITLES

GET FIELD TITLES ( aTable ; fieldTitles ; fieldNums )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇨ | Table for which you want to find out the field names |
| fieldTitles | Text array | ⇦ | Current field names |
| fieldNums | Longint array | ⇦ | Field numbers |

## Description

The **GET FIELD TITLES** command fills the *fieldTitles* and *fieldNums* arrays with the names and numbers of database fields for the desired *aTable*. The contents of these two arrays are synchronized.

If the **SET FIELD TITLES** command is called during the session, **GET FIELD TITLES** only returns the “modified” names and field numbers defined using this command.

Otherwise, **GET FIELD TITLES** returns the names of all database fields as defined in the Structure window.

In both cases, the command does not return invisible fields.

# GET MOUSE

GET MOUSE ( mouseX ; mouseY ; mouseButton {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| mouseX | Real | ⇦ | Horizontal coordinate of mouse |
| mouseY | Real | ⇦ | Vertical coordinate of mouse |
| mouseButton | Longint | ⇦ | Mouse button state: 0 = Button up 1 = Button down 2 = Right button down 3 = Both buttons down |
| * | Operator | ⇨ | If specified, global coordinate system is used If omitted, local coordinate system is used |

## Description

The **GET MOUSE** command returns the current state of the mouse.

The horizontal and vertical coordinates are returned in *mouseX* and *mouseY*. If you pass the * parameter, the coordinates are expressed relative to the screen. If you omit the * parameter, they are expressed relative to the current form window (if any) of the current process.

The parameter *mouseButton* returns the state of the buttons, as listed previously.

**Note:** The values 2 and 3 can be returned under Mac OS X starting with version 10.2.5 only.

## Example

See the example for the **Pop up menu** command.

# GET TABLE TITLES

GET TABLE TITLES ( tableTitles ; tableNums )

| Parameter | Type | | Description |
|---|---|---|---|
| tableTitles | Text array | ⇦ | Current table names |
| tableNums | Longint array | ⇦ | Table numbers |

## Description

The **GET TABLE TITLES** command fills the *tableTitles* and *tableNums* arrays with the names and numbers of database tables defined in the Structure window or using the **SET TABLE TITLES** command. The contents of these two arrays are synchronized.

If the **SET TABLE TITLES** command is called during the session, **GET TABLE TITLES** only returns the “modified” names and table numbers defined using this command.

Otherwise, **GET TABLE TITLES** returns the names of all database tables as defined in the Structure window.

In both cases, the command does not return invisible tables.

# HIDE MENU BAR

HIDE MENU BAR
Does not require any parameters

## Description

The **HIDE MENU BAR** command makes the menu bar invisible.
If the menu bar was already hidden, the command does nothing.

## Example

The following method displays a record in full-screen display (Macintosh) until you click the mouse button:

```
HIDE TOOL BAR
HIDE MENU BAR
Open window(-1;-1;1+Screen width;1+Screen height;Alternate dialog box)
FORM SET INPUT([Paintings];"Full Screen 800")
DISPLAY RECORD([Paintings])
Repeat
   GET MOUSE($vlX;$vlY;$vlButton)
Until($vlButton#0)
CLOSE WINDOW
SHOW MENU BAR
SHOW TOOL BAR
```

**Note:** On Windows, the window will be limited to the bounds of the application window.

# Macintosh command down

Macintosh command down -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | State of the Macintosh Command key (Ctrl key on Windows) |

## Description

**Macintosh command down** returns TRUE if the Macintosh command key is pressed.

**Note:** When called on a Windows platform, **Macintosh command down** returns TRUE if the Windows Ctrl key is pressed.

## Example

See example for the **Shift down** command.

# Macintosh control down

Macintosh control down -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | State of the Macintosh Control key |

## Description

**Macintosh control down** returns TRUE if the Macintosh Control key is pressed.

**Note:** When called on a Windows platform, **Macintosh control down** always return FALSE. This Macintosh key has no equivalent on Windows.

## Example

See example for the **Shift down** command.

# Macintosh option down

Macintosh option down -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | State of the Macintosh Option key (Alt key on Windows) |

## Description

**Macintosh option down** returns TRUE if the Macintosh Option key is pressed.

**Note:** When called on a Windows platform, **Macintosh option down** returns TRUE if the Windows Alt key is pressed.

## Example

See example for the **Shift down** command.

# PLAY

PLAY ( objectName {; async} )

| Parameter | Type | | Description |
|---|---|---|---|
| objectName | String | ⇒ | Name or path of sound file or system sound<br>Empty string for stopping asynchronous play |
| async | Longint | ⇒ | (Windows) If specified, asynchronous execution; If omitted, synchronous execution |

## Description

The **PLAY** command plays sound or multimedia files. You pass the full pathname of the file you want to play in *objectName*. On OS X, the command can also be used to play a system sound.

- To play a file, pass its name and pathname in *objectName*. You can pass a full pathname or a pathname relative to the database structure file.
  The main sound and multimedia file formats are supported: .WAV, .MP3, .AIFF (OS X), etc. Under OS X, the command supports more particularly the Core Audio formats.
- (OS X only) To play a system sound, pass its name directly in the *objectName* parameter.

**Note:** 'snd' resources, as used on Mac OS 9 and older, are no longer supported.

The *async* parameter specifies that the sound will play asynchronously on Windows. Synchronous play means that all processing stops until the sound has finished playing; asynchronous means that processing does not stop and the sound plays in the background. If *async* is passed and contains 0 (or any longint value), the sound is played asynchronously. If omitted, the sound is played synchronously.
**Note:** On OS X, the sound is always played asynchronously, with or without the *async* parameter.

To stop playing an asynchronous sound, use the following statement:

```
PLAY("";0)
```

## Example 1

The following example shows how to play a WAV file on Windows:

```
$DocRef :=Open document("";"WAV";Read Mode)
If(OK=1)
   CLOSE DOCUMENT($DocRef)
   PLAY(Document;0) //play asynchronously
End if
```

## Example 2

The following example code plays a system sound on OS X:

```
PLAY("Submarine.aiff")
```

# Pop up menu

Pop up menu ( contents {; default {; xCoord ; yCoord}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| contents | Text | ⇒ | Menu text definition |
| default | Longint | ⇒ | Number of menu item selected by default |
| xCoord | Longint | ⇒ | X coordinate of upper left corner |
| yCoord | Longint | ⇒ | Y coordinate of upper left corner |
| Function result | Longint | ⇐ | Selected menu item number |

## Description

The **Pop up menu** command displays a pop-up menu at the current location of the mouse.

In order to follow user interface rules, you usually call this command in response to a mouse click and if the mouse button is still down.

You define the items of the pop-up menu with the parameter *contents* as follows:

- Separate each item from the next one with a semi-colon (*;*). For example, *"ItemText1;ItemText2;ItemText3".*
- To disable an item, place an opening parenthesis (*(*) in the item text.
- To specify a separation line, pass "-" or "(-" as item text.
- To specify a font style for a line, place in the item text a less than sign (<) followed by one of these characters:

| | |
|---|---|
| <B | Bold |
| <I | Italic |
| <U | Underline |
| <O | Outline (Macintosh only) |
| <S | Shadow (Macintosh only) |

- To add a check mark to an item, place in the item text an exclamation mark (*!*) followed by the character you want as a check mark.
  - On Macintosh, the character is displayed directly. To display the standard check mark whatever the system version or language, use the following statement: *Char(18)*.
  - On Windows, a check mark is displayed, no matter what character you passed.
- To add an icon to an item, place in the item text a circumflex accent (^) followed by a character whose code plus 208 is the resource ID of a Mac OS-based icon resource.
- To add a shortcut to an item, place in the item text a slash (*/*) followed by the shortcut character for the item. Note that this last option is purely informative; no shortcut will activate the pop-up menu. However, you may want to include a shortcut if the pop-up menu item has an equivalent in the main menu bar of your application.

**Tip:** It is possible to disable the mechanism for interpreting special characters (!, /, etc.) in the pop up menu in order, for example, to have these characters included in the wording. To do this, simply have the *contents* parameter begin with the statement **Char(1)** then use this statement as a separator:

```
contents:=Char(1)+"1/4"+Char(1)+"1/2"+Char(1)+"3/4"
```

Note that once this statement has been executed, it is no longer possible to assign styles or shortcuts to the pop up menu.

The optional *default* parameter specifies the default menu item selected when the pop-up menu is displayed. Pass a value between 1 and the number of menu items. If you omit this parameter, the command selects the first menu item as the default.

The optional *xCoord* and *yCoord* parameters designate the location of the pop-up menu to be displayed. In *xCoord* and *yCoord*, pass respectively the horizontal and vertical coordinates of the upper left corner of the menu. These coordinates must be expressed in pixels in the local coordinate system of the current form. These two parameters must be passed together; if only one is passed, it will be ignored.

If you use the *xCoord* and *yCoord* parameters, the *default* parameter is ignored. In this case, the mouse is not necessarily located at the level of the pop-up menu.

These parameters are particularly useful for managing 3D buttons with an associated pop-up menu.

If you select a menu item, the command returns its number; otherwise, it returns zero (0).

**Note:** Use pop-up menus that have a reasonable number of items. If you want to display more than 50 items, you might think about a using scrollable area in a form instead of a pop-up menu.

## Example

The project method ***MY SPEED MENU*** pulls down a navigation speed menu:

```
 // MY SPEED MENU project method
GET MOUSE($vlMouseX;$vlMouseY;$vlButton)
If(Macintosh control down|($vlButton=2))
   $vtItems:="About this database...<I;(-;!-Other Options;(-"
   For($vlTable;1;Get last table number)
      If(Is table number valid($vlTable))
         $vtItems:=$vtItems+";"+Table name($vlTable)
      End if
   End for
   $vlUserChoice:=Pop up menu($vtItems)
   Case of
      :($vlUserChoice=1)
 // Display Information
      :($vlUserChoice=2)
 // Display options
      Else
         If($vlUserChoice>0)
 // Go to table whose number is $vlUserChoice-4
         End if
   End case
End if
```

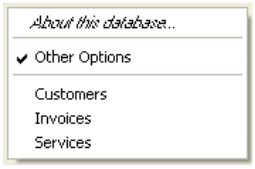
This project method can be called from:

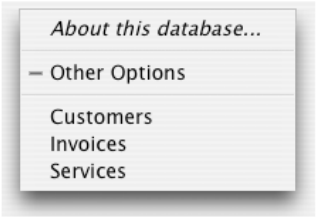
- The method of a form object that reacts to a mouse click without waiting for the mouse button to be released (i.e., an invisible button)
- A process that “spies” events and communicate with the other processes
- An event-handling method installed using **ON ERR CALL**.

In the last two cases, the click does not need to occur in any form object. This is one of the advantages of the **Pop up menu** command. Generally, you use form objects to display pop-up menus. Using **Pop up menu**, you can display the menu anywhere.

The pop-up menu is displayed on Windows by pressing the right mouse button; it is displayed on Macintosh by pressing Control-Click. Note, however, that the method does not actually check whether or not there was a mouse click; the caller method tests that.

The following is the pop-up menu as it appears on Windows (left) and Macintosh (right). Note the standard check mark for the Windows version.





# POST CLICK

POST CLICK ( mouseX ; mouseY {; process} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| mouseX | Longint | ⇒ | Horizontal coordinate |
| mouseY | Longint | ⇒ | Vertical coordinate |
| process | Longint | ⇒ | Destination process reference number, or Application event queue, if omitted, or 0 |
| * | | ⇒ | If specified, global coordinate system is used If omitted, local coordinate system is used |

## Description

The **POST CLICK** command simulates a mouse click. Its effect as if the user actually clicked the mouse button.

You pass the horizontal and vertical coordinates of the click in *mouseX* and *mouseY*. If you pass the * parameter, you express these coordinates relative to the screen. If you omit the * parameter, you express these coordinates relative to the frontmost window of the process whose process number you pass in *process*.

If you specify the *process* parameter, the click is sent to the process whose process number you pass in *process*. If you pass *0* (zero) or if you omit the parameter, the click is sent at the application level, and the 4D scheduler will dispatch it to the appropriate process.

# POST EVENT

POST EVENT ( what ; message ; when ; mouseX ; mouseY ; modifiers {; process} )

| Parameter | Type | | Description |
|---|---|---|---|
| what | Longint | ⇒ | Type of event |
| message | Longint | ⇒ | Event message |
| when | Longint | ⇒ | Event time expressed in ticks |
| mouseX | Longint | ⇒ | Horizontal coordinate of mouse |
| mouseY | Longint | ⇒ | Vertical coordinate of mouse |
| modifiers | Longint | ⇒ | Modifier keys state |
| process | Longint | ⇒ | Destination process reference number, or Application event queue, if omitted, or 0 |

## Description

The **POST EVENT** command simulates a keyboard or mouse event. Its effect is as if the user actually acted on the keyboard or the mouse.

You pass one of the following values in *what*:

| Constant | Type | Value |
|---|---|---|
| Auto key event | Longint | 5 |
| Key down event | Longint | 3 |
| Key up event | Longint | 4 |
| Mouse down event | Longint | 1 |
| Mouse up event | Longint | 2 |

If the event is a mouse-related event, you pass *0* (zero) in *message*. If the event is a keyboard-related event, you pass the code of the simulated character in *message*.

Usually, you pass the value returned by **Tickcount** in *when*.

If the event is a mouse-related event, you pass the horizontal and vertical coordinates of the click in *mouseX* and *mouseY*.

In the parameter *modifiers*, you pass one or a combination of the constants of the **Events (Modifiers)** theme.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Activate window bit | Longint | 0 | |
| Activate window mask | Longint | 1 | |
| Caps lock key bit | Longint | 10 | Windows and OS X |
| Caps lock key mask | Longint | 1024 | Windows and OS X |
| Command key bit | Longint | 8 | Ctrl key under Windows, Command key under OS X |
| Command key mask | Longint | 256 | Ctrl key under Windows, Command key under OS X |
| Control key bit | Longint | 12 | Ctrl key under OS X, or right click under Windows and OS X |
| Control key mask | Longint | 4096 | Ctrl key under OS X, or right click under Windows and OS X |
| Mouse button bit | Longint | 7 | |
| Mouse button mask | Longint | 128 | |
| Option key bit | Longint | 11 | Alt key (also called Option under OS X) |
| Option key mask | Longint | 2048 | Alt key (also called Option under OS X) |
| Right control key bit | Longint | 15 | |
| Right control key mask | Longint | 32768 | |
| Right option key bit | Longint | 14 | |
| Right option key mask | Longint | 16384 | |
| Right shift key bit | Longint | 13 | |
| Right shift key mask | Longint | 8192 | |
| Shift key bit | Longint | 9 | Windows and OS X |
| Shift key mask | Longint | 512 | Windows and OS X |

For example, to simulate the Shift key, pass Shift key bit.

If you specify the *process* parameter, the event is sent to the process whose process number you pass in *process*. If you pass *0* (zero) or if you omit the parameter, the event is sent at the application level, and the 4D scheduler will dispatch it to the appropriate process.

# POST KEY

POST KEY ( code {; modifiers {; process}} )

| Parameter | Type | | Description |
|---|---|---|---|
| code | Longint | ⇒ | Character code or function key code |
| modifiers | Longint | ⇒ | State of modifier keys |
| process | Longint | ⇒ | Destination process reference number, or Application event queue, if omitted, or 0 |

## Description

The **POST KEY** command simulates a keystroke. Its effect is as if the user actually entered a character on the keyboard.

You pass the code of the character in *code*.

If you pass the *modifiers* parameter, you pass one or a combination of the **Events (Modifiers)** constants:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Activate window bit | Longint | 0 | |
| Activate window mask | Longint | 1 | |
| Caps lock key bit | Longint | 10 | Windows and OS X |
| Caps lock key mask | Longint | 1024 | Windows and OS X |
| Command key bit | Longint | 8 | Ctrl key under Windows, Command key under OS X |
| Command key mask | Longint | 256 | Ctrl key under Windows, Command key under OS X |
| Control key bit | Longint | 12 | Ctrl key under OS X, or right click under Windows and OS X |
| Control key mask | Longint | 4096 | Ctrl key under OS X, or right click under Windows and OS X |
| Mouse button bit | Longint | 7 | |
| Mouse button mask | Longint | 128 | |
| Option key bit | Longint | 11 | Alt key (also called Option under OS X) |
| Option key mask | Longint | 2048 | Alt key (also called Option under OS X) |
| Right control key bit | Longint | 15 | |
| Right control key mask | Longint | 32768 | |
| Right option key bit | Longint | 14 | |
| Right option key mask | Longint | 16384 | |
| Right shift key bit | Longint | 13 | |
| Right shift key mask | Longint | 8192 | |
| Shift key bit | Longint | 9 | Windows and OS X |
| Shift key mask | Longint | 512 | Windows and OS X |

For example, to simulate the Shift key, pass Shift key mask. If you do not pass *modifiers*, no modifiers are simulated.

If you specify the *process* parameter, the keystroke is sent to the process whose process number you pass in *process*. If you pass *0* (zero) or if you omit the parameter, the keystroke is sent at the application level, and the 4D scheduler will dispatch it to the appropriate process.

## Example

See example for the **Process number** command.

# REDRAW

REDRAW ( object )

| Parameter | Type | | Description |
|---|---|---|---|
| object | Form object | ⇒ | Table for which to redraw the subform, or Field for which to redraw the area, or Variable for which to redraw the area, or List box to be updated |

## Description

When you use a method to change the value of a field displayed in a subform, you must execute **REDRAW** to ensure that the form is updated.

In the context of list boxes in selection mode, when the **REDRAW** statement is applied to a list box type object it refreshes the data that is displayed in the object. This statement must be called typically after data modification has occurred in the records of the selection.

# SET ABOUT

SET ABOUT ( itemText ; method )

| Parameter | Type | | Description |
|---|---|---|---|
| itemText | String | ⇒ | New About menu item text |
| method | String | ⇒ | Name of method to execute when menu item is chosen |

## Description

The **SET ABOUT** command changes the **About 4D** menu command in the Help (Windows) or in the **Application** (Mac OS X) menu to *itemText*.

After the call, when a user selects this menu command in Design or Application mode, *method* will be called. Typically, this method can open a dialog box to give version information about your database.

This command is used with 4D (all modes), 4D Desktop and 4D Server. A new process is created when it is run on a server machine.

## Example 1

The following example replaces the **About** menu command with the **About Scheduler** menu command. The ***ABOUT*** method displays a custom About box:

```
SET ABOUT("About Scheduler…";"ABOUT")
```

## Example 2

The following example resets the About 4D menu command:

```
SET ABOUT("About 4D";"")
```

# SET CURSOR

SET CURSOR {( cursor )}

| Parameter | Type | | Description |
|---|---|---|---|
| cursor | Longint | ⇒ | Cursor resource number |

## Description

The **SET CURSOR** command changes the mouse cursor to the system cursor whose ID number you pass in *cursor*.

This command must be called in the context of the On Mouse Move **Form event**.

To restore the standard mouse cursor, call the command without any parameter.

Here are the cursors that can be passed in the *cursor* parameter:

| Number | Cursor |
|---|---|
| 1 |  |
| 2 |  |
| 4 |  |
| 9000 |  |
| 9001 |  |
| 9003 |  |
| 9004 |  |
| 9005 |  |
| 9006 |  |
| 9021 |  |
| 351 |  |
| 9010 |  |
| 9011 |  |
| 9013 |  |
| 9014 |  |
| 9015 |  |
| 9016 |  |
| 9017 |  |
| 9019 |  |
| 9020 |  |
| 559 |  |
| 560 |  |

**Note:** Cursor availability and appearance may vary depending on the operating system.

## Example

You want the cursor to be displayed as a  when the mouse moves over a variable area in the form. In the object method of the variable, you can write:

```
If(Form event=On Mouse Move)
   SET CURSOR(9019)
End if
```

# SET FIELD TITLES

SET FIELD TITLES ( aTable ; fieldTitles ; fieldNumbers {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ⇒ | Table for which to set the field titles |
| fieldTitles | String array | ⇒ | Field names as they must appear in dialog boxes |
| fieldNumbers | Longint array | ⇒ | Actual field numbers |
| * | | ⇒ | Use the custom names in the formula editor |

## Description

**SET FIELD TITLES** lets you mask, rename, and reorder the fields of the table passed in *aTable* or *aSubtable* when they appear in standard 4D dialog boxes, such as the Query editor, within the Application environment (more specifically, when the editors are called using 4D language commands).

Using this command, you can also rename on the fly the labels of the fields in your forms, if you used dynamic names. For more information about inserting dynamic field and table names in forms, refer to the 4D Design Reference manual.

The *fieldTitles* and *fieldNumbers* arrays must be synchronized. In the *fieldTitles* array, you pass the name of the fields as you would like them to appear. If you do not want to show a particular field, do not include its name or new title in the array. The fields appear in the order you specify in this array. In each element of the *fieldNumbers* array, you pass the actual field number corresponding to the field name or new title passed in the same element number in the *fieldTitles* array.

For example, you have a table or subtable composed of the fields F, G, and H, created in that order. You want these fields to appear as M, N, and O. In addition you do not want to show field N. Finally, you want to show O and M in that order. To do so, pass O and M in a two-element *fieldTitles* array and pass 3 and 1 in a two-element *fieldNumbers* array.

The optional * parameter indicates whether or not custom names defined using this command can be used in 4D formulas.

- By default, when this parameter is omitted, formulas executed in 4D cannot use these custom names; it is necessary to use the real table names. Using custom names gives you greater freedom for naming fields since the language interpreter does not process custom names
- If the * parameter is passed, the names defined by this command are used in the formulas executed by 4D. **Be careful in this case**, the custom names must not contain characters that are “forbidden” by the 4D language interpreter, like -? *! (for more information, refer to the “**Identifiers**” section).

**Note:** If your application provides access to the formula editor (for example via the Quick report editor), you must pass the * parameter in order to ensure interface consistency.

**SET FIELD TITLES** does NOT change the actual structure of your table. It only affects subsequent uses of the standard 4D dialog boxes and forms using dynamic names when they are called using language commands (the real structure of the database is displayed when the editor or form is called from a menu command in Design mode). The scope of the **SET FIELD TITLES** command is the worksession. One benefit in Client/Server mode is that several remote 4D stations can simultaneously “see” your table in different ways. You can call **SET FIELD TITLES** as many times as you want.

Use the **SET FIELD TITLES** command for:

- Dynamically localizing a table.
- Showing fields the way you want, independent of the actual definition of your table.
- Showing fields in a way that depends on the identity or custom privileges of a user.

**WARNING:**

- **SET FIELD TITLES** does NOT override the Invisible property of a field. When a field is set to be invisible at the Design level of your database, even though it is included in a call to **SET FIELD TITLES**, it will not appear in Application mode.
- Plug-ins always access the "virtual" structure as specified by this command.

## Example

See example for the **SET TABLE TITLES** command.

# SET TABLE TITLES

SET TABLE TITLES ( tableTitles ; tableNumbers {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| tableTitles | String array | ⇒ | Table names as they must appear in dialog boxes |
| tableNumbers | Longint array | ⇒ | Actual table numbers |
| * | | ⇒ | Use the custom names in the formula editor |

## Description

**SET TABLE TITLES** lets you mask, rename, and reorder the tables of your database that appear in standard 4D dialog boxes within the Application environment (when these editors are called using 4D language commands). For example, this command can modify the display of tables in the Query editor in Application mode.
Using this command, you can also rename on the fly the table labels in your forms, if you used dynamic names. For more information about inserting dynamic field and table names in the forms, refer to **Using references in static text** in the *4D Design Reference* manual.

The *tableTitles* and *tableNumbers* arrays must be synchronized. In the *tableTitles* array, you pass the names of the tables as you would like them to appear. If you do not want to show a particular table, do not include its name or new title in the array. The tables appear in the order you specify in this array. In each element of the *tableNumbers* array, you pass the actual table number corresponding to the table name or new title passed in the same element number in the *tableTitles* array.

For example, you have a database composed of the tables A, B, and C, created in that order. You want these tables to appear as X, Y, and Z. In addition you do not want to show table B. Finally, you want to show Z and X, in that order. To do so, you pass Z and X in a two-element *tableTitles* array, and you pass 3 and 1 in a two-element *tableNumbers* array.

The optional * parameter indicates whether or not custom names defined using this command are used in 4D formulas:

- By default, when this parameter is omitted, formulas executed in 4D cannot use these custom names; it is necessary to use the real table names. Using custom names gives you greater freedom for naming tables since the language interpreter does not process custom names.
- If the * parameter is passed, the names defined by this command are used in the formulas executed by 4D. **Be careful in this case**, the custom names must not contain characters that are “forbidden” by the 4D language interpreter, like -? *%! For example, the name "Rate_in_%" could not be used in a formula (for more information, refer to the **Identifiers** section).

**Note:** If your application provides access to the formula editor (for example via the Quick report editor), it is necessary to pass the * parameter in order to ensure interface consistency.

**SET TABLE TITLES** does NOT change the actual structure of your database. It only affects subsequent uses of the standard 4D dialog boxes and forms using dynamic names when they are called via language commands (the real structure of the database is displayed when the editor or form is called from a menu command in Design mode). The scope of the **SET TABLE TITLES** command is the worksession. One benefit in Client/Server is that several 4D Client stations can simultaneously “see” your database in different ways. You can call **SET TABLE TITLES** as many times as you want.

Use the **SET TABLE TITLES** command for:

- Dynamically localizing a database.
- Showing tables the way you want, independent from the actual definition of your database.
- Showing tables in a way that depends on the identity or custom privileges of a user.

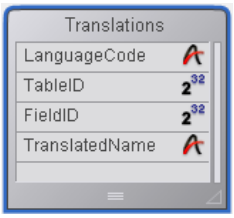
**Notes:**

- **SET TABLE TITLES** does NOT override the Invisible property of a table. When a table is set to be invisible at the structure level of your database, even though it is included in a call to **SET TABLE TITLES**, it will not appear in Application mode.
- Plug-ins always access the "virtual" structure as specified by this command.

## Example

You are building a 4D application that you plan to sell internationally. Therefore, you must carefully consider localization issues. Regarding the standard 4D dialog boxes that can appear in the Application environment and your forms that use dynamic names, you can address localization needs by using a [Translations] table and a few project methods to create and use fields localized for any number of countries.

In your database, add the following table:



Then, create the ***TRANSLATE TABLES AND FIELDS*** project method listed below. This method browses the actual structure of your database and creates all the necessary *[Translations]* records for the localization corresponding to the language passed as parameter.

```
 //TRANSLATE TABLES AND FIELDS project method
 //TRANSLATE TABLES AND FIELDS (Text)
 //TRANSLATE TABLES AND FIELDS (LanguageCode)

C_TEXT($1) //language code
C_LONGINT($vlTable;$vlField)
C_TEXT($Language)
$Language:=$1

For($vlTable;1;Get last table number) //Pass through each table
   If($vlTable#(Table(->[Translations]))) //Do not translate table of translations
 //Check if there is a translation of the table name for the specified language
      QUERY([Translations];[Translations]LanguageCode=$Language;*) //desired language
      QUERY([Translations]; & ;[Translations]TableID=$vlTable;*) //table number
      QUERY([Translations]; & ;[Translations]FieldID=0) //field number = 0 means that it is a table name
      If(Is table number valid($vlTable)) //check that the table still exists
         If(Records in selection([Translations])=0)
 //Otherwise, create the record
            CREATE RECORD([Translations])
            [Translations]LanguageCode:=$Language
            [Translations]TableID:=$vlTable
            [Translations]FieldID:=0
 //The name of the translated table will need to be entered
            [Translations]Translation:=Table name($vlTable)+" in "+$Language
            SAVE RECORD([Translations])
         End if

         For($vlField;1;Get last field number($vlTable))
 //Check if there is a translation of the field name for the specified language
            QUERY([Translations];[Translations]LanguageCode=$Language;*) //desired language
            QUERY([Translations]; & ;[Translations]TableID=$vlTable;*) //table number
            QUERY([Translations]; & ;[Translations]FieldID=$vlField) //field number
            If(Is field number valid($vlTable;$vlField))
               If(Records in selection([Translations])=0)
 //Otherwise, create the record
                  CREATE RECORD([Translations])
                  [Translations]LanguageCode:=$Language
                  [Translations]TableID:=$vlTable
                  [Translations]FieldID:=$vlField
 //The name of the translated field will need to be entered
                  [Translations]Translation:=Field name($vlTable;$vlField)+" in "+$Language
                  SAVE RECORD([Translations])
               End if
            Else
               If(Records in selection([Translations])#0)
 //If the field no longer exists, remove the translation
                  DELETE RECORD([Translations])
               End if
            End if
         End for
      Else
```

```
            If(Records in selection([Translations])#0)
   //If the table no longer exists, remove the translation
               DELETE RECORD([Translations])
            End if
         End if
      End if
   End for
```

At this point, if you execute the following line, you create as many records as needed for a Spanish localization of the tables and fields titles.

```
TRANSLATE TABLES AND FIELDS("Spanish")
```

After this call has been executed, you can then enter the *[Translations]Translated Name* for each of the newly created records.

Finally, each time you want to show your database's standard 4D dialog boxes or forms with dynamic titles using the Spanish localization, you execute the following line:

```
LOCALIZED TABLES AND FIELDS("Spanish")
```

with the project method ***LOCALIZED TABLES AND FIELDS***:

```
   //LOCALIZED TABLES AND FIELDS global method
   //LOCALIZED TABLES AND FIELDS (Text)
   //LOCALIZED TABLES AND FIELDS (LanguageCode)

C_TEXT($1) //Language code
C_LONGINT($vlTable;$vlField)
C_TEXT($Language)
C_LONGINT($vlTableNum;$vlFieldNum)
$Language:=$1

   //Updating table names
ARRAY TEXT($asNames;0) //Initialize arrays for SET TABLE TITLES and SET FIELD TITLES
ARRAY INTEGER($aiNumbers;0)
QUERY([Translations];[Translations]LanguageCode=$Language;*)
QUERY([Translations]; & ;[Translations]FieldID=0) //thus table names
SELECTION TO ARRAY([Translations]Translation;$asNames;[Translations]TableID;$aiNumbers)
SET TABLE TITLES($asNames;$aiNumbers)

   //Updating field names
$vlTableNum:=Get last table number //Get number of tables in database
For($vlTable;1;$vlTableNum) //Pass through each table
   If(Is table number valid($vlTable))
      QUERY([Translations];[Translations]LanguageCode=$Language;*)
      QUERY([Translations]; & ;[Translations]TableID=$vlTable;*)
      QUERY([Translations]; & ;[Translations]FieldID#0) //avoid the zero that serves as table name
      SELECTION TO ARRAY([Translations]Translation;$asNames;[Translations]FieldID;$aiNumbers)
      SET FIELD TITLES(Table($vlTable)->;$asNames;$aiNumbers)
   End if
End for
```

Note that new localizations can be added to the database without modifying or recompiling the code.

# Shift down

Shift down -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | State of the Shift key |

## Description

**Shift down** returns TRUE if the Shift key is pressed.

## Example

The following object method for the button *bAnyButton* performs different actions, depending on which modifier keys are pressed when the button is clicked:

```
  ` bAnyButton Object Method
Case of
  ` Other multiple key combinations could be tested here
  ` ...
  :(Shift down&Windows Ctrl down)
  ` Shift and Windows Ctrl (or Macintosh Command) keys are pressed
     DO ACTION1
  ` ...
  :(Shift down)
  ` Only Shift key is pressed
     DO ACTION2
  ` ...
  :(Windows Ctrl down)
  ` Only Windows Ctrl (or Macintosh Command) key is pressed
     DO ACTION3
  ` ...
  ` Other individual keys could be tested here
  ` ...
End case
```

# SHOW MENU BAR

SHOW MENU BAR
Does not require any parameters

## Description

The **SHOW MENU BAR** command makes the menu bar visible.
If the menu bar was already visible, the command does nothing.

## Example

See example for the **HIDE MENU BAR** command.

# Windows Alt down

Windows Alt down -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | State of the Windows Alt key (Option key on Macintosh) |

## Description

**Windows Alt down** returns TRUE if the Windows Alt key is pressed.

**Note:** When called on a Macintosh platform, **Windows Alt down** returns TRUE if the Macintosh Option key is pressed.

## Example

See example for the **Shift down** command.

# Windows Ctrl down

Windows Ctrl down -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | Boolean | State of the Windows Ctrl key (Command key on Macintosh) |

## Description

**Windows Ctrl down** returns TRUE if the Windows Ctrl key is pressed.

**Note:** When called on a Macintosh platform, **Windows Ctrl down** returns TRUE if the Macintosh Command key is pressed.

## Example

See example for the **Shift down** command.

# _o_Get platform interface

_o_Get platform interface -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Current platform interface in use |

## Compatibility Note

The platform interface is now managed automatically by 4D. This command should not be used since it no longer returns significant values.

# _o_INVERT BACKGROUND

_o_INVERT BACKGROUND ( {* ;} textObject )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | Allows entry of a variable or object name |
| textObject | Variable, Field | ⇒ | Text variable or field to invert |

## Description

This command is no longer supported in 4D.

# _o_SET PLATFORM INTERFACE

_o_SET PLATFORM INTERFACE ( interface )

| Parameter | Type | | Description |
|---|---|---|---|
| interface | Longint | ⇒ | New platform interface setting: -1 Automatic 0 Mac OS 7 1 Windows 3.11, NT 3.51 2 Windows 9x 3 Mac OS 9 4 Mac Theme |

## Compatibility Note

The platform interface is managed automatically by 4D. This command is now ignored and must no longer be used.

# Users and Groups

- BLOB TO USERS
- CHANGE CURRENT USER
- CHANGE LICENSES
- CHANGE PASSWORD
- Current user
- DELETE USER
- EDIT ACCESS
- Get default user
- GET GROUP LIST
- GET GROUP PROPERTIES
- Get plugin access
- GET USER LIST
- GET USER PROPERTIES
- Is license available
- Is user deleted
- Set group properties
- SET PLUGIN ACCESS
- Set user properties
- User in group
- USERS TO BLOB
- Validate password

# BLOB TO USERS

BLOB TO USERS ( users )

| Parameter | Type | | Description |
|---|---|---|---|
| users | BLOB | ⇒ | BLOB (encrypted) containing database user accounts created and saved by the database Administrator |

## Description

The **BLOB TO USERS** command replaces the user accounts and groups created by the Administrator in the database with the ones found in the BLOB *users*. The BLOB *users* is encrypted and must have been created using the **USERS TO BLOB** command.

Only the database Administrator or Designer can execute this command. If another user attempts to execute it, the command does nothing and a privilege error (-9949) is generated.

This command causes the replacement of any existing accounts and groups created by the Administrator in the database. If the BLOB *users* contains valid data, the command performs the following operations:

- all users and groups defined in the database whose reference numbers are negative (groups and users created by the Administrator) are removed from the structure,
- all users and groups found in the BLOB *users* are added to the structure.

**Compatibility note:** User and group files (.4UG extension) created by the **Save Groups...** menu command in versions of 4D prior to 2004 can be loaded in 4D version 2004 and higher using the following sequence:

```
DOCUMENT TO BLOB(mydoc;blob)
BLOB TO USERS(blob)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

# CHANGE CURRENT USER

CHANGE CURRENT USER {( user ; password )}

| Parameter | Type | | Description |
|---|---|---|---|
| user | String, Longint | ➡ | Name or unique user ID |
| password | String | ➡ | Password (not encrypted) |

## Description

**CHANGE CURRENT USER** changes the identity of the current user in the database, without needing to quit. The user can change their identity themselves either using the database connection dialog box (when the command is called without parameters) or directly via the command. When a user changes their identity, they abandon any former access privileges in favor of those belonging to the chosen user.

If the **CHANGE CURRENT USER** command is executed without parameters, the database connection dialog box appears. The user must then enter or select a valid name and password in order to enter the database. The contents of the connection dialog box will depend on the options set on the **Security** page of the Database Settings.

**Note:** The access control system must be enabled in order to use this command, i.e. a password must have been assigned to the *Designer*. Otherwise, **CHANGE CURRENT USER** has no effect and does not display the standard window for switching users.

You can also pass the two optional *user* and *password* parameters to specify by programming the new account to be used. In the *user* parameter, pass the name or unique user ID (*userRef*) of the account to be used. The user names and IDs can be obtained using the **GET USER LIST** command.

| User ID | User description |
|---|---|
| 1 | Designer |
| 2 | Administrator |
| 3 to 15000 | User created by the Designer<br>(user No. 3 is the first user created by the Designer, user No. 4 is the second, etc.). |
| -11 to -15010 | User created by the Administrator<br>(user No. -11 is the first user created by the Administrator, user No. -12 is the second, etc.). |

If the user account does not exist or was deleted, error -9979 is returned. You can intercept this error with the error-handling method installed by the **ON ERR CALL** command. Otherwise, you can call the function **Is user deleted** to test the user account before calling this command.

Pass the non-encrypted user account password in the *password* parameter. If the password does not match the user, the command will return error message -9978 and do nothing.

The command execution is now delayed to prevent flooding (brute force attack), in other words, attempts of multiple user name/password combinations. As a result, after the 4th call to this command, it is run only after a period of 10 seconds. This delay is throughout the entire work station.

### Offering a custom access management dialog box

The **CHANGE CURRENT USER** command can be used to set up custom dialog boxes for entering the name and password (with entry and expiration rules) that benefit from the same advantages as the access control system of 4D.
Here is how It works:

**1.** The database is entered directly in the “Default user” mode, without a dialog box.

**2.** The **On Startup database method** displays a custom dialog box for entering the user name and password. All types of processing are foreseeable in the dialog box:
- You can display the list of database users, as in the standard access dialog box of 4D, using the **GET USER LIST** command.
- The password entry field can contain various controls to check the validity of the entered characters (minimum number of characters, uniqueness, etc.).
- If you want the characters of passwords being entered to be masked on screen, you can use the **FILTER KEYSTROKE** command with the special *%password* font.
- Expiration rules can be applied at the moment when the dialog box is validated: expiration date, forced change to the initial connection, locking of account after several incorrect entries, memorization of passwords already used, etc.

**3.** When the entry is validated, the required information (user name and password) are passed to the **CHANGE CURRENT USER** command in order to open the database with the user account privileges.

## Example

The following example displays the connection dialog box:

```
CHANGE CURRENT USER
```

# CHANGE LICENSES

CHANGE LICENSES
Does not require any parameters

## Description

The **CHANGE LICENSES** command displays the 4D License Manager dialog box.

This command can only be used with 4D single-user applications and cannot be called from a component. When passwords are enabled, this command can only be executed by the Designer or Administrator; it does nothing when it is called by users that do not have appropriate access rights.

Using the License Manager dialog box, a user can activate plug-ins or the Web server on the machine where it is executed. In 4D, you can display this dialog box by selecting the **License Manager...** command in the **Help** menu.

**CHANGE LICENSES** is a convenient way to activate licenses and add expansion numbers in a compiled single-user 4D application distributed to customers. 4D developers or IS managers can use this command to distribute a 4D application and let users enter their license without sending an update of the application each time.

For more information about this dialog box, refer to the **Installation and activation** section in the *4D Installation Guide*.

## Example

In a custom configuration or preferences dialog box, you include a button whose associated method is:

```
 // Object method for bLicense button
CHANGE LICENSES
```

This way a user can activate licenses without having to modify the database.

# CHANGE PASSWORD

CHANGE PASSWORD ( password )

| Parameter | Type | | Description |
|---|---|---|---|
| password | String | ➡ | New password |

## Description

**CHANGE PASSWORD** changes the password of the current user. This command replaces the current password with the new password you pass in *password*.

**Warning:** Password are case-sensitive.

## Example

The following example allows the user to change his or her password.

```
CHANGE CURRENT USER ` Present user with password dialog
If(OK=1)
   $pw1:=Request("Enter new password for "+Current user)
 ` The password should be at least five characters long
   If(((OK=1)&($pw1#""))&(Length($pw1)>5))
 ` Make sure the password has been entered correctly
      $pw2:=Request("Enter password again")
      If((OK=1)&($pw1=$pw2))
         CHANGE PASSWORD($pw2) ` Change the password
      End if
   End if
End if
```

# Current user

Current user -> Function result

| Parameter | Type | Description |
|---|---|---|
| Function result | String | User name of the current user |

## Description

**Current user** returns the user name of the current user.

## Example

See example for the **User in group** command.

# DELETE USER

DELETE USER ( userID )

| Parameter | Type | | Description |
|---|---|---|---|
| userID | Longint | ➡ | ID number of user to delete |

## Description

The **DELETE USER** command deletes the user whose unique user ID number you pass in *userID*. You must pass a valid user ID number returned by the **GET USER LIST** command.

If the user account does not exist or has already been deleted, the error -9979 is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

Only the Designer and Administrator can delete users. It is not possible for the Administrator to delete a user created by the Designer.

Deleted user names no longer appear in the Users editor displayed when you call **EDIT ACCESS**, nor in the Design mode. Note that the numbers for deleted users can be reassigned when new user accounts are created.

## Error management

If you do not have the proper access privileges for calling **DELETE USER** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# EDIT ACCESS

EDIT ACCESS
Does not require any parameters

## Description

**EDIT ACCESS** lets the user edit the password system. When this command is executed, the Toolbox window with only the Users and User groups pages appears.

**Note:** This command opens a modal window so you must not call it from another modal window; if you do, it will not do anything.

Groups can be edited by the Designer, the Administrator and group owners. The Designer and the Administrator can edit any group. Group owners can edit only the groups they own. Users can be added to and removed from groups. The command has no effect if no groups are defined.

The Designer and the Administrator can add new users, as well as assign them to groups.

## Example

The following example displays the Users and User groups management window to the user:

```
EDIT ACCESS
```

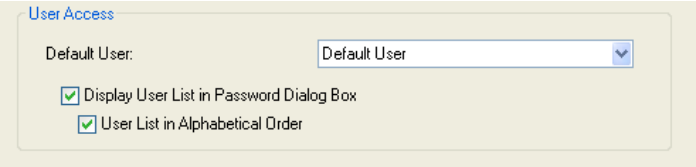
# Get default user

Get default user -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ⮌ | Unique user ID number |

## Description

The **Get default user** command returns the unique user ID of the user set as “Default user” in the database Preferences dialog box:



The following numbers can be used as user IDs:

| ID | User description |
|---|---|
| 1 | Designer |
| 2 | Administrator |
| 3 to 15000 | User created by Designer (user #3 is the 1st user created by Designer, user #4 is the second, and so on). |
| -11 to -15010 | User created by the Administrator (user #-11 is the 1st user created by Administrator, user #-12 is the second, and so on). |

If no default user has been set, the command returns 0.

# GET GROUP LIST

GET GROUP LIST ( groupNames ; groupNumbers )

| Parameter | Type | | Description |
|---|---|---|---|
| groupNames | String array | ⇐ | Names of the groups as they appear in the Password editor window |
| groupNumbers | Longint array | ⇐ | Corresponding unique group ID numbers |

## Description

**GET GROUP LIST** populates the arrays *groupNames* and *groupNumbers* with the names and unique ID numbers of the groups as they appear in the Password editor window.

The array *groupNumbers*, synchronized with *groupNames*, is filled with the corresponding unique group ID numbers. These numbers can have the following ranges:

| Group ID number | Group description |
|---|---|
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer,group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

## Error management

If you do not have the proper access privileges for calling **GET GROUP LIST** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# GET GROUP PROPERTIES

GET GROUP PROPERTIES ( groupID ; name ; owner {; members} )

| Parameter | Type | | Description |
|---|---|---|---|
| groupID | Longint | ⇒ | Unique group ID number |
| name | String | ⇐ | Name of the group |
| owner | Longint | ⇐ | User ID number of group owner |
| members | Longint array | ⇐ | Group members |

## Description

**GET GROUP PROPERTIES** returns the properties of the group whose unique group ID number you pass in *groupID*. You must pass a valid group ID number returned by the command **GET GROUP LIST**. Group ID numbers can have the following values or ranges:

| Group ID number | Group description |
|---|---|
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

If you do not pass a valid group ID number, **GET GROUP PROPERTIES** returns empty parameters.

After the call, you retrieve the name and owner of the group, in the parameters *name* and *owner*.

If you pass the optional *members* parameter, the unique ID numbers of the users and groups belonging to the group are returned. Member ID numbers can have the following ranges:

| Member ID number | Member Description |
|---|---|
| 1 | Designer user |
| 2 | Administrator user |
| 3 to 15000 | User created by the Designer of the database<br>(user #3 is the first user created by the Designer, user #4 the second, and so on). |
| -11 to -15000 | User created by the Administrator of the database<br>(user #-11 is the first user created by the Designer, user #-12 is the second, and so on). |
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

## Error management

If you do not have the proper access privileges for calling **GET GROUP PROPERTIES** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# Get plugin access

Get plugin access ( plugIn ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| plugIn | Longint | ⇒ | Plug-in number |
| Function result | String | ⇐ | Group name associated with plug-in |

## Description

The **Get plugin access** command returns the name of the user group authorized to use the plug-in whose number was passed in the *plugIn* parameter. If there is no group associated with the plug-in, the command returns an empty string ("").

Pass the number of the plug-in for which you want to find out the associated group of users in the *plugIn* parameter. Plug-in licenses include 4D Client Web and SOAP licenses. You can pass one of the following constants found in the **Is License Available** theme:

| Constant | Type | Value |
|---|---|---|
| 4D Client SOAP license | Longint | 808465465 |
| 4D Client Web license | Longint | 808465209 |
| 4D Draw license | Longint | 808464694 |
| 4D for ADO license | Longint | 808465714 |
| 4D for MySQL license | Longint | 808465712 |
| 4D for OCI license | Longint | 808465208 |
| 4D for PostgreSQL license | Longint | 808465713 |
| 4D for Sybase license | Longint | 808465715 |
| 4D ODBC Pro license | Longint | 808464946 |
| 4D View license | Longint | 808465207 |
| 4D Write license | Longint | 808464697 |

# GET USER LIST

GET USER LIST ( userNames ; userNumbers )

| Parameter | Type | | Description |
|---|---|---|---|
| userNames | String array | ⇦ | User names as they appear in the Password editor window |
| userNumbers | Longint array | ⇦ | Corresponding unique user ID numbers |

## Description

**GET USER LIST** populates the arrays *userNames* and *userNumbers* with the names and unique ID numbers of the users as they appear in the Passwords window.

The array *userNames* is filled with the user names displayed in the Passwords window, including users whose accounts are disabled (user names displayed in green in the Passwords window).

**Note:** Use the **Is user deleted** command to detect deleted users.

The array *userNumbers*, synchronized with *userNames*, is filled with the corresponding unique user ID numbers. These numbers can have the following values or ranges:

| User ID number | User description |
|---|---|
| 1 | Designer user |
| 2 | Administrator user |
| 3 to 15000 | User created by the Designer of the database<br>(user #3 is the first user created by the Designer, user #4 the second, and so on). |
| -11 to -15000 | User created by the Administrator of the database<br>(user #-11 is the first user created by the Designer, user #-12 is the second, and so on). |

## Error management

If you do not have the proper access privileges for calling **GET USER LIST** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# GET USER PROPERTIES

GET USER PROPERTIES ( userID ; name ; startup ; password ; nbLogin ; lastLogin {; memberships {; groupOwner}} )

| Parameter | Type | | Description |
|---|---|---|---|
| userID | Longint | ⇒ | Unique user ID number |
| name | String | ⇐ | Name of the user |
| startup | String | ⇐ | Startup method name |
| password | String | ⇐ | Always an empty string |
| nbLogin | Longint | ⇐ | Number of logins to the database |
| lastLogin | Date | ⇐ | Date of last login to the database |
| memberships | Longint array | ⇐ | ID numbers of groups to which the user belongs |
| groupOwner | Longint | ⇐ | ID number of user group owner |

## Description

**GET USER PROPERTIES** returns the information about the user whose unique user ID number you pass in *userID*. You must pass a valid user ID number returned by the **GET USER LIST** command.

If the user account does not exist or has been deleted, the error -9979 is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**. Otherwise, you can call **Is user deleted** to test the user account before calling **GET USER PROPERTIES**.

User ID numbers can have the following values or ranges:

| User ID number | User description |
|---|---|
| 1 | Designer user |
| 2 | Administrator user |
| 3 to 15000 | User created by the Designer of the database<br>(user #3 is the first user created by the Designer, user #4 the second, and so on). |
| -11 to -15000 | User created by the Administrator of the database<br>(user #-11 is the first user created by the Designer, user #-12 is the second, and so on). |

After the call, you retrieve the name, startup method, encrypted password, number of logins and date of last login for the user, in the parameters *name*, *startup*, *password*, *nbLogin* and *lastLogin*.

**Note:** The *password* parameter is obsolete (it always returns an empty string). If you want to check a user's password, use the **Validate password** function.

If you pass the optional *memberships* parameter, the unique ID numbers of the groups to which the user belongs are returned. Group ID numbers can have the following ranges:

If you pass the optional *groupOwner* parameter, you get the ID number of the user group “owner”, i.e. the default owner group of the objects created by this user.

The group ID numbers can be the following:

| Group ID number | Group description |
|---|---|
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

## Error management

If you do not have the proper access privileges for calling **GET USER PROPERTIES** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# Is license available

Is license available {( license )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| license | Longint | ⇒ | Plug-in for which license validity testing is desired |
| Function result | Boolean | ⇐ | True if plug-in is available, otherwise False |

## Description

The **Is license available** command lets you find out the availability of a plug-in. It is useful, for instance, for displaying or hiding functions requiring the presence of a plug-in.

The **Is license available** command can be used in three different ways:

- The *license* parameter is omitted: in this case, the command returns **False** if the 4D application is in demonstration mode.
- You pass one of the constants of the "**Is License Available**" theme in the *license* parameter:

| Constant | Type | Value |
|---|---|---|
| 4D Client SOAP license | Longint | 808465465 |
| 4D Client Web license | Longint | 808465209 |
| 4D Draw license | Longint | 808464694 |
| 4D for ADO license | Longint | 808465714 |
| 4D for MySQL license | Longint | 808465712 |
| 4D for OCI license | Longint | 808465208 |
| 4D for PostgreSQL license | Longint | 808465713 |
| 4D for Sybase license | Longint | 808465715 |
| 4D Mobile license | Longint | 808464439 |
| 4D Mobile Test license | Longint | 808465719 |
| 4D ODBC Pro license | Longint | 808464946 |
| 4D SOAP license | Longint | 808465464 |
| 4D View license | Longint | 808465207 |
| 4D Web license | Longint | 808464945 |
| 4D Write license | Longint | 808464697 |

  In this case, the command returns **True** if the corresponding plug-in has a license available. The command takes into account any licenses attributed in Design mode or via the **SET PLUGIN ACCESS** command.
  **Is license available** returns **False** if the plug-in is operating in demo mode.
- You pass the ID number of the plug-in "4BNX" resource directly in the license parameter. In this case, the command behaves as described above.

# Is user deleted

Is user deleted ( userNumber ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| userNumber | Longint | ⇒ | User ID number |
| Function result | Boolean | ⇐ | TRUE = User account is deleted or does not exist FALSE = User account is active |

## Description

The **Is user deleted** command tests the user account whose unique user ID number you pass in *userID*.

If the user account does not exist or has been deleted, **Is user deleted** returns TRUE. Otherwise, it returns FALSE.

## Error management

If you do not have the proper access privileges for calling **Is user deleted** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# Set group properties

Set group properties ( groupID ; name ; owner {; members} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| groupID | Longint | ⇒ | Unique ID number of group, or -1 for adding a Designer group, or -2 for adding an Administrator group |
| name | String | ⇒ | New group name |
| owner | Longint | ⇒ | User ID number of new group owner |
| members | Longint array | ⇒ | New group members |
| Function result | Longint | ⇐ | Unique ID number of new group |

## Description

**Set group properties** enables you to change and update the properties of an existing group whose unique group ID number you pass in *groupID*, or to add a new group affiliated with the Designer or the Administrator.

If you are changing the properties of an existing group, you must pass a valid group ID number returned by the command **GET GROUP LIST**. Group ID numbers can have the following values or ranges:

| Group ID number | Group description |
|---|---|
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

To add a new group affiliated with the Designer, pass -1 in *groupID*. To add a new group affiliated with the Administrator, pass -2 in *groupID*. After the call, if the group is successfully added, its unique ID number is returned in *groupID*.

If you do not pass -1, -2 or a valid group ID number, **Set group properties** does nothing.

Before the call, you pass the new name and owner of the group in the parameters *name* and *owner*.If you do not want to change all the properties of the group (besides the members, see below), first call **GET GROUP PROPERTIES** and pass the returned values for the properties you want to leave unchanged.

If you do not pass the optional *members* parameter, the current member list of the group is left unchanged. If you do not pass *members* while adding a group, the group will have no members.

**Note:** The group owner is not automatically set as a member of the group that he or she owns. It is up to you to include the group owner in the group, using the *members* parameter.

If you pass the optional *members* parameter, you change the whole member list for the group. Before the call, you must populate the array *members* with the unique ID numbers of the users and groups the group will get as members. Member ID numbers can have the following ranges:

| Member ID number | Member Description |
|---|---|
| 1 | Designer user |
| 2 | Administrator user |
| 3 to 15000 | User created by the Designer of the database<br>(user #3 is the first user created by the Designer, user #4 the second, and so on). |
| -11 to -15000 | User created by the Administrator of the database<br>(user #-11 is the first user created by the Designer, user #-12 is the second, and so on). |
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

To remove all the members from a group, pass an empty *members* array.

## Error management

If you do not have the proper access privileges for calling **Set group properties** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# SET PLUGIN ACCESS

SET PLUGIN ACCESS ( plugIn ; group )

| Parameter | Type | | Description |
|---|---|---|---|
| plugIn | Longint | ⇒ | Plug-in number |
| group | String | ⇒ | Group name to associate with plug-in |

## Description

The **SET PLUGIN ACCESS** command sets, by programming, the user group allowed to use each “serialized” plug-in that is installed in the database. This way you can manage how plug-in licenses are used.

**Note:** This can also be done in the Design environment using the Groups editor.

Pass the number of the plug-in to be associated with a group of users in the *plugIn* parameter. Plug-in licenses include 4D Client Web and SOAP licenses. You can pass one of the following constants found in the **Is License Available** theme:

| Constant | Type | Value |
|---|---|---|
| 4D Client SOAP license | Longint | 808465465 |
| 4D Client Web license | Longint | 808465209 |
| 4D Draw license | Longint | 808464694 |
| 4D for ADO license | Longint | 808465714 |
| 4D for MySQL license | Longint | 808465712 |
| 4D for OCI license | Longint | 808465208 |
| 4D for PostgreSQL license | Longint | 808465713 |
| 4D for Sybase license | Longint | 808465715 |
| 4D ODBC Pro license | Longint | 808464946 |
| 4D View license | Longint | 808465207 |
| 4D Write license | Longint | 808464697 |

Pass the name of the group whose users are authorized to use the plug-in in *group*.

**Note:** Only one group at a time can be allowed to use a plug-in. When this command is executed, if another group had the plug-in access rights, it loses this privilege.

# Set user properties

Set user properties ( userID ; name ; startup ; password ; nbLogin ; lastLogin {; memberships {; groupOwner}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| userID | Longint | ➡ | Unique ID number of user account, or -1 for adding a user affiliated with the Designer, or -2 for adding a user affiliated with the Administrator |
| name | String | ➡ | New user name |
| startup | String | ➡ | Name of new user startup method |
| password | String | ➡ | New (unencrypted) password, or * to leave the password unchanged |
| nbLogin | Longint | ➡ | New number of logins to the database |
| lastLogin | Date | ➡ | New date of last login to the database |
| memberships | Longint array | ➡ | ID numbers of groups to which the user belongs |
| groupOwner | Longint | ➡ | Reference number of user group owner |
| Function result | Longint | ⬅ | Unique ID number of new user |

## Description

**Set user properties** lets you change and update the properties of an existing user account whose unique user ID number you pass in *userID*, or add a new user affiliated with the Designer or the Administrator.

If you are changing the properties of an existing user account, you must pass a valid user ID number returned by the **GET USER LIST** command.

If the user account does not exist or has been deleted, the error -9979 is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**. Otherwise, you can call **Is user deleted** to test the user account before calling **Set user properties**.

User ID numbers can have the following values or ranges:

| User ID number | User description |
|---|---|
| 1 | Designer user |
| 2 | Administrator user |
| 3 to 15000 | User created by the Designer of the database (user #3 is the first user created by the Designer, user #4 the second, and so on). |
| -11 to -15000 | User created by the Administrator of the database (user #-11 is the first user created by the Administrator, user #-12 is the second, and so on). |

To add a new user affiliated with the Designer pass -1 in *userID*. To add a new user affiliated with the Administrator pass -2 in *userID*.
After the call, if the user is successfully added or modified, its unique ID number is returned in *userID*.

If you do not pass -1, -2 or a valid user ID number, **Set user properties** does nothing.

Before the call, you pass the new name, startup method, password, number of logins and date of last login for the user, in the *name*, *startup*, *password*, *nbLogin* and *lastLogin* parameters.You pass an unencrypted password in the *password* parameter. 4D will encrypt it for you before saving it in the user account.
If the new user name passed in *name* is not unique (there is already a user with the same name), the command does nothing and the error -9979 is returned. You can catch this error with an error-handling method installed using **ON ERR CALL**.

If you do not want to change all the properties of the user (aside from the memberships, see below), first call **GET USER PROPERTIES** and pass the returned values for the properties you want to leave unchanged.

If you do not want to change the password for an account, pass the * symbol as a value for the *password* parameter. This allows you to change the other properties of the user account without changing the password for the account.

If you do not pass the optional *memberships* parameter, the current memberships of the user are left unchanged. If you do not pass *memberships* when adding a user, the user will not belong to any group.
If you pass the optional *memberships* parameter, you change all the memberships for the user. Before the call, you must populate the *memberships* array with the unique ID numbers of the groups to which the user will belong.

If you pass the optional *groupOwner* parameter, you indicate the ID number of the user group “owner”, i.e. the default owner group of the objects created by this user.

The group ID numbers can be the following:

| Group ID number | Group description |
|---|---|
| 15001 to 32767 | Group created by the Designer or affiliated Group Owner<br>(group #15001 is the first group created by the Designer, group #15002 the second, and so on). |
| -15001 to -32768 | Group created by the Administrator or affiliated Group Owner<br>(group #-15001 is the first group created by the Administrator, group #-15002 the second, and so on). |

To revoke all the memberships of a user, pass an empty *memberships* array.

## Error management

If you do not have the proper access privileges for calling **Set user properties** or if the Password system is already accessed by another process, an access privilege error is generated. You can catch this error with an error-handling method installed using **ON ERR CALL**.

# User in group

User in group ( user ; group ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| user | String | ⇒ | User name |
| group | String | ⇒ | Group name |
| Function result | Boolean | ⇐ | TRUE = user is in group FALSE = user is not in group |

## Description

**User in group** returns TRUE if *user* is in *group*.

## Example

The following example searches for specific invoices. If the current user is in the Executive group, he or she is allowed access to forms that display confidential information. If the user is not in the Executive group, a different form is displayed:

```
QUERY([Invoices];[Invoices]Retail>100)
If(User in group(Current user;"Executive"))
   FORM SET OUTPUT([Invoices];"Executive Output")
   FORM SET INPUT([Invoices];"Executive Input")
Else
   FORM SET OUTPUT([Invoices];"Standard Output")
   FORM SET INPUT([Invoices];"Standard Input")
End if
MODIFY SELECTION([Invoices];*)
```

# USERS TO BLOB

USERS TO BLOB ( users )

| Parameter | Type | | Description |
|---|---|---|---|
| users | BLOB | ⇨ | BLOB that must contain users |
| | | ⇦ | User accounts (encrypted) |

## Description

The **USERS TO BLOB** command stores in the BLOB *users* the list of all user accounts and database groups created by the Administrator.

Only the database Administrator or the Designer can execute this command. If another user tries to execute it, the command does nothing and a privilege error (-9949) is generated.

The generated BLOB is encrypted automatically and can only be read using the **BLOB TO USERS** command. You can store this BLOB in a file on your hard disk or in a field.

This command is the equivalent of recording groups and users from the Toolbar. The only difference is that it lets you store user accounts in a BLOB field and not just in a file.

This lets you keep a backup of users in the database data and, as such, implements a backup mechanism as well as a system to load users automatically when a database structure file is updated (information related to user accounts are stored by 4D in the database structure file).

# Validate password

Validate password ( userID ; password {; digest} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| userID | Longint, String | ⇒ | Unique user ID or User name |
| password | String | ⇒ | Unencrypted password |
| digest | Boolean | ⇒ | Digest password = True, Plain-text password (default) = False |
| Function result | Boolean | ⇐ | True = valid password False = invalid password |

## Description

**Validate password** returns True if the string passed in *password* is the password for the user account whose ID number or name is passed in *userID*.

The optional *digest* parameter indicates whether the *password* parameter contains a plain-text password or a hashed password (digest mode):

- When you pass **True**, this indicates that *password* contains a hashed password (digest mode),
- When you pass **False** or omit this parameter, this indicates that *password* contains a plain-text password.

This parameter is particularly helpful when using authentication database methods, in particular the **On 4D Mobile Authentication database method**.

The command execution is now delayed to prevent flooding (brute force attack), in other words, attempts of multiple user name/password combinations. As a result, after the 4th call to this command, it is run only after a period of 10 seconds. This delay is throughout the entire work station.

## Example 1

This example checks whether the password of the user “Hardy” is “Laurel”:

```
GET USER LIST(atUserName;alUserID)
$vlElem:=Find in array(atUserName;"Hardy")
If($vlElem>0)
   If(Validate password(alUserID{$vlElem};"Laurel"))
      ALERT("Yep!")
   Else
      ALERT("Too bad!")
   End if
Else
   ALERT("Unknown user name")
End if
```

## Example 2

In the **On 4D Mobile Authentication database method**, you want to test a connection request (using the 4D users of the database). You can just write:

```
$0:=Validate password($1;$2;$3)
```

# Variables

- CLEAR VARIABLE
- LOAD VARIABLES
- SAVE VARIABLES
- Undefined

# CLEAR VARIABLE

CLEAR VARIABLE ( variable )

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ⇨ | Variable to clear |

## Description

**CLEAR VARIABLE** resets *variable* to its default type value (i.e., empty string for String and Text variables, *0* for numeric variables, no elements for arrays, etc.). The variable still exists in memory.

The variable you pass in *variable* can be a local, process or interprocess variable.

**Note:** You do not need to clear process variables when a process ends; 4D clears them automatically. Similarly, each local variable is automatically cleared when the method in which it was created completes execution.

## Example

In a form, you are using the drop-down list *asMyDropDown* whose sole purpose is user interface. In other words, you use that array during data entry, but once you are done with the form, you will no longer use that array. Consequently, during the On Unload event, you just get rid of the array:

```
   ` asMyDropDown drop-drop list object method
Case of
   :(Form event=On Load)
   ` Initialize the array one way or another
      ARRAY STRING(63;asMyDropDown;...)
   ` ...
   :(Form event=On Unload)
   ` No longer need the array
      CLEAR VARIABLE(asMyDropDown)
   ` ...
End case
```

# LOAD VARIABLES

LOAD VARIABLES ( document ; variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document containing 4D variables |
| variable | Variable | ⇒ | Variables to receive the values |

## Description

The **LOAD VARIABLES** command loads one or more variables from the document specified by *document*. The document must have been created using the **SAVE VARIABLES** command.

The variables *variable*, *variable2*...*variableN* are created; if they already exist, they are overwritten.

If you supply an empty string for *document*, the standard Open File dialog box appears, so the user can choose the document to open. If a document is chosen, the 4D system variable *Document* is set to the name of the document.

In compiled databases, each variable must be of the same type as those loaded from disk.

**WARNING:** This command does not support array variables. Use the new BLOB commands instead.

## Example

The following example loads three variables from a document named UserPrefs:

```
LOAD VARIABLES("User Prefs";vsName;vlCode;vgIconPicture)
```

## System variables and sets

If the variables are loaded properly, the **OK** system variable is set to 1; otherwise it is set to 0.

# SAVE VARIABLES

SAVE VARIABLES ( document ; variable {; variable2 ; ... ; variableN} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document in which to save the variables |
| variable | Variable | ⇒ | Variables to save |

## Description

The **SAVE VARIABLES** command saves one or more variables in the document whose name you pass in *document*.

The variables do not need to be of the same type, but must be of the String, Text, Real, Integer, Long Integer, Date, Time, Boolean, or Picture type.

If you pass an empty string for *document*, the standard Save File dialog box appears; the user can then choose the document to create. In this case, the 4D system variable *Document* is set to the name of the document if one is created.

If the variables are properly saved, the OK variable is set to 1. If not, OK is set to 0.

**Note:** When you write variables to documents with **SAVE VARIABLES**, 4D uses an internal data format. You can retrieve the variables only with the **LOAD VARIABLES** command. Do not use **RECEIVE PACKET** or **RECEIVE VARIABLE** to read a document created by **SAVE VARIABLES**.

**WARNING:** This command does not support array variables. Use the new BLOB commands instead.

## Example

The following example saves three variables to a document named UserPrefs:

```
SAVE VARIABLES("User Prefs";vsName;vlCode;vgIconPicture)
```

## System variables and sets

If the variables are saved properly, the **OK** system variable is set to 1; otherwise it is set to 0.

# Undefined

Undefined ( variable ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ⇒ | Variable to test |
| Function result | Boolean | ⇐ | True = Variable is currently undefined False = Variable is currently defined |

## Description

**Undefined** returns True if *variable* has not been defined, and False if *variable* has been defined. A variable is defined if it has been created via a compilation directive or if a value is assigned to it. It is undefined in all other cases.

If the database has been compiled, the **Undefined** function returns False for all variables.

## Example

The following code manages the creation of processes when a menu item for a particular module of your application is chosen. If the process already exists, you bring it to the front; if it does not exist, you start it. To do so, for each module of the application, you maintain an interprocess variable ◊*PID_...* that you initialize in the **On Startup database method**.

When developing the database, you add new modules. Instead modifying the **On Startup database method** (to add the initialization of the corresponding ◊*PID_...*) and then reopening the database to reinitialize everything each time you add a module, you use the **Undefined** command to manage the addition of the new module, on the fly:

```
 //M_ADD_CUSTOMERS global procedure

If(Undefined(◊PID_ADD_CUSTOMERS)) // Takes care of intermediate development stages
   C_LONGINT(◊PID_ADD_CUSTOMERS)
   ◊PID_ADD_CUSTOMERS:=0
End if

If(◊PID_ADD_CUSTOMERS=0)
   ◊PID_ADD_CUSTOMERS:=New process("P_ADD_CUSTOMERS";64*1024;"P_ADD_CUSTOMERS")
Else
   SHOW PROCESS(◊PID_ADD_CUSTOMERS)
   BRING TO FRONT(◊PID_ADD_CUSTOMERS)
End if
 //Note: P_ADD_CUSTOMERS, the process master method,
 // sets ◊PID_ADD_CUSTOMERS to zero when it ends.
```

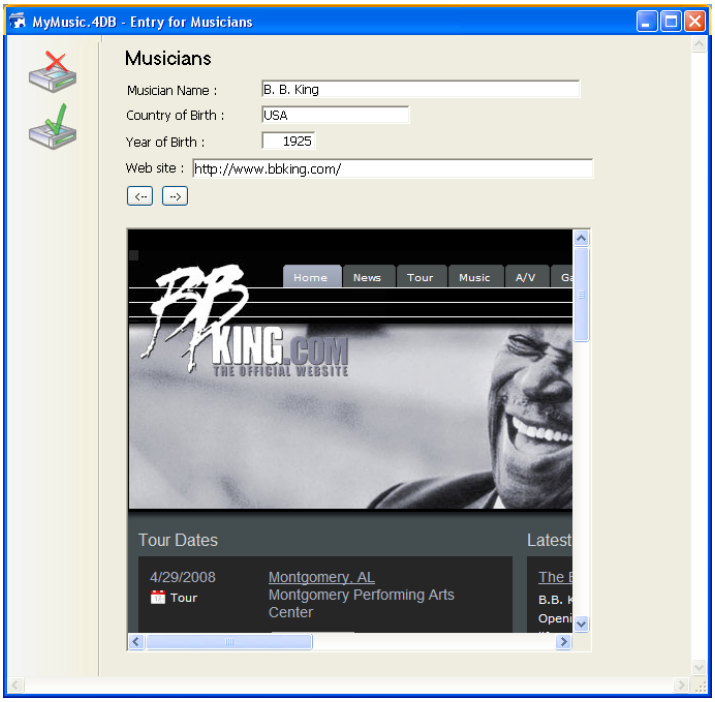
# Web Area

- Programmed management of Web Areas
- WA Back URL available
- WA Create URL history menu
- WA Evaluate JavaScript
- WA EXECUTE JAVASCRIPT FUNCTION
- WA Forward URL available
- WA Get current URL
- WA GET EXTERNAL LINKS FILTERS
- WA Get last filtered URL
- WA GET LAST URL ERROR
- WA Get page content
- WA Get page title
- WA GET PREFERENCE
- WA GET URL FILTERS
- WA GET URL HISTORY
- WA OPEN BACK URL
- WA OPEN FORWARD URL
- WA OPEN URL
- WA REFRESH CURRENT URL
- WA SET EXTERNAL LINKS FILTERS
- WA SET PAGE CONTENT
- WA SET PAGE TEXT LARGER
- WA SET PAGE TEXT SMALLER
- WA SET PREFERENCE
- WA SET URL FILTERS
- WA STOP LOADING URL

# Programmed management of Web Areas

The commands of this theme are dedicated to the programmed management of Web Area type form objects.

Web areas can display any type of Web content(*) within your 4D environment: HTML pages with static or dynamic contents, files, pictures, Javascript, etc. The following picture shows a Web area included in a form and displaying an HTML page:



(*) However, the use of Web plugins and Java applets is not recommended (see **Notes about use of Web areas**).

In addition to the commands of the Web Area theme, several standard actions and form events allow the developer to control the functioning of these Web areas. Specific variables can be used to exchange information between the area and the 4D environment. These tools can be used to develop a basic Web browser in your forms.

## Creating and addressing a Web area

A Web area is created using a variant of the Plug-in Area/Subform button found in the object bar of the 4D Form editor (for more information, please refer to **Web areas** in the *Design Reference* manual).

**Note:** When a Web area that uses the embedded Web rendering engine is displayed in a new process, in particular one created with the **New process** command, it is necessary to use the default value (0) for the *stack* parameter in order to ensure its correct display.

Like other dynamic form objects, a Web area has an object name and a variable name, which can be used to handle it by programming. The standard variable associated with a Web area object is of the Text type. More specifically, you can use the **OBJECT SET VISIBLE** and **OBJECT MOVE** commands with Web areas.

**Note**: The text variable associated with the Web area does not contain a reference therefore it cannot be passed as a parameter for a method. For example, for a Web area named *MyArea*, the following code cannot be used:

```
Mymethod(MyArea)
```

Code for Mymethod:

```
WA REFRESH CURRENT URL($1) //Does not work
```

For this type of programming, you will need to use pointers:

```
Mymethod(->MyArea)
```

Code for Mymethod:

```
WA REFRESH CURRENT URL($1->) //Works
```

## Management of associated variables

In addition to the standard object variable (see previous paragraph), two specific variables are automatically associated with each Web area:

- The "URL" variable
- The "Progression" variable.

You can name these variables as desired. These variables can be accessed in the Property List:

### URL Variable

"URL" is a String type variable. It contains the URL loaded or being loading by the associated Web area.
The association between the variable and the Web area works in both directions:

- If the user assigns a new URL to the variable, this URL is automatically loaded by the Web area.
- Any browsing done within the Web area will automatically update the contents of the variable.
  Schematically, this variable functions like the address area of a Web browser. You can represent it via a text area above the Web area.

**URL Variable and WA OPEN URL command**
The URL variable produces the same effects as the **WA OPEN URL** command. The following differences should nevertheless be noted:

- For access to documents, this variable only accepts URLs that are RFC-compliant ("file://c:/My%20Doc") and not system pathnames ("c:¥MyDoc"). The **WA OPEN URL** command accepts both notations.
- If the URL variable contains an empty string, the Web area does not attempt to load the URL. The **WA OPEN URL** command generates an error in this case.
- If the URL variable does not contain a protocol (http, mailto, file, etc.), the Web area adds "http://", which is not the case for the **WA OPEN URL** command.
- When the Web area is not displayed in the form (when it is located on another page of the form), executing the **WA OPEN URL** command has no effect, whereas assigning a value to the URL variable can be used to update the current URL.

### Progression Variable

"Progression" is a Longint type variable. It contains a value between 0 and 100, representing the percentage of loading that is complete for the page displayed in the Web area.
This variable is automatically updated by 4D. It is not possible to modify it manually.

## Accessing 4D methods

You can call 4D methods from the JavaScript code executed in a Web area and get values in return.

**Important:** This feature is only available if the Web area uses the embedded Web rendering engine.

### Configuring the Web area

To be able to call 4D methods from a Web area, you must check the **Access 4D methods** option for the area in the Property List:

**Note:** This option is only shown when **Use embedded Web rendering engine** option is checked.

When this property is checked, a special JavaScript object ($4d) is instantiated in the Web area, which you can use to manage calls to 4D project methods.

### Using the $4d object

When the **Access 4D methods** option is checked, the 4D embedded Web rendering engine supplies the area with a JavaScript object named *$4d* that you can associate with any 4D project method using the "." object notation.

For example, to call the ***HelloWorld*** 4D method, you just execute the following statement:

```
$4d.HelloWorld();
```

**Warning**: JavaScript is case sensitive so it is important to note that the object is named $4d (with a lowercase "d").

The syntax of calls to 4D methods is as follows:

```
$4d.4DMethodName(param1,paramN,function(result){})
```

- *param1...paramN*: You can pass as many parameters as you need to the 4D method.
  These parameters can be of any type supported by JavaScript (string, number, array, object).
- *function(result)*: Function to pass as last argument. This "callback" function is called synchronously once the 4D method finishes executing. It receives the *result* parameter:
  - *result*: Execution result of the 4D method, returned in the "$0" expression.
    This result can be of any type supported by JavaScript (string, number, array, object). You can use the **C_OBJECT** command to return the objects.
    **Note:** By default, 4D works in UTF-8. When you return text containing extended characters, for example characters with accents, make sure the encoding of the page displayed in the Web area is declared as UTF-8, otherwise the characters may be rendered incorrectly. In this case, add the following line in the HTML page to declare the encoding:
    <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" />

### Example 1

Given a 4D project method named ***today*** that does not receive parameters and returns the current date as a string.

4D code of ***today*** method:

```
C_TEXT($0)
$0:=String(Current date;System date long)
```

In the Web area, the 4D method can be called with the following syntax:

```
$4d.today()
```

The 4D method does not receive any parameters but it does return the value of *$0* to the callback function called by 4D after the execution of the method.
We want to display the date in the HTML page that is loaded by the Web area.

Here is the code of the HTML page:

```
<html> <head> <meta http-equiv="Content-Type" content="text/html; charset=UTF-8" /> <script type="text/javascript">
$4d.today(function(dollarZero) {     var curDate = dollarZero;     document.getElementById("mydiv").innerHTML=curDate; });
</script> </head> <body>Today is: <div id="mydiv"></div> </body> </html>
```

### Example 2

The 4D project method ***calcSum*** receives parameters ($1...$n) and returns their sum in $0:

4D code of ***calcSum*** method:

```
C_REAL(${1}) // receives n REAL type parameters
C_REAL($0) // returns a Real
C_LONGINT($i;$n)
$n:=Count parameters
For($i;1;$n)
   $0:=$0+${$i}
End for
```

The JavaScript code run in the Web area is:

```
$4d.calcSum(33, 45, 75, 102.5, 7, function(dollarZero)     {         var result = dollarZero // result is 262.5     });
```

## Form events

Specific form events are intended for programmed management of Web areas, more particularly concerning the activation of links:

- On Begin URL Loading
- On URL Resource Loading

- On End URL Loading
- On URL Loading Error
- On URL Filtering
- On Open External Link
- On Window Opening Denied

In addition, Web areas support the following generic form events:

- On Load
- On Unload
- On Getting Focus
- On Losing Focus

For more information about these events, please refer to the description of the **Form event** command.

## Access to Web inspector

You can view and use a Web inspector within Web areas of your forms. The Web inspector is a debugger which is provided by the embedded Web engine. It allows to parse the code and the flow of information of the Web pages.

### Displaying the Web inspector

The following conditions must be met in order to view the Web inspector in a Web area:

- You must select the embedded Web rendering engine for the area (the Web inspector is only available with this configuration) (see **Use integrated Web rendering engine**)
- You must enable the context menu for the area (this menu is used to call the inspector) (see **Context Menu**)
- You must expressly enable the use of the inspector in the area by means of the following statement:

```
WA SET PREFERENCE(*;"WA";WA enable Web inspector;True)
```

  For more information, refer to the description of the **WA SET PREFERENCE** command.

### Using the Web inspector

When you have done the settings as described above, you then have new options such as **Inspect Element** in the context menu of the area:

When you select this option, the Web inspector window is displayed.

The Web inspector is included in the embedded Web rendering engine. For a detailed description of the features of this debugger, refer to the documentation provided by the Web rendering engine.

## Notes about use of Web areas

### User interface

When the form is executed, standard browser interface functions are available to the user in the Web area, which permit interaction with other form areas:

- **Edit menu commands:** When the Web area has the focus, the **Edit** menu commands can be used to carry out actions such as copy, paste, select all, etc., according to the selection.
- **Context menu:** It is possible to use the standard context menu of the system with the Web area (see **Context Menu**). Display of the context menu can be controlled using the **WA SET PREFERENCE** command.
- **Drag and drop:** The user can drag and drop text, pictures and documents within the Web area or between a Web area and the 4D form objects, according to the 4D object properties.
  For security reasons, changing the contents of a Web area by means of dragging and dropping a file or URL is not allowed by default beginning with 4D v14 R2. In this case, the mouse cursor displays a "forbidden" icon  . You have to use the **WA SET PREFERENCE** command to explicitly allow the dropping of URLs or files in the area.

### Web Area and Web server conflict (Windows)

Under Windows, it is not recommended to access, via a Web area, the Web server of the 4D application containing the area because this configuration could lead to a conflict that freezes the application. Of course, a remote 4D can access the Web

server of 4D Server, but not its own Web server.

### Web plugins and Java applets

The use of Web plugins and Java applets is **not recommended** in Web areas because they may lead to instability in the operation of 4D, particularly at the event management level.

### Insertion of protocol (Mac OS)

The URLs handled by programming in Web areas under Mac OS must begin with the protocol. For example, you need to pass the string "http://www.mysite.com" and not just "www.mysite.com".

# WA Back URL available

WA Back URL available ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Boolean | ⇐ | True if there is a previous URL in the sequence of URLs opened;otherwise, False |

## Description

The **WA Back URL available** command finds out whether there is a previous URL available in the sequence of URLs opened in the Web area designated by the * and *object* parameters.

The command returns **True** if a URL exists and **False** otherwise. More particularly, this command can be used, in a custom interface, to enable or disable navigation buttons.

# WA Create URL history menu

WA Create URL history menu ( {* ;} object {; direction} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| direction | Longint | ⇒ | 0 or omitted=List of previous URLs, 1=List of next URLs |
| Function result | MenuRef | ⇐ | Menu reference |

## Description

The **WA Create URL history menu** command creates and fills a menu that can be used directly for navigation among the URLs visited during the session in the Web area designated by the * and *object* parameters. It can be used to build a custom navigation interface.

The information provided concerns the session; in other words, the navigation carried out in the same Web area as long as the form has not been closed.

Pass a value indicating the list to recover in *direction*. You can use one of the following constants, found in the **Web Area** theme:

| Constant | Type | Value |
|---|---|---|
| WA next URLs | Longint | 1 |
| WA previous URLs | Longint | 0 |

If you omit the *direction* parameter, the value 0 is used.

Once the menu has been generated, you can display it using the 4D **Dynamic pop up menu** command and you can work with it using the standard 4D menu management commands. The string returned by this command contains the URL of the page visited (see example).

Call the **RELEASE MENU** command to delete a URL history menu when it is no longer useful.

## Example

The following code can be associated with a 3D button having a pop-up menu entitled "Previous":

```
Case of
 //Single click
   :(Form event=On Clicked)
      WA OPEN BACK URL(WA_area)
 //Click on arrow -> display of pop up
   :(Form event=On Alternative Click)
 //Create a previous history menu
      $Menu:=WA Create URL history menu(WA_area;WA previous URLs)
 //Display this menu in a pop-up
      $URL:=Dynamic pop up menu($Menu)
 //If an item is selected
      If($URL#"")
 //Open Web page
         WA OPEN URL(WA_area;$URL)
      End if
 //Delete menu to free up memory
      RELEASE MENU($Menu)
End case
```

# WA Evaluate JavaScript

WA Evaluate JavaScript ( {* ;} object ; jsCode {; type} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| jsCode | String | ➡ | JavaScript code |
| type | Longint | ➡ | Type into which to convert result |
| Function result | Date, Object, Pointer, Real, Text, Time | ↩ | Result of evaluation |

## Description

The **WA Evaluate JavaScript** command executes, in the Web area designated by the * and *object* parameters, the JavaScript code passed in *jsCode* and returns the result.

By default, the command returns values as strings. You can use the optional *type* parameter to specify typing for the value returned. To do this, pass one of the following constants, found in the "**Field and Variable Types**" theme:

| Constant | Type | Value |
|---|---|---|
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is longint | Longint | 9 |
| Is object | Longint | 38 |
| Is real | Longint | 1 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |

## Example 1

This example of JavaScript code causes the previous URL to be displayed:

```
$result:=WA Evaluate JavaScript(MyWArea;"history.back()")
```

## Example 2

This example shows a few evaluations with conversion of the values received.

JavaScript functions placed in an HTML file:

```
<!DOCTYPE html> <html>     <head>         <script>         function evalLong(){             return 123;         }
function evalText(){            return "456";        }        function evalObject(){            return {a:1,b:"hello
world"};         }        function evalDate(){            return new Date();         }     </script>     </head>
<body>         TEST PAGE     </body> </html>
```

In the 4D form method, you write:

```
If(Form event=On Load)
   WA OPEN URL(*;"Web Area";"C:¥¥myDatabase¥¥index.html")
End if
```

You can then evaluate the JavaScript code from 4D:

```
$Eval1:=WA Evaluate JavaScript(*;"Web Area";"evalLong()";Is longint)
 //$Eval1 = 123
 //$Eval1 = "123" if type is omitted
$Eval2:=WA Evaluate JavaScript(*;"Web Area";"evalText()";Is text)
 //$Eval2 = "456"
$Eval3:=WA Evaluate JavaScript(*;"Web Area";"evalObject()";Is object)
```

```
 //$Eval3 = {"a":1,"b":"hello world"}
$Eval4:=WA Evaluate JavaScript(*;"Web Area";"evalDate()";ls date)
 // $Eval4 = 06/21/13
 // $Eval4 = "2013-06-21T14:45:09.694Z" if type is omitted
```

# WA EXECUTE JAVASCRIPT FUNCTION

WA EXECUTE JAVASCRIPT FUNCTION ( {* ;} object ; jsFunction ; result|* {; param}{; param2 ; ... ; paramN} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| jsFunction | String | ⇒ | Name of JavaScript function to execute |
| result\|* | Variable | ⇒ | * for a function with no result or |
| | | ⇐ | Function result (if expected) |
| param | String, Number, Date, Object | ⇒ | Parameter(s) to pass to function |

## Description

The **WA EXECUTE JAVASCRIPT FUNCTION** command executes, in the Web area designated by the * and *object* parameters, the JavaScript function *jsFunction* and optionally returns its result in the *result* parameter.

If the function does not return a result, pass * in the *result* parameter.

You can pass one or more parameters containing the parameters of the function in *param*.

The command supports several types of parameters for both input (*param*) and output (*result*). You can pass and retrieve data of the number, date, object and string types.

## Example 1

Calling a JavaScript function with 3 parameters:

```
$JavaScriptFunction:="TheFunctionToBeExecuted"
$Param1:="10"
$Param2:="true"
$Param3:="1,000.2" `note "," as thousands separator and "." as the decimal separator

WA EXECUTE JAVASCRIPT FUNCTION(MyWArea;$JavaScriptFunction;$Result;$Param1;$Param2;$Param3)
```

## Example 2

The "getCustomerInfo" JavaScript function receive a number ID as parameter and returns an object:

```
C_OBJECT($Result)
C_LONGINT($ID)
$ID:=1000
WA EXECUTE JAVASCRIPT FUNCTION(*;"WA";"getCustomerInfo";$Result;$ID)
```

# WA Forward URL available

WA Forward URL available ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | Boolean | ⇐ | True if there is a following URL in the sequence of URLs opened;otherwise, False |

## Description

The **WA Forward URL available** command finds out whether there is a following URL available in the sequence of URLs opened in the Web area designated by the * and *object* parameters.

The command returns **True** if a URL exists and **False** otherwise. More particularly, this command can be used, in a custom interface, to enable or disable navigation buttons.

# WA Get current URL

WA Get current URL ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | String | ⇐ | URL currently loaded in the Web area |

## Description

The **WA Get current URL** command returns the URL address of the page displayed in the Web area designated by the * and *object* parameters.

If the current URL is not available, the command returns an empty string.

If the Web page is completely loaded, the value returned by the function is the same as that of the "URL" variable associated with the Web area. If the page is in the process of being loaded, the two values will be different: the function returns the completely loaded URL and the variable contains the URL in the process of being loaded.

## Example

The page displayed is the URL "www.apple.com" and the "www.4d.com" page is in the process of being loaded:

```
$url:=WA Get current URL(MyWArea) `returns "http://www.apple.com"
 `The associated URL variable contains "http://www.4d.com"
```

# WA GET EXTERNAL LINKS FILTERS

WA GET EXTERNAL LINKS FILTERS ( {* ;} object ; filtersArr ; allowDenyArr )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| filtersArr | String array | ⇐ | Filters array |
| allowDenyArr | Boolean array | ⇐ | Allow-deny array |

## Description

The **WA GET EXTERNAL LINKS FILTERS** command returns, in the *filtersArr* and *allowDenyArr* arrays, the external link filters of the Web area designated by the * and *object* parameters. If no filter is active, the arrays are returned empty.

The filters are installed by the **WA SET EXTERNAL LINKS FILTERS** command. If the arrays are reinitialized during the session, the **WA GET EXTERNAL LINKS FILTERS** command can be used to find out the current settings.

# WA Get last filtered URL

WA Get last filtered URL ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | String | ⇐ | Last filtered URL |

## Description

The **WA Get last filtered URL** command returns the last URL that was filtered in the Web area designated by the * and *object* parameters.

The URL may have been filtered for one of the following reasons:

- The URL was denied because of a filter (**WA SET URL FILTERS** command),
- The link is open in the default browser (**WA SET EXTERNAL LINKS FILTERS** command),
- The URL attempts to open a pop-up window.

It is advisable to call this command in the context of the On URL Filtering, On Open External Link and On Window Opening Denied form events in order to find out the URL that was filtered.

# WA GET LAST URL ERROR

WA GET LAST URL ERROR ( {* ;} object ; url ; description ; errorCode )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| url | String | ⇐ | URL at origin of error |
| description | String | ⇐ | Description of error (Mac OS) |
| errorCode | Longint | ⇐ | Error code |

## Description

The **WA GET LAST URL ERROR** command recovers several items of information about the last error that occurred in the Web area designated by the * and *object* parameters.

This information is returned in three variables:

- *url*: URL causing error.
- *description* (Mac OS only): A text describing the error (if available). If it is not possible to associate a text with the error, an empty string is returned. Under Windows, this parameter is always returned empty.
- *errorCode*: The error code.
  - If the code is >=400, it is an error related to the HTTP protocol. For more information about this type of error, refer to the following address:
    *http://www.w3.org/Protocols/rfc2616/rfc2616-sec10.html*
  - Otherwise, it is an error returned by the WebKit (Mac OS) or ActiveX (Windows).

It is recommended to call this command within the framework of the On URL Loading Error form event to find out the cause of the error that just occurred.

# WA Get page content

WA Get page content ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | String | ⇐ | HTML source code |

## Description

The **WA Get page content** command returns the HTML code of the current page or the page being displayed in the Web area designated by the * and *object* parameters.

This command returns an empty string if the contents of the current page is not available.

# WA Get page title

WA Get page title ( {* ;} object ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| Function result | String | ⇐ | Title of current page |

## Description

The **WA Get page title** command returns the title of the current page or the page being displayed in the Web area designated by the * and *object* parameters. The title corresponds to the HTML "Title" tag.

This command returns an empty string if there is no title available for the current URL.

# WA GET PREFERENCE

WA GET PREFERENCE ( {* ;} object ; selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| selector | Longint | ⇒ | Preference to get |
| value | Variable | ⇐ | Current value of the preference |

## Description

The **WA GET PREFERENCE** command gets the current value of the preference in the Web area designated by the * and *object* parameters.

Pass the preference whose value you want to get in the *selector* parameter. You can pass one of the following constants, found in the **Web Area** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| WA enable contextual menu | Longint | 4 | Allow the display of a standard contextual menu in the Web area |
| WA enable Java applets | Longint | 1 | Allow the execution of Java applets in the Web area. |
| WA enable JavaScript | Longint | 2 | Allow the execution of JavaScript code in the Web area |
| WA enable plugins | Longint | 3 | Allow the installation of plug-ins in the Web area |
| WA enable URL drop | Longint | 101 | Allow dropping of URLs or files in the Web area (default = False) |
| WA enable Web inspector | Longint | 100 | Allow the display of the Web inspector in the area |

For more information about these preferences, refer to the description of the **WA SET PREFERENCE** command.

In the *value* parameter, pass a variable that will receive the current value of the preference. The type of variable depends on the preference. The *value* variable is always a Boolean: it contains **True** if the preference is active and **False** otherwise.

# WA GET URL FILTERS

WA GET URL FILTERS ( {* ;} object ; filtersArr ; allowDenyArr )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| filtersArr | String array | ⇐ | Filters array |
| allowDenyArr | Boolean array | ⇐ | Allow-deny array |

## Description

The **WA GET URL FILTERS** command returns, in the *filtersArr* and *allowDenyArr* arrays, the filters that are active in the Web area designated by the * and *object* parameters. If no filter is active, the arrays are returned empty.

The filters are installed by the **WA SET URL FILTERS** command. If the arrays are reinitialized during the session, the **WA GET URL FILTERS** command can be used to find out the current settings

# WA GET URL HISTORY

WA GET URL HISTORY ( {* ;} object ; urlsArr {; direction {; titlesArr}} )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| urlsArr | String array | ⇐ | Array of URLs visited |
| direction | Longint | ⇒ | 0 or omitted=List of previous URLs, 1=List of next URLs |
| titlesArr | String array | ⇐ | Array of window titles |

## Description

The **WA GET URL HISTORY** command returns one or two arrays containing the URLs visited during the session in the Web area designated by the * and *object* parameters. It can be used to build a custom navigation interface.

The information provided concerns the session; in other words, the navigation carried out in the same Web area as long as the form has not been closed.

The *urlsArr* array is filled with the list of URLs visited. Depending on the value of the *direction* parameter (if it is passed), the array recovers the list of previous URLs (default operation), or the list of next URLs. These lists correspond to the content of the standard Back and Forward buttons of browsers.

The URLs are classed by chronological order.

Pass a value indicating the list to recover in *direction*. You can use one of the following constants, found in the **Web Area** theme:

| Constant | Type | Value |
|---|---|---|
| WA next URLs | Longint | 1 |
| WA previous URLs | Longint | 0 |

If you omit the *direction* parameter, the value 0 is used.

If it is passed, the *titlesArr* parameter contains the list of window names associated with the URLs. This array is synchronized with the *urlsArr* array.

# WA OPEN BACK URL

WA OPEN BACK URL ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA OPEN BACK URL** command loads the previous URL in the sequence of URLs opened into the Web area designated by the * and *object* parameters.

If there is no previous URL, the command does nothing. You can test whether a previous URL is available using the **WA Back URL available** command.

# WA OPEN FORWARD URL

WA OPEN FORWARD URL ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA OPEN FORWARD URL** command loads the next URL in the sequence of URLs opened into the Web area designated by the * and *object* parameters.

If there is no next URL (in other words, if the user has never returned to a previous URL), the command does nothing. You can test whether a next URL is available using the **WA Forward URL available** command.

# WA OPEN URL

WA OPEN URL ( {* ;} object ; url )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| url | String | ➡ | URL to load in Web area |

## Description

The **WA OPEN URL** command loads the URL passed in the *url* parameter into the Web area designated by the * and *object* parameters.

If an empty string is passed in *url*, the command does nothing and no error is generated. To load a blank page into the Web area, pass the string "about:blank" in *url*.

Like the existing **OPEN URL** command, **WA OPEN URL** accepts several types of syntaxes in the *url* parameter to designate the files:

- posix syntax: "file:///c:/My%20File"
- system syntax: "c:¥MyFolder¥MyFile" (Windows) or "MyDisk:MyFolder:MyFile" (Mac OS).

**Note:** For compatibility, the "file://" syntax (using two "/") is accepted in 4D but it does not conform to RFC. We recommend using the "file:///" syntax (with three "/") that complies with RFC.

On Mac OS, when FileVault is activated, you must use the Posix syntax. You can transform paths of the system using the **Convert path system to POSIX** command.

This command has the same effect as modifying the value of the "URL" variable associated with the area. For example, if the variable of the area is named MyWArea_url:

```
MyWArea_url:="http://www.4d.com/"
```

is the same as:

```
WA OPEN URL(MyWArea;"http://www.4d.com/")
```

# WA REFRESH CURRENT URL

WA REFRESH CURRENT URL ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA REFRESH CURRENT URL** command reloads the current URL displayed in the Web area designated by the * and *object* parameters.

# WA SET EXTERNAL LINKS FILTERS

WA SET EXTERNAL LINKS FILTERS ( {* ;} object ; filtersArr ; allowDenyArr )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| filtersArr | String array | ⇒ | Filters array |
| allowDenyArr | Boolean array | ⇒ | Allow-deny array |

## Description

The **WA SET EXTERNAL LINKS FILTERS** command sets up one or more external link filters for the Web area designated by the * and *object* parameters. External link filters determine whether a URL associated with the current page via a link must be opened in the Web area or in the default Web browser of the machine.

When the user clicks on a link in the current page, 4D consults the list of external link filters in order to check whether the URL requested must be opened in the browser of the machine. If so, the page corresponding to the URL is displayed in the Web browser and the On Open External Link form event is generated. Otherwise (default operation), the page corresponding to the URL is displayed in the Web area. The evaluation of the URL is based on the contents of the *filtersArr* and *allowDenyArr* arrays.

The *filtersArr* and *allowDenyArr* arrays must be synchronized.

- Each element of the *filtersArr* array must contain a URL to be filtered. You can use the * as a wildcard to replace one or more characters.
- Each corresponding element in the *allowDenyArr* array must contain a Boolean indicating whether the URL must be opened in the Web area (**True**) or in the Web browser (**False**).

If there is a contradiction at the configuration level (the same URL is both allowed and denied), the last setting is the one taken into account.

To disable URL filtering, call the command and pass empty arrays or pass, respectively, the values "*" and **True** in the last elements of the *filtersArr* and *allowDenyArr* arrays.

**Important:** The filtering established by the **WA SET URL FILTERS** command is taken into account before that of the **WA SET EXTERNAL LINKS FILTERS** command. This means that if a URL is denied because of a **WA SET URL FILTERS** command filter, it cannot be opened in the browser even if it is explicitly specified by the **WA SET EXTERNAL LINKS FILTERS** command (see example 2).

## Example 1

This example causes sites to be opened in external browsers:

```
ARRAY STRING(0;$filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*www.google.*") `Select "google"
APPEND TO ARRAY($AllowDeny;False)
 `False: this link will be opened in an external browser
APPEND TO ARRAY($filters;"*www.apple.*")
APPEND TO ARRAY($AllowDeny;False)
 `False: this link will be opened in an external browser
WA SET EXTERNAL LINKS FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 2

This example combines the filtering of both sites and external links:

```
ARRAY STRING(0;$filters;0)
ARRAY BOOLEAN($AllowDeny;0)
APPEND TO ARRAY($filters;"*www.google.*") `Select "google"
```

```
APPEND TO ARRAY($AllowDeny;False) `Deny this link
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)

ARRAY STRING(0;$filters;0)
ARRAY BOOLEAN($AllowDeny;0)
APPEND TO ARRAY($filters;"*www.google.*") `Select "google"
APPEND TO ARRAY($AllowDeny;False)
 `False: this link should be opened in an external browser but this setting
 `has no effect because the link will be blocked by the URL filtering.
WA SET EXTERNAL LINKS FILTERS(MyWArea;$filters;$AllowDeny)
```

# WA SET PAGE CONTENT

WA SET PAGE CONTENT ( {* ;} object ; content ; baseURL )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| content | String | ⇒ | HTML source code |
| baseURL | String | ⇒ | URL for relative references (Mac OS) |

## Description

The **WA SET PAGE CONTENT** command replaces the page displayed in the Web area designated by the * and *object* parameters by the HTML code passed in the *content* parameter.

The *baseURL* parameter specifies, under Mac OS, a base URL that will be added in front of any relative links found in the page.

Under Windows, this parameter has no effect and the base URL is not specified so it is not possible to use relative references on this platform.

**Note:** Under Windows, you cannot call this command unless a page has already been loaded previously into the Web area. If necessary, you can pass the "about:blank" URL in order to load a blank page.

## Example

Displays "Hello world!" and sets a "file:///" base URL (Mac OS only):

```
WA SET PAGE CONTENT(MyWArea;"<html><body><h1>Hello World!</h1></body></html>";"file:///")
```

# WA SET PAGE TEXT LARGER

WA SET PAGE TEXT LARGER ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA SET PAGE TEXT LARGER** command increases the size of the text displayed in the Web area designated by the * and *object* parameters.

Under Mac OS, the scope of this command is the 4D session: the configuration carried out by this command is not retained after the 4D application is closed.

Under Windows, the scope of this command is global: the configuration is retained after the 4D application is closed.

# WA SET PAGE TEXT SMALLER

WA SET PAGE TEXT SMALLER ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA SET PAGE TEXT SMALLER** command reduces the size of the text displayed in the Web area designated by the * and *object* parameters.

Under Mac OS, the scope of this command is the 4D session: the configuration carried out by this command is not retained after the 4D application is closed.

Under Windows, the scope of this command is global: the configuration is retained after the 4D application is closed.

# WA SET PREFERENCE

WA SET PREFERENCE ( {* ;} object ; selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ➡ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ➡ | Object name (if * is specified) or Variable (if * is omitted) |
| selector | Longint | ➡ | Preference to be modified |
| value | Boolean | ➡ | Value of the preference (True = allowed, False = not allowed) |

## Description

The **WA SET PREFERENCE** command sets different preferences for the Web area designated by the * and *object* parameters.

Pass the preference to be modified in the *selector* parameter and the value to be assigned to it in the *value* parameter. In *selector*, you can pass one of the following constants, found in the **Web Area** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| WA enable contextual menu | Longint | 4 | Allow the display of a standard contextual menu in the Web area |
| WA enable Java applets | Longint | 1 | Allow the execution of Java applets in the Web area. |
| WA enable JavaScript | Longint | 2 | Allow the execution of JavaScript code in the Web area |
| WA enable plugins | Longint | 3 | Allow the installation of plug-ins in the Web area |
| WA enable URL drop | Longint | 101 | Allow dropping of URLs or files in the Web area (default = False) |
| WA enable Web inspector | Longint | 100 | Allow the display of the Web inspector in the area |

For each preference, pass **True** in *value* to activate it and **False** to deactivate it.

**Note:** The use of Web plugins and Java applets is **not recommended** in Web areas because they may lead to instability in the operation of 4D, particularly at the event management level.

## Example

To enable URL drops in the 'myarea' Web area:

```
WA SET PREFERENCE(*;"myarea";WA enable URL drop;True)
```

# WA SET URL FILTERS

WA SET URL FILTERS ( {* ;} object ; filtersArr ; allowDenyArr )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |
| filtersArr | String array | ⇒ | Filters array |
| allowDenyArr | Boolean array | ⇒ | Allow-deny array |

## Description

The **WA SET URL FILTERS** command sets up one or more filters for the Web area designated by the * and *object* parameters.

Before loading any page requested by the user, 4D consults the list of filters in order to check whether or not the target URL is allowed. The evaluation of the URL is based on the contents of the *filtersArr* and *allowDenyArr* arrays.

If the requested URL is not allowed, it is not loaded and the On URL Filtering form event is generated.

The *filtersArr* and *allowDenyArr* arrays must be synchronized.

- Each element of the *filtersArr* array must contain a URL to be filtered. You can use the * as a wildcard to replace one or more characters.
- Each corresponding element in the *allowDenyArr* array must contain a Boolean indicating whether the URL must be allowed (**True**) or denied (**False**).

If there is a contradiction at the configuration level (the same URL is both allowed and denied), the last setting is the one taken into account.

To disable URL filtering, call the command and pass empty arrays or pass, respectively, the values "*" and **True** in the last elements of the *filtersArr* and *allowDenyArr* arrays.

Once the command has been executed, the filters become a property of the Web area. If the *filtersArr* and *allowDenyArr* arrays are deleted or reinitialized, the filters remain active as long as the command has not been executed again. To find out the active filters for an area, you must use the **WA GET URL FILTERS** command.

**Important:** The filtering of URLs carried out by this command only applies to the "URL" variable associated with the Web area (variable usually enterable and displayed in the form).
The filtering does not apply to the **WA OPEN URL** command, nor to the other navigation commands.

## Example 1

You want to deny access for all the .org, .net and .fr Web sites:

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*.org")
APPEND TO ARRAY($AllowDeny;False)
APPEND TO ARRAY($filters;"*.net")
APPEND TO ARRAY($AllowDeny;False)
APPEND TO ARRAY($filters;"*.fr")
APPEND TO ARRAY($AllowDeny;False)
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 2

You want to deny access for all Web sites except Russian ones (.ru):

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*") `Select all
```

```
APPEND TO ARRAY($AllowDeny;False) `Deny all
APPEND TO ARRAY($filters;"www.*.ru") `Select *.ru
APPEND TO ARRAY($AllowDeny;True) `Allow
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 3

You want to allow access only to 4D Web sites (.com, .fr, .es, etc.):

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*") `Select all
APPEND TO ARRAY($AllowDeny;False) `Deny all
APPEND TO ARRAY($filters;"www.4D.*") `Select 4d.fr, 4d.com...
APPEND TO ARRAY($AllowDeny;True) `Allow
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 4

You want to allow local access to the documentation only (found in the folder C://doc):

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*") `Select all
APPEND TO ARRAY($AllowDeny;False) `Deny all
APPEND TO ARRAY($filters;"file://C:/doc/*")
 `Select the path file:// allowed
APPEND TO ARRAY($AllowDeny;True) `Allow
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 5

You want to allow access for all sites except one, for example the Elcaro site:

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*")
APPEND TO ARRAY($AllowDeny;True) `Allow all
APPEND TO ARRAY($filters;"*elcaro*") `Deny all that contain elcaro
APPEND TO ARRAY($AllowDeny;False)
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
```

## Example 6

You want to deny access to specific IP addresses:

```
ARRAY TEXT($filters;0)
ARRAY BOOLEAN($AllowDeny;0)

APPEND TO ARRAY($filters;"*") `Select all
APPEND TO ARRAY($AllowDeny;True) `Allow all
APPEND TO ARRAY($filters;86.83.*")  `Select IP addresses beginning with 86.83.
APPEND TO ARRAY($AllowDeny;False) `Deny
APPEND TO ARRAY($filters;86.1*")  `Select IP addresses beginning with 86.1 (86.10, 86.135 etc.)
APPEND TO ARRAY($AllowDeny;False) `Deny
WA SET URL FILTERS(MyWArea;$filters;$AllowDeny)
 `(Note that the IP address of a domain may vary).
```

# WA STOP LOADING URL

WA STOP LOADING URL ( {* ;} object )

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, object is an object name (string) If omitted, object is a variable |
| object | Form object | ⇒ | Object name (if * is specified) or Variable (if * is omitted) |

## Description

The **WA STOP LOADING URL** command stops loading the resources of the current URL of the Web area designated by the * and *object* parameters.

# Web Server

- Web Server, Overview
- Web server configuration and connection management
- Support of IPv6
- Connection Security
- On Web Authentication Database Method
- On Web Connection Database Method

# Web Server, Overview

---

4D in local mode, 4D in remote mode and 4D Server include a Web Server engine that enables you to publish 4D databases or any type of HTML page on the Web. The principal characteristics of the 4D Web Server engine are:

- **Easy publication**

You can start or stop publication of the database on the Web at any time. To do so, you just need to choose a menu command or execute a language command.

- **Dedicated database methods**

**On Web Authentication Database Method** and **On Web Connection Database Method** are the entry points of requests in the Web server; they can be used to evaluate and route any type of request.

- **Use of special tags and URLs**

The 4D Web server offers numerous mechanisms that enable interaction with user actions, in particular:
- special tags can be included in Web pages in order to initiate processing by the Web server at the time when they are sent to browsers.
- special URLs that enable 4D to be called in order to execute any action.
- these URLs can also be used as form actions to trigger processing when the user posts HTML forms.

- **Managing user sessions**

The 4D Web server includes complete automatic features for easily managing Web sessions (user sessions) based on cookies.

- **Access Security**

Several automatic configuration options allow you to grant specific access authorizations to Web browsers or to use the password system integrated into 4D. You can define a "Generic Web User" to simplify access management within the database.
The **On Web Authentication Database Method** allows you to evaluate any request before it is processed by the Web server. Moreover, the ability to define a default HTML root folder allows you to restrict access to files on disk.
Finally, you must designate individually the project methods that may be executed via the Web.

- **SSL Connections**

Your 4D Web server can communicate with browsers in secured mode through the SSL protocol (Secured Socket Layer). This protocol, compatible with most Web browsers, authenticates the sender and receiver and guaranties the confidentiality and integrity of the exchanged information.

- **Extended support for Internet formats**

The 4D Web server is HTTP/1.1 compatible and supports XML documents and WML (Wireless Markup Language) technology. The 4D Web server also extends the support of gzip compression: after a "negotiation" between the Web server and client, all exchanges can potentially be compressed, for an immediate performance boost.

- **Simultaneous operation of databases**
  - **4D in local mode and the Web**
    If you publish a 4D database on the Web using 4D in local mode, you can simultaneously:
    - Use the database locally with 4D
    - Connect to the database using Web browsers.
  - **4D Server and the Web**
    If you publish a 4D database on the Web using 4D Server, you can simultaneously connect to and operate the 4D database, using:
    - 4D remote workstations
    - Web browsers.

- **4D in remote mode and the Web**
  When a 4D database is published on the Web with 4D client, it is possible to connect to the 4D database and to simultaneously use it:
  - via 4D remote machines
  - via Web browsers. In this case, if the database is also published with 4D Server, the Web browsers can connect to the published database via a 4D client machine or via 4D Server. Moreover, this allows different data access modes to be handled (public, administration, etc.).
  The basic mechanisms of the 4D Web server are used in a similar manner by 4D in remote mode. The operation of language commands is usually identical, whether the command be executed on 4D in local mode, 4D Server or 4D in remote mode. The main point is that commands are applied to the Web site of the machine on which they are executed. You must manage this using the **Execute on server** / **EXECUTE ON CLIENT** commands.

- **Load balancing with 4D clients**: since any 4D machine in remote mode can be used as a Web server, you can set up a dynamic Web server system with a load balancer. This offers extensive development possibilities, including, more particularly:
  - the setting-up of a load-balancing system in order to optimize the performance of the 4D Web server: using a mirror of the Web site that is installed on each 4D Web server, a load balancer (hardware or software) will send requests to the client machines on the basis of their current load.

  - the setting-up of a fault tolerance Web server: the 4D Web site is mirrored on two or more 4D client machines. If one 4D Web server fails, another one takes over.
  - the creation of different views of the same data, for instance depending on the origin of the requests. Within a company network, a Web server on a protected 4D client machine can serve Intranet requests and a Web server on another 4D client machine, located beyond the firewall, will serve Internet requests.
  - the distribution of tasks between Web servers on different 4D client machines: one 4D Web server can be in charge of SOAP requests, another can handle standard requests, and so on.

# Web server configuration and connection management

4D and 4D Server include a Web server (also called the HTTP server) that enables you to publish the data of your databases on the Web, transparently and dynamically.

This section describes the steps necessary for launching the Web server and for the connection of browsers, as well as the process of connection management.

## Conditions for publishing a 4D database on the Web

To be able to launch the HTTP server of 4D or 4D Server, you must have the elements described below:

- A "4D Web Application" license. For more information, please refer to your 4D installation guide.
- Web connections are made over the network using the TCP/IP protocol. Consequently:
  - You must have TCP/IP installed on your machine and correctly configured. Refer to your computer or Operating System manuals for more information.
  - If you want to use SSL for network connections, make sure that requested components are correctly installed (see the **Using TLS Protocol** section).
- After all the previous points have been checked and taken care of, you need to start the Web server from within 4D. This last point is discussed further on in this section.

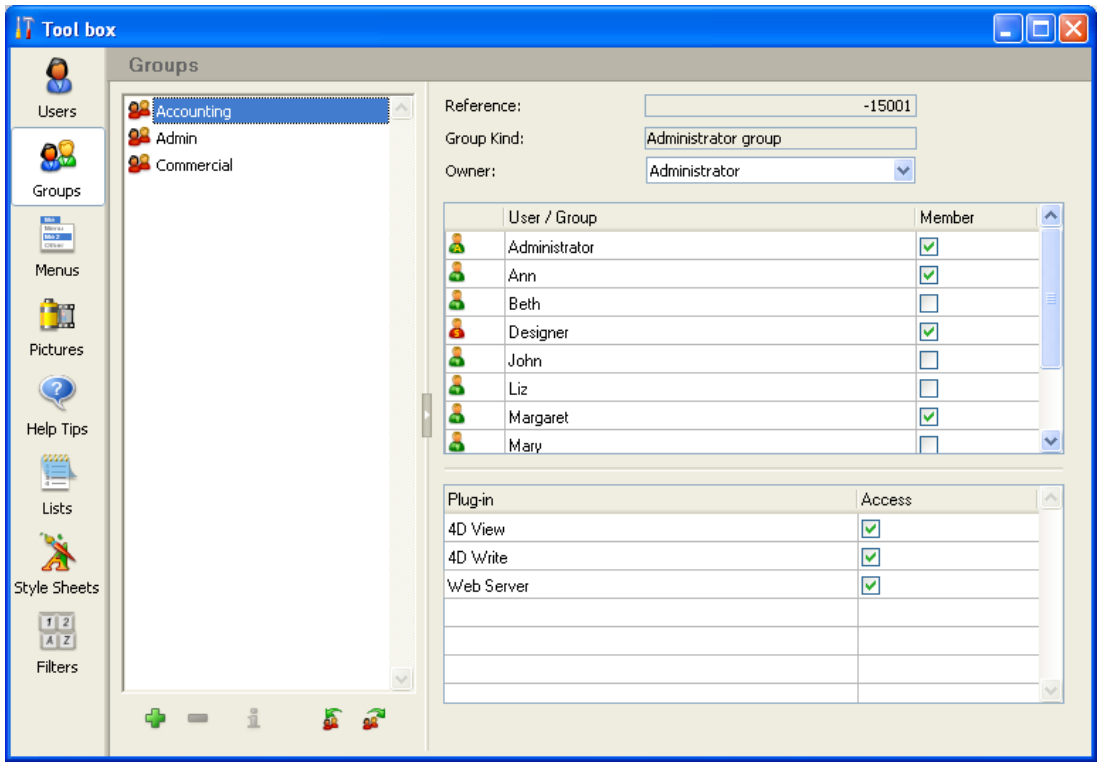
### Publication authorization (4D in remote mode)

By default, any 4D client machine can publish the database to which it is connected on the Web. However, you can control the possibility of Web publication for each remote 4D machine by using the 4D password system.

In fact, 4D Web licenses are considered as plug-in licenses by 4D Server. Therefore, in the same way as for plug-ins, you must retrict the right to use Web Server licenses to a specific group of users.

To do this, display the **Groups** page in the Toolbox using 4D (you must have suitable access authorization to modify these parameters).

Select a group in the list on the left, then check the **Access** option next to the **4D Client Web Server** line in the Plug-in distribution area:



Above: only users belonging to the "Web" group are authorized to publish their 4D machine as a Web server.

## HelperTool under Mac OS X

Under Mac OS X, using TCP/IP ports reserved for Web publishing (ports 0 to 1023) requires specific access privileges. In order for you to be able to use these ports, 4D provides a utility program named HelperTool. When this program is installed, it retrieves the appropriate access rights and automatically takes charge of opening the Web ports. This mechanism functions with 4D (all modes), 4D Server and 4D Volume Desktop executable applications.

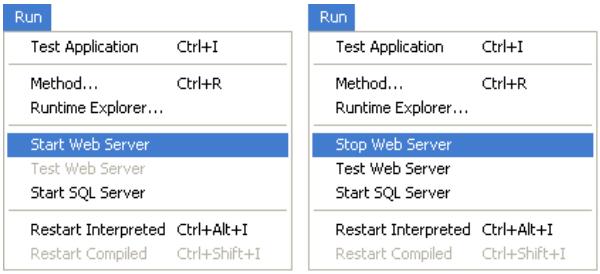
The HelperTool application is included in the 4D software. Installation takes place automatically during the first opening of a port <1024 on the machine. The user is informed that a tool is going to be installed and is prompted to enter a name and an administrator password for the machine. This operation only takes place once.
The application is renamed "com.4D.HelperTool" and is installed in the folder "/Library/PrivilegedHelperTools/." After the initial sequence, the 4D Web server can be started and stopped transparently, regardless of the 4D version used.

## Starting the 4D Web Server

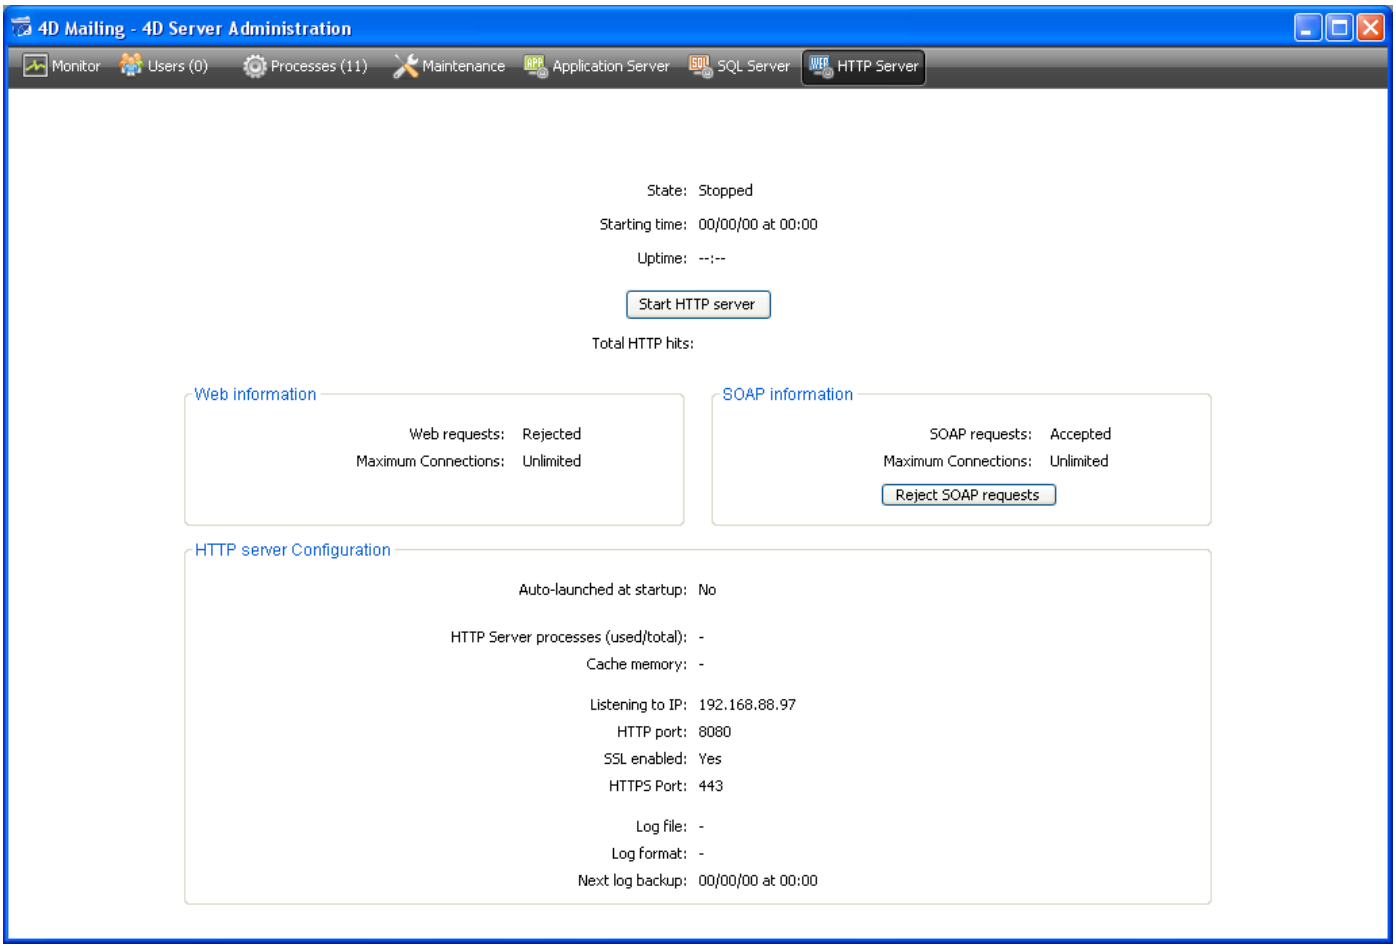
The 4D WebServer can be started in three different ways:

- Using the **Run** menu of 4D or the HTTP Server page of 4D Server(**Start HTTP server** button). These commands allow you to start and stop the WebServer at your convenience:

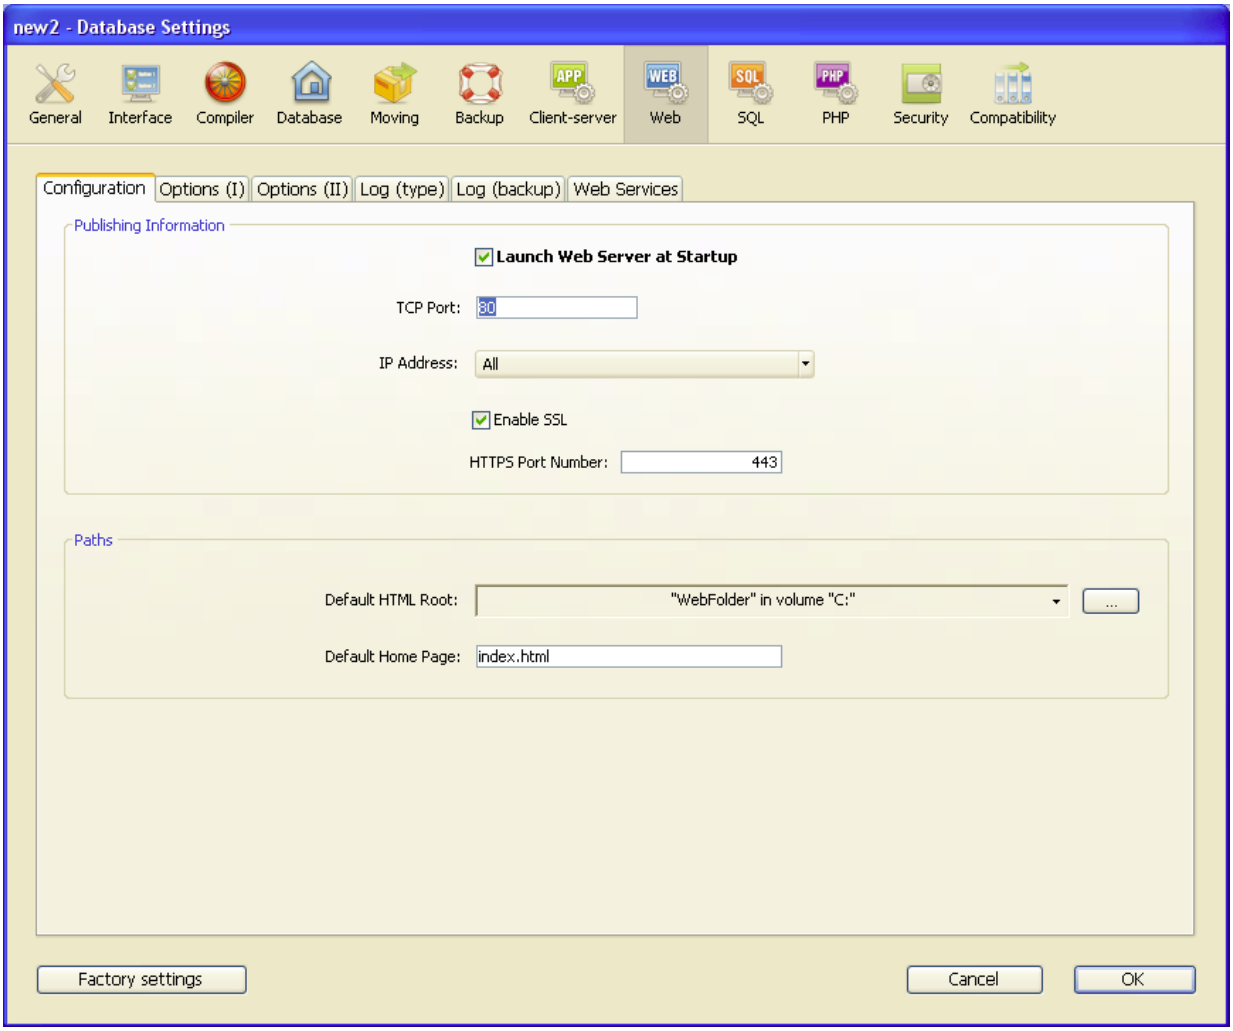
4D:



4D Server:



- Automatically starting it each time the 4D application is opened. To do this, display the **Configuration** page of the **Web** theme of the Database Settings:



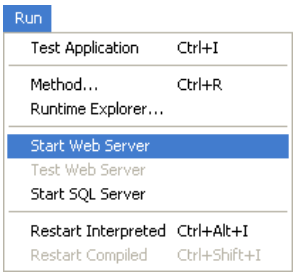
In the “Publishing Information” section, select the **Launch Web Server at Startup** check box, then click **OK**. Once this is done, the database will be automatically published on the Web each time you open it with 4D or 4D Server.

- Programmatically, by calling the **WEB START SERVER** command.

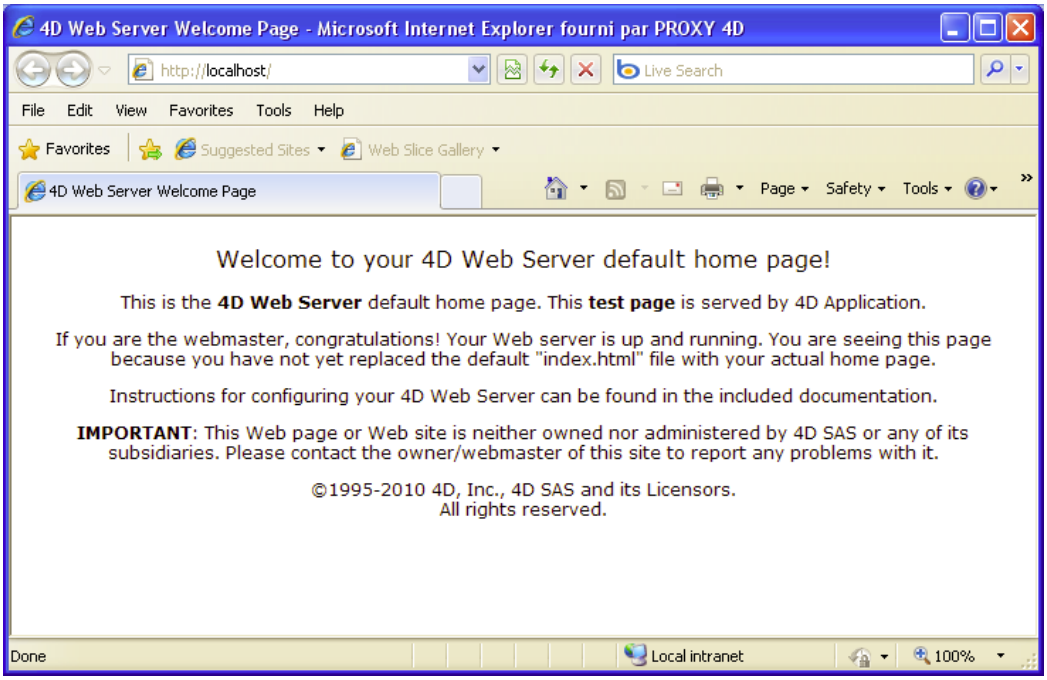
**Tip:** You do not need to quit 4D and reopen your database to start or stop publishing a database on the Web. You can interrupt and restart the Web server as many times as you want, using the **Run** menu, the **Start HTTP server** button or by calling the **WEB START SERVER** and **WEB STOP SERVER** commands.

## Testing the Web server

The **Test Web Server** command can be used to make sure the built-in Web server is functioning correctly (4D only). This command is accessible in the **Run** menu when the Web server is launched:



When you select this command, the home page of the Web site published by the 4D application is displayed in a window of your default Web browser:



This command lets you verify that the Web server, home page display, etc. work correctly. The page is called using the URL Localhost, which is the standard shortcut designating the IP address of the machine on which the Web browser is executed. The command takes into account the TCP publication port number specified in the database settings.

## Connecting to a 4D database published on the Web

After you have started publishing a 4D database on the Web, you can connect to it using a Web browser. To do so:

- If your Web site has a registered name (i.e., " *www.flowersforever.com*"), indicate that name in the Open, Address, or Location area of your browser. Then press **Enter** to connect.
- If your Web Site does not have a registered name, indicate the IP address of your machine (i.e., 123.4.567.89) in the Open, Address, or Location area of your browser. Then press **Enter**.

At this time, your browser should display the home page of your Web site. If you have published a database in keeping with standard configurations, you should obtain the default home page of the 4D Web server. This page lets you test the connection and the server operation.

You may also encounter one of the following situations:

1. The connection fails and you get a message such as "...the server may not be accepting connections or may be busy...". In this case, check the following:

- Verify that the name or the IP address you entered is correct.
- Verify that 4D or 4D Server is up and running and has started its Web server.
- Check if the database is configured for being served on a TCP Port other than the default Web TCP Port (see situation 3).
- Check whether TCP/IP is correctly configured on both the server and browser machines. Both machines must be on the same net and subnet, or your routers must be correctly configured.
- Check your hardware connections.
- If you are not locally testing your own site, but rather attempting to connect to a Web database served on Internet or Intranet by someone else, ultimately, the message might be true: the server may be off or busy. So, retry later until you can log on, or contact the Web provider.

2. You connect, but you get an HTTP 404 "File not found" error. This means that the site home page has not be served. In this case, check that the home page actually exists at the location defined in the database settings (see the **Web Server Settings** section) or using the **WEB SET HOME PAGE** command.

3. You connect, but you do NOT obtain the Web page you were expecting! This can occur when you have several Web servers running simultaneously on the same machine. Examples:

- You are running only one 4D Web database on a Windows system that is already running its own Web server.
- You are running several 4D Web databases on the same machine.

In this kind of situation, you need to change the TCP port number on which your 4D Web database is published. To do so, refer to the **Web Server Settings** section.

**Note:** If your database is protected by a password system, you may have to enter a valid user name and password (for more information, refer to the **Connection Security** section).

## Web Processes

Each time a Web browser attempts to connect to the database, the request is handled as follows:

- First, one or more temporary local 4D processes called **Web Connection Processes** are created in order to evaluate and manage the connection with the Web browser.
  These temporary processes manage every HTTP request. They execute quickly and are then aborted or delayed. In order to optimize the Web server, once a request has been handled, 4D freezes this “pool” of Web processes for a few seconds so that it can reuse them if necessary when another request arrives. You can customize this behavior (timeout, minimum and maximum number of processes to be kept in the "pool") using the **SET DATABASE PARAMETER** command.
- The Web process handles the processing of the request and sends a response (if necessary) to the browser. The temporary process is then aborted or delayed (see above).

## Support of IPv6

---

Starting with version 14, 4D supports IPv6 address notation. This concerns the following 4D integrated servers:

- the Web server as well as the SOAP server,
- the SQL server.

**Note:** For more information about IPv6, refer to the following specification: RFC 2460.

Support of IPv6 is transparent for users and for 4D developers: the program accepts either IPv6 or IPv4 connections indiscriminately when the listening "IP address" of the server is set to **All** (see **Defining the IP Address for the HTTP Requests** (HTTP server) and **SQL Server Publishing Preferences** (SQL server).

However, you should pay attention to the following points:

- **Indication of port numbers**
  Since IPv6 notation uses colons (:), adding port numbers may lead to some confusion, for example:

  ```
  2001:0DB8::85a3:0:ac1f:8001 // IPv6 address
  2001:0DB8::85a3:0:ac1f:8001:8081 // IPv6 address with port 8081
  ```

  To avoid this confusion, we recommend using the [ ] notation whenever you combine an IPv6 address with a port number, for instance:

  ```
  [2001:0DB8::85a3:0:ac1f:8001]:8081 //IPv6 address with port 8081
  ```

- **No longer any warning when TCP port is occupied**
  Unlike previous versions of 4D, when the server is set to respond on "all" IP addresses with 4D v14, if the TCP port is being used by another application, this is no longer indicated when the server is started. In fact, 4D server does not detect any error in this case because the port remains free on the IPv6 address. However, it is not possible to access it using the IPv4 address of the machine, nor by means of the local address: 127.0.0.1.
  If your 4D server does not seem to be responding on the port defined, you can test the address [::1] on the server machine (equivalent to 127.0.0.1 for IPv6, add :*portNum* to test another port number). If 4D responds, it is likely that another application is using the port in IPv4.

- **IPv4-mapped IPv6 addresses**
  To standardize processing, 4D provides a standard hybrid representation of IPv4 addresses in IPv6. These addresses are written with a 96-bit prefix in IPv6 format, followed by 32 bits written in the dot-decimal notation of IPv4. For example, ::ffff:192.168.2.34 represents the IPv4 address 192.168.2.34.

## Connection Security

The security of your 4D Web Server is based on the following elements:

- The combination of the Web password management system (BASIC mode or DIGEST mode) and the **On Web Authentication Database Method**,
- The definition of a Generic Web User,
- The definition of a HTML Root folder by default,
- The definition of the “Available through 4D tags and URLs (4DACTION…)” property for each project method of the database.
- The option for the specific support of synchronization requests through HTTP.

**Note:** The security of the connection itself can be managed through the SSL protocol. For more information, refer to the **Using TLS Protocol** section.

### Password Management System for Web Access

#### BASIC Mode and DIGEST Mode

In the Database Settings, you can set the access control system that you want to apply to your Web server. Two authentication modes are provided: BASIC mode and DIGEST mode. The authentication mode concerns the way the information concerning the user name and password are collected and processed.

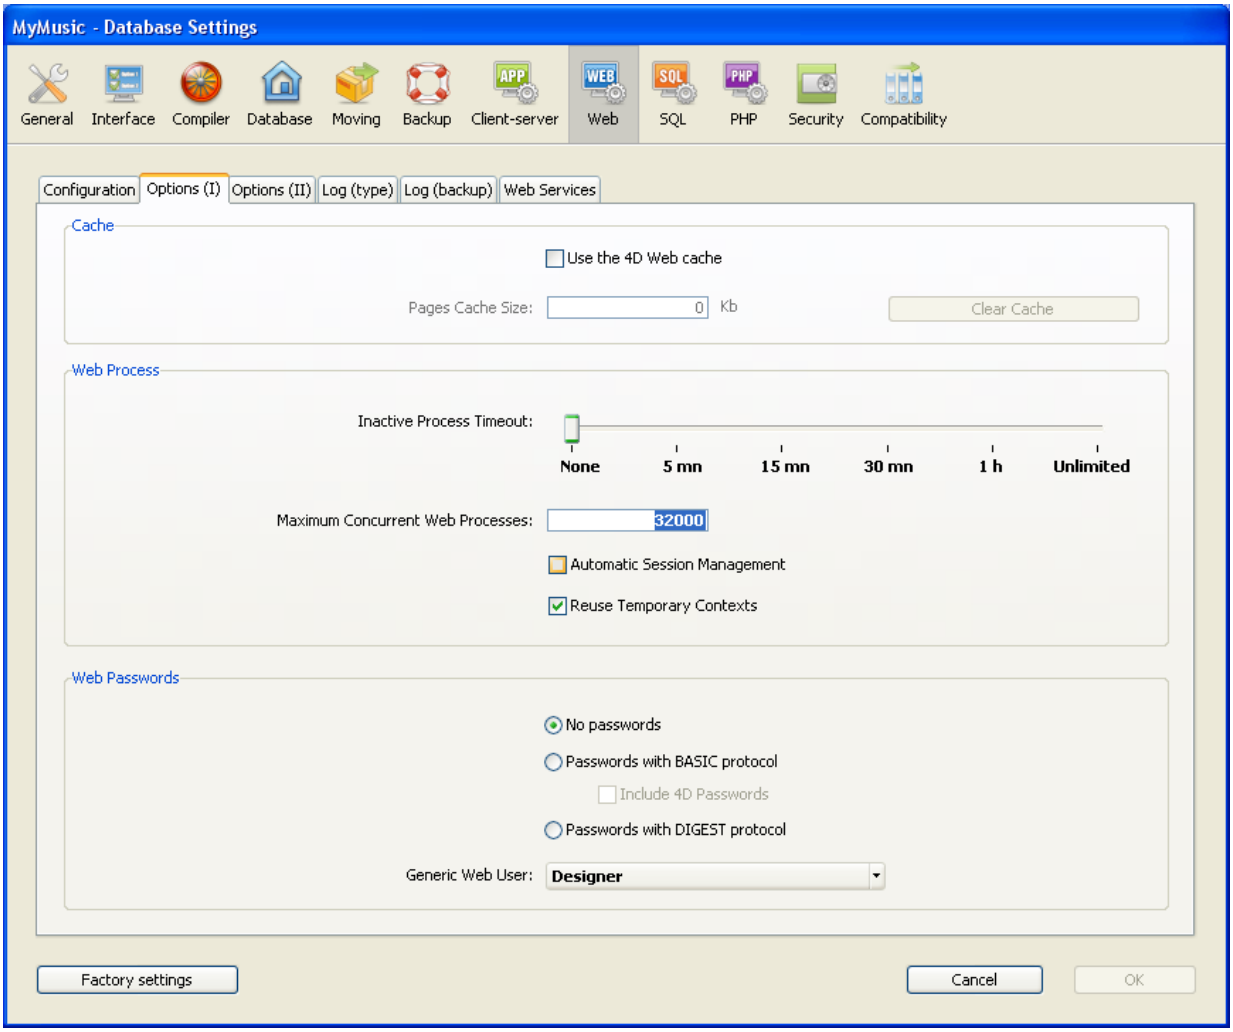
- In BASIC mode, the name and password entered by the user are sent unencrypted in the HTTP requests. This does not ensure total system security since this information could be intercepted and used by a third party.
- The DIGEST mode provides a greater level of security since the authentication information is processed by a one-way process called hashing which makes their contents impossible to decipher.

For the user, the use of either authentication mode is transparent.

**Notes:**

- For compatibility reasons, the BASIC authentication mode is used by default in 4D databases that are converted to version 11 (if the “Use Passwords” option was checked in the previous version). You must explicitly activate the Digest mode.
- Digest authentication is an HTTP1.1 function and is not supported by all browsers. For example, only versions 5.0 and later of Microsoft Internet Explorer accept this mode. If a browser that does not support this functionality sends a request to a Web server when Digest authentication is activated, the server will reject the request and return an error message to the browser.

You can now define, in the Database Settings dialog box, the access control system you want to apply to your Web server. To do this, choose the **Options (I)** page of the **Web** theme:



In the "Passwords" area, three options are available to you:

- **No passwords**: No authentication is carried out for connections to the Web server. In this case:
  - If the **On Web Authentication Database Method** exists, it is executed and, in addition to $1 and $2, only the IP addresses of the browser and the server ($3 and $4) are provided, the user name and password ($5 and $6) are empty. In this case, you can filter connections according to the IP address of the browser and/or the requested IP address of the server.
  - If the **On Web Authentication Database Method** does not exist, connections are automatically accepted.
- **Passwords with BASIC protocol**: Standard authentication in BASIC mode. When a user connects to the server, a dialog box appears on their browser in order for them to enter their user name and password. These two values are then sent to the **On Web Authentication Database Method** along with the other connection parameters (IP address and port, URL...) so that you can process them.
  This mode provides access to the **Include 4D passwords** option that allows you to use, instead of or in addition to your own password system, 4D's database password system (as defined in 4D).
- **Passwords with DIGEST protocol**: Authentication in DIGEST mode. As in BASIC mode, users must enter their name and password when they connect. These two values are then sent encrypted to the **On Web Authentication Database Method** with the other connection parameters. You must authenticate a user using the **WEB Validate digest** command.

**Notes:**

- You must restart the Web server in order for the changes made to these parameters to be taken into account
- With the 4D Client Web server, keep in mind that all the sites published by the 4D Client machines will share the same table of users. Validation of users/passwords is carried out by the 4D Server application.

### BASIC Mode: Combination of passwords and the On Web Authentication Database Method

If you use the BASIC mode, the system that filters connections to the 4D Web server depends on the combination of two parameters:

- The Web password options in the Database Settings dialog box,
- The existence of the **On Web Authentication Database Method**.

Here are the different resulting systems:

The “Passwords with BASIC protocol” option is selected and the “Include 4D Passwords” option is not selected.

- If the **On Web Authentication Database Method** exists, it is executed and all its parameters are given. You can therefore filter more precisely the connections according to the user name, password, and/or the browser’s or Web server’s IP address.
- If the **On Web Authentication Database Method** doesn’t exist, the connection is automatically refused and a message indicating that the Authentication method doesn’t exist is sent to the browser.

**Note:** If the user name sent by the browser is an empty string and if the **On Web Authentication Database Method** doesn’t exist, a password dialog box is sent to the browser.

The “Passwords with BASIC protocol” and “Include 4D Passwords” options are selected.

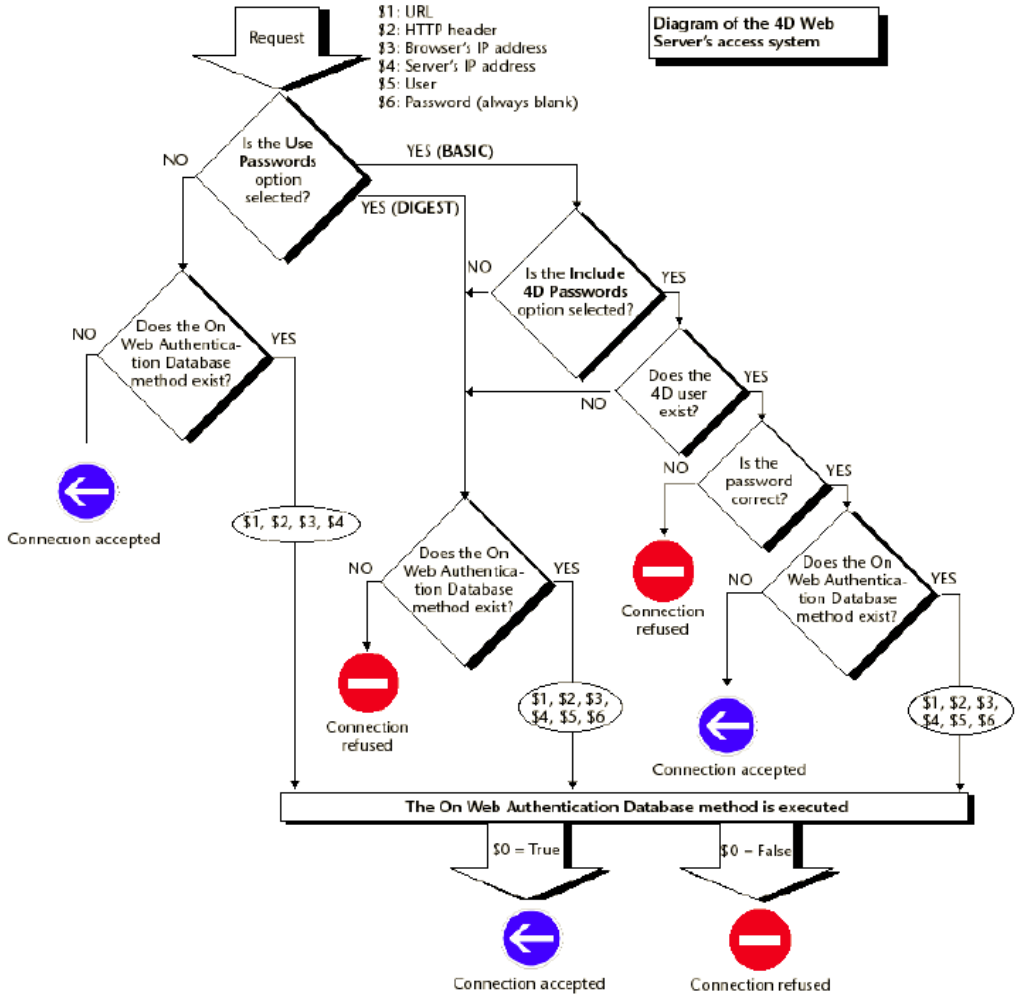
- If the user name sent by the browser exists in the table of 4D users and the password is correct, the connection is accepted. If the password is incorrect, the connection is refused.
- If the user name sent by the browser doesn’t exist in 4D, two results are then possible:
  - If the **On Web Authentication Database Method** exists, the parameters $1, $2, $3, $4, $5, and $6 are returned. You can therefore filter the connections according to the user name, password, and/or the browser’s or Web server’s IP address.
  - If the **On Web Authentication Database Method** doesn’t exist, the connection is refused.

### DIGEST Mode

Unlike BASIC mode, the DIGEST mode is not compatible with standard 4D passwords: it is not possible to use 4D passwords as Web IDs. The “Include 4D passwords” option is dimmed when this mode is selected. The IDs for Web users must be managed in a customized manner (for example, via a table).

When the DIGEST mode is activated, the $6 parameter (password) is always returned empty in the **On Web Authentication Database Method**. In fact, when using this mode, this information does not pass by the network as clear text (unencrypted). It is therefore imperative in this case to evaluate connection requests using the **WEB Validate digest** command.

The operation of the 4D Web server's access system is summarized in the following diagram:



### About robots (security note)

Certain robots (query engines, spiders...) scroll through Web servers and static pages. If you want robots to be able to access your entire site, you can define which URLs they are not allowed to access.
To do so, put the ROBOTS.TXT file at the server's root. This file must be structured in the following manner:

```
User-Agent: <name>
Disallow: <URL> or <beginning of the URL>
```

For example:

```
User-Agent: *
Disallow: /4D
Disallow: /%23%23
Disallow: /GIFS/
```

"User-Agent: *" means that all robots are affected.
"Disallow: /4D" means that robots are not allowed to access URLs beginning with /4D.
"Disallow: /%23%23" means that robots are not allowed to access URLs beginning with /%23%23.
"Disallow: /GIFS/' means that robots are not allowed to access the /GIFS/ folder or its subfolders.

Another example:

```
User-Agent: *
Disallow: /
```

In this case, robots are not allowed to access the entire site.

## Generic Web User

You can designate a user, previously defined in the 4D password table, as a "Generic Web User." In this case, each browser that connects to the database can use the access authorizations and restrictions associated with this generic user. You can therefore easily control the browser's access to the different parts of the database.

**Note:** Do not confuse this option, which allows you to restrict the browser's access to different parts of the application (methods, forms, etc.), with the Web server's connection control system, managed by the password system and the **On Web Authentication Database Method**.

To define a Generic Web User:

1. In the Design mode, create at least one user with the Users editor of the Tool Box.
   You can associate a password with the user if you wish.
2. In the different 4D editors, authorize or restrict access to this user.
3. In the Database Settings dialog, choose the **Options (I)** page of the **Web** theme.
   The "Web Passwords" area contains the **Generic Web User** drop-down list.By default, the Generic Web User is the Designer and the browsers have full access to the entire database.
4. Choose a user in the drop-down list and validate the dialog box

All the Web browsers that are authorized to connect to the database will benefit from the access authorizations and restrictions associated with this Generic Web User (except when the BASIC mode and the "Include 4D Passwords" option are checked and the user that connects does not exist in the 4D password table, see below).

### Interaction with the BASIC protocol

The "Passwords with BASIC protocol" option does not influence how the Generic Web User operates. Whatever the state of this option, the access authorizations and restrictions associated with the "Generic Web User" will be applied to all the Web browsers that are authorized to connect to the database.

However, when the "Include 4D passwords" option is selected, two possible results can occur:

- The user's name and password don't exist in 4D's password table. In this case, if the connection has been accepted by the **On Web Authentication Database Method**, the Generic Web User's access rights will be applied to the browser.
- If the user's name and password exist in 4D's password table, the "Generic Web User" parameter is ignored. The user connects with his own access rights.

## Default HTML Root

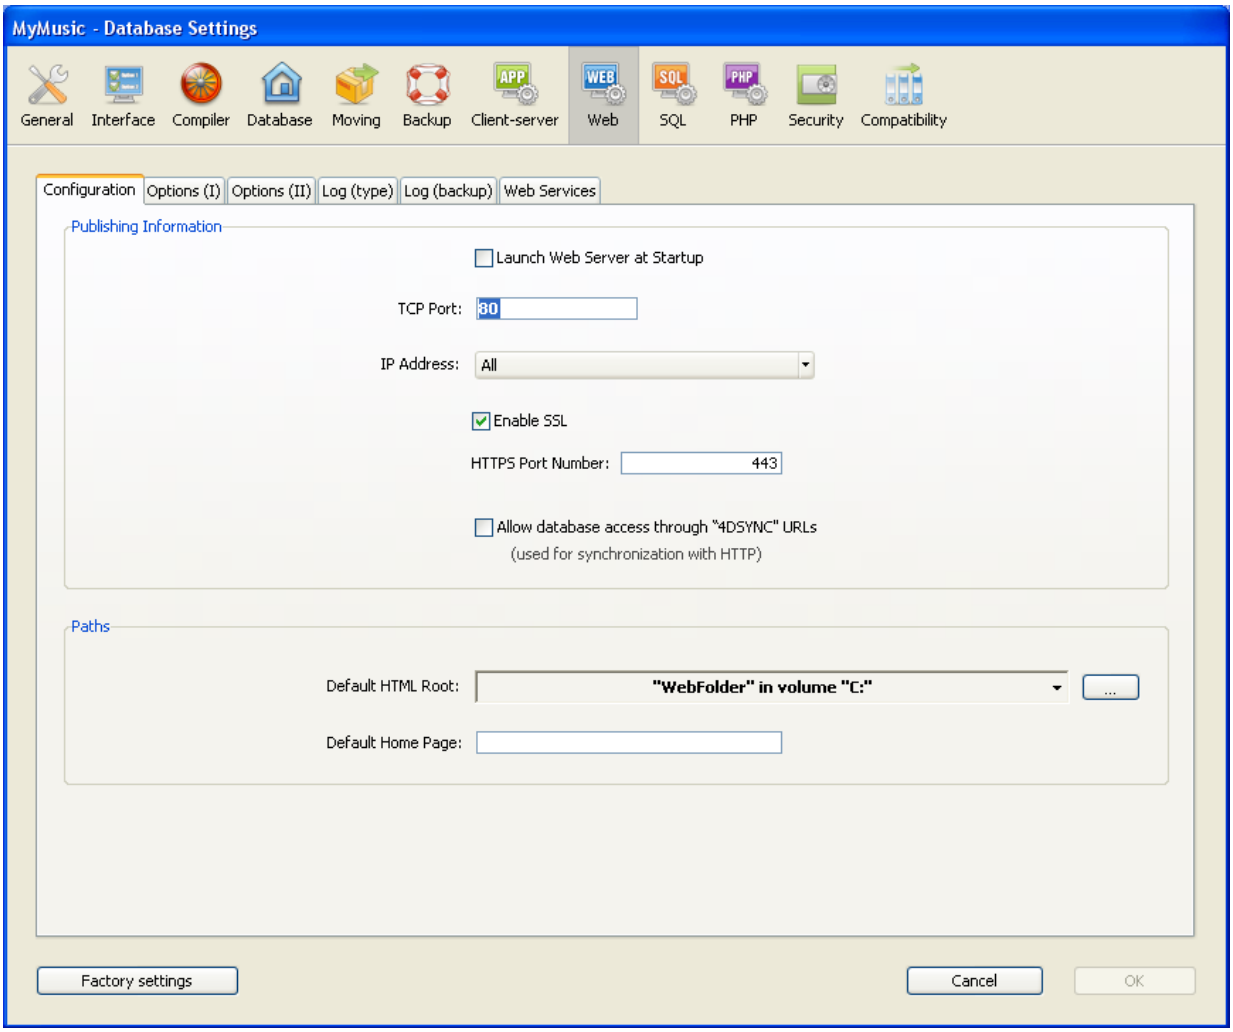
This option in the Database Settings allows you to define the folder in which 4D will search for the static and semi-dynamic HTML pages, pictures, etc., to send to the browsers.

Moreover, the HTML root folder defines, on the Web server hard drive, the hierarchical level above which the files will not be accessible. This access restriction applies to URLs sent to Web browsers as well as to 4D's Web server commands, such as **WEB SEND FILE**. If a URL is sent to the database by a browser or if a 4D command tries to access a file located above the HTML root folder, an error is returned indicating that the file has not been found.

By default, 4D defines a HTML Root folder named **WebFolder**. If it does not already exist, the HTML root folder is physically created on disk at the moment the Web server is launched for the first time.
If you keep the default location, the root folder is created:

- with 4D in local mode and 4D Server, at the same level as that of the database structure file.
  **Note:** as part of a compiled and merged application, the structure file is placed in the **Database** subfolder.
- with 4D in remote mode, in the local folder of the 4D database (see the **Get 4D folder** command).

You can modify the default HTML root folder name and location in the Database Settings dialog box (**Web** theme, **Configuration** page):



In the "Default HTML Root" entry area, enter the new access path of the folder that you wish to define.

The access path entered in this dialog box is relative: it is established from the folder containing the structure of the database (4D in local mode or 4D Server) or the folder containing the 4D application or software package (4D in remote mode).

For multi-platform compatibility of your databases, the 4D Web server uses particular writing conventions to describe access paths. The syntax rules are as follows:

- Folders are separated by a slash ("/")
- The access path must not end with a slash ("/")
- To "go up" one level in the folder hierarchy, enter ".." (two periods) before the folder name
- The access path must not start with a slash ("/") (except if you want the HTML root folder to be the database or 4D remote folder, see below).

For example, if you want the HTML root folder to be the "Web" subfolder in the "4DDatabase" folder, enter **4DDatabase/Web**.

If you want the HTML root folder to be the database or 4D remote folder, but for access to the folders above to be forbidden, enter "/" in the area. For a completely free access to the volumes, leave the "Default HTML Root" area empty.

**WARNING:** If you do not define a default HTML Root folder in the Preferences dialog box, the folder that contains the structure file of the database or the 4D application will be used. **Be careful because in this case there are no access restrictions** (users can access all the volumes).

**Notes:**

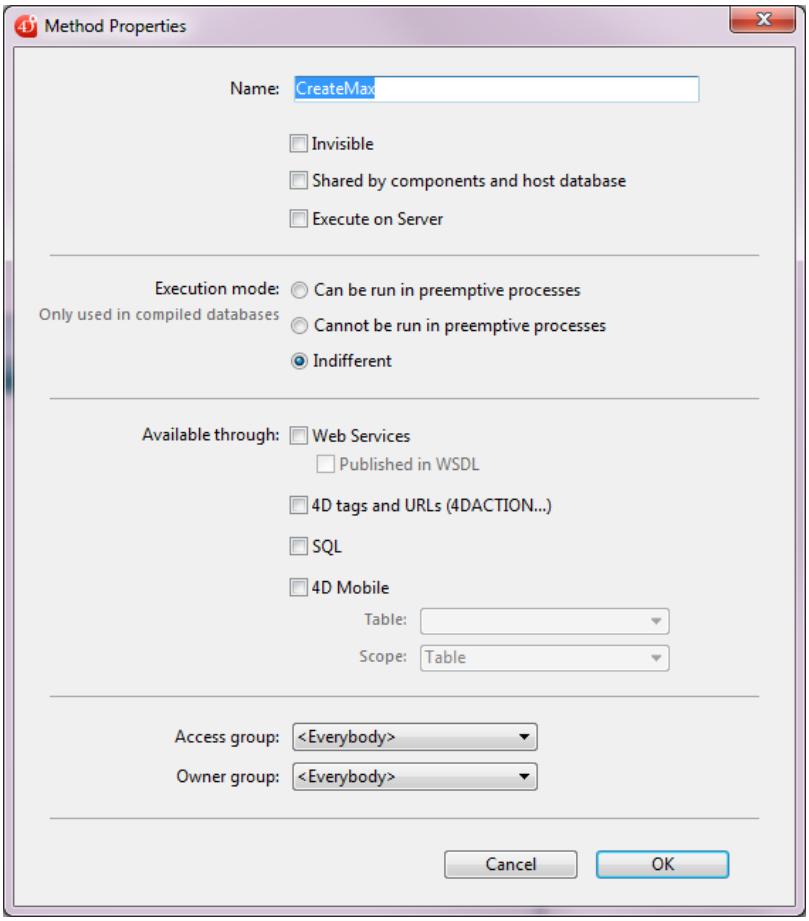
- When the HTML root folder is modified in the Database Settings dialog box, the cache is cleared so as to not store files whose access is restricted.
- You can also dynamically define the HTML root folder by using the **WEB SET ROOT FOLDER** command. In this case, the modification applies to all the current Web process for the worksession. The cache of the HTML pages is therefore cleared.

## Available through 4D tags and URLs

The special *4DACTION* URL and the *4DSCRIPT*, *4DEVAL, 4DTEXT, 4DHTML* (as well as the former *4DVAR* and *4DHTMLVAR*) tags, allow you to trigger the execution of any project method of a 4D database published on the Web. For example, the request *http://www.server.com/4DACTION/Erase_All* causes the execution of the ***Erase_All*** project method, if it exists.

This mechanism therefore presents a security risk for the database, in particular if an Internet user intentionally (or unintentionally) triggers a method not intended for execution via the Web. You can avoid this risk in three ways:

- Restrict access to project methods using the 4D password system. Drawbacks: This system requires the use of 4D passwords and forbids any type of method execution (including using HTML tags).
- Filter the methods called via the URLS using the **On Web Authentication Database Method**. Drawbacks: If the database includes a great number of methods, this system may by difficult to manage.
- Use the **Available through 4D tags and URLs (4DACTION...)** option found in the Method properties dialog box:



This option is used to individually designate each project method that can be called using the special URL, *4DACTION*, or the *4DSCRIPT*, *4DEVAL, 4DTEXT and 4DHTML* (as well as *4DVAR* and *4DHTMLVAR*) tags. When it is not checked, the project method concerned cannot be executed using an HTTP request containing a special URL or tag. Conversely, it can be executed using other types of calls (formulas, other methods, etc.).

This option is unchecked by default for databases created. Methods that can be executed using the *4DACTION* Web URL or the tags must be specifically indicated.

In the Explorer, Project methods with this property are given a specific icon:

## Allow database access through 4DSYNC URLs

This option on the "Web/Configuration" page of the Database SEttings lets you control support of requests containing /4DSYNC URLs. These URLs are used for synchronizing data through HTTP ((for more information about this mechanism, refer to **URL 4DSYNC/**).

This option enables or disables specific processing of requests containing /4DSYNC:

- When it is not checked, /4DSYNC requests are considered as standard requests and do not allow specific processing (using a synchronization request causes a "404 - resource unavailable" type response to be sent).
- When it is checked, the synchronization mechanism is enabled; /4DSYNC requests are considered as special requests and are parsed by the 4D HTTP server.

By default:

- this option is **not checked** in databases created with 4D beginning with version 13.
- this option is **checked** in databases converted from a previous version of 4D, for compatibility reasons. We recommend that you deselect it if your application does not use the HTTP replication function.

The scope of this option is local to the application and the Web server must be restarted to take it into account.

# On Web Authentication Database Method

## Description

The **On Web Authentication Database Method** is in charge of managing Web server engine access. It is called by 4D or 4D Server when a Web browser request requires the execution of a 4D method on the server (method called using a *4DACTION* URL, a *4DSCRIPT* tag, etc.).

This method receives six Text parameters: $1, $2, $3, $4, $5, and $6, and returns one Boolean parameter, $0. The description of these parameters is as follows:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | URL |
| $2 | Text | HTTP header + HTTP body (32 KB maximum) |
| $3 | Text | IP address of the Web client (browser) |
| $4 | Text | IP address of the server |
| $5 | Text | User name |
| $6 | Text | Password |
| $0 | Boolean | True = request accepted, False = request rejected |

You must declare these parameters as follows:

```
` On Web Authentication Database Method

C_TEXT($1;$2;$3;$4;$5;$6)
C_BOOLEAN($0)

` Code for the method
```

**Note:** All the On Web Authentication database method's parameters are not necessarily filled in. The information received by the database method depends on the options that you have previously selected in the Database Settings dialog box (please refer to the section **Connection Security**).

- **URL**

  The first parameter (*$1*) is the URL entered by the user in the location area of his or her Web browser, from which the host address has been removed.

  Let's take the example of an Intranet connection. Suppose that the IP address of your 4D Web Server machine is *123.4.567.89*. The following table shows the values of *$1* depending on the URL entered in the Web browser:

| URL entered in Web browser Location area | Value of parameter $1 |
|---|---|
| 123.4.567.89 | / |
| http://123.4.567.89 | / |
| 123.4.567.89/Customers | /Customers |
| http://123.4.567.89/Customers | /Customers |
| http://123.4.567.89/Customers/Add | /Customers/Add |
| 123.4.567.89/Do_This/If_OK/Do_That | /Do_This/If_OK/Do_That |

- **Header and Body of the HTTP request**

  The second parameter (*$2*) is the header and the body of the HTTP request sent by the Web browser. Note that this information is passed to your **On Web Authentication Database Method** as it is. Its contents will vary depending on the nature of the Web browser which is attempting the connection.
  If your application deals with this information, it is up to you to parse the header and the body.

**Notes:**

- For performance reasons, the size of data passing through the $2 parameter must not exceed 32 KB. Beyond this size, they are truncated by the 4D HTTP server.
- For more information about this parameter, please refer to the description of the **On Web Connection database method**.

- **Web client IP address**

  The $3 parameter receives the IP address of the browser's machine. This information can allow you to distinguish between Intranet and Internet connections.
  **Note:** 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

- **Server IP address**

  The $4 parameter receives the IP address used to call the Web server. 4D since version 6.5 allows for multi-homing, which allows you to exploit machines with more than one IP address. For more information, please refer to the section **Web Server Settings**

- **User Name and Password**

  The $5 and $6 parameters receive the user name and password entered by the user in the standard identification dialog box displayed by the browser. This dialog box appears for each connection, if a password management option has been selected in the Database Settings dialog box (see section **Connection Security**).

**Note:** If the user name sent by the browser exists in 4D, the $6 parameter (the user's password) is not returned for security reasons.

- **$0 parameter**

  The **On Web Authentication Database Method** returns a boolean in $0:
  - If $0 is **True**, the connection is accepted.
  - If $0 is **False**, the connection is refused.

The **On Web Connection database method** is only executed if the connection has been accepted by **On Web Authentication**.

**WARNING:** If no value is set to *$0* or if *$0* is not defined in the **On Web Authentication Database Method**, the connection is considered as accepted and the **On Web Connection database method** is executed.

**Notes :**

- Do not call any interface elements in the **On Web Authentication Database Method** (**ALERT**, **DIALOG**, etc.) because otherwise its execution will be interrupted and the connection refused. The same thing will happen if an error occurs during its processing.
- It is possible to prevent execution by *4DACTION* or *4DSCRIPT* for each project method via the "Available through 4D HTML tags and URLs (4DACTION...)" option in the Method properties dialog box. For more information about this point, please refer to the **Connection Security** section.

## On Web Authentication Database Method calls

The **On Web Authentication Database Method** is automatically called, regardless of the mode, when a request or processing requires the execution of a 4D method. It is also called when the Web server receives an invalid static URL (for example, if the static page requested does not exist).

The **On Web Authentication Database Method** is therefore called in the following cases:

- when 4D receives a URL beginning with *4DACTION/*
- when 4D receives a URL beginning with *4DCGI/*
- when 4D receives a URL beginning with *4DSYNC/*
- when 4D receives a URL requesting a static page that does not exist
- when 4D receives a root access URL and no home page has been set in the Database Settings or by means of the **WEB SET HOME PAGE** command
- when 4D processes a *4DSCRIPT* tag in a semi-dynamic page
- when 4D processes a *4DLOOP* tag based on a method in a semi-dynamic page.

**Compatibility note:** The database method is also called when 4D receives a URL beginning with *4DMETHOD/*. This URL is obsolete and is only kept for compatibility's sake.

Note that the **On Web Authentication Database Method** is NOT called when the server receives a URL requesting a valid static page.

## Example 1

Example of the **On Web Authentication Database Method** in BASIC mode:

```
 `On Web Authentication Database Method
C_TEXT($5;$6;$3;$4)
C_TEXT($user;$password;$BrowserIP;$ServerIP)
C_BOOLEAN($4Duser)
ARRAY TEXT($users;0)
ARRAY LONGINT($nums;0)
C_LONGINT($upos)
C_BOOLEAN($0)

$0:=False

$user:=$5
$password:=$6
$BrowserIP:=$3
$ServerIP:=$4

 `For security reasons, refuse names that contain @
If(WithWildcard($user)|WithWildcard($password))
   $0:=False
 `The WithWildcard method is described below
Else
 `Check to see if it' s a 4D user
   GET USER LIST($users;$nums)
   $upos:=Find in array($users;$user)
   If($upos >0)
      $4Duser:=Not(Is user deleted($nums{$upos}))
   Else
      $4Duser:=False
   End if

   If(Not($4Duser))
 `It is not a user defined 4D, look in the table of Web users
      QUERY([WebUsers];[WebUsers]User=$user;*)
      QUERY([WebUsers]; & [WebUsers]Password=$password)
      $0:=(Records in selection([WebUsers])=1)
   Else
      $0:=True
   End if
End if
 `Is this an intranet connection?
If(Substring($BrowserIP;1;7)#"192.100.")
   $0:=False
End if
```

## Example 2

Example of the **On Web Authentication Database Method** in DIGEST mode:

```
 // On Web Authentication Database Method
C_TEXT($1;$2;$5;$6;$3;$4)
C_TEXT($user)
C_BOOLEAN($0)
$0:=False
$user:=$5
 // For security reasons, refuse names that contain @
If(WithWildcard($user))
   $0:=False
 // The <span class="rte4d_met">WithWildcard</span> method is described below
Else
   QUERY([WebUsers];[WebUsers]User=$user)
   If(OK=1)
      $0:=WEB Validate digest($user;[WebUsers]password)
   Else
      $0:=False // User does not exist
   End if
End if
```

The WithWildcard method is as follows:

```
// WithWildcard Method
// WithWildcard ( String ) -> Boolean
// WithWildcard ( Name ) -> Contains a Wilcard character

C_LONGINT($i)
C_BOOLEAN($0)
C_TEXT($1)

$0:=False
For($i;1;Length($1))
   If(Character code(Substring($1;$i;1))=Character code("@"))
      $0:=True
   End if
End for
```

## On Web Connection Database Method

---

The **On Web Connection Database Method** can be called in the following cases:

- the Web server receives a request beginning with the *4DCGI* URL.
- the Web server receives an invalid request.

For more information, refer to the paragraph “On Web Connection Database Method calls” below.

**Compatibility note**: The database method is also called when a context is created in contextual mode (obsolete mode that could be used in converted 4D databases).

The request should have been previously accepted by the **On Web Authentication database method** (if it exists) and the Web server must be launched.

The **On Web Connection Database Method** receives six text parameters that are passed by 4D. The contents of these parameters are as follows:

| Parameters | Type | Description |
|---|---|---|
| $1 | Text | URL |
| $2 | Text | HTTP header + HTTP body (up to 32 kb limit) |
| $3 | Text | IP address of the Web client (browser) |
| $4 | Text | IP address of the server |
| $5 | Text | User name |
| $6 | Text | Password |

You must declare these parameters as follows:

```
` On Web Connection Database Method

C_TEXT($1;$2;$3;$4;$5;$6)

` Code for the method
```

- **URL extra data**

  The first parameter (*$1*) is the URL entered by the user in the location area of his or her Web browser, from which the host address has been removed.
  Let’s take the example of an Intranet connection. Suppose that the IP address of your 4D Web Server machine is *123.4.567.89*. The following table shows the values of *$1* depending on the URL entered in the Web browser:

  | URL entered in Web browser Location area | Value of parameter $1 |
  |---|---|
  | 123.4.567.89 | / |
  | http://123.4.567.89 | / |
  | 123.4.567.89/Customers | /Customers |
  | http://123.4.567.89/Customers | /Customers |
  | http://123.4.567.89/Customers/Add | /Customers/Add |
  | 123.4.567.89/Do_This/If_OK/Do_That | /Do_This/If_OK/Do_That |

  Note that you are free to use this parameter at your convenience. 4D simply ignores the value passed beyond the host part of the URL.
  For example, you can establish a convention where the value *"/Customers/Add"* means “go directly to add a new record in the *[Customers]* table.” By supplying the Web users of your database with a list of possible values and/or default bookmarks, you can provide shortcuts to the different parts of your application. This way, Web users can quickly access resources of your Web site without going through the whole navigation path each time they make a new connection to your database.

**WARNING:** In order to prevent a user from reentering a database with a bookmark created during a previous session, 4D intercepts any URL that corresponds to one of the standard 4D URLs.

- **Header of the HTTP request followed by the HTTP body**
  The second parameter (*$2*) is the header and the body of the HTTP request sent by the Web browser. Note that this information is passed to your **On Web Connection Database Method** as it is. Its contents will vary depending on the nature of the Web browser which is attempting the connection.

  With Safari running on Mac OS, you may receive a header similar to this:

  ```
  GET /favicon.ico HTTP/1.1
  Referer: http://123.45.67.89/4dcgi/test
  User-Agent: Mozilla/5.0 (Macintosh; U; Intel Mac OS X; fr-fr) AppleWebKit/523.10.3 (KHTML, like Gecko) Version/3.0.4
  Safari/523.10
  Cache-Control: max-age=0
  Accept: */*
  Accept-Language: fr-fr
  Accept-Encoding: gzip, deflate
  Connection: keep-alive
  Host: 123.45.67.89
  ```

  With Microsoft Internet Explorer 8 running on Windows, you may receive a header similar to this:

  ```
  GET / HTTP/1.1
  Accept: image/jpeg, application/x-ms-application, image/gif, application/xaml+xml, image/pjpeg, application/x-ms-xbap,
  application/vnd.ms-powerpoint, application/vnd.ms-excel, application/msword, */*
  Accept-Language: fr-FR
  User-Agent: Mozilla/4.0 (compatible; MSIE 8.0; Windows NT 6.1; Trident/4.0; SLCC2; .NET CLR 2.0.50727; .NET CLR
  3.5.30729; .NET CLR 3.0.30729; Media Center PC 6.0; .NET4.0C)
  Accept-Encoding: gzip, deflate
  Host: 123.45.67.89
  Connection: Keep-Alive
  ```

  If your application deals with this information, it is up to you to parse the header and the body.
  **Note:** For performance reasons, the size of these data cannot be more than 32 KB. Beyond this, they are truncated by the 4D HTTP server.

- **IP address of the Web client**
  The *$3* parameter receives the IP address of the browser's machine. This information can allow you to distinguish between Intranet and Internet connections.
  **Note:** 4D returns IPv4 addresses in a hybrid IPv6/IPv4 format written with a 96-bit prefix, for example ::ffff:192.168.2.34 for the IPv4 address 192.168.2.34. For more information, refer to the **Support of IPv6** section.

- **IP address of the server**
  The *$4* parameter receives the IP address to which the HTTP request was sent. 4D allows for multi-homing, which allows you to exploit machines with more than one IP address. For more information, please refer to the section **Web Server Settings**.

- **User Name and Password**
  The *$5* and *$6* parameters receive the user name and password entered by the user in the standard identification dialog box displayed by the browser. This dialog box appears for each connection, if the **Use Passwords** option has been selected in the Database Settings dialog box (see section **Connection Security**).

**Note:** If the user name sent by the browser exists in 4D, the *$6* parameter (the user's password) is not returned for security reasons.

## On Web Connection Database Method Calls

The **On Web Connection Database Method** can be used as the entry point for the 4D Web server, either using the special *4DCGI* URL, or using customized command URLs.

**Warning:** Calling a 4D command that displays an interface element (**DIALOG**, **ALERT**, etc.) ends the method processing.

The **On Web Connection Database Method** is therefore called in the following cases:

- When 4D receives the */4DCGI* URL. The database method is called with the */4DCGI/<action>* URL in *$1*.
- When a Web page is called with a URL of type *<path>/<file>* is not found. The database method is called with the URL (*).
- When a Web page is called with a URL of type *<file>/* and no home page has been defined by default. The database method is called with the URL (*).

(*) In this particular cases, the URL received in *$1* does NOT start with the "/" character.

## On Web Close Process database method

---

The **On Web Close Process database method** is called by the 4D Web server each time a Web session is about to be closed. A session can be closed in the following cases:

- when the maximum number of simultaneous sessions is reached (100 by default, modifiable using the **WEB SET OPTION** command), and 4D needs to create new ones (4D automatically kills the process of the oldest inactive session),
- when the maximum period of inactivity for the session process is reached (480 minutes by default, modifiable using the **WEB SET OPTION** command),
- when the **WEB CLOSE SESSION** command is called.

When this database method is called, the context of the session (variables and selections generated by the user) is still valid. This means that you can save data related to the session in order to be able to use them again subsequently, more specifically using the **On Web Connection Database Method**.

**Note:** In the context of a 4D Mobile session (which can generate several processes), the **On Web Close Process database method** is called for each Web process that is closed, allowing you to save all types of data (variables, selection, etc.) generated by the 4D Mobile session process.

An example of the **On Web Close Process database method** is provided in the **Web Sessions Management** section.

# Web Sessions Management

The 4D Web Server provides a simple and complete mechanism for managing user sessions. This automatic mechanism allows successive Web clients to reuse the same context (selections and variable instances) from one request to another.

This is done through a private cookie set by 4D itself: "4DSID". On each web client request, 4D checks for the presence and the value of the 4DSID cookie:

- If the cookie has a value, 4D tries to find the context that created this cookie among the existing contexts,
  - If this context is found, it is reused for the call; the ***Compiler_Web*** method is not executed,
  - If no context is found, 4D creates a new one,
- If the cookie does not have a value or if it is not present (because it is expired, for instance), 4D creates a new context.

## Enabling and disabling the mechanism

The session management mechanism must be enabled on your 4D Web server so that you can use it in your application.

By default, this mechanism is enabled in databases created with 4D v13 and later versions. However, for compatibility reasons, it is disabled in databases converted from previous versions of 4D. You must enable it explicitly in order to benefit from this new functionality.

There are two ways to enable automatic session management:

- Using the **Automatic Session Management** option on the "Options (I)" page of the Database Settings:

  When you do this, the setting is permanent; it is saved to disk.
- Using the Web Keep session option of the **WEB SET OPTION** command. In this case, this setting is applied only to the session and "overrides" the setting defined in the database settings.

In both cases, the setting is local to the machine; so it can be different on the 4D Server Web server and the Web servers of remote 4D machines.

## Cookie expiration and preserving of contexts

The lifespan of an inactive cookie is 8 hours (480 minutes) by default but this can be changed using the **WEB SET OPTION** command. You can set a different lifespan for cookies (Web Inactive session timeout option) from the one for processes associated with server sessions (Web Inactive process timeout option): for instance, you may want for a shopping "basket" to remain valid for 24 hours but, for optimization purposes, you do not want to keep the process for that long. In this case, you can set a process life duration of 4 hours, for example. At the end of this period, the **On Web Close Process database method** is called and you can store the variables and selections related to the session before the process is killed. The next time the Web client connects (up to 24 hours later), the cookie is sent back to the server and you can reload the session information in the **On Web Connection Database Method** (see example below).

If necessary, you can use the **WEB CLOSE SESSION** command to force the expiration of the cookie at any time and thus close the session.

## Destruction of inactive contexts

4D automatically destroys the oldest inactive contexts when the maximum number of kept contexts is reached (this number is 100 by default and can be changed using the **WEB SET OPTION** command).
When a context is about to be destroyed (closing of the associated Web process), the **On Web Close Process database method** is called, which lets you save the context variables and selections, in anticipation of subsequent reuse.

## Example

This example shows how easy it is to manage sessions using the **On Web Connection Database Method**and the **On Web Close Process database method**.

Here is the code of the **On Web Connection Database Method**:

```
 // On Web Connection (or On Web Authentication)
C_TEXT(www_SessionID)
If(www_SessionID=WEB Get Current Session ID)
 // Compiler_Web is not called
 // All variables and selection already exist
   ...
Else
 // Compiler_Web has just been executed.
 // This is a new session, no variable or selection exists
 // Keep track of the session that 4D just created
   www_SessionID:=WEB Get Current Session ID

 // Initialization of session
 // Set up selections
 // find connected user
   QUERY([User];[User]Login=www_Login)
   QUERY([prefs];[prefs]Login=www_Login)

 // find employee coordinates
   QUERY([employees];[employees]Name=[user]name)
   QUERY([company];[company]Name=[user]company)

 // Setup variables
 // Get prefs for this user
   SELECTION TO ARRAY([prefs]name;prefNames;[prefs]values;prefValues)
   www_UserName:=[User]Name
   www_UserMail:=[User]mail

 // Session is now initialized
End if
```

Code for **On Web Close Process database method** :

```
 // On Web Session Suspend
 // After a period of inactivity or whenever necessary, 4D closes the session
```

```
C_TEXT(www_SessionID)
www_SessionID:=""
 // We store the session info
 // We save the preferences of the previously connected user
QUERY([prefs];[prefs]Login=www_Login) // kept in the session
ARRAY TO SELECTION(prefNames;[prefs]name;prefValues;[prefs]values)

 // Important: the process is then killed
 // 4D deletes the variables, selections, etc.
```

## In Case of Rejected Cookies

Since the session management mechanism is based on the use of cookies, the 4D HTTP server is not able to maintain a session if the Web client does not accept cookies. In this case, each request is treated as a new connection and the ***Compiler_Web*** method is executed on each connection.

You can check for cookie support with the **WEB GET HTTP HEADER** command.

## Session and IP management

The 4D HTTP Server keeps track of the IP that started a session. If a different IP tries to access an existing session, an HTTP 400 error is returned to the client.

# Semi-dynamic pages

4D's Web server allows you to use **semi-dynamic pages**.

These pages are HTML 'templates' containing **4D Transformation Tags**, i.e. a mix of static HTML code and 4D references added by means of transformation tags such as 4DHTML, 4DIF, or 4DINCLUDE. These tags are inserted as HTML type comments (*<!--#Tag Contents-->*) into the HTML source code.

**Note:** An alternative $-based syntax is used in certain conditions for 4DHTML, 4DTEXT and 4DEVAL tags in order to make them XML-compliant. For more information, refer to **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL** section.

When these pages are sent by the HTTP server, they are parsed and the tags they contain are executed and replaced with the resulting data. The pages received by the browsers are thus a combination of static elements and values coming from 4D.

## Principles

You can use programming to give default values to HTML objects by including *<!--#4DTEXT VarName-->* in the **value** field of the HTML object, where **VarName** is the name of the 4D process variable as defined in the current Web process. This is the name that you surround with the standard HTML notation for comments *<!--#...-->*.

**Note**: Some HTML editors may not accept *<!--#4DTEXT VarName-->* in the **value** field of HTML objects. In this case, you will have to type it in the HTML code.

In fact, the syntax *<!--#4DTEXT VarName-->* allows you to insert 4D data anywhere in the HTML page. For example, if you write:

<P>Welcome to *<!--#4DTEXT vtSiteName-->*!</P>

The value of the 4D variable *vtSiteName* will be inserted in the HTML page.

Here is an example:

```
 // The following piece of 4D code assigns "4D4D" to the process variable vs4D
vs4D:="4D4D"
 // Then it sends the HTML page "AnyPage.HTM"
SEND HTML FILE("AnyPage.HTM")
```

The source of the HTML page **AnyPage.HTM** is listed here:

```
<html> <head>     <title>AnyPage</title> <script language="JavaScript"><!-- function Is4DWebServer(){     return (document.frm.vs4D.value=="4D4D") } function HandleButton(){     if(Is4DWebServer()){         alert("You are connected to 4D Web Server!")     } else {         alert("You are NOT connected to 4D Web Server!") } //--></script> </head> <body> <form action="/4DACTION/WWW_STD_FORM_POST" method="post" name="frm"> <p><input type="hidden" name="vs4D" value="<!--#4DTEXT vs4D-->"</p> <p><a href="JavaScript:HandleButton()"><img src="AnyGIF.GIF" border=0 align=bottom></a></p> <p><input type="submit" name="bOK" value="OK"></p> </form> </body> </html>
```

The *<!--#4DTEXT -->* tag also allows the insertion of **4D expressions** in the pages sent (fields, array elements, etc.). The operation of this tag with this type of data is identical to that with variables. You can also insert HTML code into 4D variables using the *4DHTML* tag. Other tags such as *4DIF* allow you to control the executed code. A description of all the tags that you can use is found in the **4D Transformation Tags** section.

## Processing tags

Parsing of the contents of semi-dynamic pages sent by 4D takes place when **WEB SEND FILE** (.htm, .html, .shtm, .shtml), **WEB SEND BLOB** (text/html type BLOB) or **WEB SEND TEXT** commands are called, as well as when sending pages called using URLs. In this last case, for reasons of optimization, pages that are suffixed with “.htm” and “.html” are NOT parsed. In order to "force" the parsing of HTML pages in this case, you must add the suffix “.shtm” or “.shtml” (for example, http://www.server.com/dir/page.shtm). An example of the use of this type of page is given in the description of the **WEB GET STATISTICS** command. XML pages (.xml, .xsl) and WML pages (.wml) are also supported and always parsed by 4D (see **XML and WML Support** section).

You can also carry out parsing outside of the Web context when you use the **PROCESS 4D TAGS** command.

Internally, the parser works with UTF-16 strings, but the data to parse may have been encoded differently. When tags contain text  (for example, 4DHTML), 4D converts the data when necessary depending on its origin and the information

available (*charset*). Below are the cases where 4D parses the tags contained in the HTML pages, as well as any conversions carried out:

| Action | Content analysis of the sent pages | Support of $ syntax(*) | Character set used for parsing tags |
|---|---|---|---|
| Pages called via URLs | X, except for pages with ".htm" or ".html" extensions | X, except for pages with ".htm" or ".html" extensions | Use of charset passed as parameter of the "Content-Type" header of the page. If there is none, search for a META-HTTP EQUIV tag with a charset. Otherwise, use of default character set for the HTTP server |
| **WEB SEND FILE** command call | X | - | Use of charset passed as parameter of the "Content-Type" header of the page. If there is none, search for a META-HTTP EQUIV tag with a charset. Otherwise, use of default character set for the HTTP server |
| **WEB SEND TEXT** command call | X | - | No conversion necessary |
| **WEB SEND BLOB** command call | X, if BLOB is of the "text/html" type | - | Use of charset set in the "Content-Type" header of the response. Otherwise, use of default character set for the HTTP server |
| Inclusion by the *<!--#4DINCLUDE-->* tag | X | X | Use of charset passed as parameter of the "Content-Type" header of the page. If there is none, search for a META-HTTP EQUIV tag with a charset. Otherwise, use of default character set for the HTTP server |
| **PROCESS 4D TAGS** command call | X | X | Text data: no conversion. BLOB data: automatic conversion from the Mac-Roman character set for compatibility |

(*) The alternative $-based syntax is available for 4DHTML, 4DTEXT and 4DEVAL tags (see **Alternative syntax for 4DTEXT, 4DHTML, 4DEVAL** section).

## JavaScript Encapsulation

4D supports JavaScript source code embedded into HTML documents, and also JavaScript *.js* files embedded in HTML documents (for example *<SCRIPT SRC="...">*).

Using **WEB SEND FILE** or **WEB SEND BLOB**, you send a page that you have prepared in an HTML source editor or built programmatically using 4D and saved as a document on disk. In both cases, you have full control of the page. You can insert JavaScript scripts in the HEAD section of the document as well as use scripts with the FORM markup. In the previous example, the script refers to the form "frm" because you were able to name the form. You can also trigger, accept, or reject the submission of the form at the FORM markup level.

**Note**: 4D supports Java applets transport.

# URLs and Form Actions

The 4D Web Server offers different URLs and HTML form actions that allow you to implement various actions in your database.

These URLs are the following:

- *4DACTION/*, to link any HTML object to a project method of your database,
- *4DCGI/*, to call the **On Web Connection Database Method** from any HTML object.
- *4DSYNC/*, to synchronize the data of the tables.

In addition, the 4D Web Server accepts several additional URLs:

- */4DSTATS*, */4DHTMLSTATS*, */4DCACHECLEAR* and */4DWEBTEST*, to allow you to obtain information about the functioning of your 4D Web site. These URLs are described in the section **Information about the Web Site**.
- */4DWSDL*, to allow you to access the declaration file of Web Services published on the server. For more information, refer to the **Web Services (Server) Commands** section and to the Design Reference manual.

## URL 4DACTION/

**Syntax:** *4DACTION/MyMethod{/Param}*

**Usage:** URL or Form action.

This URL allows you to link an HTML object (text, button...) to a 4D project method. The link will be */4DACTION/MyMethod/Param* where ***MyMethod*** is the name of the 4D project method to be executed when the user clicks on the link and *Param* an optional Text parameter to pass to the method in *$1* (see paragraph “The Text Parameters Passed to 4D Methods Called via URLs” below).

When 4D receives a */4DACTION/MyMethod/Param* request, the **On Web Authentication Database Method** (if it exists) is called. If it returns **True**, the ***MyMethod*** method is executed.
*4DACTION/* can be associated with a URL in a static Web page. The syntax of the URL must be in the following form:

```
<A HREF="/4DACTION/MyMethod/Param"> Do Something</A>
```

The ***MyMethod*** project method should generally return a "reply" (sending of an HTML page using **WEB SEND FILE** or **WEB SEND BLOB**, etc.). Be sure to make the processing as short as possible in order not to block the browser.

**Note:** A method called by *4DACTION* must not call interface elements (**DIALOG**, **ALERT**, etc.).

**Warning:** For a 4D method to be able to be executed using the *4DACTION/* URL, it must have the “Available through 4D HTML tags and URLS (4DACTION...)” attribute (unchecked by default), defined in the Method properties. For more information on this point, refer to the section **Connection Security**.

### Example 1

This example describes the association of the *4DACTION/* URL with an HTML picture object in order to dynamically display a picture in the page. You insert the following instructions in a static HTML page:

```
<IMG SRC="/4DACTION/PICTFROMLIB/1000">
```

The ***PICTFROMLIB*** method is as follows:

```
C_TEXT($1) // This parameter must always be declared
C_PICTURE($PictVar)
C_BLOB($BlobVar)
C_LONGINT($Number)
 // We retrieve the picture' s number in the string $1
$Number:=Num(Substring($1;2;99))
GET PICTURE FROM LIBRARY($Number;$PictVar)
```

```
PICTURE TO GIF($PictVar;$BlobVar)
WEB SEND BLOB($BlobVar;"Pict/gif")
```

### 4DACTION to post forms

The 4D Web server also allows you to use “posted” forms, which are static HTML pages that send data to the Web server, and to easily retrieve all the values. The POST type must be associated to them and the form’s action must imperatively start with */4DACTION/MethodName*.

**Note:** A form can be submitted through two methods (both can be used with 4D):

- POST, usually used to add data into the Web server - to a database,
- GET, usually used to request the Web server - data coming from a database.

In this case, when the Web server receives a posted form, it calls the **On Web Authentication Database Method** (if it exists). If it returns **True**, the ***MethodName*** method is executed. In this method, you must call the **WEB GET VARIABLES** command in order to retrieve the names and values of all the fields included in an HTML page submitted to the server.

**Compatibility note:** In converted databases, if the "Automatic variable assignment" option on the **Compatibility page** is checked, the special ***COMPILER_WEB*** project method (if it exists) is called first; 4D retrieves the values of HTML fields found in the form and automatically fills the 4D variables in the called method with their contents if they have the same name. This functioning is obsolete. For more information, refer to the **Binding 4D objects with HTML objects** section.

The HTML syntax to apply in the form is of the following type:

- to define the action in a form:

```
<FORM ACTION="/4DACTION/MethodName" METHOD=POST>
```

- to define a field in a form:

```
<INPUT TYPE=Field type NAME=Field name VALUE="Default value">
```

For each field in the form, 4D sets the value of the field to the variable with the same name.

### Example 2

In a 4D Web database, we would like for the browsers to be able to search among the records by using a static HTML page. This page is called “search.htm”. The database contains other static pages that allow you to, for example, display the search result (“results.htm”). The POST type has been associated to the page, as well as the */4DACTION/SEARCH* action.

Here is the HTML code that corresponds to this page:

```
<FORM ACTION="/4DACTION/PROCESSFORM" METHOD=POST> <INPUT TYPE=TEXT NAME=VNAME VALUE=""><BR> <INPUT TYPE=CHECKBOX NAME=EXACT
VALUE="Word">Whole word<BR> <INPUT TYPE=SUBMIT NAME=OK VALUE="Search"> </FORM>
```

During data entry, type “ABCD” in the data entry area, check the "Whole word" option and validate it by clicking the **Search** button.

In the request sent to the Web server:

```
VNAME="ABCD"
vEXACT="Word"
OK="Search"
```

4D calls the **On Web Authentication Database Method** (if it exists), then the PROCESSFORM project method is called, which is as follows:

```
C_TEXT($1) //mandatory for compiled mode
C_LONGINT($vName)
C_TEXT(vNAME;vLIST)
ARRAY TEXT($arrNames;0)
ARRAY TEXT($arrVals;0)
WEB GET VARIABLES($arrNames;$arrVals) //we retrieve all the variables of the form
$vName:=Find in array($arrNames;"vNAME")
vNAME:=$arrVals{$vName}
If(Find in array($arrNames;"vEXACT")=-1) //If the option has not been checked
```

```
      vNAME:=VNAME+"@"
   End if
   QUERY([Jockeys];[Jockeys]Name=vNAME)
   FIRST RECORD([Jockeys])
   While(Not(End selection([Jockeys])))
      vLIST:=vLIST+[Jockeys]Name+" "+[Jockeys]Tel+"<BR>"
      NEXT RECORD([Jockeys])
   End while
   WEB SEND FILE("results.htm") //Send the list to the results.htm form
    //which contains a reference to the variable vLIST,
    //for example <!--4DHTML vLIST-->
    //...
  End if
```

## URL 4DCGI/

**Syntax:** *4DCGI/<action>*

**Usage:** URL.

When the 4D Web server receives the */4DCGI/<action>* URL, the **On Web Authentication Database Method**(if it exists) is called. If it returns **True**, the Web server calls the **On Web Connection Database Method** by sending the URL "as is " to *$1*.

The *4DCGI/* URL does not correspond to any file. Its role is to call 4D using the **On Web Connection Database Method**. The "<action>" parameter can contain any type of information.

This URL allows you to perform any type of action. You just need to test the value of *$1* in the **On Web Connection Database Method** or in one of its submethods and have 4D perform the appropriate action. For example, you can build completely custom static HTML pages to add, search, or sort records or to generate GIF images on-the-fly. Examples of how to use this URL are in the descriptions of the **PICTURE TO GIF** and **WEB SEND HTTP REDIRECT** commands.

When issuing an action, a "response" must be returned, by using commands that send data (**WEB SEND FILE**, **WEB SEND BLOB**, etc.).

**Warning:** Please be sure to execute the shortest possible actions so as not to hold up the browser.

## The Text Parameters Passed to 4D Methods Called via URLs

4D sends text parameters to any 4D method called via special URLs (*4DACTION/* and *4DCGI/*), in both contextual and non-contextual modes. Regarding these text parameters:

- Although you do not use these parameters, you must explicitly declare them with the **C_TEXT** command, otherwise runtime errors will occur while using the Web to access a database that runs in compiled mode. The message is of the following type:
  *"**Error in dynamic code***
  *Invalid parameters in an EXECUTE command*
  *Method Name:*
  *Line Number:*
  *Description: [<date and time>]"*
  This runtime error is caused by the fact that the text parameter *$1* was not declared in the 4D method called when you clicked on the HTML link. Since the execution context is the current HTML page, the error does not specifically reference the method line. Explicitly declaring the text parameter *$1* will eliminate these errors:

  ```
   //M_SEND_PAGE project method
  C_TEXT($1) // This parameter MUST be explicitly declared
   //...
  WEB SEND FILE($mypage)
  ```

- The *$1* parameter returns the extra data placed at the end of the URL, and can be used as a placeholder for passing values from the HTML environment to the 4D environment.

### Parameters to declare explicitly in the called 4D method

You must declare different parameters depending on the nature and the origin of the call to a 4D method.

- **On Web Authentication Database Method** (if any) and **On Web Connection Database Method**
  You must declare the six parameters of the connection:

```
 //On Web Connection Database Method
C_TEXT($1;$2;$3;$4;$5;$6) //These parameters MUST be explicitly declared
```

- Method called by the URL *4DACTION/*
  You must declare the *$1* parameter:

```
 //Method called by the URL 4DACTION/
C_TEXT($1) //This parameter MUST be explicitly declared
```

- Method called by the tag *4DSCRIPT/* as an HTML comment in a document
  The method should return a value in $0. You must declare the *$0* and *$1* parameter:

```
 //Method called by the tag 4DSCRIPT/ as an HTML comment
C_TEXT($0;$1) //These parameters MUST be explicitly declared
```

## URL 4DSYNC/

**Syntax:**
*4DSYNC/$catalog{/TableName}*
*4DSYNC/TableName{/TableName}{/FieldName1,...,FieldNameN}{Params}*

**Usage:** URL in POST or GET method

This URL synchronizes the data in the tables of the local 4D database with a remote database using HTTP. It is used to synchronize a 4D database with a client application installed for example on a Smartphone or other third-party HTTP applications.

The *4DSYNC/* URL is used in a GET method to recover the data of the 4D database or in a POST method to update the data in the 4D database.

Here are the different HTTP requests that can be received:

- *GET /4DSYNC/$catalog*
  Returns the list of database tables and how many records they contain. For example, if you have a structure with two tables: PEOPLE (2 records) and INVOICES (3 records), when you use the syntax: *http://localhost/4DSYNC/$catalog/* it returns PEOPLE 2 INVOICES 3 in the browser.

- *GET /4DSYNC/$catalog/TableName*
  Returns a description of the *TableName* structure (XML format).

- *GET /4DSYNC/TableName/FieldName1{,FieldName2},...*
  Returns the data of the *FieldName* field in the *TableName* table.

- *GET /4DSYNC/TableName/FieldName1?$stamp=0&$format=json*
  Returns the data of the *FieldName* field in the *TableName* table starting from *stamp* 0 and in the *json* format.

- *POST /4DSYNC/TableName/FieldName1{,FieldName2},...*
  Integrates the modifications made on the client machine into the 4D database.

**Note:** The data exchange format is JavaScript Objet Notation (JSON). The complete grammar is available from the technical support of 4D, Inc.

**Note:** In order for synchronization mechanisms to be enabled, the **Allow database access through "4DSYNC" URLs** option must be checked on the "Web/Configuration" page of the Database Settings (see below). Otherwise, requests containing 4DSYNC URLs will fail.

### Notes about synchronization with HTTP

When using the *4DSYNC/* URL, you need to take the following principles into account:

- 4D works with the virtual structure of the database if it exists. In this case, the *TableName* and *FieldName* parameters correspond to table and field names that have been specified using the **SET FIELD TITLES** and **SET TABLE TITLES** commands. Note that the scope of these commands is the session and when using 4D Server you must call them in a stored procedure on the server.
- Replication of BLOB and Picture type fields is not supported.

- To be able to synchronize data:
  - The HTTP server must be launched.
  - The **Allow database access through "4DSYNC" URLs** option must be checked on the "Web/Configuration" page of the Database Settings (see the **Connection Security** section).
  - The "Enable Replication" property must be checked for each table where you want to synhronize the data. If a virtual structure has been defined, these tables must be included in it. Warning: checking this option publishes additional information; you must make sure that access to your database is protected (see the description of this option in **Connection Security**).
- When 4D receives a */4DSYNC* request, the **On Web Authentication Database Method** is called (except when the password is incorrect, see the connection diagram in **Connection Security**). If it returns **True**, the request is executed; otherwise it is refused.

# Binding 4D objects with HTML objects

4D's Web server lets you recover "posted" data, i.e. data entered by users through Web forms and sent to the server by means of buttons or interface elements, in POST mode or in GET mode.

The Web server accepts several specific URLs that can be associated with buttons so that the submission of the form triggers server-side processing. These URLs are described in the **URLs and Form Actions** section.

This chapter covers the principles implemented in order to recover data found in forms that were returned to the server.

## Receiving dynamic values

When the 4D Web server receives a posted form, 4D can retrieve the values of any HTML objects it contains. This principle can be implemented in the case of a Web form, sent for example using **WEB SEND FILE** or **WEB SEND BLOB**, where the user enters or modifies values, then clicks on the validation button. In this case, there are two ways that 4D can retrieve the values of the HTML objects found in the request:

- using the **WEB GET VARIABLES** command, or
- using the **WEB GET BODY PART** and **WEB Get body part count** commands.

The **WEB GET VARIABLES** command retrieves the values as text, while the **WEB GET BODY PART** and **WEB Get body part count** commands can retrieve the files posted, using BLOBs.

**Compatibility note (4D v13.4):** In previous versions, 4D copied the values of variables received by means of a posted Web form or a GET URL directly into 4D process variables (in compiled mode, these variables had to have been declared in the COMPILER_WEB method). This functioning is removed starting with 4D v13.4; it is maintained by compatibility in converted databases but can be disabled using the **Automatic variable assignment** compatibility option on the **Compatibility page** of the Database Settings (we recommend that you uncheck this option and use the **WEB GET VARIABLES** or **WEB GET BODY PART** commands in your databases).

Consider the following HTML page source code:

```
<html> <head>  <title>Welcome</title>  <script language="JavaScript"><!-- function GetBrowserInformation(formObj){ formObj.vtNav_appName.value = navigator.appName formObj.vtNav_appVersion.value = navigator.appVersion formObj.vtNav_appCodeName.value = navigator.appCodeName formObj.vtNav_userAgent.value = navigator.userAgent return true } function LogOn(formObj){ if(formObj.vtUserName.value!=""){ return true } else { alert("Enter your name, then try again.") return false } } //--></script> </head> <body> <form action="/4DACTION/WWW_STD_FORM_POST" method="post" name="frmWelcome" onsubmit="return GetBrowserInformation(frmWelcome)">  <h1>Welcome to Spiders United</h1>  <p><b>Please enter your name:</b> <input name="vtUserName" value="" size="30" type="text"></p>  <p> <input name="vsbLogOn" value="Log On" onclick="return LogOn(frmWelcome)" type="submit"> <input name="vsbRegister" value="Register" type="submit"> <input name="vsbInformation" value="Information" type="submit"></p> <p> <input name="vtNav_appName" value="" type="hidden"> <input name="vtNav_appVersion" value="" type="hidden"> <input name="vtNav_appCodeName" value="" type="hidden"> <input name="vtNav_userAgent" value="" type="hidden"></p> </form> </body> </html>
```

When 4D sends the page to a Web Browser, it looks like this:

The main features of this page are:

- It includes three Submit buttons: *vsbLogOn*, *vsbRegister* and *vsbInformation*.
- When you click Log On, the submission of the form is first processed by the JavaScript function **LogOn**. If no name is entered, the form is not even submitted to 4D, and a JavaScript alert is displayed.
- The form has a POST 4D Method as well as a Submit script (*GetBrowserInformation*) that copies the Navigator properties to the four hidden objects whose names starts with *vtNav_App*.
- It also includes the *vtUserName* object.

Let's examine the 4D method ***WWW_STD_FORM_POST*** that is called when the user clicks on one of the buttons on the HTML form.

```
 // Retrieval of value of variables
ARRAY TEXT($arrNames;0)
ARRAY TEXT($arrValues;0)
```

```
WEB GET VARIABLES($arrNames;$arrValues)
C_TEXT($user)

Case of

 // The Log On button was clicked
   :(Find in array($arrNames;"vsbLogOn")#-1)
      $user :=Find in array($arrNames;"vtUserName")
      QUERY([WWW Users];[WWW Users]UserName=$arrValues{$user})
      $0:=(Records in selection([WWW Users])>0)
      If($0)
         WWW POST EVENT("Log On";WWW Log information)
 // The WWW POST EVENT method saves the information in a database table
      Else

         $0:=WWW Register
 // The WWW Register method lets a new Web user register
      End if

 // The Register button was clicked
   :(Find in array($arrNames;"vsbRegister")#-1)
      $0:=WWW Register

 // The Information button was clicked
   :(Find in array($arrNames;"vsbInformation")#-1)
      WEB SEND FILE("userinfos.html")
End case
```

The features of this method are:

- The values of the variables *vtNav_appName*, *vtNav_appVersion*, *vtNav_appCodeName*, and *vtNav_userAgent* (bound to the HTML objects having the same names) are retrieved using the **WEB GET VARIABLES** command from HTML objects created by the *GetBrowserInformation* JavaScript script.
- Out of the *vsbLogOn*, *vsbRegister* and *vsbInformation* variables bound to the three Submit buttons, only the one corresponding to the button that was clicked will be retrieved by the **WEB GET VARIABLES** command. When the submit is performed by one of these buttons, the browser returns the value of the clicked button to 4D. This tells you which button was clicked. Note that 4D buttons in a 4D form are numeric variables. However, with HTML, all objects are text objects.

If you use a SELECT object, it is the value of the highlighted element in the object that is returned in the **WEB GET VARIABLES** command, and not the position of the element in the array as in 4D.

**WEB GET VARIABLES** always returns values of the Text type.

## Support of chunked transfer encoding

Starting with 4D v15 R3, the built-in 4D Web Server supports files uploaded in chunked transfer encoding from any Web client. Chunked transfer encoding is a data transfer mechanism specified in HTTP/1.1. It allows data to be transferred in a series of "chunks" (parts) without knowing the final data size.

**Note:** The 4D Web Server also supports chunked transfer encoding from the server to Web clients (see **WEB SEND RAW DATA**).

For more information about client-side implementation for chunked transfers, please refer to RFC7230 or the related page on Wikipedia.

## COMPILER_WEB Project Method

The **COMPILER_WEB** method, if it exists, is systematically called when the HTTP server receives a dynamic request and calls the 4D engine. This is the case, for example, when the 4D Web server receives a posted form or a URL containing the 4DCGI/ action. This method is intended to contain typing and/or variable initialization directives used during Web exchanges. It is used by the compiler when the database is compiled. The **COMPILER_WEB** method is common to all the Web forms. By default, the **COMPILER_WEB** method does not exist. You must explicitly create it.

**Web Services:** The **COMPILER_WEB** project method is called, if it exists, for each SOAP request accepted. You must use this method to declare all the 4D variables associated with incoming SOAP arguments, for all methods published as Web

Services. In fact, the use of process variables in Web Services methods requires that they be declared before the method is called. For more information on this point, refer to the description of the **SOAP DECLARATION** command.

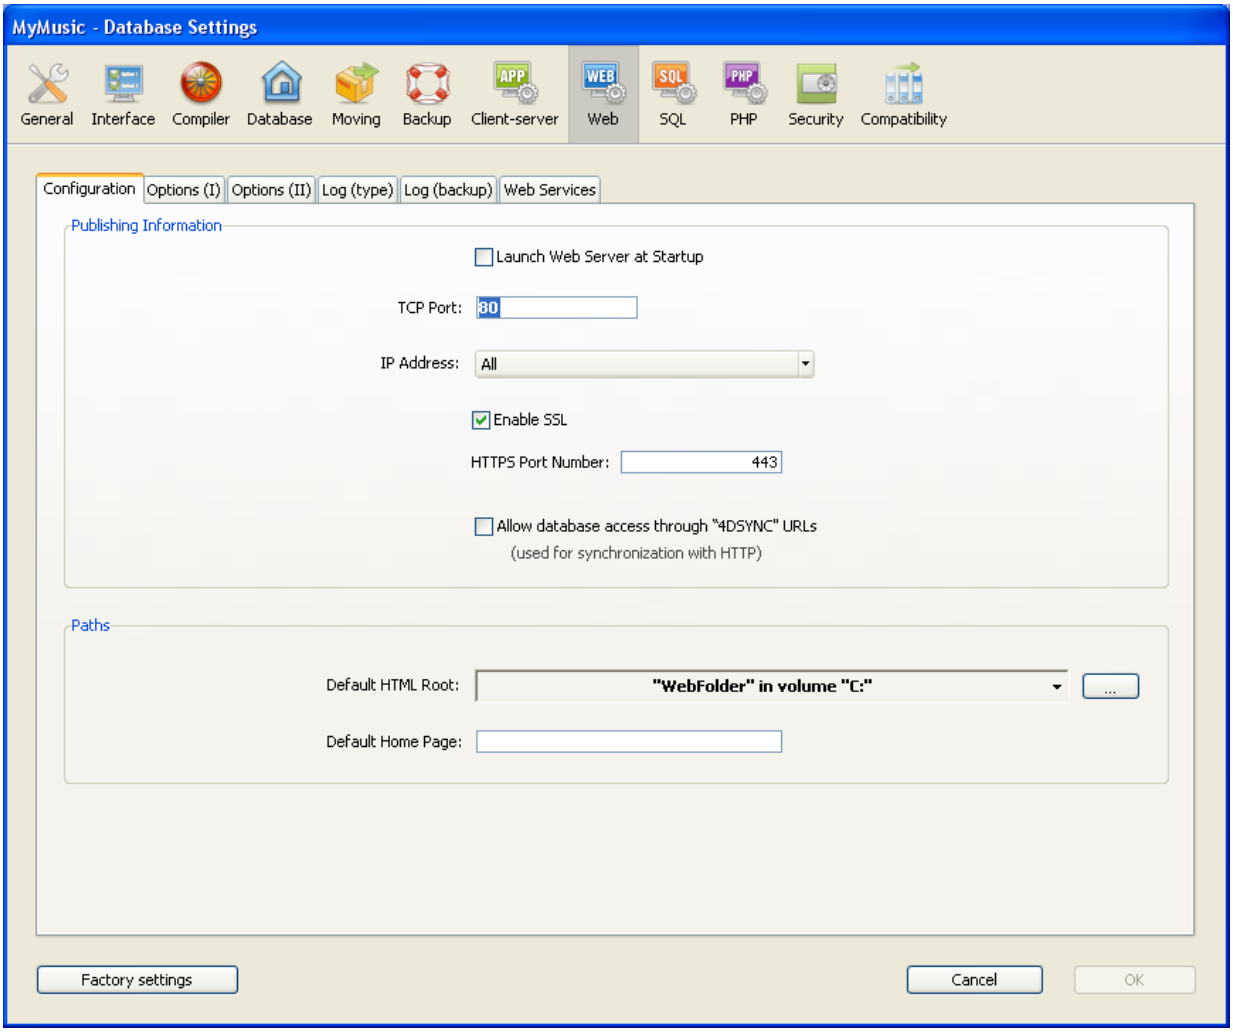
# Web Server Settings

You can configure the operation of the 4D Web server using the parameters set on the **Web** page of the Database Settings. This section describes the parameters of the **Configuration**, **Options (I)** and **(II)** tabs of this page.

- The parameters of the **Log** pages are covered in the **Information about the Web Site** section.
- The parameters of the **Web Services** page are covered in the "Design Reference" manual.

**Compatibility note:** Certain Web mechanisms found in previous versions of 4D are now considered obsolete (for example, "Do not remove “/” on unknown URLs"). For compatibility's sake, these mechanisms can still be used in converted databases. In this case, you can display them and if necessary disable them on the **Compatibility** page of the Database Settings.

## Configuration page



### Launch Web Server at Startup

Indicates whether the Web server will be launched on startup of the 4D application. This option is described in the **Web server configuration and connection management** section.

### TCP port number

By default, 4D publishes a Web database on the regular Web TCP Port, which is port 80. If that port is already used by another Web service, you need to change the TCP Port used by 4D for this database. Modifying the TCP port allows you to start the 4D Web server under Mac OS X without being the root user of the machine (see **Web server configuration and connection management** section).

To do so, go to the **TCP Port** enterable area and indicate an appropriate value (a TCP port not already used by another TCP/IP service running on the same machine).

**Note:** If you specify 0, 4D will use the default TCP port number 80.

From a Web browser, you need to include that non-default TCP port number into the address you enter for connecting to the Web database. The address must have a suffix consisting of a colon followed by the port number. For example, if you are using the TCP port number 8080, you will specify “123.4.567.89:8080”.

**WARNING:** If you use TCP port numbers other than the default numbers (80 for standard mode and 443 for SLL mode), be careful not to use port numbers that are defaults for other services that you might want to use simultaneously. For example, if you also plan to use the FTP protocol on your Web server machine, do not use the TCP port 20 and 21, which are the default ports for that protocol (unless you know what you are doing). To find out the standard assignment of TCP port numbers, refer to the **Appendix B, TCP Port Numbers** section in the documentation of the 4D Internet Commands. Ports numbers below 256 are reserved for well known services and ports numbers from 256 to 1024 are reserved for specific services originated on the UNIX platforms. For maximum security, specify a port number beyond these intervals, for example in the 2000's or 3000's.

### Defining the IP Address for the HTTP Requests

You can define the IP address on which the Web server must receive HTTP requests.

**Note:** Starting with 4D v14, the HTTP server automatically supports IPv6 address notation when the **All** option is selected in the "IP Address" list. For more information, refer to **Support of IPv6**.

By default, the server responds to all IP addresses (**All** option).

The drop-down list automatically lists all available IP addresses on the machine. When you select a specific address, the server only responds to requests sent to this address. This feature is for 4D Web Servers located on machines with multiple TCP/IP addresses. It is, for example, frequently the case of most Internet host providers. Implementing such a MultiHoming system requires specific configurations on the Web server machine:

- **Installing secondary IP addresses on Mac OS**

To configure a MultiHoming system on Mac OS:

1. Open the **TCP/IP** Control Panel.
2. Select the **Manually** option from the **Configuration** pop up menu.
3. Create a text file called "Secondary IP Addresses" and save it in the Preferences subfolder of your System folder.
   Each line of the "Secondary IP Addresses" file should contain a secondary IP address and an optional subnet mask and router address for the secondary IP address.

Please check the Apple documentation for more information.

- **Installing secondary IP addresses on Windows**

To configure a MultiHoming system on Windows:

1. Select the following sequences of commands (or their equivalents according to your version of Windows):
   **Start** menu > **Control Panel** > **Network and Internet Connections** > **Network connections** > **Local Area Connection** (Properties) > **Internet Protocol (TCP/IP)** > **Properties** button > **Advanced...** button. The "Advanced TCP/IP Settings" dialog is displayed.
2. Click the **Add...**. button in the "IP Addresses" area, and add additional IP addresses.

You can define up to 5 different IP addresses. You may need to consult your systems administrator in order to do so.

### Enable SSL

Indicates whether or not the Web server will accept secure connections. This option is described in the **Using TLS Protocol** section.

### HTTPS Port Number

Allows you to modify the TCP/IP port number used by the Web server for secured HTTP connections over SSL (HTTPS protocol). By default, the HTTPS port number is set to 443 (standard value).
You may consider changing this port number for two main reasons:

- for security reasons — hacker attacks against Web servers are generally concentrated on standard TCP ports (80 and 443).
- under Mac OS X, in order to allow “standard” users to launch the Web server in a secured mode — under Mac OS X, the use of TCP/IP ports reserved for Web publications (0 to 1023) requires specific access privileges: only the root user can

launch an application using these ports. In order for standard users to be able to launch the Web server, one solution is to modify the TCP/IP port number (see the **Web server configuration and connection management** section). You can pass any valid value (in order to avoid access restrictions under Mac OS X, you should pass a value greater than 1023). For more information about TCP port numbers, refer to the “TCP port number” paragraph above.

### Allow database access through 4DSYNC URLs

This option controls support of HTTP synchronization requests containing /4DSYNC URLs. It is covered in the **Connection Security** section.

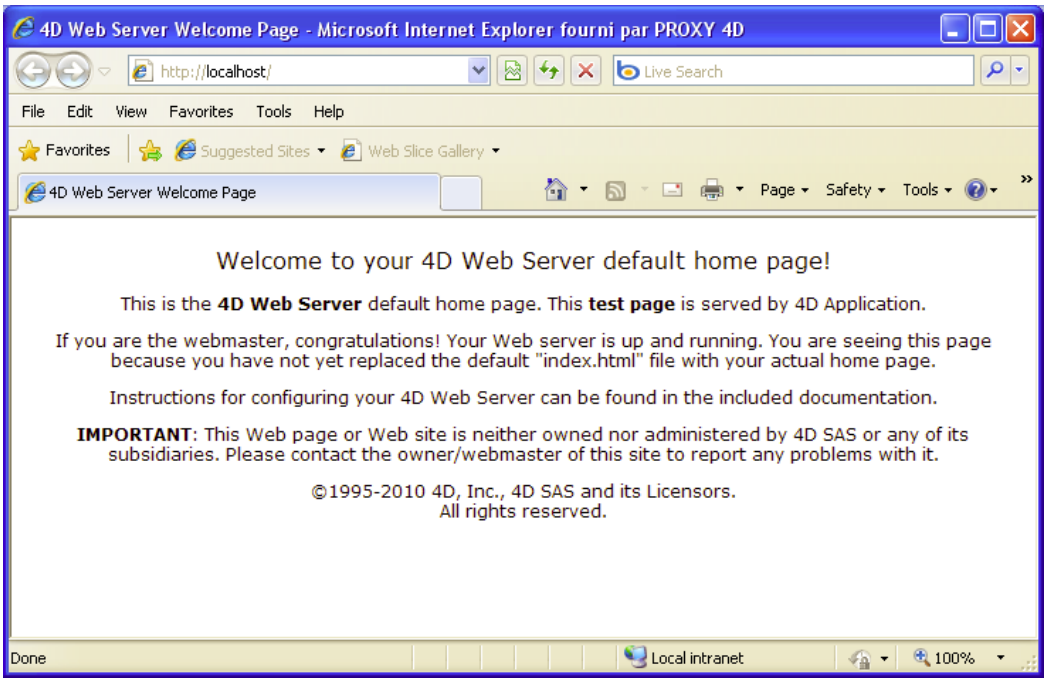
### Default HTML Root

Allows you to define the default location of the Web site files and to indicate the hierarchical level on the disk above which the files will not be accessible. This option is described in the **Connection Security** section**.**

### Defining a Default Home Page

You can designate a default home page for all the browsers that connect to the database. This page can be static or semi-dynamic.

By default, when the Web server is launched for the first time, 4D creates a home page named “index.html” and puts it in the HTML root folder. If you do not modify this configuration, any browser connecting to the Web server will obtain the following page:



To modify the default home page, simply replace it in the database root folder with your own “index.html” page or enter the relative access path of the page that you want to define in the “Default Home Page” entry area.
The access path must be set up in relation to the default HTML root folder.
In order to ensure multi-platform compatibility of your databases, the 4D Web server uses particular writing conventions to define access paths. The syntax rules are as follows:

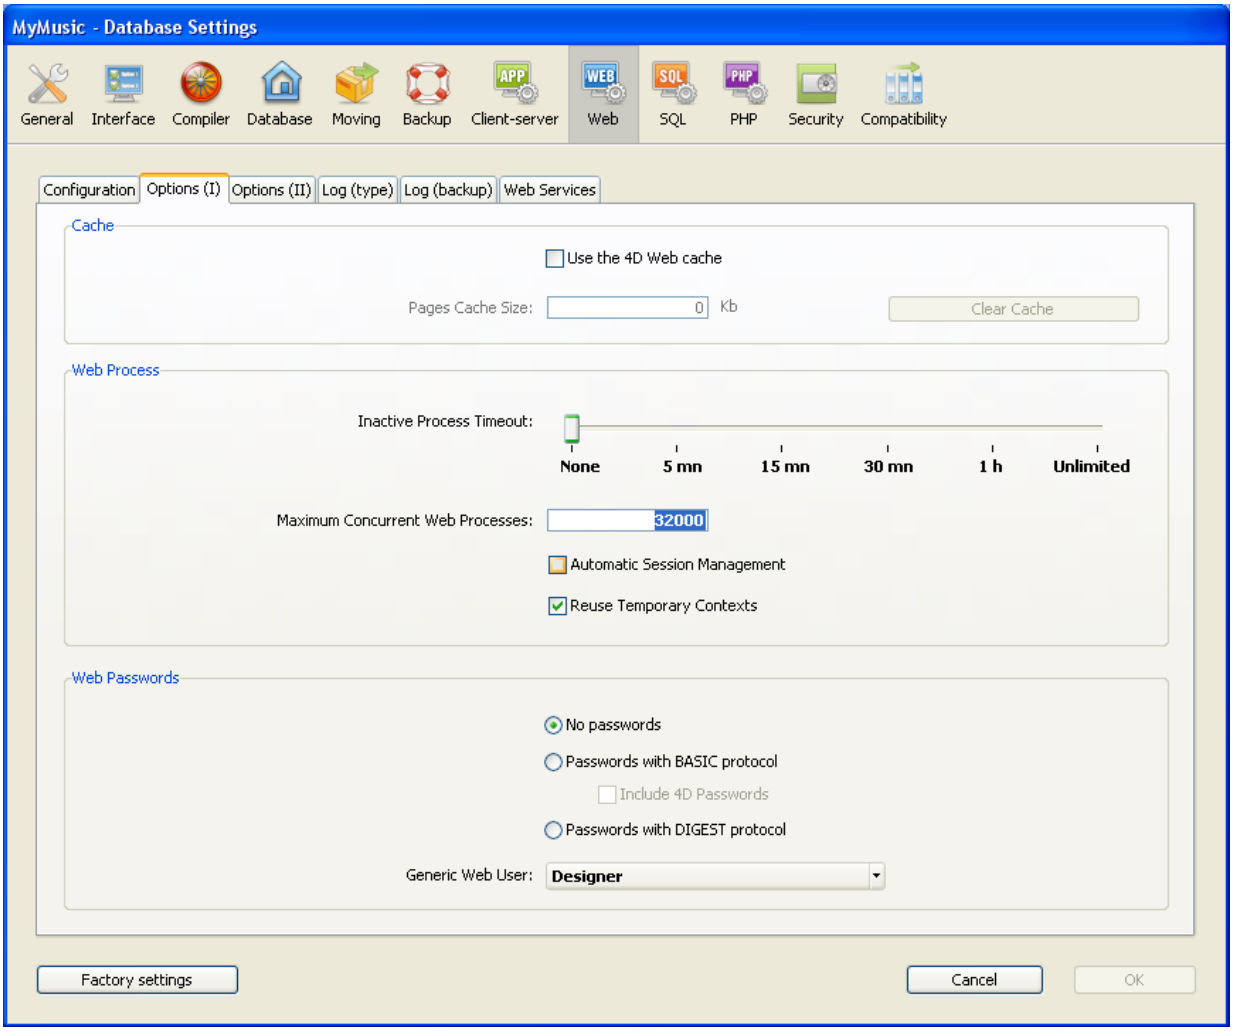
- folders are separated by a slash (“/”)
- the access path must not end with a slash (“/”)
- to “go up” one level in the folder hierarchy, enter “..” (two periods) before the folder name
- the access path must not start with a slash (“/”)

For example, if you want the default home page to be “MyHome.htm”, and it is located in the “Web” folder (itself located in the default HTML root folder of the database), enter “Web/MyHome.htm”.

**Note:** You can also define a default home page for each Web process by using the routine **WEB SET HOME PAGE**.

If you do not specify a default custom home page, the **On Web Connection Database Method** is called. It is up to you to process the request procedurally.

## Options (I) Page



## Cache for Static Pages

The 4D Web Server has a cache that allows you to load static pages, GIF images, JPEG images (<512 kb) and style sheets (.css files) in memory, as they are requested.
Using the cache allows you to significantly increase the Web server's performance when sending static pages.

The cache is shared between all the Web processes. You can set the size of the cache in the Preferences. By default, the cache of the static pages is not enabled. To activate it, simply check the **Use the 4D Web cache** option.

You can modify the size of the cache in the **Pages Cache Size** area. The value you set depends on the number and size of your Web site's static pages, as well as the resources that the host machines has at its disposal.

**Note:** While using your Web database, you can check the performance of the cache by using the routine **WEB GET STATISTICS**. If, for example, you notice that the cache's rate of use is close to 100%, you may want to consider increasing the size that has been allocated to it.
The /4DSTATS and /4DHTMLSTATS URLs allow you to also obtain information about the cache's state. Please refer to **Information about the Web Site**.

Once the cache has been enabled, the 4D Web server looks for the page requested by the browser first in the cache. If it finds the page, it sends it immediately. If not, 4D loads the page from disk and places it in the cache.
When the cache is full and additional space is required, 4D "unloads" the oldest pages first, among the least demanded ones.

### *Clearing the Cache*

At any moment, you can clear the cache of the pages and images that it contains (if, for example, you have modified a static page and you want to reload it in the cache).
To do so, you just have to click on the **Clear Cache** button. The cache is then immediately cleared.

**Note:** You can also use the special URL **/4DCACHECLEAR**.

## Inactive Process Timeout

Allows you to set the maximum timeout before closing for inactive Web processes on the server.

## Maximum Concurrent Web Processes

This option indicates the strictly high limit of **Maximum Concurrent Web Processes** of any type (standard Web processes or belonging to the"pool of processes") that can be simultaneously open on the server. This parameter allows prevention of

4D Server saturation as the result of massive number of requests.

By default, this value is 32000. You can set the number anywhere between 10 and 32000.

When the maximum number of concurrent Web processes (minus one) is reached, 4D no longer creates new processes and sends the following message “Server unavailable” (status HTTP 503 – Service Unavailable) for each new request.

**Note:** You can also set the maximum number of Web using the **WEB SET OPTION** command.

***About the Pool of Web Processes***

The “pool” of Web processes allows increasing the reactivity of the Web server. This reserve is sized by a minimum (0 by default) and a maximum (10 by default) of processes to recycle. These processes can be modified using the **SET DATABASE PARAMETER** command. Once the maximum number of Web processes has been changed, if this number is inferior to the superior limit in the “pool”, this limit is lowered to the maximum number of Web processes.

***How to determine the right value?***

In theory, the maximum number of Web processes is the result of the following formula: Available memory/Web process stack size(*).
Another solution is to visualize the information on Web processes displayed in the Runtime Explorer: the current number of Web processes and the maximum number reached since the Web server boot are indicated.

(*) The stack size allocated by 4D for a Web process is around 512 KB for 64-bit versions and around 256 KB for 32-bit versions (indicative values, which may vary based on context).

### Automatic Session Management

Enables or disables the internal mechanism for automatic handling of user sessions by the 4D HTTP server. This mechanism is described in the **Web Sessions Management** section.

By default, this mechanism is enabled in databases created with 4D v13 and later versions. However, for compatibility reasons, it is disabled in databases converted from previous versions of 4D. You must enable it explicitly in order to benefit from this functionality.

When this option is checked, the "Reuse Temporary Contexts" option is automatically checked (and locked).

### Reuse temporary contexts (in remote mode)

Allows you to optimize the operation of the 4D Web server in remote mode by reusing Web processes created for processing previous Web requests. In fact, the Web server of 4D needs a specific Web process for the handling of each Web request; in remote mode, when necessary, this process connects to the 4D Server machine in order to access the data and database engine. It thus generates a temporary context using its own variables, selections, etc. Once the request has been dealt with, this process is killed.

When the **Reuse Temporary Contexts** option is checked, in remote mode 4D maintains the specific Web processes and reuses them for subsequent requests. By removing the process creation stage, Web server performance is improved.

In return, you must make sure in this case to systematically initialize the variables used in 4D methods in order to avoid getting incorrect results. Similarly, it is necessary to erase any current selections or records defined during the previous request.

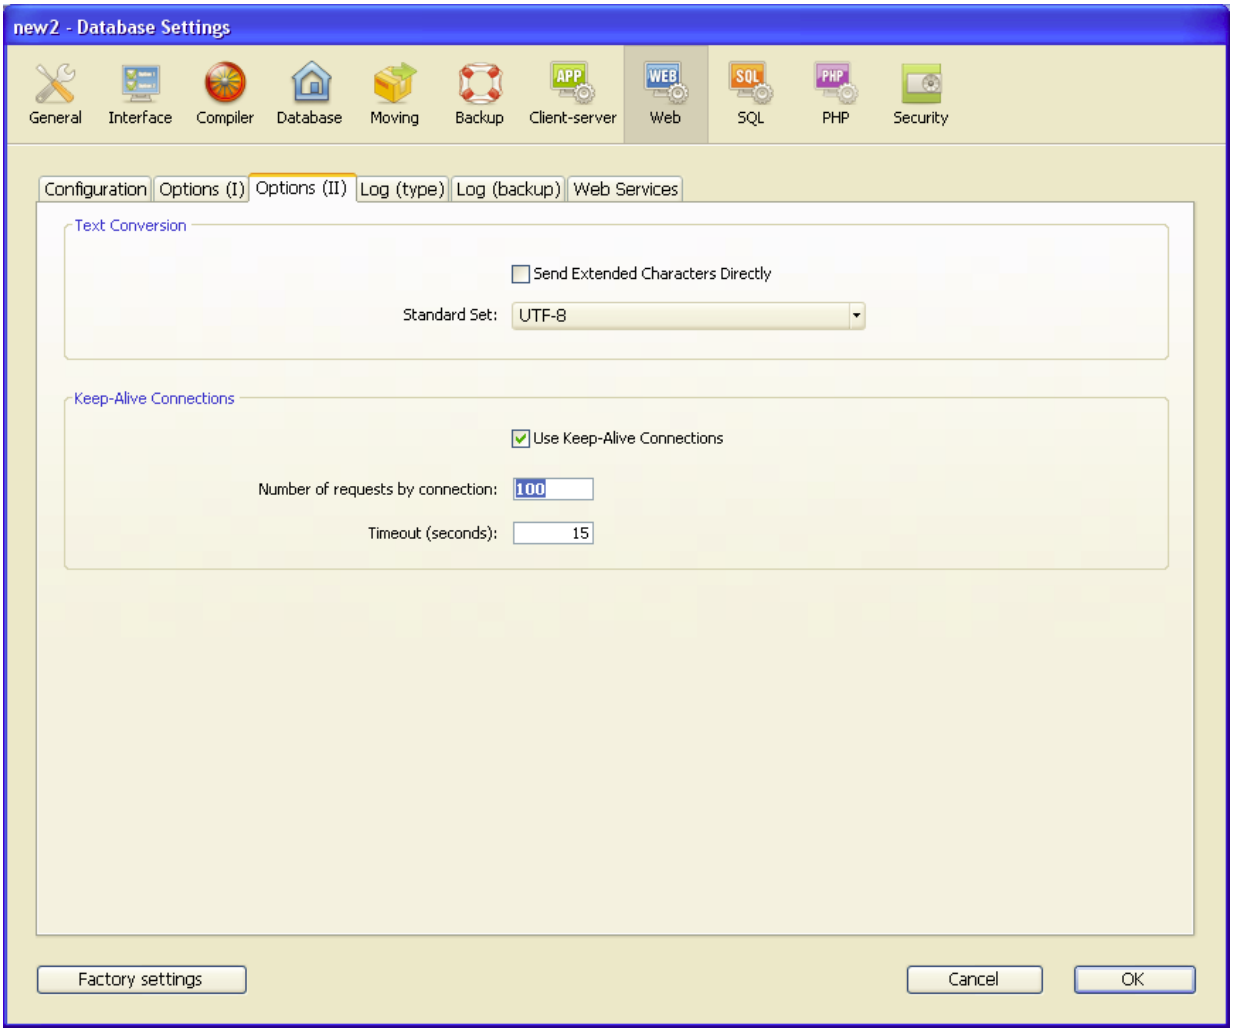
**Notes:**

- This option is checked (and locked) automatically when the **Automatic Session Management** option is checked. In fact, the session management mechanism is actually based on the principle of recycling Web processes: each session uses the same process that is maintained during the lifespan of the session. However, note that session processes cannot be "shared" between different sessions: once the session is over, the process is automatically killed (and not reused). It is therefore unnecessary to reset the selections or variables in this case.
- This option only has an effect with a 4D Web server in remote mode. With a 4D in local mode, all Web processes (other than session processes) are killed after their use.

### “Passwords” area

Configuration of Web site access protection using passwords. This option is described in the **Connection Security** section.

## Options (II) Page



### Directly Sending Extended Characters

By default, the 4D Web server converts the extended characters in the dynamic and static Web pages according to HTML standards before sending them. They are then interpreted by the browsers.
You can set the Web server so that the extended characters are sent “as is”, without converting them into HTML entities. This option has shown a speed increase on most foreign operating systems (especially the Japanese system).

To do this, check the **Send Extended Characters Directly** option.

### Standard Sets

The **Standard Set** drop-down list allows you to define the set of characters to be used by the 4D Web server. By default, the character set is UTF-8.

**Note:** This setting is also used for generating Quick Reports in HTML format (see **Executing a quick report**).

### Keep-Alive Connections

The Web server of 4D can use keep-alive connections. The keep-alive option allows you to maintain a single open TCP connection for the set of exchanges between the Web browser and the server to save system resources and to optimize transfers.

The **Use Keep-Alive Connections** option enables or disables keep-alive TCP connections for the Web server. This option is enabled by default. In most cases, it is advisable to keep this option check since it accelerates the exchanges. If the Web browser does not support connection keep alive, the 4D Web server automatically switches to HTTP/1.0.

The 4D Web server keep-alive function concerns all TCP/IP connections (HTTP, HTTPS). Note however that keep-alive connections are not always used for all 4D Web processes.

In some cases, other optimized internal functions may be invoked. Keep-alive connections are useful mainly for static pages.

Two options allow you to set how the keep-alive connections work:

- **Number of requests by connection**: Allows you to set the maximum number of requests and responses able to travel over a connection keep alive. Limiting the number of requests per connection allows you to prevent server flooding due to a large number of incoming requests (a technique used by hackers).

The default value (100) can be increased or decreased depending on the resources of the machine hosting the 4D Web server.

- **Timeout**: This value defines the maximum wait period (in seconds) during which the Web server maintains an open TCP connection without receiving any requests from the Web browser. Once this period is over, the server closes the connection.
  If the Web browser sends a request after the connection is closed, a new TCP connection is automatically created. This operation is not visible for the user.

# Using preemptive Web processes

The built-in Web Server of 4D 64-bit for Windows and OS X allows you to take full advantage of multi-core computers by using preemptive Web processes in your compiled applications. You can configure your Web-related code, including 4D tags and Web database methods, to run simultaneously on as many cores as possible.

For more information on preemptive process feature in 4D, please refer to the **Preemptive 4D processes** section.

## Availability of preemptive mode for Web processes

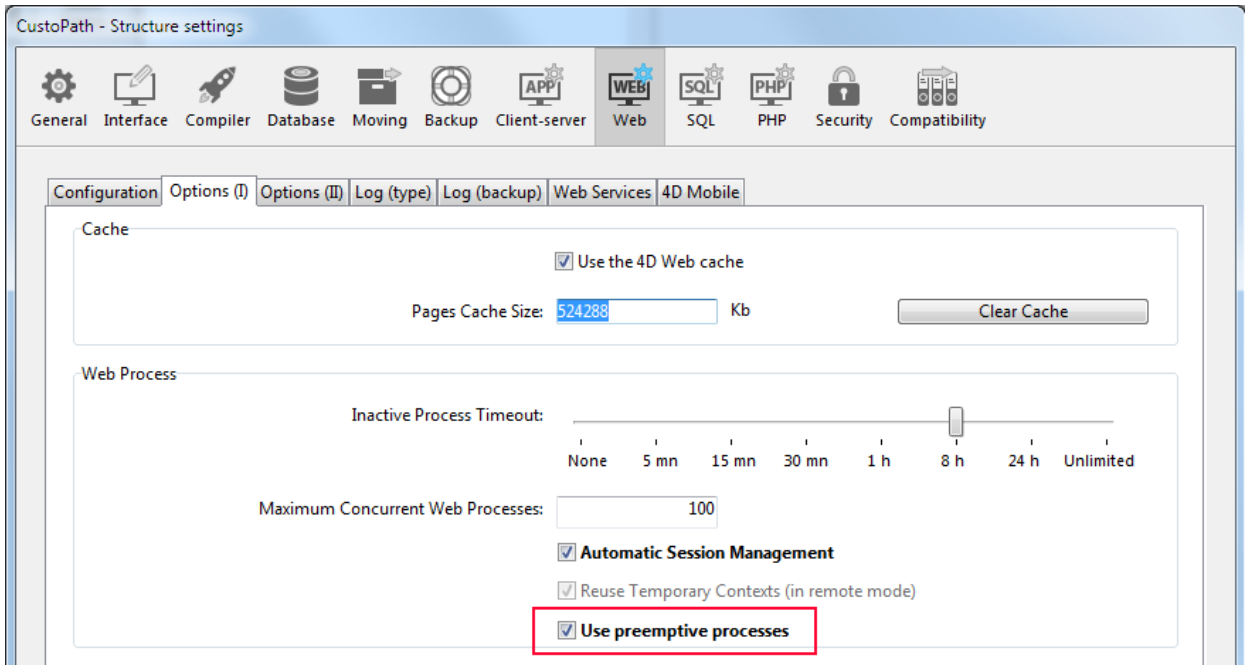
The use of preemptive mode for Web processes is only available in the following contexts:

- use of a 64-bit version of 4D
- use of 4D Server or 4D local mode (4D in remote mode does not support preemptive mode)
- use of a compiled database
- **Use preemptive processes** database setting checked (see below)
- all Web-related database methods and project methods are confirmed thread-safe by 4D Compiler

If any requirement is missing, the Web Server will use cooperative processes.

## Enabling the preemptive mode for the Web Server

To enable the preemptive mode for the Web Server code of your application, you must check the **Use preemptive processes** option on the "Web/Options (I)" page of the Database Settings dialog box:



When this option is checked, the 4D compiler will automatically evaluate the thread-safety property of each piece of Web-related code (see below) and return errors in case of incompatibility.

## Writing thread-safe Web Server code

All 4D code executed by the Web Server must be thread-safe if you want your Web processes to be run in preemptive mode. When the **Use preemptive processes** option is checked in the Database Settings dialog box, the following parts of the application will be automatically evaluated by the 4D compiler:

- All Web-related database methods:
  - **On Web Authentication database method**
  - **On Web Connection database method**

    - **On Web Close Process database method**
    - **On 4D Mobile Authentication database method**
- The ***compiler_web*** project method (regardless of its actual "Execution mode" property);
- Basically any code processed by the **PROCESS 4D TAGS** command in the Web context, for example through .shtml pages.
- Any project method with the "Available through 4D HTML tags and URLS (4DACTION...)" attribute
- Triggers for tables with "Expose with 4D Mobile Service" attribute
- Project methods available through 4D Mobile ("4D Mobile" property checked)

For each of these methods and code parts, the compiler will check if the thread-safety rules are respected, and will return errors in case of issues. For more information about thread-safety rules, please refer to the **Writing a thread-safe method** paragraph.

## Thread-safety of 4D commands and Web URLs

Starting with 4D v16, most of the Web-related 4D commands, database methods and URLs are thread-safe and can be used in preemptive mode:

### 4D commands

All 4D Web-related commands are thread-safe, i.e.:

- all commands from the "**Web Server**" theme,
- all commands from the "**HTTP Client**" theme.

### Database methods

The following database methods are thread-safe and can be used in preemptive mode:

- **On Web Authentication database method**
- **On Web Connection database method**
- **On Web Close Process database method**
- **On 4D Mobile Authentication database method**

Of course, the code executed by these methods must also be thread-safe.

### Web Server URLs

The following 4D Web Server URLs are thread-safe and can be used in preemptive mode:

- 4daction/ (the called project method must also be thread-safe)
- 4dcgi/ (the called database methods must also be thread-safe)
- 4dscript/ (deprecated as URL, used as a tag)
- 4dwebtest/
- 4dblank/
- 4dstats/
- 4dhtmlstats/
- 4dcacheclear/
- rest/
- 4dimgfield/ (generated by **PROCESS 4D TAGS** for web request on picture fields)
- 4dimg/ (generated by **PROCESS 4D TAGS** for web request on picture variables)

The following 4D Web Server URLs are not thread-safe and not supported in preemptive mode:

- 4dsync
- 4dsqlauth (deprecated, used for Flex 1.1)

## Preemptive Web process icon

Both the Runtime Explorer and the 4D Server administration window display a specific icon for preemptive Web processes:

| Process type | Icon |
| --- | --- |
| Preemptive Web method |  |

## Information about the Web Site

4D allows you to obtain information about the functioning of your 4D Web site.

- You can control the site by using particular URLs (*/4DSTATS*, */4DHTMLSTATS*, */4DCACHECLEAR* and */4DWEBTEST*).
- You can generate a log of all the requests.
- You can obtain information regarding the Web Server in the Watch page of the Runtime Explorer window.

**Note:** For security reasons, starting with 4D v15 R2, the HTTP TRACE method is disabled by default in the 4D Web Server. This means that when an HTTP TRACE request is received, the 4D Web Server now returns a 405 error ("method not allowed"). If you want to explicitly enable the HTTP TRACE method, you must use the Web HTTP TRACE option with the **WEB SET OPTION** command.

### Web Server Management URLs

4D Web Server accepts four particular URLs: */4DSTATS*, */4DHTMLSTATS*, */4DCACHECLEAR* and */4DWEBTEST*.

- */4DSTATS*, */4DHTMLSTATS* and */4DCACHECLEAR* are only available to the Designer and Administrator of the database. If the database's 4D password system has not been activated, these URLs are available to all the users.
- */4DWEBTEST* is always available.

#### /4DSTATS

The */4DSTATS* URL returns several items of information in an HTML table (displayable in a browser):

- **Cache Current Size**: Current size of Web server cache (in bytes)
- **Cache Max Size**: Maximum size of cache (in bytes)
- **Cached Object Max Size**: Maximum size of each object in the cache (in bytes)
- **Cache Use**: Percentage of cache used
- **Cached Objects**: Number of objects (pages, picture files, etc.) found in the cache.

(*) For more information about the cache of static pages and pictures, please refer to the **Web Server Settings** section.

This information can allow you to check the functioning of your server and eventually adapt the corresponding parameters.

**Note:** The command **WEB GET STATISTICS** allows you to also obtain information about how the cache is being used for static pages.

#### /4DHTMLSTATS

The */4DHTMLSTATS* URL returns, also as an HTML table, the same information as the */4DSTATS* URL. The difference is that the **Cached Objects** field only counts HTML pages (without counting picture files). Moreover, this URL returns the **Filtered Objects** field.

- **Filtered Objects**: Number of objects in cache not counted by URL, in particular, pictures.

#### /4DCACHECLEAR

The */4DCACHECLEAR* URL immediately clears the cache of the static pages and images. It allows you to therefore "force" the update of the pages that have been modified.

#### /4DWEBTEST

The */4DWEBTEST* URL is designed to check the Web Server status. When this URL is called, 4D returns a text file only with the following HTTP fields filled:

- **Date:** current date at the RFC 822 format
  For example: "Mon, 16 Jan 2012 13:12:50 GMT"
- **Server:** 4D_version/internal version number
  For example: "4D_v12/12.3.0"
- **User-Agent:** name and version @ IP client address
  For example: "Mozilla/5.0 (Windows NT 6.1; WOW64; rv:9.0.1) Gecko/20100101 Firefox/9.0.1 @ 127.0.0.1

## Connection Log File

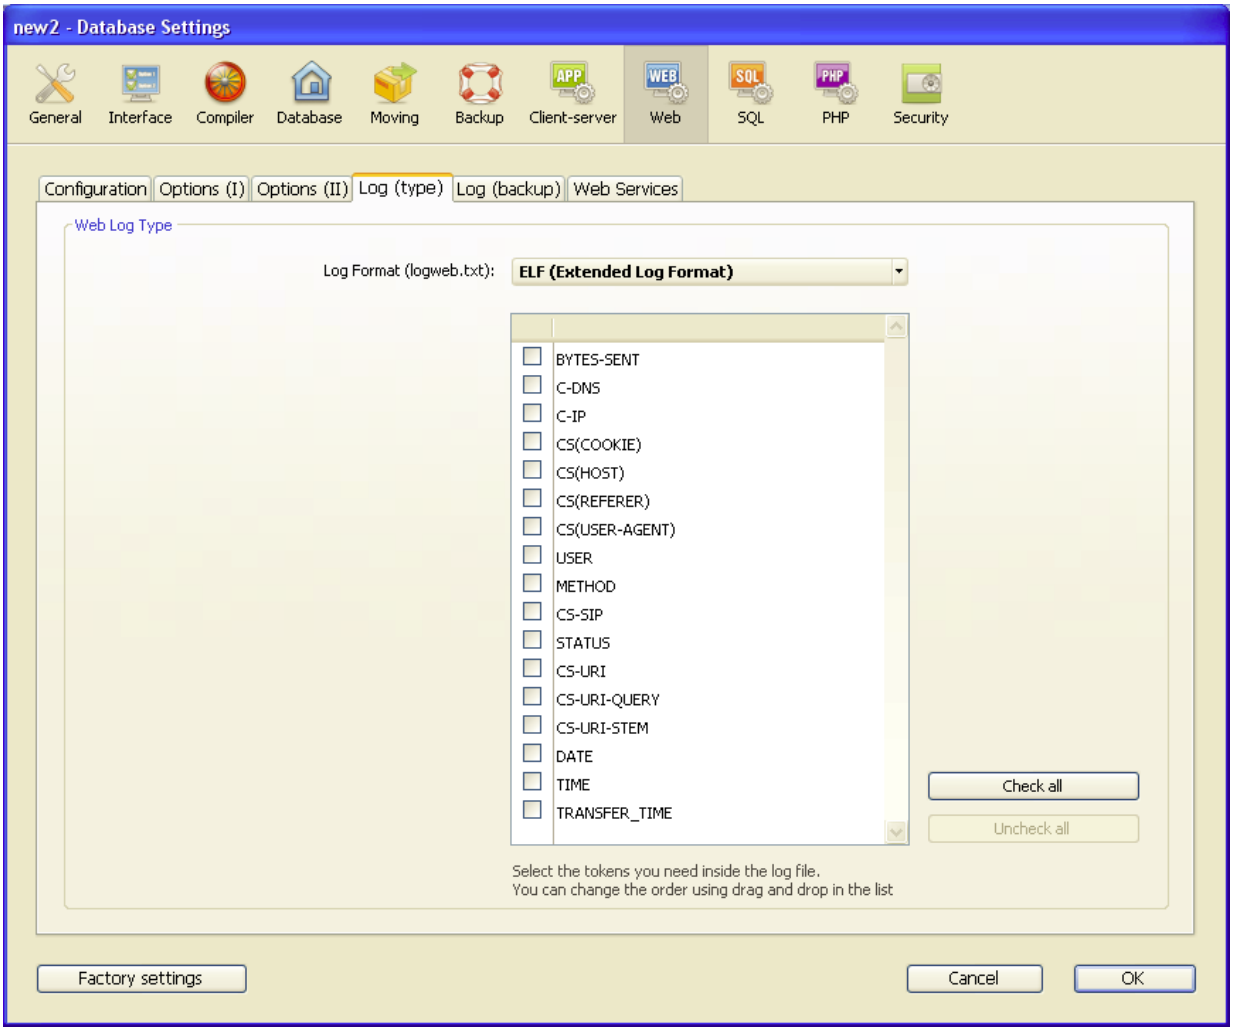
4D allows you to obtain a log of requests.

This file is named “logweb.txt” and is automatically located:

- with 4D in local mode and 4D Server, in the Logs folder located next to the database structure file.
- with 4D in remote mode, in the Logs subfolder of the 4D client database folder (cache folder).

### Activation and Format

The activation and configuration of the log file contents is carried out in the Database Settings on the **Web/Log (type)** page:



**Note:** The activation and deactivation of the log file of requests can also be carried out by programming using the **SET DATABASE PARAMETER** (4D v12) or **WEB SET OPTION** (4D v13 and higher) commands.

The log format menu provides the following options:

- **No Log File**: When this option is selected, 4D will not generate a log file of requests.
- **CLF (Common Log Format)**: When this option is selected, the log of requests is generated in CLF format. With the CLF format, each line of the file represents a request, such as:
  *host rfc931 user [DD/MMM/YYYY:HH:MM:SS] "request" state length*
  Each field is separated by a space and each line ends by the CR/LF sequence (character 13, character 10).
  - host: IP address of the client (ex. 192.100.100.10)
  - rfc931: information not generated by 4D, it’s always - (a minus sign)
  - user: user name as it is authenticated, or else it is - (a minus sign). If the user name contains spaces, they will be replaced by _ (an underscore).
  - DD: day, MMM: a 3-letter abbreviation for the month name (Jan, Feb,...), YYYY: year, HH: hour, MM: minutes, SS: seconds

  The date and time are local to the server.

  - request: request sent by the client (ex. GET /index.htm HTTP/1.0)
  - state: reply given by the server.

- length: size of the data returned (except the HTTP header) or 0.

**Note:** For performance reasons, the operations are saved in a memory buffer in packets of 1Kb before being written to disk. The operations are also written to disk if no request has been sent every 5 seconds.
The possible values of state are as follows:
200: OK
204: No contents
302: Redirection
304: Not modified
400: Incorrect request
401: Authentication required
404: Not found
500: Internal error
The CLF format cannot be customized.

- **DLF (Combined Log Format)**: When this option is selected, the request log is generated in DLF format. DLF format is similar to CLF format and uses exactly the same structure. It simply adds two additional HTTP fields at the end of each request: Referer and User-agent.
  - Referer: Contains the URL of the page pointing to the requested document.
  - User-agent: Contains the name and version of the browser or software of the client at the origin of the request.

  The DLF format cannot be customized.

- **ELF (Extended Log Format)**: When this option is selected, the request log is generated in ELF format. The ELF format is very widespread in the world of HTTP browsers. It can be used to build sophisticated logs that meet specific needs. For this reason, the ELF format can be customized: it is possible to choose the fields to be recorded as well as their order of insertion into the file.

- **WLF (WebStar Log Format)**: When this option is selected, the request log is generated in WLF format. WLF format was developed specifically for the 4D WebSTAR server. It is similar to the ELF format, with only a few additional fields. Like the ELF format, it can be customized.

**Configuring the fields**
When you choose the ELF (Extended Log Format) or WLF (WebStar Log Format) format, the “Weg Log Token Selection” area displays the fields available for the chosen format. You will need to select each field to be included in the log. To do so, use the arrow buttons or simply drag and drop the desired fields into the “Selected Tokens” area.

**Note**: You cannot select the same field twice.

The following table lists the fields available for each format (in alphabetical order) and describes its contents:

| Field | ELF | WLF | Value |
|---|---|---|---|
| BYTES_RECEIVED | | X | Number of bytes received by the server |
| BYTES_SENT | X | X | Number of bytes sent by the server to the client |
| C_DNS | X | X | IP address of the DNS (ELF: field identical to the C_IP field) |
| C_IP | X | X | IP address of the client (for example 192.100.100.10) |
| CONNECTION_ID | | X | Connection ID number |
| CS(COOKIE) | X | X | Information about cookies contained in the HTTP request |
| CS(HOST) | X | X | Host field of the HTTP request |
| CS(REFERER) | X | X | URL of the page pointing to the requested document |
| CS(USER_AGENT) | X | X | Information about the software and operating system of the client |
| CS_SIP | X | X | IP address of the server |
| CS_URI | X | X | URI on which the request is made |
| CS_URI_QUERY | X | X | Request query parameters |
| CS_URI_STEM | X | X | Part of request without query parameters |
| DATE | X | X | DD: day, MMM: 3-letter abbreviation for month (Jan, Feb, etc.), YYYY: year |
| METHOD | X | X | HTTP method used for the request sent to the server |
| PATH_ARGS | | X | CGI parameters: string located after the “$” character |
| STATUS | X | X | Reply provided by the server |
| TIME | X | X | HH: hour, MM: minutes, SS: seconds |
| TRANSFER_TIME | X | X | Time requested by server to generate the reply |
| USER | X | X | User name if authenticated; otherwise - (minus sign).<br>If the user name contains spaces, they are replaced by _ (underlines) |
| URL | | X | URL requested by the client |

**Note:** Dates and times are given in GMT.

### Periodicity of Backups

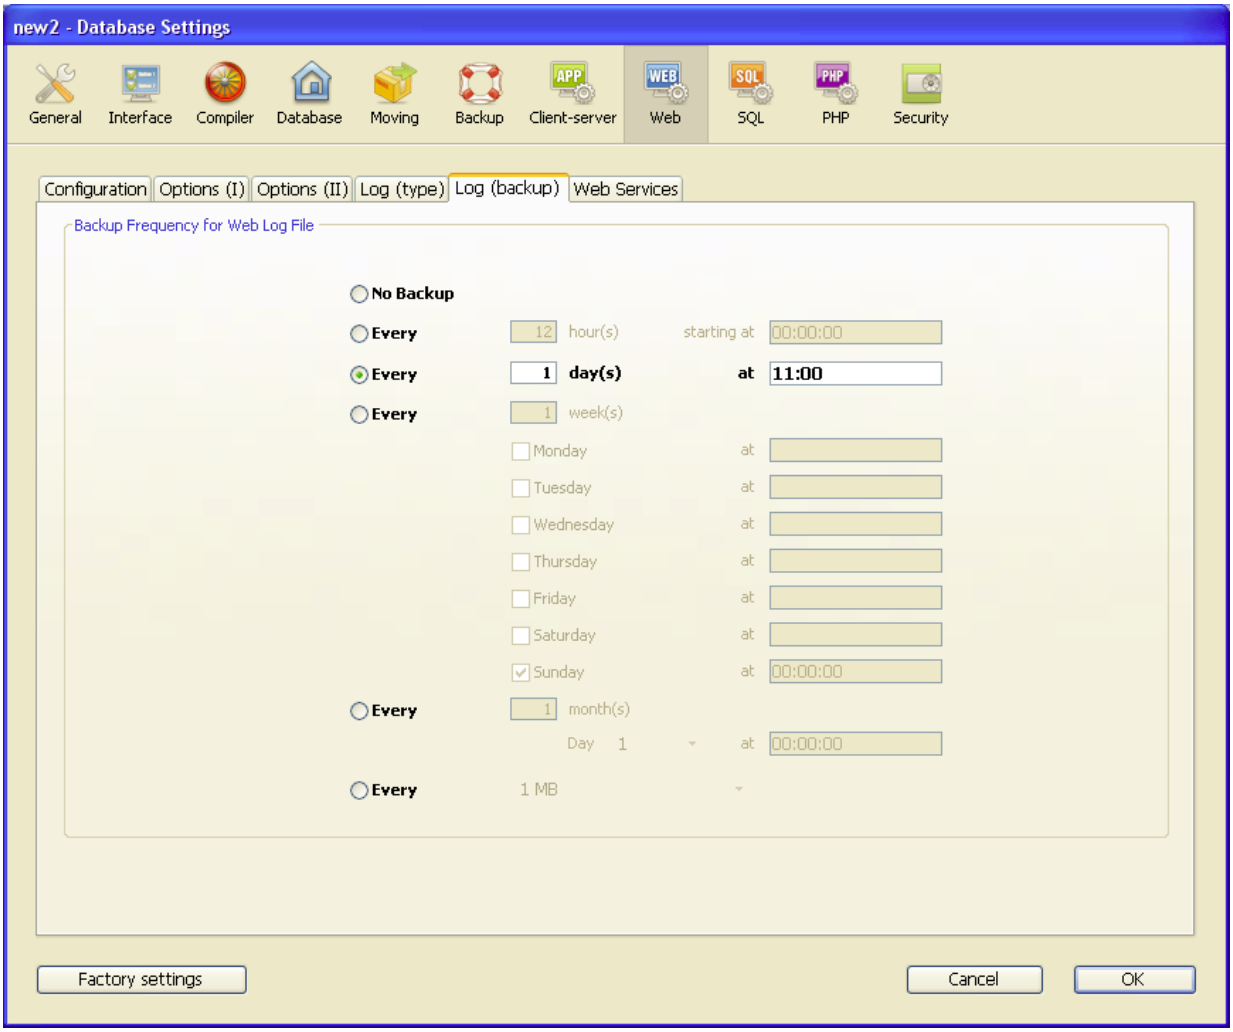
Since a Web log file can become considerably large, it is possible to set up an automatic archiving mechanism. The triggering of a backup can be based on a certain period of time (expressed in hours, days, week or months), or based on the file size; when the set deadline (or file size) is reached, 4D automatically closes and archives the current log file and creates a new one.

When the Web log file backup is triggered, the log file is archived in a folder named “Logweb Archives,” which is created at the same level as the logweb.txt file (that is, next to the database structure file).

The archived ile is renamed based on the following example: “DYYYY_MM_DD_Thh_mm_ss.txt.” For instance, for a file archived on September 4, 2006 at 3:50 p.m. and 7 seconds: “D2006_09_04_T15_50_07.txt.”

### Backup Parameters

The automatic backup parameters for the request log are set on the **Web/Log (backup)** page of the Database Settings:



First you must choose the frequency (days, weeks, etc.) or the file size limit criterion by clicking on the corresponding radio button. You must then specify the precise moment of the backup if necessary.

- **No Backup**: The scheduled backup function is deactivated.
- **Every X hour(s)**: This option is used to program backups on an hourly basis. You can enter a value between 1 and 24 .
  - **starting at**: Used to set the time at which the first back up will begin.
- **Every X day(s) at X**: This option is used to program backups on a daily basis. Enter 1 if you want to perform a daily backup. When this option is checked, you must indicate the time when the backup must be started.
- **Every X week(s), day at X**: This option is used to program backups on a weekly basis. Enter 1 if you want to perform a weekly backup. When this option is checked, you must indicate the day(s) of the week and the time when each backup must be started. You can select several days of the week if desired. For example, you can use this option to set two weekly backups: one on Wednesdays and one on Fridays.
- **Every X month(s), Xth day at X**: This option is used to program backups on a monthly basis. Enter 1 if you want to perform a monthly backup. When this option is checked, you must indicate the day of the month and the time when the backup must be started.
- **Every X MB**: This option is used to program backups based on the size of the current request log file. A backup is automatically triggered when the file reaches the set size. You can set a size limit of 1, 10, 100 or 1000 MB.

**Note:** In the case of scheduled backups, if the Web server was not launched when the backup was scheduled to occur, on the next startup 4D considers the backup as failed and applies the appropriate settings, set via the Database Settings.

## Runtime Explorer Information

The **Watch** page (“Web” heading) in the Runtime Explorer displays information related to the Web Server, more particularly:

- **Web Cache Usage**: indicates the number of pages present in the Web cache as well as its use percentage. This information is only available if the Web server is active and if the cache size is greater than 0.
- **Web Server Elapsed Time**: indicates the duration of use (in hours:minutes:seconds format) of the Web server. This information is only available if the Web server is active.
- **Web Hits Count**: indicates the total number of HTTP requests received since the Web server boot, as well as an instantaneous number of requests per second (measure taken between two Runtime Explorer updates). This

information is only available if the Web server is active.

**Note:** For more information about the Runtime Explorer, refer to 4D *Design Reference* manual.

# Using TLS Protocol

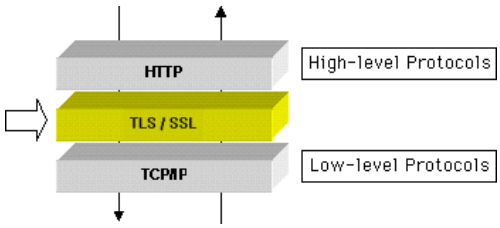
The 4D Web server can communicate in secured mode through the TLS (Transport Layer Security) protocol -- the successor of the SSL (Secured Socket Layer) protocol.

## TLS Protocol Definition

The TLS protocol (successor of SSL) has been designed to secure data exchanges between two applications —mainly between a Web server and a browser. This protocol is widely used and is compatible with most Web browsers.

At the network level, the security protocol is inserted between the TCP/IP layer (low level) and the HTTP high level protocol. It has been designed mainly to work with HTTP.

Network configuration using TSL:



**Note:** The TLS protocol can also be used to secure standard 4D Server client/server connections as well as SQL server connections. For more information, refer to the section **Encrypting Client/Server Connections** in the 4D Server Reference manual as well as the **Configuration of 4D SQL Server** section in the SQL Reference manual.

The TLS protocol is designed to authenticate the sender and receiver and to guarantee the confidentiality and integrity of the exchanged information:

- **Authentication**: The sender and receiver identities are confirmed.
- **Confidentiality**: The sent data is encrypted so that no third person can understand the message.
- **Integrity**: The received data has not been changed, by accident or malevolently.

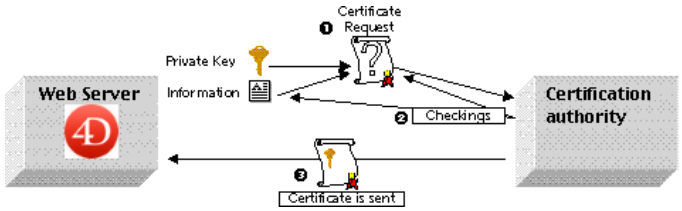
TLS uses a public key encryption technique based on a pair of asymmetric keys for encryption and decryption: a public key and a private key.
The private key is used to encrypt data. The sender (the web site) does not give it to anyone. The public key is used to decrypt the information and is sent to the receivers (Web browsers) through a certificate. When using TLS with the Internet, the certificate is delivered through a certification authority, such as Verisign®. The Web site pays the Certificate Authority to deliver a certificate which guaranties the server authentication and contains the public key allowing to exchange data in a secured mode.

**Note**: For more information on the encryption method and the public and private key issues, refer to the **ENCRYPT BLOB** command description.

## How to get a certificate?

A server working in secured mode means that you need a digital certificate from a certification authority. This certificate contains various information such as the site ID as well as the public key used to communicate with the site. This certificate is transmitted to the clients (Web browsers) connecting to this site. Once the certificate has been identified and accepted, the communication is made in secured mode.

**Note:** A browser authorizes only the certificates issued by a certification authority referenced in its properties.



The certification authority is chosen according to several criteria. If the certification authority is well known, the certificate will be authorized by many browsers, however the price to pay will be expensive.

To get a digital certificate:

1. Generate a private key using the **GENERATE ENCRYPTION KEYPAIR** command.

**Warning:** For security reasons, the private key should always be kept secret. Actually, it should always remain with the server machine. For the Web server, the **Key.pem** file must be placed in the Database structure folder.

2. Use the **GENERATE CERTIFICATE REQUEST** command to issue a certificate request.

3. Send the certificate request to the chosen certificate authority.
To fill in a certificate request, you might need to contact the certification authority. The certification authority checks that the information transmitted are correct. The certificate request is generated in a BLOB using the PKCS format encoded in base64 (PEM format). This principle allows you to copy and paste the keys as text and to send them via E-mail without modifying the key content. For example, you can save the BLOB containing the certificate request in a text document (using the **BLOB TO DOCUMENT** command), then open and copy and paste its content in a mail or a Web form to be sent to the certification authority.

4. Once you get your certificate, create a text file named “cert.pem” and paste the contents of the certificate into it.
You can receive a certificate in different ways (usually by E-mail or HTML form). 4D accepts all platform-related text formats for certificates (OS X, PC, Linux...). However, the certificate must be in PEM format, i.e. PKCS encoded in base64.

**Note:** CR line-ending characters are not supported on their own; you must use CRLF or LF.

5. Place the “cert.pem” file in the correct location. For the Web server, this is the folder containing the database structure.
The Web server can now work in a secured mode. A certificate is valid between 6 months to a year.

## TLS installation and activation within 4D

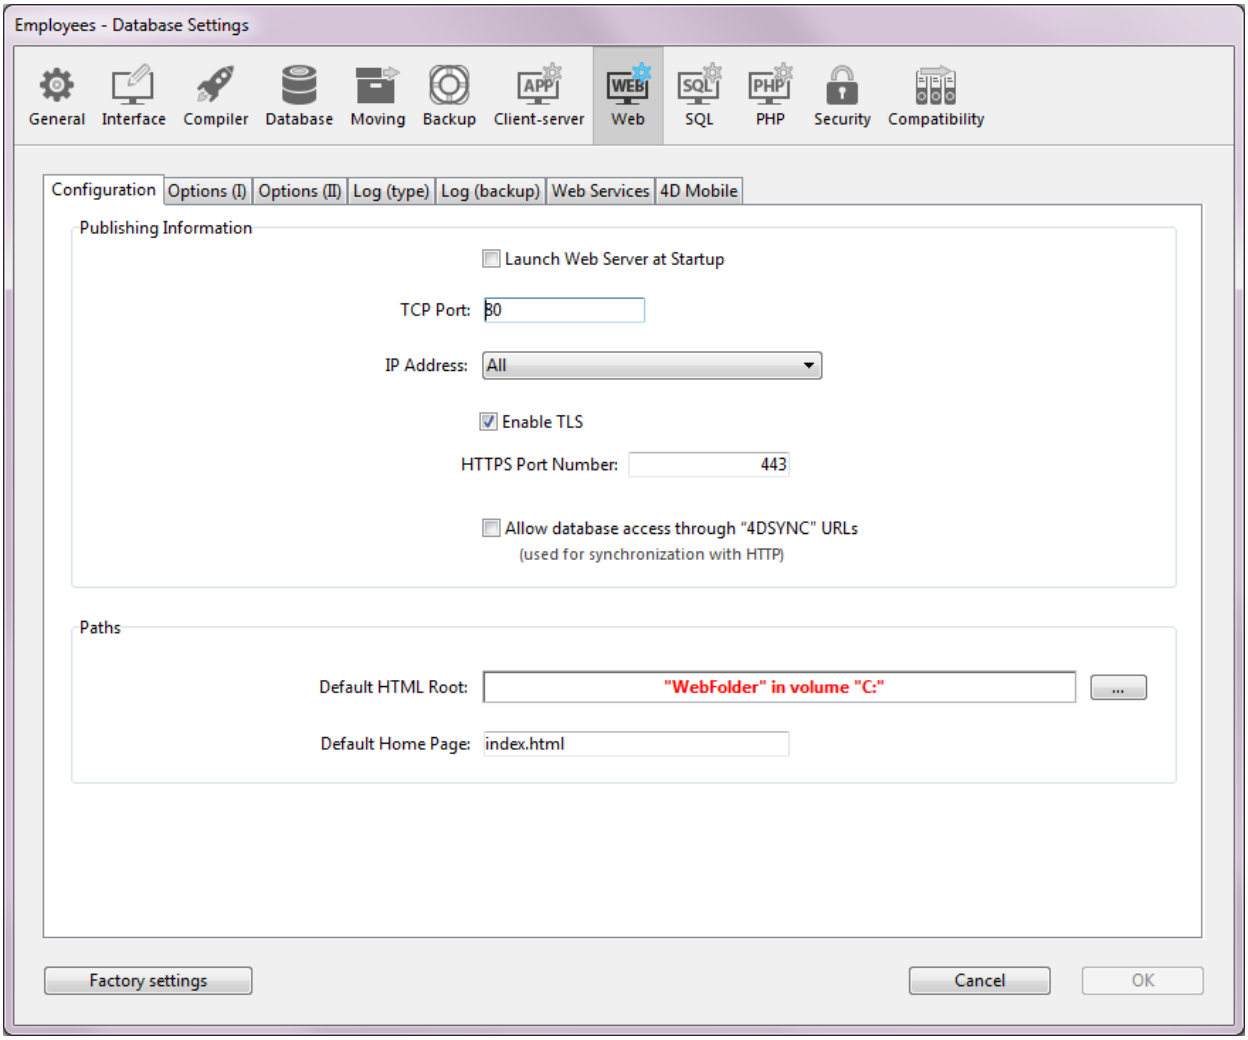
If you want to use the TLS protocol with the 4D Web server, the following components should be installed on the server, at different locations:

- *4DSLI.DLL* (Windows) or *4DSLI.bundle* (Mac OS): Secured Layer Interface dedicated to the TLS management.
  This file is installed by default, it is placed:
  - Under Windows, next to the executable file of the 4D or 4D Server application
  - Under Mac OS, in the *Native Components* subfolder of the 4D or 4D Server package.

- *key.pem* (document containing the private encryption key) and *cert.pem* (document containing the certificate):
  - with 4D in local mode or 4D Server, these files must be placed next to the database structure file
  - with 4D in remote mode, these files must be located in the local resources folder of the database on the remote machine (for more information about the location of this folder, refer to the 4D Client Database Folder paragraph in the description of the **Get 4D folder** command). Note that you must copy these files manually on the remote machine.

**Note:** *4DSLI* is also necessary to use the encryption commands **ENCRYPT BLOB** and **DECRYPT BLOB**.

The installation of these elements makes it possible to use TLS for connections to the 4D Web server. However, in order for TLS connections to be accepted by the 4D Web server, you must “activate” the TLS. This parameter is accessible on the **Configuration** tab of the **Web** page in the Database Settings:



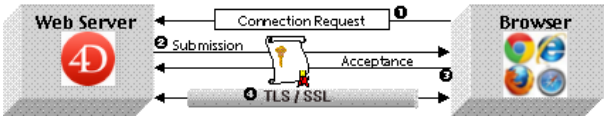
By default, the TLS connections are allowed. You can uncheck this option if you do not want to use TLS functionalities with your Web server, or if another Web server allowing secure connections is operating on the same machine.

The TCP port dedicated to TLS data exchange is 443 by default. This port number can be modified in the **HTTPS Port Number** area in order, for example, to reinforce the security of the Web server (for more information about this pont, refer to the **Web Server Settings** section). The TCP port defined on this page of the Database Settings is used for standard mode Web server connections.

**Note**: The other settings defined for the 4D Web Server management (password, timeout, cache size, etc.) are applied, regardless of whether or not the server is operating in TLS mode.

## Browser connection with TLS

For a Web connection to be carried out in secure mode, the URL sent by the browser simply needs to begin with “https” (instead of “http”).
In this case, a warning dialog appears on the browser. If the user clicks **OK**, the Web server sends the certificate to the browser.



The encryption algorithm used for the connection is then decided by the browser and the Web server. The server offers several symetric encryption algorithms (RC2, RC4, DES...). The most powerful common algorithm is used.

**Warning:** The level of encryption allowed might depend on current laws in the country of use.

### Management of the connection mode

Using TLS with a 4D Web server does not require any specific system configuration. However, you should keep in mind that a TLS Web server can also work in a non-secured mode. The connection mode can switch to another mode if the browser so requires (for example, in the browser URL area, the user can replace “HTTPS” by “HTTP”). The developer can forbid or redirect requests made in a non-secured mode. You can get the current connection mode using the **WEB Is secured connection** command.

## XML and WML Support

### WML

4D Web Server supports WML (Wireless Markup Language) technology. This feature allows a mobile phone or a PDA's owner to read and enter data in a 4D database.

**Note:** The WML language associated to the WAP (Wireless Application Protocol) is developed by several companies. The WAP technology offers a set of network communication tools so that mobile phones and PDA users can visualize text published on Web pages. The WML technology is open and free of charge. For more information on WML, please refer to the Phone.com Web site: *http://www.phone.com/*.

The data can be entered or read through WML pages using *4DTEXT* or *4DSCRIPT* tags.

Here is the list of the WML documents supported by 4D Web server:

| Extension | MIME Type | Description |
|---|---|---|
| .wml | text/vnd.wap.wml | WML pages (always supported by 4D*) |
| .wmls | text/vnd.wap.wmlscript | WML Scripts (on the client's side) |
| .wmlc | application/vnd.wap.wmlc | WML binary pages |
| .wmlsc | application/vnd.wap.wmlscript | WML binary scripts |
| .wbmp | picture/vnd.wap.wbmp | Bitmap images for mobile phones (not always supported) |

* Allows dynamic data insertion through *4DTEXT* and *4DSCRIPT* type tags.

### XML

The 4D Web server supports .xml,.xls and .dtd documents which are sent with the following MIME type: "text/xml" and "text/xsl".

4D analyzes their content and processes their *4DTEXT* or *4DSCRIPT* type tags (if any) in order to generate dynamic XML.

# WEB CLOSE SESSION

WEB CLOSE SESSION ( sessionID )

| Parameter | Type | | Description |
|---|---|---|---|
| sessionID | Text | ⇨ | Session UUID |

## Description

The **WEB CLOSE SESSION** command invalidates an existing session designated by the *sessionID* parameter. If the session does not exist, the command does nothing.

When this command is called from a Web process or any other process:

- The cookie expiration date is set to 0,
- The **On Web Close Process database method** is called, allowing you to store session information,
- Selections are erased, records are unlocked and variables are reset.

After this command is executed, if a Web client sends a request using an invalid cookie, a new session is opened and a new cookie is sent.

**Note:** In the context of a 4D Mobile session, the **WEB CLOSE SESSION** command closes the 4D Mobile session whose ID is passed in the *sessionID* parameter. Since a 4D Mobile session can manage several processes, this command actually requests all the Web processes related to the session to finish their execution.

# WEB GET BODY PART

WEB GET BODY PART ( part ; contents ; name ; mimeType ; fileName )

| Parameter | Type | | Description |
|---|---|---|---|
| part | Longint | ⇒ | Part number |
| contents | BLOB, Text | ⇐ | Contents of part |
| name | Text | ⇐ | Name of "input" variable |
| mimeType | Text | ⇐ | Mime type of submitted file |
| fileName | Text | ⇐ | Name of submitted file |

## Description

The **WEB GET BODY PART** command, when called in the context of a Web process, parses the "body" part of a multi-part request.

In the *part* parameter, pass the number of the part to be parsed. You can get the total number of parts using the **WEB Get body part count** command.

The *contents* parameter receives the contents of the part. When the parts to be retrieved are files, you must pass a BLOB type parameter. In the case of TEXT variables submitted in a Web form, you can pass a Text type parameter.

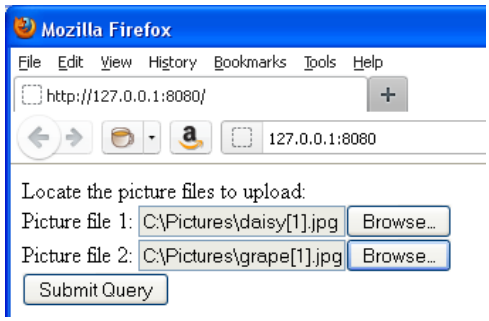
The *name* parameter receives the variable name of the HTTP input field.

The *mimeType* and *name* parameters receive the Mime type and the name of the original file, if any. A *name* is only received when the file was submitted as **<input type="file">**.
*mimeType* and *name* are optional but must be passed together.

**Note:** In the context of a multi-part request, the first array of the **WEB GET VARIABLES** command returns all parts of the form, in the same order as the **WEB GET BODY PART** command. You can use it in order to get the position of the parts of the form directly.

## Example

In this example, a Web form downloads several pictures using a browser onto the HTTP server and displays them in the page. Here is the Web form:



Here is the code for the <body> part of the page:

```
<body>        <form enctype="multipart/form-data" action="/4DACTION/GetFile/" method="post">            Locate the
picture files to upload: <br>            Picture file 1: <input name="file1" type="file"><br>            Picture file 2:
<input name="file2" type="file"><br>            <input type="submit">                                </form>            <hr/>
    <!--4DSCRIPT/galleryInit-->    <!--4Dloop aFileNames-->        <img src="/photos/<!--4Dvar aFileNames{aFileNames}--
>"/>    <!--4Dendloop--> </body>
```

Two 4D methods are called by the page:

- ***galleryInit*** on loading (4DSCRIPT tag), displays the pictures found in the destination folder.
- ***GetFile*** when sending data (4DACTION URL of multi-part form), processes the submission.

Here is the code for ***galleryInit***:

```
C_TEXT($vDestinationFolder)
ARRAY TEXT(aFileNames;0)
C_LONGINT($i)
```

```
$vDestinationFolder:=Get 4D folder(HTML Root folder)+"photos"+Folder separator //"WebFolder/photos" folder
DOCUMENT LIST($vDestinationFolder;aFileNames)
```

Here is the code for ***GetFile***:

```
C_TEXT($vPartName;$vPartMimeType;$vPartFileName;$vDestinationFolder)
C_BLOB($vPartContentBlob)
C_LONGINT($i)
$vDestinationFolder:=Get 4D folder(HTML Root folder)+"photos"+Folder separator
For($i;1;WEB Get body part count) //for each part
   WEB GET BODY PART($i;$vPartContentBlob;$vPartName;$vPartMimeType;$vPartFileName)
   If($vPartFileName#"")
      BLOB TO DOCUMENT($vDestinationFolder+$vPartFileName;$vPartContentBlob)
   End if
End for
WEB SEND HTTP REDIRECT("/") // return to page
```

# WEB Get body part count

WEB Get body part count -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Number of parts in the body |

## Description

The **WEB Get body part count** command returns the number of parts making up the body received.

## Example

Refer to the example for the **WEB GET BODY PART** command.

# WEB Get Current Session ID

WEB Get Current Session ID -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Text |  | Session UUID |

## Description

The **WEB Get Current Session ID** command returns the ID of the session open for the Web request. This ID is generated automatically by 4D as an UUID.

If this command is called outside of the context of a Web session, it returns an empty string "".

# WEB GET HTTP BODY

WEB GET HTTP BODY ( body )

| Parameter | Type | | Description |
|---|---|---|---|
| body | BLOB, Text | ⇐ | Body of the HTTP request |

## Description

The **WEB GET HTTP BODY** command returns the body of the HTTP request being processed. The HTTP body is returned as is, without processing or parsing.

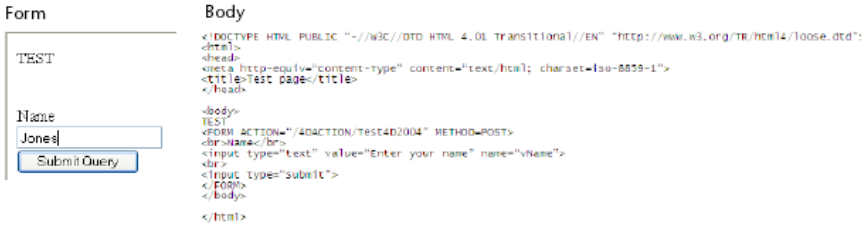
This command can be called using a Web database method (**On Web Authentication Database Method**, **On Web Connection Database Method**) or any Web method.

In *body*, you can pass a variable or a field of the BLOB or Text type. The Text type is generally sufficient (the *body* parameter can receive up to 2 GB of text).

This command allows you, for example, to carry out queries in the body of requests. It also permits advanced users to set up a WebDAV server within a 4D database.

## Example

In this example, a simple request is sent to the 4D Web server and the contents of the HTTP body are displayed in the debugger. Here is the form sent to the 4D Web server, as well as the corresponding HTML code:



Here is the Test4D2004 method:

```
C_BLOB($request)
C_TEXT($requestText)

WEB GET HTTP BODY($request)
$requestText:=BLOB to text($request;UTF8 text without length)
WEB SEND FILE("page.html")
```

**Note:** This method is declared “Available through 4D HTML tags and URLs (4DACTION...)” in its properties.

When the form is submitted to the Web server, the $requestText variable receives the text of the HTTP request body.

# WEB GET HTTP HEADER

WEB GET HTTP HEADER ( header|fieldArray {; valueArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| header\|fieldArray | Text, Text array | ⇦ | Request HTTP header or HTTP header fields |
| valueArray | Text array | ⇦ | HTTP header fields content |

## Description

The **WEB GET HTTP HEADER** command returns either a string or two arrays, containing the HTTP header used for the currently processed request.

This command can be called from within any method (**On Web Authentication Database Method** or **On Web Connection Database Method**, method called by "*/4DACTION*"...) executed in a Web process.

- **First syntax: WEB GET HTTP HEADER (header)**

When this syntax is used, the result returned in the *header* variable is as follows:

```
"GET /page.html HTTP¥1.0"+Char(13)+Char(10)+"User-Agent: browser"+Char(13)+Char(10)+"Cookie: C=HELLO"
```

Each header field is separated by a CR+LF (Carriage return+Line feed) sequence under Windows and Mac OS.

- **Second syntax: WEB GET HTTP HEADER (fieldArray; valueArray)**

When this syntax is used, the returned results in the *fieldArray* and *valueArray* are as follows:

| | |
|---|---|
| *fieldArray{1} = "X-METHOD"* | *valueArray{1} = "GET" ** |
| *fieldArray{2} = "X-URL"* | *valueArray{2} = "/page.html" ** |
| *fieldArray{3} = "X-VERSION"* | *valueArray{3} = "HTTP/1.0" ** |
| *fieldArray{4} = "User-Agent"* | *valueArray{4} = "browser"* |
| *fieldArray{5} = "Cookie"* | *valueArray{5} = "C=HELLO"* |

* These first three items are not HTTP fields. They are part of the first line of the request.

To comply with the HTTP standard, field names are always written in English.

Here is a list of some HTTP fields that can be used in a request:

- **Accept**: content allowed by the browser.
- **Accept-Language**: language(s) that can be used by the browser (for information). Allows to select a web page using the language defined in the browser.
- **Cookie**: cookies list
- **From**: browser user email address.
- **Host**: server name or address (for example using an URL, http://mywebserver/mypage.html, **Host** takes the «mywebserver» value). Allows to manage several names pointing towards the same IP address (virtual hosting).
- **Referer**: request origin (for example http://mywebserver/mypage1.html), i.e. the page which is displayed when clicking on the **Previous** button.
- **User-Agent**: browser or proxy name and version.

## Example

The following method allows getting any HTTP request header field content:

```
  ` Project method GetHTTPField
  ` GetHTTPField (Text) -> Text
  ` GetHTTPField (HTTP header name) -> HTTP header content

C_TEXT($0;$1)
C_LONGINT($vlItem)
ARRAY TEXT($names;0)
```

```
ARRAY TEXT($values;0)
$0:=""
WEB GET HTTP HEADER($names;$values)
$vlItem:=Find in array($names;$1)
If($vlItem>0)
   $0:=$values{$vlItem}
End if
```

- Once this project method has been written, it can be called as follows:

```
` Cookie header content
$cookie:=GetHTTPField("Cookie")
```

- You can send different pages according to the language set in the browser (for example in the **On Web Connection Database Method**):

```
$language:=GetHTTPField("Accept-Language")
Case of
   :($language="@fr@") `French (see list ISO 639)
      WEB SEND FILE("index_fr.html")
   :($language="@sp@") `Spanish (see list ISO 639)
      WEB SEND FILE("index_es.html")
   Else
      WEB SEND FILE("index.html")
End case
```

**Note:** Web browsers allow defining several languages by default. They are listed in the "Accept-Language" field, separated by a ";". Their priority is defined according to their position within the string; therefore it is a good idea to test language positions in the string.

- Here is an example of virtual hosts (for example, in the **On Web Connection Database Method**). The following names "home_site.com", "home_site1.com" and "home_site2.com" are directed towards the same IP address, for example 192.1.2.3.

```
$host:=GetHTTPField("Host")
Case of
   :($host="www.site1.com")
      WEB SEND FILE("home_site1.com")
   :($host="www.site2.com")
      WEB SEND FILE("home_site2.com")
   Else
      WEB SEND FILE("home_site.com")
End case
```

# WEB GET OPTION

WEB GET OPTION ( selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ⇒ | Code of option to modify |
| value | Longint, Text | ⇐ | Value of option |

## Description

The **WEB GET OPTION** command gets the current value of an option for the 4D Web server operation.

The *selector* parameter indicates which Web option to get. In this parameter, you pass one of the constants available in the **Web Server** theme:

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Character set that the 4D Web Server (with 4D in local mode and 4D Server) should use to communicate with browsers connecting to the database. The default value actually depends on the language of the operating system. This parameter is set in the Database settings.<br>**Possible values**: The possible values depend on the operating mode of the database relating to the character set.<br><br>• *Unicode Mode*: When the application is operating in Unicode mode, the values to pass for this parameter are character set identifiers (*MIBEnum* longint or *Name* string, identifiers defined by IANA, see the following address: http://www.iana.org/assignments/character-sets). Here is the list of identifiers corresponding to the character sets supported by the 4D Web server:<br>4=ISO-8859-1<br>12=ISO-8859-9<br>13=ISO-8859-10<br>17=Shift-JIS<br>2024=Windows-31J<br>2026=Big5<br>38=euc-kr<br>106=UTF-8<br>2250=Windows-1250<br>2251=Windows-1251<br>2253=Windows-1253<br>2255=Windows-1255<br>2256=Windows-1256<br><br>• *ASCII compatibility mode*:<br>Western European<br>1: Japanese<br>2: Chinese<br>3: Korean<br>4: User-defined<br>5: Reserved<br>6: Central European<br>7: Cyrillic<br>8: Arabic<br>9: Greek<br>10: Hebrew<br>11: Turkish<br>12: Baltic |
| Web debug log | Longint | 84 | **Scope:** Local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted (a new log file is used in this case)<br>**Description:** Allows you to get or set the status of the HTTP request log file of the 4D Web server. When enabled, this file, named "**HTTPDebugLog_*nn*.txt**", is stored in the "Logs" folder of the application (*nn* is the file number). It is useful for debugging issues related to the Web server. It records each request and each response in raw mode. Whole requests, including headers, are logged; optionally, body parts can be logged as well.<br>**Values**: One of the constants prefixed with "wdl" (refer to the descriptions of these constants in this theme).<br>**Default value**: 0 (not enabled) |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web HTTP compression level | Longint | 50 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Compression level for all compressed HTTP exchanges for the 4D HTTP server (client requests or server replies, Web and Web Service). This selector lets you optimize exchanges by either privileging speed of execution (less compression) or the amount of compression (less speed). The choice of a value depends on the size and type of data exchanged. Pass 1 to 9 in the *value* parameter where 1 is the fastest compression and 9 the highest. You can also pass -1 to get a compromise between speed and rate of compression. By default, the compression level is 1 (faster compression).<br>**Possible values**: 1 to 9 (1 = faster, 9 = more compressed) or -1 = best compromise. |
| Web HTTP compression threshold | Longint | 51 | **Scope**: Local HTTP server<br>**Kept between two sessions**: No<br>**Description**: In the framework of optimized HTTP exchanges, size threshold for requests below which exchanges should not be compressed. This setting is useful in order to avoid losing machine time by compressing small exchanges.<br>**Possible values**: Any Longint type value. Pass the size expressed in bytes in *vaue*. By default, the compression threshold is set to 1024 bytes |
| Web HTTP TRACE | Longint | 85 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Allows you to disable or enable the HTTP TRACE method in the 4D Web server. For security reasons, starting with 4D v15 R2, by default the 4D Web server rejects HTTP TRACE requests with an error 405 (see HTTP TRACE disabled). If necessary, you can enable the HTTP TRACE method for the session by passing this constant with value 1. When this option is enabled, the 4D Web server replies to HTTP TRACE requests with the request line, header, and body.<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 0 (disabled) |
| Web HTTPS port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: TCP port number used by the Web server of 4D in local mode and of 4D Server for secure connections via SSL (HTTPS protocol). The HTTPS port number is set on the “Web/Configuration” page of the Database settings dialog box.<br>By default, the value is 443 (standard value). You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>**Possible values**: 0 to 65535 |
| Web inactive process timeout | Longint | 78 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Modifies the life duration of the inactive processes associated with sessions. At the end of the timeout, the process is killed on the server, the **On Web Close Process database method** is called then the session context is destroyed.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |
| Web inactive session timeout | Longint | 72 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Modifies the life duration of inactive sessions (duration set in cookie). At the end of this period, the session cookie expires and is no longer sent by the HTTP client.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web IP address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: IP address on which the 4D Web server will receive HTTP requests with 4D in local mode and 4D Server. By default, no specific address is defined (*value* = 0). This parameter can be set in the Database settings. The *Web IP Address to listen* selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode).<br>You pass a hexadecimal IP address in the *value* parameter. In other words, to designate a IP address such as "a.b.c.d", you should write:<br>`C_LONGINT($addr)`<br>`$addr:=($a<<24)\|($b<<16)\|($c<<8)\|$d`<br>`WEB SET OPTION(Web IP address to listen;$addr)` |
| Web keep session | Longint | 70 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Enables or disables the session management mode (described in the **Web Sessions Management** section)<br>**Possible values**: 1 (enable mode) or 0 (disable mode)<br>**Default value**: 1 for databases created in v13, 0 for converted databases. Note that this mode also enables the mechanism for reusing temporary contexts in remote mode. For more information about this mechanism, refer to the description of this option in the **Web Server Settings** section. |
| Web log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Starts or stops the recording of Web requests received by the Web server of 4D in local mode or 4D Server. By default, the value is 0 (requests not recorded).<br>The log of Web requests is stored as a text file named "logweb.txt" that is automatically placed in the Logs folder of the database, next to the structure file. The format of this file is determined by the value that you pass. For more information about Web log file formats, please refer to the **Information about the Web Site** section.<br>This file can also be activated on the "Web/Log" page of the Database settings.<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br>**Warning**: Formats 3 and 4 are custom formats whose contents must be set beforehand in the Database settings. If you use one of these formats without any of its fields having been selected on this page, the log file will not be generated. |
| Web max concurrent processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Strictly upper limit of concurrent Web processes of any type supported by the 4D Web Server with 4D in local mode and 4D Server. When this number (minus one) is reached, 4D will not create any other processes and returns the HTTP status 503 - Service Unavailable to all new requests.<br>This parameter can prevent the 4D Web Server from saturation, which can occur when an exceedingly large number of concurrent requests are sent, or when too many context creations are requested. This parameter can also be set in the Database settings.<br>In theory, the maximum number of Web processes is the result of the following formula: Available memory/Web process stack size. Another solution is to view the information on Web processes displayed in the Runtime Explorer: the current number of Web processes and the maximum number reached since the Web server boot are indicated.<br>**Possible values**: Any value between 10 and 32 000. The default value is 100. |
| Web max sessions | Longint | 71 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Limits the number of simultaneous sessions. When you reach the limit set, the oldest session is closed (and **On Web Close Process database method** is called) if the Web server needs to create a new one.<br>**Possible values**: Longint. The number of simultaneous sessions cannot exceed the total number of Web processes (Web Max Concurrent Processes option, 100 by default)<br>**Default value**: 100 (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web maximum requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Maximum size (in bytes) of incoming HTTP requests (POST) that the Web server is authorized to process. By default, the value is 2 000 000, i.e. a little less than 2 MB. Passing the maximum value (2 147 483 648) means that, in practice, no limit is set. This limit is used to avoid Web server saturation due to incoming requests that are too large. When a request reaches this limit, the 4D Web server refuses it.<br>**Possible values**: 500 000 to 2 147 483 648. |
| Web port ID | Longint | 15 | **Scope**: 4D in local mode and 4D Server.<br>**Kept between two sessions:** No<br>**Description:** Sets or gets the number of the TCP port used by the 4D Web server with 4D in local mode and 4D Server. By default, the value is 80. The TCP port number is set on the "Web/Configuration" page of the Database Settings dialog box. You can use one of the constants in the **TCP Port Numbers** theme for the *value* parameter. This selector is useful within the framework of 4D Web servers that are compiled and merged using 4D Desktop (no access to the Design environment).<br>**Possible values:** For more information about the TCP port number, refer to the **Web Server Settings** section.<br>**Default value:** 80 |
| Web session cookie domain | Longint | 81 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "domain" field of the session cookie. This selector (as well as selector 82) is useful for controlling the scope of the session cookies: If you set, for example, the value "/*.4d.fr" for this selector, the client will only send a cookie when the request is addressed to the domain ".4d.fr", which excludes servers hosting external static data.<br>**Possible values:** Text |
| Web session cookie name | Longint | 73 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Sets the name of the cookie used for saving the session ID.<br>**Possible values:** Text<br>**Default value:** "4DSID" (pass an empty string to restore the default value) |
| Web session cookie path | Longint | 82 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "path" field of the session cookie. This selector (as well as selector 81) is useful for controlling the scope of the session cookies: If you set, for example, the value "/4DACTION" for this selector, the client will only send a cookie for dynamic requests beginning with 4DACTION, and not for pictures, static pages, etc.<br>**Possible values:** Text |
| Web session enable IP address validation | Longint | 83 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Enables or disables IP address validation for session cookies. For security reasons, by default the 4D Web server checks the IP address of each request containing a session cookie and rejects it if this address does not match the IP address used to create the cookie. In some specific applications, you may want to disable this validation and accept session cookies, even when their IP addresses do not match. For example when mobile devices switch between Wifi and 3G/4G networks, their IP address will change. In this case, you must pass 0 in this option to allow clients to be able to continue using their Web sessions even when the IP addresses change. Note that this setting lowers the security level of your application.<br>When it is modified, this setting is effective immediately (you do not need to restart the HTTP server).<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 1 (IP addresses are checked) |

When you use the Web debug log *selector*, you can receive one of the following constants in the *value* parameter:

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| wdl disable | Longint | 0 | Web HTTP debug log is disabled |
| wdl enable with all body parts | Longint | 7 | Web HTTP debug log is enabled with body parts in response and request |
| wdl enable with request body | Longint | 5 | Web HTTP debug log is enabled with body part in request only |
| wdl enable with response body | Longint | 3 | Web HTTP debug log is enabled with body part in response only |
| wdl enable without body | Longint | 1 | Web HTTP debug log is enabled without body parts (body size is provided in this case) |

# WEB GET SESSION EXPIRATION

WEB GET SESSION EXPIRATION ( sessionID ; expDate ; expTime )

| Parameter | Type | | Description |
|---|---|---|---|
| sessionID | Text | ⇨ | Session UUID |
| expDate | Date | ⇦ | Date of cookie expiration |
| expTime | Time | ⇦ | Time of cookie expiration |

## Description

The **WEB GET SESSION EXPIRATION** command returns the expiration information for the cookie of the session whose UUID you passed in *sessionID*.

The *expDate* parameter receives the expiration date and the *expTime* parameter receives the expiration time of the cookie.

**Note:** Each time a web request is sent, the expiration date and time of the cookie are reset to a value corresponding to the time of the request+the value of the Web Inactive session timeout. For example:
*First request, Monday at 1:00*
-> Sends a cookie 4DSID xxxyyy expiration I+24h = Tuesday 01:00
*Second request, Monday at 1:10*
-> Sends a cookie 4DSID xxxyyy expiration I+24h = Tuesday 01:10
*Third request, Tuesday at 4:00: cookie expired*
-> Sends a cookie 4DSID aaabbb expiration I+24h = Wednesday 01:00

# WEB Get session process count

WEB Get session process count ( sessionID ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| sessionID | Text | ⇒ | Session UUID |
| Function result | Longint | ⇐ | Number of processes attached to the session |

## Description

The **WEB Get session process count** command returns the number of running processes attached to the session whose UUID you passed in *sessionID*.

This command is added in the context of the **Handling of 4D Mobile sessions by programming** feature introduced in 4D v15 R4. It is mainly designed to count the number of processes run by a 4D Mobile session.

- For a 4D Mobile session, this command returns the actual number of processes. A 4D Mobile session can run several processes.
- For a regular Web session, this command always return 1 (one Web session = one process).

## Example

You want to store information on the current 4D Mobile session in arrays:

```
C_TEXT($sessionID)
C_LONGINT($count)
C_DATE($expDate)
C_TIME($expTime)

$sessionID:=WEB Get Current Session ID
$count:=WEB Get session process count($sessionID)
WEB GET SESSION EXPIRATION($sessionID;$expDate;$expTime)

APPEND TO ARRAY($aTimestamp;String(Current date)+" "+String(Current time))
APPEND TO ARRAY($aSessionUID;$sessionID)
APPEND TO ARRAY($aNbProcesses;$count)
APPEND TO ARRAY($aExpirationDate;$expDate)
APPEND TO ARRAY($aExpirationTime;$expTime)
```

# WEB GET STATISTICS

WEB GET STATISTICS ( pages ; hits ; usage )

| Parameter | Type | | Description |
|---|---|---|---|
| pages | Text array | ⇦ | Names of the most consulted pages |
| hits | Longint array | ⇦ | Number of hits for each page |
| usage | Longint | ⇦ | Percentage of the cache used |

## Description

The **WEB GET STATISTICS** command lets you get information about the most consulted pages loaded in the Web server's cache. Consequently, these statistics only concern static pages, GIF pictures, JPEG pictures <100 KB and style sheets (.css).

**Note:** For more information about setting the 4D Web server's cache, refer to the **Web Server Settings** section.

The command fills the pages Text array with the names of the most consulted pages. The *hits* Longint array receives the number of "hits" for each page. The *usage* parameter receives the percentage of the Web cache used by each page.

## Example

Let's assume that you want to generate a semi-dynamic page that displays the statistics of the Web cache. For this, in a static HTML page named "stats.shtm" (pages suffixed .shtm are automatically parsed by the Web server), you place the tag *<!--#4DSCRIPT/STATS-->* as well as references to the *vPages* and *vUsage* variables, for example:

```
<html> <head><title>4D Web Stats</title></head> <!--#4DSCRIPT/STATS--> <body> <strong>Percentage of cache used: </strong>
<!--#4DTEXT vUsage--> <hr> <strong>Pages consulted most often: </strong> <!--#4DHTML vPages--> </body> </html>
```

In the project method ***STATS***, you write the following code:

```
C_TEXT($1)
C_TEXT(vPages)
ARRAY TEXT(pages;0)
ARRAY LONGINT(hits;0)
C_LONGINT(vUsage)

WEB CACHE STATISTICS(pages;hits;vUsage)
For($i;1;Size of array(pages))
   ¥¥For each page present in the cache
   vPages:=pages{$i}+"   "+String(hits{$i})+"<br>"
   ¥¥Insert the name of the page and the HTML code
End for
```

You can send the "stats.shtm" page using a URL link or using the **WEB SEND FILE** command.

# WEB GET VARIABLES

WEB GET VARIABLES ( nameArray ; valueArray )

| Parameter | Type | | Description |
|---|---|---|---|
| nameArray | Text array | ⇐ | Web form variable names |
| valueArray | Text array | ⇐ | Web form variable values |

## Description

The **WEB GET VARIABLES** command fills the text arrays *nameArray* and *valueArray* with the variable names and values contained in the Web form "submitted" (i.e. sent to the Web server).

This command gets the value for all the variables which can be included in HTML pages: text area, button, check box, radio button, pop up menu, choice list...

**Note:** Regarding check boxes, the variable name and value are returned only if the check box has been actually checked.

This command is valid regardless of the type of URL or form (POST or GET method) sent to the Web server.

This command can be called, if necessary, in the **On Web Connection Database Method** or any other 4D method resulting from a form submission.

### About Web forms and their associated actions

Each form contains named data entry area (text area, buttons, checkboxes).
When a form is submitted (a request is sent to the Web server), the request contains (within others) the list of the data entry areas and their associated values.
A form can be submitted through two methods (both can be used with 4D):

- POST, usually used to add data into the Web server - to a database,
- GET, usually used to request the Web server - data coming from a database.

## Example

A form contains two fields, vName and vCity with "ROBERT" and "DALLAS" values. The action associated to the form is "/4DACTION/WEBFORM".

- If the form method is POST (most frequently used), the data entered will not be visible in the URL (http://127.0.0.1/4DACTION/WEBFORM).
- If the form method is GET, the data entered will be visible in the URL (http://127.0.0.1/4DACTION/WEBFORM?vNAME=ROBERT&vCITY=DALLAS).

The WEBFORM method can be as follows:

```
ARRAY TEXT($anames;0)
ARRAY TEXT($avalues;0)
WEB GET VARIABLES($anames;$avalues)
```

The result will be:

```
$anames{1}="vNAME"
$anames{2}="vCITY"
$avalues{1}="ROBERT"
$avalues{2}="DALLAS"
```

The vNAME variable contains ROBERT and the vCITY variable contains DALLAS.

# WEB Is secured connection

WEB Is secured connection -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ➲ | True = the web connection is secured. False = the web connection is not secured. |

## Description

The **WEB Is secured connection** command returns a Boolean indicating if the 4D Web server connection was done in secured mode through TLS/SSL (the request starts with “https:” instead of “http:”).

- If the connection is made through TLS or SSL, the function returns True.
- If the connection is made in a non-secured mode, the function returns False.

**Note:** For more information on the TLS protocol, refer to the **Using TLS Protocol** section.

This command allows, for example, denying connections made in a non-secured mode (if any).

# WEB Is server running

WEB Is server running -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | True if the Web Server is running, otherwise False |

## Description

The new **WEB Is server running** command returns **True** if the 4D built-in Web server is running, and **False** if the Web server is off.

This command returns the running status of the Web Server where it is executed:

| Execution context | Returns the status of |
|---|---|
| 4D stand-alone application | Local 4D Web server |
| 4D Server | 4D Server Web server |
| 4D remote mode (local process) | Local 4D Web server |
| 4D remote mode (4D Server stored procedure) | 4D Server Web server |
| 4D remote mode (other 4D remote stored procedure) | Remote 4D Web server |

## Example

You want to check that the Web server is running:

```
If(WEB Is server running)
   ... //do appropriate actions
End if
```

# WEB SEND BLOB

WEB SEND BLOB ( blob ; type )

| Parameter | Type | | Description |
|---|---|---|---|
| blob | BLOB | ⇒ | BLOB to send to the browser |
| type | String | ⇒ | Data type of the BLOB |

## Description

The **WEB SEND BLOB** command allows you to send *blob* to the browser.

The type of data contained in the BLOB is indicated by *type*. This parameter can be one of the following types:

- *type* = **Empty String** (""): In this case, you don't need to supply any more information in the BLOB. The browser will try to interpret the contents of the BLOB.
- *type* = **File extension** (example: ".HTM", ".GIF", ".JPEG", etc.): In this case, you specify the MIME type of the data contained in the BLOB by indicating its extension. The BLOB will then be interpreted according to its extension. However, the extension must be a standard one so that the browser can correctly interpret it.
- *type* = **Mime/Type** (example: "text/html", "image/tiff", etc.): In this case, you directly specify the MIME type of data contained in the BLOB. This solution offers you more freedom. Besides the standard types, you can pass a custom MIME type to send proprietary documents via Intranet. To do so, you only need to configure the browsers so that they recognize the type sent and so that they can open the appropriate application. The value you pass to *type* is, in this case, "application/x-[TypeName]". In the client workstations's browser, you reference this type and associate it to the "Launch the application" action. The **WEB SEND BLOB** command allows you to therefore send all types of documents, the Intranet clients automatically open the associated application.

  **Note:** For more information about MIME types, refer to the page: http://www.iana.org/assignments/media-types.

Here is a list of the most common MIME types:

| Extension | Mime/Type |
|---|---|
| .htm | text/html |
| .html | text/html |
| .shtml | text/html |
| .shtm | text/html |
| .css | text/css |
| .pdf | application/pdf |
| .rtf | application/rtf |
| .ps | application/postscript |
| .eps | application/postscript |
| .hqx | application/mac-binhex40 |
| .js | application/javascript |
| .json | application/json |
| .txt | text/plain |
| .text | text/plain |
| .gif | image/gif |
| .jpg | image/jpeg |
| .jpeg | image/jpeg |
| .jpe | image/jpeg |
| .jfif | image/jpeg |
| .pic | image/pict |
| .pict | image/pict |
| .tif | image/tiff |
| .tiff | image/tiff |
| .mpeg | video/mpeg |
| .mpg | video/mpeg |
| .mov | video/quicktime |
| .moov | video/quicktime |
| .aif | audio/aiff |
| .aiff | audio/aiff |
| .wav | audio/wav |
| .ram | audio/x-pn-realaudio |
| .sit | application/x-stuffit |
| .bin | application/x-stuffit |
| .xml | application/xml |
| .z | application/x-zip |
| .zip | application/x-zip |
| .gz | application/x-gzip |
| .tar | application/x-tar |

**Note:** The list of MIME types supported by the 4D HTTP server is saved in the "MimeTypes.xml" file found in the following folder of the 4D application: *[Contents]¥Native components¥HTTPServer.bundle¥Contents¥Resources*.

The references to 4D variables and *4DSCRIPT* type tags in the page are always parsed.

## Example

Refer to the example of the **PICTURE TO GIF** routine.

# WEB SEND FILE

WEB SEND FILE ( htmlFile )

| Parameter | Type | | Description |
|---|---|---|---|
| htmlFile | String | ⇒ | HTML Pathname to HTML file or empty string for terminating SEND HTML FILE |

## Description

The **WEB SEND FILE** command sends, to the Web browser, the HTML page or the Web file stored in the document whose pathname you pass in *htmlFile*.

By default, 4D looks for the HTML document within the root folder, defined in the Database Settings.

This command accepts as a parameter either pathnames in Posix syntax (names of directories or folders are separated with a slash "/") or in the system syntax.
Specifying an invalid pathname generates an error related to file management for your operating system. You can intercept this error using a method installed by the **ON ERR CALL** command. If the method displays a warning or message dialog box, it will appear on the browser machine.

Once **WEB SEND FILE** is executed, the OK system variable is updated: if the file to be sent exists and if the timeout has not run out, OK is equal to 1. Otherwise, it is equal to 0.

**Note:** If you call **WEB SEND FILE** from within a process that is not a Web process, the command does nothing and returns no error; the call is simply ignored.

The references to 4D variables and *4DSCRIPT* type tags found on the page are parsed when the document type allows for it (document based on text).

## Example

The HTML root folder of the database is the *WebDocs* folder. It contains the following elements:

```
..¥WebDocs¥HTM¥MyPage.HTM
```

Sending the Web page *"MyPage.HTM"* must be carried out in the following manner :

```
WEB SEND FILE("HTM/MyPage.HTM")
```

## System variables and sets

If the file to be sent exists and if the timeout has not run out, OK is set to 1. Otherwise, it is equal to 0.

# WEB SEND HTTP REDIRECT

WEB SEND HTTP REDIRECT ( url {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| url | String | ⇒ | New URL |
| * | Operator | ⇒ | If specified = URL is not translated, If omitted = URL is translated |

## Description

The **WEB SEND HTTP REDIRECT** command allows you to transform a URL into another one.

The *url* parameter contains the new URL that allows you to redirect the request. If this parameter is a url to a file, it must contain the reference to this file, for example: **WEB SEND HTTP REDIRECT** ("/MyPage.HTM").

This command prevails over commands that send data (**WEB SEND FILE**, **WEB SEND BLOB**, etc.) that may be in the same method.

This command also allows you to redirect a request to another Web server.

4D automatically encodes the URL's special characters. If you pass the * character, 4D will not translate them.

Note that the status of the request sent by this command is **302: Moved Temporarily**. If you need a "moved permanently" status (status 301), you can set a HTTP *X-STATUS: 301* field in the header of the reply.

## Example

You can use this command to execute custom requests in 4D by using static pages. Imagine that you have placed the following elements in a static HTML page:

**Note:** The POST action "/4dcgi/rech" has been associated to the text area and to the **OK** and **Cancel** buttons.

In the **On Web Connection Database Method**, you insert the following code:

```
Case of
   :($1="/4dcgi/rech") //When 4D receives this URL
 //If the OK button has been used and the 'name' field contains a Value
      If((bOK="OK") & (name#""))
 //Change the URL to execute the request code,
 //placed farther down in the same method
         WEB SEND HTTP REDIRECT("/4dcgi/rech?"+name)
      Else
 //Else return to the beginning page
         WEB SEND HTTP REDIRECT("/page1.htm")
      End if
      ...
   :($1="/4dcgi/rech?@") //If the URL has been redirected
      ... //Put the request code here
End case
```

# WEB SEND RAW DATA

WEB SEND RAW DATA ( data {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| data | BLOB | ➡ | HTTP data to send |
| * | Operator | ➡ | Send chunked |

## Description

The **WEB SEND RAW DATA** command lets the 4D Web server send “raw” HTTP data, which can be chunked. .

The *data* parameter contains the two standard parts of an HTTP response, i.e. Header and Body. The data are sent without prior formatting by the server. However, 4D carries out a basic check of the response header and body in order to make sure that they are valid:

- If the header is incomplete or does not comply with the HTTP protocol specifications, 4D will change it accordingly.
- If the HTTP request is incomplete, 4D adds the missing information. If, for instance, you want to redirect the request, you must write:

```
HTTP/1.1 302    Location: http://...
```

If you only pass:

```
Location: http://...
```

4D will complete the request by adding *HTTP/1.1 302*.

The optional * parameter lets you specify that the response will be sent “chunked”. The cutting up of responses into chunks can be useful when the server sends a response without knowing its total length (if, for instance, the response has not yet been generated). All HTTP/1.1-compatible browsers accept chunked responses.

If you pass the * parameter, the Web server will automatically include the *transfer-encoding: chunked* field in the header of the response, if necessary (you can handle the response header manually if you so desire).

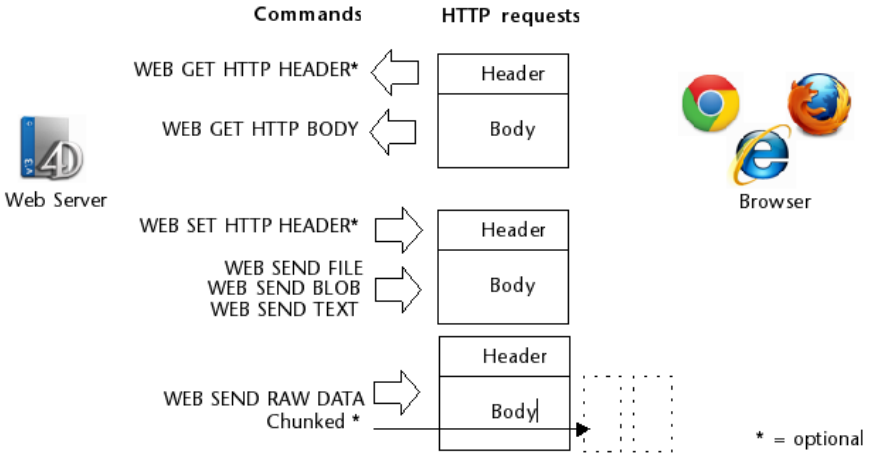
The remainder of the response will also be formatted in order to respect the syntax of the chunked option. Chunked responses contain a single header and an undefined number of body “chunks”.

All the **WEB SEND RAW DATA** statements that follow the execution of **WEB SEND RAW DATA**(data;*) within the same method will be considered as part of the response (regardless of whether they contain the * parameter). The server puts an end to the chunked send when the method execution is terminated.

**Note:** If the Web client does not support HTTP/1.1, 4D will automatically convert the response into an HTTP/1.0-compatible format (the data sent will not be chunked). However, in this case, the result may not correspond to your wishes. It is therefore recommended to check whether the Web browser supports HTTP/1.1 and to send an appropriate response. To do so, you can use a method such as:

```
C_BOOLEAN($0)
ARRAY TEXT(arFields;0)
ARRAY TEXT(arValues;0)
WEB GET HTTP HEADER(arFields;arValues)
$0:=False
If(Size of array(arValues)>=3)
   If(Position("HTTP/1.1";arValues{3})>0)
      $0:=True //The browser supports HTTP/1.1; $0 returns True
   End if
End if
```

Combined with the **WEB GET HTTP BODY** command and other commands of the “Web Server” theme, this command completes the range of tools available to 4D developers in order to entirely customize the processing of incoming and outgoing HTTP connections. These different tools are shown in the following diagram:



## Example

This example illustrates the use of the chunked option with the **WEB SEND RAW DATA** command. The data (a sequence of numbers) are sent in 100 chunks generated on the fly in a loop. Keep in mind that the header of the response is not explicitly set: the command will send it automatically and insert the *transfer-encoding: chunked* field into it since the * parameter is used.

```
C_LONGINT($cpt)
C_BLOB($my_blob)
C_TEXT($output)

For($cpt;1;100)
   $output:="["+String($cpt)+"]"
   TEXT TO BLOB($output;$my_blob;UTF8 text without length)
   WEB SEND RAW DATA($my_blob;*)
End for
```

# WEB SEND TEXT

WEB SEND TEXT ( htmlText {; type} )

| Parameter | Type | | Description |
|---|---|---|---|
| htmlText | Text | ⇒ | HTML text field or variable to be sent to the Web browser |
| type | Text | ⇒ | MIME type |

## Description

The **WEB SEND TEXT** command directly sends HTML formatted text data.

The *htmlText* parameter contains the data to be sent. Since 4D does not check the parameter content, make sure that the HTML encoding is correct.

Any references to 4D variables and *4DSCRIPT* type tags in the text are always parsed.

By default, if you omit the *type* parameter, 4D assumes that the data sent is of the "text/html" type. The command is then exactly the same as sending a BLOB of the "text/html" type using the **WEB SEND BLOB** command.
You can also use the *type* parameter to specify the MIME type of the text to be sent. For more information about the MIME types supported, refer to the description of the **WEB SEND BLOB** command.

## Example

The following method:

```
TEXT TO BLOB("<html><head></head><body>"+String(Current time)+"</body></html>";$blob;UTF8 Text without length)
WEB SEND BLOB($blob;"text/html")
```

... can be replaced by the single line:

```
WEB SEND TEXT("<html><head></head><body>"+String(Current time)+"</body></html>")
```

# WEB SET HOME PAGE

WEB SET HOME PAGE ( homePage )

| Parameter | Type | | Description |
|---|---|---|---|
| homePage | String | ⇒ | Page name or HTML access path to the page or "" to not send the custom home page |

## Description

The **WEB SET HOME PAGE** command allows you to modify the custom home page for the current Web process.

The defined page is linked to the Web process, you can therefore define the different home pages depending, for example, on the user that is connected. This page can either be static or semi-dynamic.

You pass the name of the HTML home page or the page's HTML access path to the *homePage* parameter.

**Note:** If the page specified in the *homePage* parameter does not exist when the Web process accesses it for the first time, the Web server creates it and assigns it the contents of the default home page (see **Defining a Default Home Page**).

To stop sending *homePage* as home page for the current Web process, execute **WEB SET HOME PAGE** with an empty string ("") passed in *homePage*.

**Note:** The default home page of the Web server is specified in the Database Settings dialog box.

# WEB SET HTTP HEADER

WEB SET HTTP HEADER ( header|fieldArray {; valueArray} )

| Parameter | Type | | Description |
|---|---|---|---|
| header\|fieldArray | Text, Text array | ⇒ | Field or variable containing the request HTTP header or HTTP header fields |
| valueArray | Text array | ⇒ | HTTP header field content |

## Description

The **WEB SET HTTP HEADER** command allows you to set the fields in the HTTP header of the reply sent to the Web browser by 4D. It only has an effect in a Web process.
This command allows you to manage “cookies”.

Two syntaxes are available for this command:

- First syntax: **WEB SET HTTP HEADER** (header)
  You pass the HTTP header fields to the *fields* parameter, of the Text type (variable or field), that you want to set. This syntax allows writing header types such as "*HTTP/1.0 200 OK"+Char(13)+"Set-Cookie: C=HELLO*". Header fields must be separated by the CR or CR+LF (Carriage return + Line feed) sequence, under Windows and Mac OS, 4D formats the reply.

Here is an example of a custom “cookie”:

```
C_TEXT($vTcookie)
$vTcookie:="Set-Cookie: USER="+String(Abs(Random))+"; PATH=/"
WEB SET HTTP HEADER($vTcookie)
```

**Note:** The command will not accept a literal text type constant as the *header* parameter; it must be a 4D variable or field.

For more information about the syntax, please refer to the R.F.Cs (Request For Comments) that can be found at the following Internet address: http://www.w3c.org.

- Second syntax: **WEB SET HTTP HEADER** (fieldArray; valueArray)
  The HTTP header is defined through two text arrays, *fieldArray* and *valueArray*. The header will be written as follows:

```
fieldArray{1}:="X-VERSION"
fieldArray{2}:="X-STATUS"
fieldArray{3}:="Set-Cookie"
fieldArray{4}:="Server"

valueArray{1}:="HTTP/1.0"*
valueArray{2}:="200 OK"*
valueArray{3}:="C=HELLO"
valueArray{4}:="North_Carolina"
```

* The first two items are the first line of the reply. When they are entered, they must be the first and second items of the arrays. However, it is possible to omit them and to write only the following (4D will handle the header format):

```
fieldArray{1}:="Set-Cookie"
valueArray{1}:="C=HELLO"
```

If you do not specify a state, it will automatically be HTTP/1.0 200 OK. By default, the **Server** field is "4D/<version>". The **Date** and **Content-Length** fields are also set by default by 4D.

# WEB SET OPTION

WEB SET OPTION ( selector ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| selector | Longint | ⇒ | Option code |
| value | Longint, Text | ⇒ | Option value |

## Description

The **WEB SET OPTION** command modifies the current value of various options concerning the functioning of the 4D Web server.

In the *selector* parameter, pass one of the constants from the **Web Server** theme and pass the new value of the option in *value*:

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Character set that the 4D Web Server (with 4D in local mode and 4D Server) should use to communicate with browsers connecting to the database. The default value actually depends on the language of the operating system. This parameter is set in the Database settings.<br>**Possible values**: The possible values depend on the operating mode of the database relating to the character set.<br>• *Unicode Mode*: When the application is operating in Unicode mode, the values to pass for this parameter are character set identifiers (*MIBEnum* longint or *Name* string, identifiers defined by IANA, see the following address: http://www.iana.org/assignments/character-sets). Here is the list of identifiers corresponding to the character sets supported by the 4D Web server:<br>4=ISO-8859-1<br>12=ISO-8859-9<br>13=ISO-8859-10<br>17=Shift-JIS<br>2024=Windows-31J<br>2026=Big5<br>38=euc-kr<br>106=UTF-8<br>2250=Windows-1250<br>2251=Windows-1251<br>2253=Windows-1253<br>2255=Windows-1255<br>2256=Windows-1256<br>• *ASCII compatibility mode*:<br>Western European<br>1: Japanese<br>2: Chinese<br>3: Korean<br>4: User-defined<br>5: Reserved<br>6: Central European<br>7: Cyrillic<br>8: Arabic<br>9: Greek<br>10: Hebrew<br>11: Turkish<br>12: Baltic |
| Web debug log | Longint | 84 | **Scope:** Local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted (a new log file is used in this case)<br>**Description:** Allows you to get or set the status of the HTTP request log file of the 4D Web server. When enabled, this file, named "**HTTPDebugLog_*nn*.txt**", is stored in the "Logs" folder of the application (*nn* is the file number). It is useful for debugging issues related to the Web server. It records each request and each response in raw mode. Whole requests, including headers, are logged; optionally, body parts can be logged as well.<br>**Values**: One of the constants prefixed with "wdl" (refer to the descriptions of these constants in this theme).<br>**Default value**: 0 (not enabled) |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web HTTP compression level | Longint | 50 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Compression level for all compressed HTTP exchanges for the 4D HTTP server (client requests or server replies, Web and Web Service). This selector lets you optimize exchanges by either privileging speed of execution (less compression) or the amount of compression (less speed). The choice of a value depends on the size and type of data exchanged. Pass 1 to 9 in the *value* parameter where 1 is the fastest compression and 9 the highest. You can also pass -1 to get a compromise between speed and rate of compression. By default, the compression level is 1 (faster compression).<br>**Possible values**: 1 to 9 (1 = faster, 9 = more compressed) or -1 = best compromise. |
| Web HTTP compression threshold | Longint | 51 | **Scope**: Local HTTP server<br>**Kept between two sessions**: No<br>**Description**: In the framework of optimized HTTP exchanges, size threshold for requests below which exchanges should not be compressed. This setting is useful in order to avoid losing machine time by compressing small exchanges.<br>**Possible values**: Any Longint type value. Pass the size expressed in bytes in *vaue*. By default, the compression threshold is set to 1024 bytes |
| Web HTTP TRACE | Longint | 85 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Allows you to disable or enable the HTTP TRACE method in the 4D Web server. For security reasons, starting with 4D v15 R2, by default the 4D Web server rejects HTTP TRACE requests with an error 405 (see HTTP TRACE disabled). If necessary, you can enable the HTTP TRACE method for the session by passing this constant with value 1. When this option is enabled, the 4D Web server replies to HTTP TRACE requests with the request line, header, and body.<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 0 (disabled) |
| Web HTTPS port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: TCP port number used by the Web server of 4D in local mode and of 4D Server for secure connections via SSL (HTTPS protocol). The HTTPS port number is set on the “Web/Configuration” page of the Database settings dialog box.<br>By default, the value is 443 (standard value). You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>**Possible values**: 0 to 65535 |
| Web inactive process timeout | Longint | 78 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Modifies the life duration of the inactive processes associated with sessions. At the end of the timeout, the process is killed on the server, the **On Web Close Process database method** is called then the session context is destroyed.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |
| Web inactive session timeout | Longint | 72 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Modifies the life duration of inactive sessions (duration set in cookie). At the end of this period, the session cookie expires and is no longer sent by the HTTP client.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web IP address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: IP address on which the 4D Web server will receive HTTP requests with 4D in local mode and 4D Server. By default, no specific address is defined (*value* = 0). This parameter can be set in the Database settings. The *Web IP Address to listen* selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode).<br>You pass a hexadecimal IP address in the *value* parameter. In other words, to designate a IP address such as "a.b.c.d", you should write:<br>`C_LONGINT($addr)`<br>`$addr:=($a<<24)\|($b<<16)\|($c<<8)\|$d`<br>`WEB SET OPTION(Web IP address to listen;$addr)` |
| Web keep session | Longint | 70 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Enables or disables the session management mode (described in the **Web Sessions Management** section)<br>**Possible values**: 1 (enable mode) or 0 (disable mode)<br>**Default value**: 1 for databases created in v13, 0 for converted databases. Note that this mode also enables the mechanism for reusing temporary contexts in remote mode. For more information about this mechanism, refer to the description of this option in the **Web Server Settings** section. |
| Web log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Starts or stops the recording of Web requests received by the Web server of 4D in local mode or 4D Server. By default, the value is 0 (requests not recorded).<br>The log of Web requests is stored as a text file named "logweb.txt" that is automatically placed in the Logs folder of the database, next to the structure file. The format of this file is determined by the value that you pass. For more information about Web log file formats, please refer to the **Information about the Web Site** section.<br>This file can also be activated on the "Web/Log" page of the Database settings.<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br>**Warning**: Formats 3 and 4 are custom formats whose contents must be set beforehand in the Database settings. If you use one of these formats without any of its fields having been selected on this page, the log file will not be generated. |
| Web max concurrent processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Strictly upper limit of concurrent Web processes of any type supported by the 4D Web Server with 4D in local mode and 4D Server. When this number (minus one) is reached, 4D will not create any other processes and returns the HTTP status 503 - Service Unavailable to all new requests.<br>This parameter can prevent the 4D Web Server from saturation, which can occur when an exceedingly large number of concurrent requests are sent, or when too many context creations are requested. This parameter can also be set in the Database settings.<br>In theory, the maximum number of Web processes is the result of the following formula: Available memory/Web process stack size. Another solution is to view the information on Web processes displayed in the Runtime Explorer: the current number of Web processes and the maximum number reached since the Web server boot are indicated.<br>**Possible values**: Any value between 10 and 32 000. The default value is 100. |
| Web max sessions | Longint | 71 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Limits the number of simultaneous sessions. When you reach the limit set, the oldest session is closed (and **On Web Close Process database method** is called) if the Web server needs to create a new one.<br>**Possible values**: Longint. The number of simultaneous sessions cannot exceed the total number of Web processes (Web Max Concurrent Processes option, 100 by default)<br>**Default value**: 100 (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web maximum requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Maximum size (in bytes) of incoming HTTP requests (POST) that the Web server is authorized to process. By default, the value is 2 000 000, i.e. a little less than 2 MB. Passing the maximum value (2 147 483 648) means that, in practice, no limit is set. This limit is used to avoid Web server saturation due to incoming requests that are too large. When a request reaches this limit, the 4D Web server refuses it.<br>**Possible values**: 500 000 to 2 147 483 648. |
| Web port ID | Longint | 15 | **Scope**: 4D in local mode and 4D Server.<br>**Kept between two sessions:** No<br>**Description:** Sets or gets the number of the TCP port used by the 4D Web server with 4D in local mode and 4D Server. By default, the value is 80. The TCP port number is set on the "Web/Configuration" page of the Database Settings dialog box. You can use one of the constants in the **TCP Port Numbers** theme for the *value* parameter. This selector is useful within the framework of 4D Web servers that are compiled and merged using 4D Desktop (no access to the Design environment).<br>**Possible values:** For more information about the TCP port number, refer to the **Web Server Settings** section.<br>**Default value:** 80 |
| Web session cookie domain | Longint | 81 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "domain" field of the session cookie. This selector (as well as selector 82) is useful for controlling the scope of the session cookies: If you set, for example, the value "/*.4d.fr" for this selector, the client will only send a cookie when the request is addressed to the domain ".4d.fr", which excludes servers hosting external static data.<br>**Possible values:** Text |
| Web session cookie name | Longint | 73 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Sets the name of the cookie used for saving the session ID.<br>**Possible values:** Text<br>**Default value:** "4DSID" (pass an empty string to restore the default value) |
| Web session cookie path | Longint | 82 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "path" field of the session cookie. This selector (as well as selector 81) is useful for controlling the scope of the session cookies: If you set, for example, the value "/4DACTION" for this selector, the client will only send a cookie for dynamic requests beginning with 4DACTION, and not for pictures, static pages, etc.<br>**Possible values:** Text |
| Web session enable IP address validation | Longint | 83 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Enables or disables IP address validation for session cookies. For security reasons, by default the 4D Web server checks the IP address of each request containing a session cookie and rejects it if this address does not match the IP address used to create the cookie. In some specific applications, you may want to disable this validation and accept session cookies, even when their IP addresses do not match. For example when mobile devices switch between Wifi and 3G/4G networks, their IP address will change. In this case, you must pass 0 in this option to allow clients to be able to continue using their Web sessions even when the IP addresses change. Note that this setting lowers the security level of your application.<br>When it is modified, this setting is effective immediately (you do not need to restart the HTTP server).<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 1 (IP addresses are checked) |

When you use the Web debug log *selector*, you can pass one of the following constants in the *value* parameter:

| Constant | Type | Value | Comment |
|---|---|---|---|
| wdl disable | Longint | 0 | Web HTTP debug log is disabled |
| wdl enable with all body parts | Longint | 7 | Web HTTP debug log is enabled with body parts in response and request |
| wdl enable with request body | Longint | 5 | Web HTTP debug log is enabled with body part in request only |
| wdl enable with response body | Longint | 3 | Web HTTP debug log is enabled with body part in response only |
| wdl enable without body | Longint | 1 | Web HTTP debug log is enabled without body parts (body size is provided in this case) |

## Example

Enabling the HTTP debug log without body parts:

```
WEB SET OPTION(Web debug log;wdl enable without body)
```

A log entry looks like this:

```
# REQUEST
# SocketID: 1592
# PeerIP: 127.0.0.1
# PeerPort: 54912
# TimeStamp: 39089388
GET /4DWEBTEST HTTP/1.1
Connection: Close
Host: 127.0.0.1
User-Agent: 4D_HTTP_Client/0.0.0.0

# RESPONSE
# SocketID: 1592
# PeerIP: 127.0.0.1
# PeerPort: 54912
# TimeStamp: 39089389 (elapsed time: 1 ms)
HTTP/1.1 200 OK
Accept-Ranges: bytes
Connection: close
Content-Length: 3555
Content-Type: text/plain; charset=UTF-8
Date: Tue, 20 Jan 2015 10:51:29 GMT
Expires: Tue, 20 Jan 2015 10:51:29 GMT
Pragma: no-cache
Server: 4D/14.6.0

[Body Size: 3555]
```

# WEB SET ROOT FOLDER

WEB SET ROOT FOLDER ( rootFolder )

| Parameter | Type | | Description |
|---|---|---|---|
| rootFolder | String | ⇒ | Pathname of Web server root folder |

## Description

The **WEB SET ROOT FOLDER** command is used to modify the default root folder where 4D looks for the HTML files requested of the Web server.

This command does not take the default root folder that may have been set in the Database Settings into account. For more information about this folder, please refer to the **Connection Security** section.

The location of the root folder can be expression either in HTML syntax (URL type), or in system syntax (absolute path):

- HTML syntax: folder names are separated by a slash ("/"), regardless of the platform you use.
- System syntax: absolute pathname (“long name”) respecting the syntax of the current platform, for example:
  - (Mac OS) Disk:Applications:myserv:folder
  - (Windows) C:¥Applications¥myserv¥folder

**Notes:**

- The Web server will need to be restarted in order for the new root folder to be taken into account.
- You can find out the location of the current root folder at any time using the **Get 4D folder** command.

If you specify an invalid pathname, an OS File manager error is generated. You can intercept the error with an **ON ERR CALL** method. If you display an alert or a message from within the error method, it will appear on the browser side.

# WEB START SERVER

WEB START SERVER
Does not require any parameters

## Description

The **WEB START SERVER** command starts the Web server of the 4D application on which it has been executed (4D or 4D Server). The database is therefore published on your Intranet network or on the Internet.

If the Web Server is successfully started, **OK** is set to *1*, otherwise **OK** is set to *0* (zero). For example, if the TCP/IP network protocol is not properly configured, **OK** is set to *0*.

## System variables and sets

If the Web Server is successfully started, **OK** is set to 1; otherwise **OK** is set to 0.

# WEB STOP SERVER

WEB STOP SERVER
Does not require any parameters

## Description

The **WEB STOP SERVER** command stops the Web server of the 4D application on which it has been executed (4D ou 4D Server). If the Web server has been started, all Web connections are stopped, and all Web processes terminated.

If the Web server has not been started, the command does nothing.

# WEB Validate digest

WEB Validate digest ( userName ; password ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| userName | Text | ➡ | User name |
| password | Text | ➡ | User password |
| Function result | Boolean | ⮌ | True=Authentication OK, False=Authentication failed |

## Description

The **WEB Validate digest** command checks the validity of the identifying information (name and password) provided by a user connecting to the Web server. This command must be used in the **On Web Authentication Database Method** in the context of Web authentication in Digest mode (see the **Connection Security** section).

In the *userName* and *password* parameters, pass the identifying information of the user stored locally. The command uses this information to generate a value that it compares with the information sent by the Web browser.

If the values are the same, the command returns True. Otherwise, it returns False.

You can use this mechanism to manage and maintain your own secure access system to the Web server by programming. Note that Digest validation cannot be used jointly with 4D passwords.

**Note:** If the browser does not support Digest authentication, an error is returned (authentication error).

## Example

Example using **On Web Authentication Database Method** in Digest mode:

```
  ` On Web Authentication Database Method
C_TEXT($1;$2;$5;$6;$3;$4)
C_TEXT($user)
C_BOOLEAN($0)
$0:=False
$user:=$5
 `For security reasons, refuse names containing @
If(WithWildcard($user))
   $0:=False
 `The WithWildcard method is described in the "On Web Authentication Database Method" section
Else
   QUERY([WebUsers];[WebUsers]User=$user)
   If(OK=1)
      $0:=WEB Validate digest($user;[WebUsers]password)
   Else
      $0:=False `User does not exist
   End if
End if
```

# _o_SET CGI EXECUTABLE

_o_SET CGI EXECUTABLE ( url1 {; url2} )

| Parameter | Type | | Description |
|---|---|---|---|
| url1 | String | ➡ | Access URL |
| url2 | String | ➡ | Access URL |

## Command disabled

This command is disabled starting with 4D v13. If it is called, the error 33 ("Method  or function not implemented") is generated.

# _o_SET WEB DISPLAY LIMITS

_o_SET WEB DISPLAY LIMITS ( numberRecords {; numberPages {; picRef}} )

| Parameter | Type | | Description |
|---|---|---|---|
| numberRecords | Longint | ⇒ | *** Disabled *** |
| numberPages | Longint | ⇒ | *** Disabled *** |
| picRef | Longint | ⇒ | *** Disabled *** |

## Command disabled

This command is disabled starting with 4D v13. If it is called, the error 33 ("Method  or function not implemented") is generated.

# _o_SET WEB TIMEOUT

_o_SET WEB TIMEOUT ( timeout )

| Parameter | Type | | Description |
|---|---|---|---|
| timeout | Longint | ⇨ | *** Disabled *** |

## Command disabled

This command is disabled starting with 4D v13. If it is called, the error 33 ("Method  or function not implemented") is generated.

# _o_Web Context

_o_Web Context -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | ⮌ | Always returns False |

## Command disabled

This command is disabled starting with 4D v13. If it is called, the error 33 ("Method  or function not implemented") is generated.

# Web Services (Client)

- Web Services (Client) Commands
- WEB SERVICE AUTHENTICATE
- WEB SERVICE CALL
- WEB SERVICE Get info
- WEB SERVICE GET RESULT
- WEB SERVICE SET OPTION
- WEB SERVICE SET PARAMETER

# Web Services (Client) Commands

Starting with version 2003, 4D supports“Web Services”, meaning that the program enables you to publish (server part) and/or use (client part) Web Services directly from your database. A Web Service is a set of functions published on a network. These functions can be called and used by any application compatible with Web Services and connected to a network. Web Services can carry out all types of tasks, such as supervising the routing of packages at a transporter’s, e-commerce, monitoring market values, etc.

For more information about the concept and operation of Web Services, refer to the Design Reference manual.

Subscription to Web Services with 4D is easy to carry out using the Web Services Wizard. In most cases, this Wizard will be sufficient for you to be able to use Web Services. However, if you want to customize certain mechanisms, you must use the client SOAP commands of 4D.

This section describes the commands used for subscription to external Web Services (**client part**). For a description of the commands used for the publication of Web Services (server part), refer to the **Web Services (Server) Commands** theme.

**Note**: By convention, the terms “SOAP” and “Web Service” have been used to differentiate between command (and constant) names on the server and client side, respectively. These two concepts refer to the same technology.

# WEB SERVICE AUTHENTICATE

WEB SERVICE AUTHENTICATE ( name ; password {; authMethod} {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| name | String | ⇒ | User name |
| password | String | ⇒ | User password |
| authMethod | Longint | ⇒ | Authentication method 0 or omitted = not specified, 1 = BASIC, 2 = DIGEST |
| * | Operator | ⇒ | If passed: authentication by proxy |

## Description

The **WEB SERVICE AUTHENTICATE** command enables the use of Web Services requiring authentication of the client application (simple authentication). The BASIC and DIGEST methods are supported, as well as the presence of a proxy.

**Note:** For more information about the BASIC and DIGEST authentication methods, refer to the **Connection Security** section.

In the *name* and *password* parameters, pass the required identification information (user name and password). This information will be encoded and added to the HTTP request sent to the Web Service using the **WEB SERVICE CALL** command. It is thus necessary to call the **WEB SERVICE AUTHENTICATE** command before calling the **WEB SERVICE CALL** command.

The optional *authMethod* parameter indicate the authentication method to be used for the next call to the **WEB SERVICE CALL** command. You can pass one of the following values:

- 2 = use the DIGEST authentication method
- 1 = use the BASIC authentication method
- 0 (or parameter omitted) = use the appropriate method. In this case, 4D sends an additional request in order to negotiate the authentication method.

If you pass the * parameter, you indicate that the authentication information is to be sent to an HTTP proxy. This configuration must be implemented when there is a proxy that requires authentication between the Web Service client and the Web Service itself. If the Web Service is itself authenticated, a double authentication is required (see the example).

By default, the authentication information is reset to zero after each request. Therefore, you must use the **WEB SERVICE AUTHENTICATE** command before each **WEB SERVICE CALL** command. It is nevertheless possible to keep this information temporarily using an option of the **WEB SERVICE SET OPTION** command. In this case, it is not necessary to execute the **WEB SERVICE AUTHENTICATE** command before each **WEB SERVICE CALL** command.

If authentication fails, the SOAP server returns an error that you can identify using the **WEB SERVICE Get info** command.

## Example

Authentication with a Web Service located behind a proxy:

```
 // Authentication to Web Service in DIGEST mode
WEB SERVICE AUTHENTICATE("SoapUser";"123";2)
 // Authentication to proxy in default mode
WEB SERVICE AUTHENTICATE("ProxyUser";"456";*)
WEB SERVICE CALL(...)
```

# WEB SERVICE CALL

WEB SERVICE CALL ( accessURL ; soapAction ; methodName ; nameSpace {; complexType {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| accessURL | String | ⇒ | Access URL to Web Service |
| soapAction | String | ⇒ | Contents of SOAPAction field |
| methodName | String | ⇒ | Name of the method |
| nameSpace | String | ⇒ | Namespace |
| complexType | Longint | ⇒ | Configuration of complex types (simple types if omitted) |
| * | Operator | ⇒ | Do not close connection |

## Description

The **WEB SERVICE CALL** command calls a Web Service by sending an HTTP request. This request contains the SOAP message created previously using the **WEB SERVICE SET PARAMETER** command.

Any subsequent call to the **WEB SERVICE SET PARAMETER** command will cause the creation of a new request. The execution of the **WEB SERVICE CALL** command also erases any result from a previously-called Web Service and replaces it with the new result(s).

In *accessURL*, pass the complete URL allowing access to the Web Service (do not confuse this URL with that of the WSDL file, which describes the Web Service).

- **Access in secure mode (SSL)**: If you want to use a Web Service in secure mode using SSL, pass https:// in front of the URL instead of http://. This configuration automatically enables connection in secure mode.
  Note that this command can use a server certificate (see the **HTTP SET CERTIFICATES FOLDER** command). If this certificate is not valid (expired or revoked), the OK system variable is set to 0 and error 901 "Invalid server certificate" is returned. You can intercept this error using an error-handling method installed by the **ON ERR CALL** command.

In *soapAction*, pass the contents of the SOAPAction field of the request. This field generally contains the value “ServiceName#MethodName”.

In *methodName*, pass the name of the remote method (belonging to the Web Service) that you want to execute.

In *namespace*, pass the XML namespace used for the SOAP request. For more information about XML namespaces, refer to the Design Mode manual of 4D.

The optional *complexType* parameter specifies the configuration of the Web Service parameters sent or received (defined using the **WEB SERVICE SET PARAMETER** and **WEB SERVICE GET RESULT** commands).

The value of the *complexType* parameter depends on the publication mode of the Web Service (DOC or RPC, see the Design Reference manual of 4D) and on its own parameters.
In *complexType*, you must pass one of the following constants, located in the theme **Web Services (Client)**:

| Constant | Type | Value |
|---|---|---|
| Web Service dynamic | Longint | 0 |
| Web Service manual | Longint | 3 |
| Web Service manual in | Longint | 1 |
| Web Service manual out | Longint | 2 |

Each constant corresponds to a Web Services “configuration”. A configuration represents the combination of a publication mode (RPC/DOC) and the types of parameters (input/output, simple or complex) implemented.

**Note:** Remember that the “input” or “output” characteristic of parameters is evaluated from the point of view of the proxy method/Web Service:

- an “input” parameter is a value passed to the proxy method and thus to the Web Service,
- an “output” parameter is returned by the Web Service and thus by the proxy method (generally via $0).

The following table shows all the possible configurations as well as the corresponding constants:

| | Input parameters | |
|---|---|---|
| **Output parameters** | **Simple** | **Complex** |
| **Simple** | Web Service dynamic (RPC mode) | Web Service manual in (RPC mode) |
| **Complex** | Web Service manual out (RPC mode) | Web Service manual (RPC or DOC mode) |

The five configurations described below can therefore be implemented. In all cases, 4D will handle the formatting of the SOAP request to be sent to the Web Service as well as its envelope. It is up to you to format the contents of this request according to the configuration used.

**Note:** Despite the fact that they are complex XML types, data arrays are handled by 4D as simple types.

### RPC mode, simple input and output

This configuration is the easiest to use. In this case, the *complexType* contains the Web Service dynamic constant or is omitted.

The parameters sent and responses received can be handled directly, without prior processing.

Refer to the example of the command **WEB SERVICE GET RESULT**.

### RPC mode, complex input and simple output

In this case, the *complexType* parameter contains the Web Service manual in constant. With this configuration, you must "manually" pass each XML source element in the form of a BLOB to the Web Service, using the **WEB SERVICE SET PARAMETER** command.

It is up to you to format the initial BLOB as a valid XML element. As its first element, this BLOB must contain the first apparent "child" element of the <Body> element of the final request.

**Example**

```
C_BLOB($1)
C_BOOLEAN($0)

WEB SERVICE SET PARAMETER("MyXMLBlob";$1)
WEB SERVICE CALL("http://my.domain.com/my_service";"MySoapAction";"TheMethod";"http://my.namespace.com/";Web Service manual in)
WEB SERVICE GET RESULT($0;"MyOutputVar";*)
```

### RPC mode, simple input and complex output

In this case, the *complexType* parameter contains the Web Service manual out constant. Each output parameter will be returned by the Web Service in the form of an XML element stored in a BLOB. You retrieve this parameter using the **WEB SERVICE GET RESULT** command. You can then parse the contents of the BLOB received using the XML commands of 4D.

**Example**

```
C_BLOB($0)
C_BOOLEAN($1)

WEB SERVICE SET PARAMETER("MyInputVar";$1)
WEB SERVICE CALL("http://my.domain.com/my_service";"MySoapAction";"TheMethod";"http://my.namespace.com/";Web Service manual out)
WEB SERVICE GET RESULT($0;"MyXMLOutput";*)
```

### RPC mode, complex input and output

In this case, the *complexType* parameter contains the Web Service manual constant. Each input and output parameter must be stored in the form of XML elements in BLOBs, as described in the two previous configurations.

**Example**

```
C_BLOB($0)
C_BLOB($1)
```

```
WEB SERVICE SET PARAMETER("MyXMLInputBlob";$1)
WEB SERVICE CALL("http://my.domain.com/my_service";"MySoapAction";"TheMethod";"http://my.namespace.com/";Web Service manual)
WEB SERVICE GET RESULT($0;"MyXMLOutput";*)
```

### DOC mode

A proxy calling method for a DOC Web Service is similar to a proxy calling method for an RPC Web Service using complex type input and output parameters.

The only difference between these two configurations lies at the level of the XML content of BLOB parameters sent and received. From 4D's point of view, the building and sending of the SOAP request are identical.

#### Example

```
C_BLOB($0)
C_BLOB($1)

WEB SERVICE SET PARAMETER("MyXMLInput";$1)
WEB SERVICE CALL("http://my.domain.com/my_service";"MySoapAction";"TheMethod";"http://my.namespace.com/";Web Service manual)
WEB SERVICE GET RESULT($0;"MyXMLOutput";*)
```

**Note:** In the case of DOC Web Services, the value of the strings ("MyXMLInput" and "MyXMLOutput" above) passed as parameters is of no importance; it is even possible to pass empty strings "". In fact, these values are not used in the SOAP request containing the XML document. It is, nevertheless, mandatory to pass these parameters.

To use a Web Service published in DOC mode (or in RPC mode with complex types), it is advisable to proceed as follows:

- Generate the proxy method using the Client Web Services Wizard.
  The proxy method will be called in the following manner: *$XMLresultBlob:=$DOCproxy_Method($XMLparamBlob)*
- Familiarize yourself with the contents of SOAP requests to be sent to the Web Service using an on-line test (for instance, *http://soapclient.com/soaptest.html*). This type of tool is used to generate HTML test forms based on the WSDL of the Web Service.
- Copy the XML contents generated from the first child element of *<body>*.
- Write the method enabling you to place the real parameter values into the XML code; this code must then be placed in the *$XMLparamBlob* BLOB.
- To parse the response, you can also use an on-line test, or make use of the WSDL that specifies the returned elements.

The * parameter can be used to optimize calls. When it is passed, the command does not close the connection used by the process at the end of its execution. In this case, the next call to **WEB SERVICE CALL** will reuse this same connection if the * parameter is passed, and so on. To close the connection, simply execute the command without the * parameter. This mechanism can be used to noticeably accelerate the processing of successive calls of several different Web Services on the same server, in particular in a WAN configuration (via the Internet, for example). Note that this mechanism depends on the "keep-alive" setting of the Web server. This setting generally defines a maximum number of requests via the same connection, and can even deny requests. If the **WEB SERVICE CALL** requests following each other in the same connection reach this maximum number, or if keep-alive connections are not allowed, 4D will create a new connection for each request.

## System variables and sets

If the request has been correctly routed and the Web Service has accepted it, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is returned.

# WEB SERVICE Get info

WEB SERVICE Get info ( infoType ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| infoType | Longint | ⇒ | Information to be retrieved |
| Function result | String | ⇐ | Information about the last SOAP error |

## Description

The **WEB SERVICE Get info** command returns information about any error generated during the execution of the last SOAP request sent to a remote Web Service. This command should generally be called within an error-handling method installed by the **ON ERR CALL** command.

The *infoType* parameter allows you to indicate the type of information that you want to obtain. You must pass one of the constants listed below, located in the **Web Services (Client)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web Service detailed message | Longint | 1 | Detailed message describing the error. The type of message differs according to the main error type.<br>- If the main error = 9910 (Soap fault): the cause of the SOAP fault is returned (e.g.: “the remote method does not exist”).<br>- If the main error = 9911 (Parser fault): the location of the error in the XML document is returned.<br>- If the main error = 9912 (HTTP fault):<br>- if the HTTP error is located in the interval [300-400] (problems linked to the location of the requested document), the new location of the requested URL is returned.<br>- for any other HTTP error code, the <body> is returned.<br>- If the main error = 9913 (Network fault): the cause of the network fault is returned (e.g.: “ServerAddress: DNS lookup failure”)<br>- If the main error = 9914 (Internal fault): the cause of the internal fault is returned |
| Web Service error code | Longint | 0 | Main error code (defined by 4D). This code is also returned in the Error system variable.<br>List of codes that may be returned:<br>9910: Soap fault (see also Web Service Fault Actor)<br>9911: Parser fault<br>9912: HTTP fault (see also Web Service HTTP Error code)<br>9913: Network fault<br>9914: Internal fault. |
| Web Service fault actor | Longint | 3 | Cause of the error (returned by the SOAP protocol — to be used in the case of main error 9910).<br>- Version Mismatch<br>- Must Understand (the server was unable to interpret a parameter defined as mandatory)<br>- Sender Fault<br>- Receiver Fault<br>- Encoding Unknown |
| Web Service HTTP error code | Longint | 2 | HTTP error code (to be used in case of main error 9912). |

An empty string is returned when no information is available, more particularly when the last SOAP request did not generate any errors.

# WEB SERVICE GET RESULT

WEB SERVICE GET RESULT ( returnValue {; returnName {; *}} )

| Parameter | Type | | Description |
|---|---|---|---|
| returnValue | Variable | ⇐ | Value returned by the Web Service |
| returnName | String | ⇒ | Name of the parameter to be retrieved |
| * | | ⇒ | Free up memory |

## Description

The **WEB SERVICE GET RESULT** command retrieves a value sent back by the Web Service as a result of the processing performed.

**Note:** This command must be used only after the **WEB SERVICE CALL** command.

The *returnValue* parameter receives the value sent back by the Web Service. Pass a 4D variable in this parameter. This variable is generally $0, corresponding to the value returned by the proxy method. It is, however, possible to use intermediary variables (you must use process variables only).

**Note:** Each 4D variable or array used must be previously declared using the commands of the "**Compiler** and **Arrays**" themes.

The optional *returnName* parameter specifies the name of the parameter to be retrieved. However, since most Web Services only return a single value, this parameter is generally not necessary.

The optional * parameter signals the program to free up the memory devoted to the processing of the request. You must pass this parameter after retrieving the last value sent by the Web Service.

## Example

Imagine that a Web Service returns the current time in any city in the world. The parameters received by the Web Service are the name of the city and the country code. In return, the Web Service sends the corresponding time. The proxy calling method could be in the following form:

```
C_TEXT($1)
C_TEXT($2)
C_TIME($0)

WEB SERVICE SET PARAMETER("city";$1)
WEB SERVICE SET PARAMETER("country_code";$2)

WEB SERVICE CALL("http://www.citiesoftheworld.com/WS";"WSTime#City_time";"City_time";
"http://www.citiesoftheworld.com/namespace/default")

If(OK=1)
   WEB SERVICE GET RESULT($0;"return";*)
End if
```

# WEB SERVICE SET OPTION

WEB SERVICE SET OPTION ( option ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| option | Longint | ⇨ | Code of the option to set |
| value | Longint, Text | ⇨ | Value of the option |

## Preliminary note

This command is designed for advanced Web Services users. Its use is optional.

## Description

The **WEB SERVICE SET OPTION** command sets different options to be used during the next SOAP request triggered using the **WEB SERVICE CALL** command.
You can call this command as many times as there are options to be set.

In the *option* parameter, pass the number of the option to set and in the *value* parameter, pass the new value of the option. For these parameters, you can use one of the following predefined constants of the **Web Services (Client)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web Service display auth dialog | Longint | 4 | *value* = 0 (do not display dialog box) or 1 (display dialog box)<br>This option manages the display of the authentication dialog box during execution of the **WEB SERVICE CALL** command. By default, this command never displays the dialog box; normally, you have to use the **WEB SERVICE AUTHENTICATE** command to do so. However, if you want the authentication dialog box to appear in order for the user to enter their identifiers, you will need to use this option: pass 1 in *value* to display the dialog box and 0 otherwise. The dialog box only appears if the Web service requires authentication |
| Web Service HTTP compression | Longint | 6 | *value* = Web Service Compression<br>This option is used to enable an internal compression mechanism for SOAP requests in order to accelerate inter-4D application exchanges. When you execute the statement **WEB SERVICE SET OPTION**(Web Service HTTP Compression; Web Service Compression) on the 4D client of the Web Service, the data of the next SOAP request sent by the client will be compressed using a standard HTTP mechanism ("gzip" or "deflate", depending on the request contents) before being sent to the 4D SOAP server. The server will decompress and parse the request, then will reply automatically using the same mechanism. Only the request that follows the call to the **WEB SERVICE SET OPTION** command is affected. You must therefore call this command each time you want to use compression. By default, 4D does not compress Web Service HTTP requests.<br>**Note:** This mechanism cannot be used for requests sent to a 4D SOAP server whose version is earlier than 11.3. So that you can further optimize this functioning, additional options configure the threshold and compression rate of the requests. These options can be accessed via the **SET DATABASE PARAMETER** command |
| Web Service HTTP timeout | Longint | 1 | *value* = timeout of the client portion expressed in seconds.<br>The timeout of the client portion is the wait period of the Web Service client in case the server does not respond. After this period, the client closes the session and the request is lost.<br>This timeout is 180 seconds by default. It can be modified for specific reasons (network status, Web Service specifics, etc.). |
| Web Service reset auth settings | Longint | 5 | *value* = 0 (do not erase information) or 1 (erase information)<br>This option lets you indicate to 4D whether to memorize the authentication information of the user (user name, password, method, etc.), in order to reuse it subsequently. By default, this information is erased after each execution of the **WEB SERVICE CALL** command. Pass 0 in value to store the information and 1 to erase it. Note that when you pass 0, the information is kept during the session but is not stored. |
| Web Service SOAP header | Longint | 2 | *value* = XML root element reference to insert as a header in the SOAP request.<br>This option allows you to insert a header in a SOAP request generated using the **WEB SERVICE CALL** command. SOAP requests do not contain a specific header by default. However, certain Web Services require a header, for example when managing identification parameters |
| Web Service SOAP version | Longint | 3 | *value* = Web Service SOAP 1 1 or Web Service SOAP 1 2<br>This option lets you specify the SOAP protocol version used in the request. Pass the Web Service SOAP 1 1 constant in value to indicate version 1.1 and Web Service SOAP 1 2 to indicate version 1.2. |

The order in which the options are called is not important. If the same *option* is set several times, only the value of the last call is taken into account.

## Example 1

Inserting a customized header in the SOAP request:

```
  ` Creating an XML reference
C_TEXT(vRootRef;vElemRef)
vRootRef:=DOM Create XML Ref("RootElement")
vxPath:="/RootElement/Elem1/Elem2/Elem3"
vElemRef:=DOM Create XML element(vRootRef;vxPath)
  `Modifying SOAP header with reference
WEB SERVICE SET OPTION(Web Service SOAP header;vElemRef)
```

## Example 2

Using version 1.2 of the SOAP protocol:

```
WEB SERVICE SET OPTION(Web Service SOAP version;Web Service SOAP_1_2)
```

# WEB SERVICE SET PARAMETER

WEB SERVICE SET PARAMETER ( name ; value {; soapType} )

| Parameter | Type | | Description |
|---|---|---|---|
| name | String | ➡ | Name of parameter to include in SOAP request |
| value | Variable | ➡ | 4D variable containing the value of the parameter |
| soapType | String | ➡ | SOAP type of the parameter |

## Description

The **WEB SERVICE SET PARAMETER** command enables the definition of a parameter used for a client SOAP request. Call this command for each parameter in the request (the number of times the command is called depends on the number of parameters).

In *name*, pass the name of the parameter as it must appear in the SOAP request.

In *value*, pass the 4D variable containing the value of the parameter. In the case of proxy methods, this variable is generally *$1*, *$2*, *$3*, etc., corresponding to a 4D parameter passed to the proxy method when it was called. It is, however, possible to use intermediary variables.

**Note:** Each 4D variable or array used must first be declared using the commands of the theme **Compiler** or **Arrays**.

By default, 4D automatically determines the most appropriate SOAP type for the *name* parameter according to the content of *value*. The indication of the type is included in the request.

However, you may want to “force” the definition of the SOAP type of a parameter. In this case, you can pass the optional *soapType* parameter using one of the following character strings (primary data types):

| soapType | Description |
|---|---|
| string | String |
| int | Longint |
| boolean | Boolean |
| float | 32-bit real |
| decimal | Real with decimal |
| double | 64-bit real |
| duration | Duration in years, months, days, hours, minutes, seconds, for example P1Y2M3DT10H30M |
| datetime | Date and time in ISO8601 format, for example 2003-05-31T13:20:00 |
| time | Time, for example 13:20:00 |
| date | Date, for example 2003-05-31 |
| gyearmonth | Year and month (Gregorian calender), for example 2003-05 |
| gyear | Year (Gregorian calender), for example 2003 |
| gmonthday | Month and day (Gregorian calender), for example --05-31 |
| gday | Day (Gregorian calender), for example ---31 |
| gmonth | Month (Gregorian calender), for example --10-- |
| hexbinary | Value expressed in hexadecimal |
| base64binary | BLOB |
| anyuri | Uniform Resource Identifier (URI), for example http://www.company.com/page |
| qname | Qualified XML name (namespace and local part) |
| notation | Notation attribute |

**Note:** For more information about XML data types, refer to the URL *http://www.w3.org/TR/xmlschema-2/*

## Example

This example defines two parameters:

```
C_TEXT($1)
C_TEXT($2)
WEB SERVICE SET PARAMETER("city";$1)
WEB SERVICE SET PARAMETER("country";$2)
```

# Web Services (Server)

- Web Services (Server) Commands
- SOAP DECLARATION
- SOAP Get info
- SOAP Request
- SOAP SEND FAULT

## Web Services (Server) Commands

---

Publication of Web Services with 4D is carried out easily using options in the method properties. In most cases, this operation will be sufficient to enable you to publish Web Services. However, if you want to customize certain mechanisms, use data arrays, etc., you must use the server SOAP commands of 4D.

This section describes the commands used for the publication of Web Services in 4D (**server part**). For more general information about Web Services or for a description of the commands used for subscription to Web Services (client part), refer to the **Web Services (Client) Commands** section.

**Note**: By convention, the terms “SOAP” and “Web Service” have been used to differentiate between command (and constant) names on the server and client side, respectively. These two concepts refer to the same technology.

# SOAP DECLARATION

SOAP DECLARATION ( variable ; type ; input_output {; alias} )

| Parameter | Type | | Description |
|---|---|---|---|
| variable | Variable | ⇒ | Variable referring to an incoming or outgoing SOAP argument |
| type | Longint | ⇒ | 4D type to which the argument points |
| input_output | Longint | ⇒ | 1 = SOAP Input, 2 = SOAP Output |
| alias | String | ⇒ | Name published for this argument during SOAP exchanges |

## Description

The **SOAP DECLARATION** command explicitly declares the type of parameters used in a 4D method published as a Web Service.

When a method is published as a Web Service, the standard parameters *$0*, *$1*... *$n* describe the parameters of the Web Service to the outside world (more particularly in the WSDL file). The SOAP protocol requires that parameters be explicitly named; 4D uses the names “FourD_arg0, FourD_arg1 ... FourD_argn” by default.

This default operation can nevertheless prove to be problematic for the following reasons:

- It is not possible to declare *$0* or *$1*, *$2*, etc. as an array. Therefore, it is necessary to use pointers; however, in this case, the type of values must be known for the generation of the WSDL file.
- It can be useful or necessary to customize the parameter names (incoming and outgoing).
- You may want to use parameters such as XML structures and DOM references.
- It may also be necessary to retur values with a size greater than 32 KB (limit for Text arguments in databases that are in non-Unicode mode).
- Finally, this operation makes it impossible to return more than one value per RPC call (in *$0*).

The **SOAP DECLARATION** command lets you be free from these limits. You can execute this command for each incoming and outgoing parameter to assign it a name and a type.

**Note:** Even when the this command is used, it is still necessary to declare 4D variables and arrays in the Compiler_Web method using commands of the “**Compiler**” theme.

In *variable*, pass the 4D variable to be referred to when calling the Web Service.

**Warning:** You can only refer to process variables or 4D method arguments (*$0* to *$n*). Local and interprocess variables cannot be used.

By default, because only Text type arguments can be used, the SOAP server responses are limited to 32 KB in databases that are in non-Unicode mode. However, it is possible to return SOAP arguments with a size greater than 32 KB, using BLOBs. To exceed this limit, you simply need to declare the arguments as BLOBs before calling the **SOAP DECLARATION** command (see example 4).

**Note:** On the client side, if you subscribe to this type of Web Service with 4D, the Web Services Wizard will of course generate a Text type variable. To be able to use it, you just need to re-type this return variable as a BLOB in the proxy method.

In *type*, pass the corresponding 4D type. Most types of 4D variables and arrays can be used. You can use the following predefined constants, located in the “**Field and Variable Types**” theme, as well as, for XML types, two constants of the **Web Services (Server)** theme:

| Constant | Type | Value |
|---|---|---|
| Boolean array | Longint | 22 |
| Date array | Longint | 17 |
| Integer array | Longint | 15 |
| Is BLOB | Longint | 30 |
| Is Boolean | Longint | 6 |
| Is date | Longint | 4 |
| Is integer | Longint | 8 |
| Is longint | Longint | 9 |
| Is real | Longint | 1 |
| Is string var | Longint | 24 |
| Is text | Longint | 2 |
| Is time | Longint | 11 |
| LongInt array | Longint | 16 |
| Real array | Longint | 14 |
| String array | Longint | 21 |
| Text array | Longint | 18 |

| Constant | Type | Value |
|---|---|---|
| Is DOM reference | Longint | 37 |
| Is XML | Longint | 36 |

In *input_output*, pass a value indicating whether the processed parameter is “incoming” (i.e. corresponding to a value received by the method) or “outgoing” (i.e. corresponding to a value returned by the method). You can use the following predefined constants, located in the **Web Services (Server)** theme:

| Constant | Type | Value |
|---|---|---|
| SOAP input | Longint | 1 |
| SOAP output | Longint | 2 |

### Use of XML types

You can declare variables of the "XML structure" and "DOM reference" type, both incoming and outgoing, via the Is XML and Is DOM reference constants. When parameters of this type are specified, no processing or encoding is applied to them and the data are transmitted "as is" (see example 5).

- Outgoing parameters:
  - Is XML indicates that the parameter contains an XML structure,
  - Is DOM reference indicates that the parameter contains the DOM reference of an XML structure. In this case, inserting the XML structure into the SOAP message is equivalent to executing the **DOM EXPORT TO VAR** command.

**Note:** In the case of DOM references used as outgoing parameters, it is recommended to use global references, created, for example, on startup and closed when the application is closed. In fact, a DOM reference created within the Web Service itself cannot be closed with **DOM CLOSE XML**, otherwise the Web Service no longer returns anything. Multiple calls to the Web Service therefore involve creating multiple unclosed DOM references, which can lead to memory saturation

- Incoming parameters:
  - Is XML indicates that the parameter must receive an XML argument sent by the SOAP client.
  - Is DOM reference indicates that the parameter must receive the DOM reference of an XML structure corresponding to the XML argument sent by the SOAP client.

- Modification of the WSDL: These XML structures will be declared by 4D as the "anyType" type (undetermined) in the WSDL. If you want to type an XML structure precisely, you must save the WSDL file and manually add the desired data schema in the <types> section of the WSDL

### COMPILER_WEB method

Incoming SOAP arguments referred to using 4D variables (and not 4D method arguments) must first be declared in the COMPILER_WEB project method. In fact, the use of process variables in Web Services methods requires that they be declared before the method is called. The COMPILER_WEB project method is called, if it exists, for each SOAP request accepted. By default, the COMPILER_WEB method does not exist. You must specifically create it.

Note that the COMPILER_WEB method is also called by the 4D Web server when receiving “conventional” Web requests of the POST type (see **URLs and Form Actions** section).

In *alias*, pass the name of the argument as it must appear in the WSDL and in the SOAP exchanges.

**Warning:** This name must be unique in the RPC call (both input and output parameters taken together), otherwise, only the last declaration will be taken into account by 4D.

**Note:** The argument names must not begin with a number nor contain spaces. Moreover, to avoid any risks of incompatibility, it is recommended to not use extended characters (such as accented characters).
If the *alias* parameter is omitted, 4D will use, by default, the name of the variable or *FourD_argN* for the 4D method arguments (*$0* to *$n*).

**Note:** The **SOAP DECLARATION** command must be included in the method published as a Web Service. It is not possible to call it from another method.

## Example 1

This example specifies a parameter name:

```
 ` In the COMPILER_WEB method
C_LONGINT($1)

 ` In the Web Service method
 ` During generation of the WSDL file and SOAP calls, the word
 ` zipcode will be used instead of fourD_arg1
SOAP DECLARATION($1;Is longint;SOAP input;"zipcode")
```

## Example 2

This example retrieves an array of zip codes in the form of longints:

```
 `In the COMPILER_WEB method
ARRAY LONGINT(codes;0)

 `In the Web service method
SOAP DECLARATION(codes;LongInt array;SOAP input;"in_codes")
```

## Example 3

This example refers to two return values without specifying an argument name:

```
SOAP DECLARATION(ret1;Is longint;SOAP output)
SOAP DECLARATION(ret2;Is longint;SOAP output)
```

## Example 4

This example allows the 4D SOAP server to return an argument with a size greater than 32 KB in databases in non-Unicode mode:

```
C_BLOB($0)
SOAP DECLARATION($0;Is text;SOAP output)
```

Note the type Is text (and not Is BLOB). This allows the argument to be correctly processed.

## Example 5

This example illustrates the results of different types of declarations:

```
ALL RECORDS([Contact])

 `Build an XML structure from the Contacts selection and store the XML in a BLOB
C_BLOB(ws_vx_xmlBlob)
```

```
getContactsXML(->ws_vx_xmlBlob)
 `Retrieve the XML structure in a text variable
C_TEXT(ws_vt_xml)
ws_vt_xml:=BLOB to text(ws_vx_xmlBlob;UTF8 text without length)
 `Retrieve a DOM reference to the XML structure
C_TEXT(ws_vt_xmlRef)
ws_vt_xmlRef:=DOM Parse XML variable(ws_vt_xml)

 `Test the various declarations
SOAP DECLARATION(ws_vx_xmlBlob;Is BLOB;SOAP output;"contactListsX")
 `The XML is converted into Base64 by 4D

SOAP DECLARATION(ws_vt_xml;Is text;SOAP output;"contactListsText")
 `The XML is converted into text by 4D (< > become entities)

SOAP DECLARATION(ws_vt_xml;Is XML;SOAP output;"xmlContacts")
 `The XML is passed as XML text

SOAP DECLARATION(ws_vx_xmlBlob;Is XML;SOAP output;"blobContacts")
 `The XML is passed as an XML BLOB

SOAP DECLARATION(ws_vt_xmlRef;Is DOM reference;SOAP output;"contactByRef")
 `The XML is passed as a reference
```

# SOAP Get info

SOAP Get info ( infoNum ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| infoNum | Longint | ⇒ | Number of type of SOAP info to get |
| Function result | String | ⇐ | SOAP Information |

## Description

The **SOAP Get info** command retrieves, in the form of a character string, the different types of information concerning a SOAP request.

When you process a SOAP request, it can be useful to obtain additional information — other than the RPC parameter values — about the request. For instance, for security reasons, you can use this command in the **On Web Authentication Database Method** to find out the name of the requested Web Service method.

Pass the number of the type of SOAP information you want to get in the *infoNum* parameter. You can use the following predefined constants, located in the **Web Services (Server)** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| SOAP method name | Longint | 1 | Name of the Web Service method about to be executed |
| SOAP service name | Longint | 2 | Name of the Web Service to which the method belongs |

**Note:** Also for security reasons, it is possible to set the maximum size for Web Services requests sent to 4D. This configuration is carried out using the **SET DATABASE PARAMETER** command.

# SOAP Request

SOAP Request -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Boolean | | True if the request is SOAP; otherwise, False |

## Description

The **SOAP Request** command returns **True** if the code being executed is part of a SOAP request.

This command can be used for security reasons in the **On Web Authentication Database Method** in order to determine the nature of the received requests.

# SOAP SEND FAULT

SOAP SEND FAULT ( faultType ; description )

| Parameter | Type | | Description |
|---|---|---|---|
| faultType | Longint | ⇒ | 1 = Client fault, 2 = Server fault |
| description | String | ⇒ | Description of error to be sent to SOAP client |

## Description

The **SOAP SEND FAULT** command returns an error to a SOAP client indicating the origin of the fault: client or server. Using this command lets you indicate an error to a client without having to return a result.

For instance, a fault on the client side may be detected when you publish a “Square_root” Web Service and a client sends a request with a negative number; you can use this command to indicate to the client that a positive value is required.

A possible fault on the server side may be, for instance, a lack of memory occurring during method execution.

Pass the origin of the error in *faultType*. You can use the following predefined constants, located in the **Web Services (Server)** theme:

| Constant | Type | Value |
|---|---|---|
| SOAP client fault | Longint | 1 |
| SOAP server fault | Longint | 2 |

Pass a description of the error in *description*. If the client implementation is in conformity, the error can be processed.

## Example

To go back to the example of the “Square_root” Web Service provided in the command description, the following command can be used to process requests with negative numbers:

```
SEND SOAP FAULT(SOAP client fault;"Positive values required")
```

# Windows

- *_o_Open external window*

# Managing Windows

Windows are used to display information to the user. They have three main uses: to enter data, to display data, and to inform the user in messages and dialogs.

There is always at least one window open. Scroll bars are added, when needed, to let the user scroll in a form that is larger than the window. In the Design environment, this window displays either the record list (output form) or the data entry screen (input form). In the Application environment, this window displays a splash screen (a custom graphic).

When you execute a menu command within the Application process, the splash screen can be replaced with data by commands that display forms. When the commands finish executing, the splash screen is displayed again by default.

## WinRef

You can open various types of custom windows with the **Open window** or **Open form window** commands (see the **Window Types** section). All windows opened by these commands are referenced through a **WinRef** expression. A *WinRef* is the unique ID of each open window. It is a Longint expression. All commands working with custom windows expect a *WinRef* parameter.

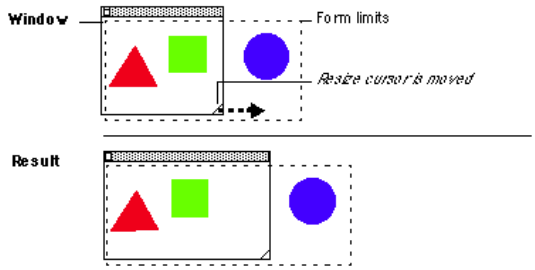
When you no longer need a custom window, you should close it using the **CLOSE WINDOW** command or by clicking the Control-menu box (Windows) or Close Box (Macintosh), if it exists.

Some commands open their own windows. Commands such as **QR REPORT** and **PRINT LABEL** open a window that becomes the frontmost window.

If you start a new process and do not open a window at the beginning of the process method, 4D will automatically open a default one as soon as a form is to be displayed.

## Side pushers

The right side and bottom of windows have become “pusher” splitters by default. This means that objects found to the right or below the limits of a window on screen are automatically pushed to the right or towards the bottom if the window is enlarged:



This mechanism allows you to manage retractable windows like the Explorer window (see the example of the **FORM SET SIZE** command).

**Note:** This does not work with windows that have scrollbars.

## Window coordinates and "right-to-left" mode

In window management commands, the window coordinates are determined with respect to a point of origin generally situated at the top left of the window/screen.
However, when the "right-to-left" mode is activated for the application, the coordinates are reversed and the point of origin switches to the top right of the window/screen. Consequently, in this mode the horizontal coordinates used by the following commands must also be reversed:

**Open window**
**Open form window**
**_o_Open external window**
**GET WINDOW RECT**

**SET WINDOW RECT**
**Find window**

**Note:** For more information about "right-to-left" mode, please refer to the Design Reference manual and to the description of the **SET DATABASE PARAMETER** command.

# Window Types

You can use one of the following predefined constants to specify the type of window that you open with **Open window**:

| Constant | Type | Value | Comment |
|---|---|---|---|
| Plain no zoom box window | Longint | 0 | |
| Modal dialog box | Longint | 1 | |
| Plain dialog box | Longint | 2 | Can be a floating window |
| Alternate dialog box | Longint | 3 | Can be a floating window |
| Plain fixed size window | Longint | 4 | |
| Movable dialog box | Longint | 5 | Can be a floating window |
| Plain window | Longint | 8 | |
| Round corner window | Longint | 16 | |
| Pop up window | Longint | 32 | |
| Sheet window | Longint | 33 | |
| Resizable sheet window | Longint | 34 | |
| Palette window | Longint | 1984 | Can be a floating window |

### Floating Windows

If you pass one of these constants to **Open window**, you open a regular windows. To open a floating windows, pass a negative window type value to **Open window**.

The main characteristic of floating windows is that they remain in the foreground even if the user clicks on another window of the process. Floating windows are generally used to display permanent information or tool bars.

### Modal windows

A modal window places the user in a state (or “mode”) where they can only act within this window. As long as the modal window is displayed, the menu commands and other application windows are inaccessible. To close a modal window, the user must either validate it, cancel it, or choose one of the options it offers. Warning dialog boxes are a typical example of modal windows.
In 4D, windows of the types 1 and 5 are modal windows.

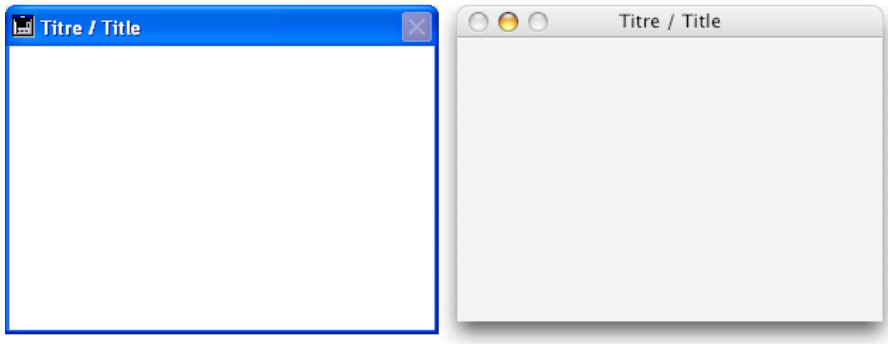
**Note:** A modal window always stays in the foreground. As a consequence, when a modal window calls a non-modal window, this latter window is displayed in the background, even though it was called subsequent to the modal window. You should thus avoid this type of operation.

On the other hand, when a modal window calls another modal window, this latter window will be displayed in the foreground.

## Description

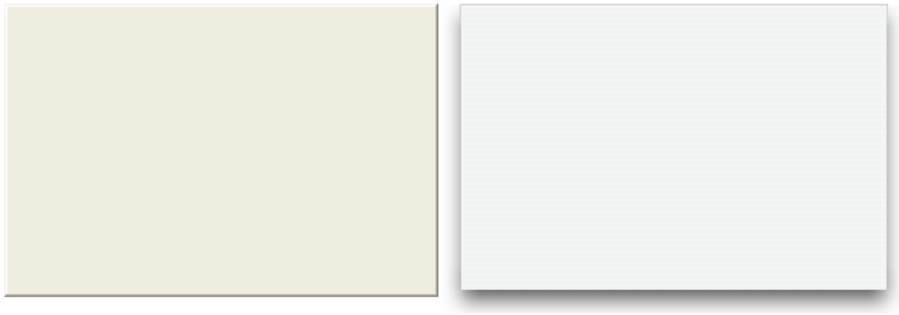
Here are the descriptions for each type of window under Windows (left) and Mac OS (right).

### Plain fixed size window (4)



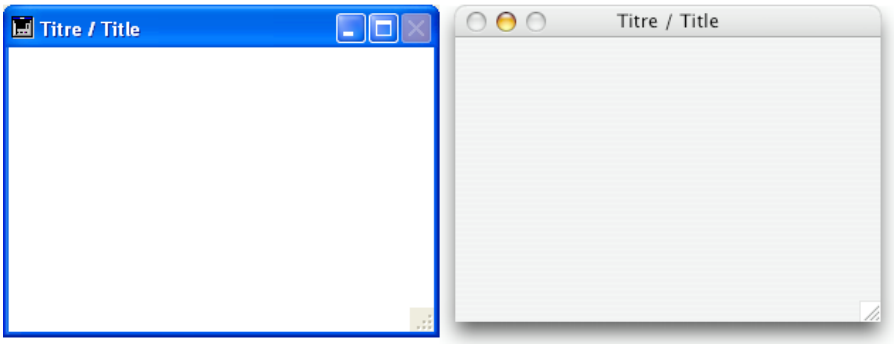
- Can have a title: Yes
- Can have a close box or equivalent: Yes
- Can be resized: No on Macintosh
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: Yes and No
- Usage: data entry with **ADD RECORD** or equivalent

### Modal dialog box (1)



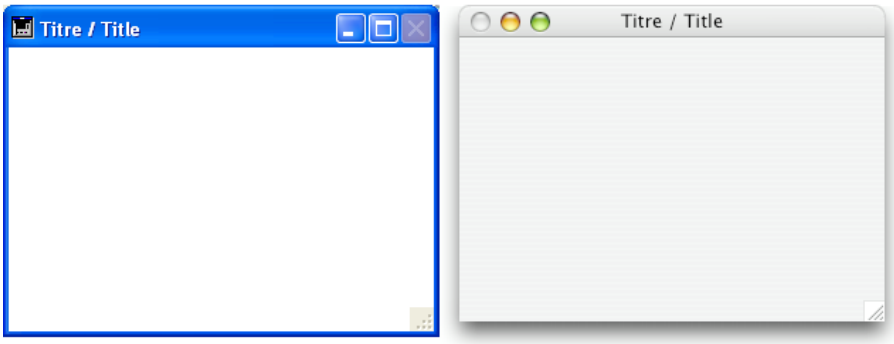
- Can have a title: No
- Can have a close box or equivalent: No
- Can be resized: No
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: No
- Usage: **DIALOG**, **ADD RECORD** or equivalent
- Windows of this type are modal

### Plain no zoom box window (0)



- Can have a title: Yes
- Can have a close box or equivalent: Yes
- Can be resized: Yes
- Can be minimized/maximized or zoomed: No on Macintosh
- Suitable for scroll bars: Yes
- Usage: data entry with scrollbars, **DISPLAY SELECTION**, **MODIFY SELECTION**, etc.

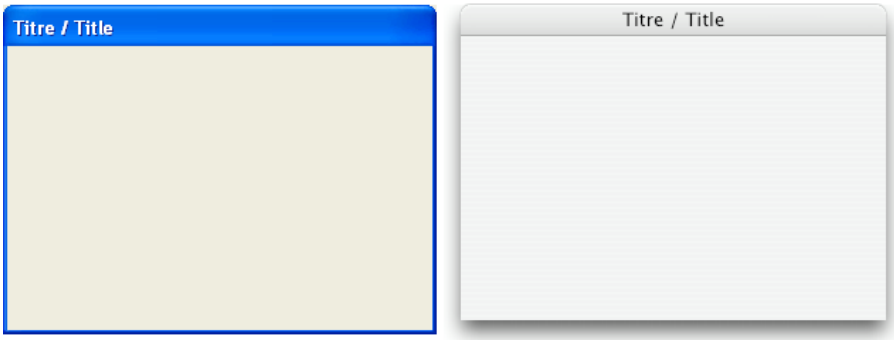
### Plain window (8)



- Can have a title: Yes
- Can have a close box or equivalent: Yes
- Can be resized: Yes
- Can be minimized/maximized or zoomed: Yes
- Suitable for scroll bars: Yes

- Usage: data entry with scrollbars, **DISPLAY SELECTION**, **MODIFY SELECTION**, etc.

### Movable dialog box (5)



- Can have a title: Yes
- Can have a close box or equivalent: No
- Can be resized: No
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: No
- Usage: **DIALOG**, **ADD RECORD** or equivalent
- Windows of this type are modal, but can be moved and can be used as floating windows

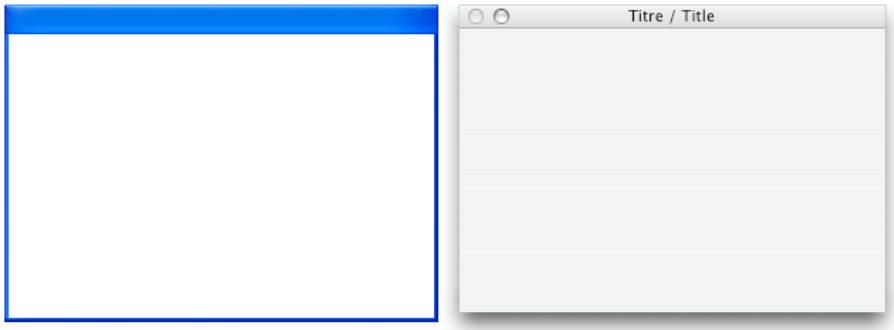
### Alternate dialog box (3)

- Can have a title: No
- Can have a close box or equivalent: No
- Can be resized: No
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: No
- Usage: **DIALOG**, **ADD RECORD** or equivalent
- Windows of this type are modal, unless used as floating windows

### Plain dialog box (2)

- Can have a title: No
- Can have a close box or equivalent: No
- Can be resized: No
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: No
- Usage: **DIALOG**, **ADD RECORD** or equivalent, splashscreens
- Windows of this type are modal, unless used as floating windows

### Palette window (1984)



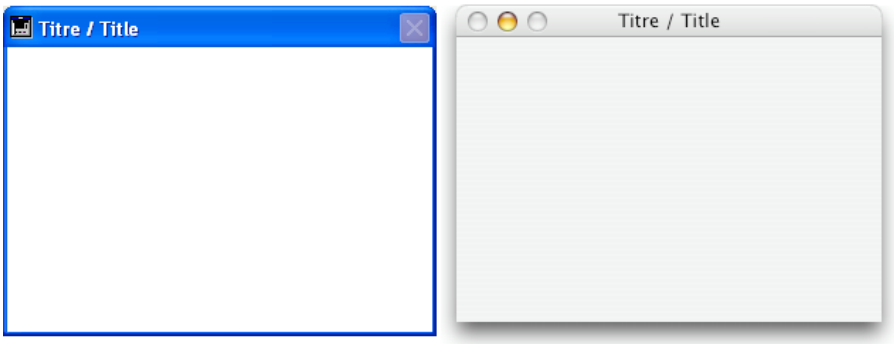
This type of window allows you to generate floating windows which can be defined as resizable or not. Only the following options are supported:

| Option | Value to pass under Windows | Value to pass under macOS |
|---|---|---|
| Not resizable | -(Palette window+2) | -Palette window |
| Resizable | -(Palette window+6) | -(Palette window+6) |

- Can have a title: Yes, if passed
- Can be resized: Yes, if the appropriate value is passed
- Usage: Floating windows with **DIALOG** or **DISPLAY SELECTION** (no data entry).

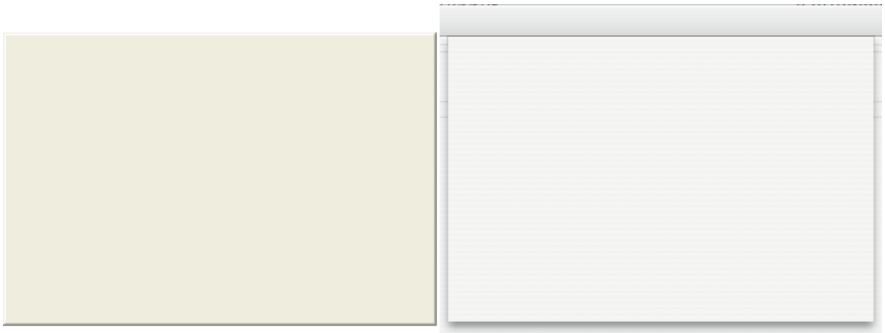
**Note:** With this type of window, the set of values (constant+option) must always be passed as a negative value. Make sure that you pass, for example, -(Palette window+6) and not (-Palette window+6).

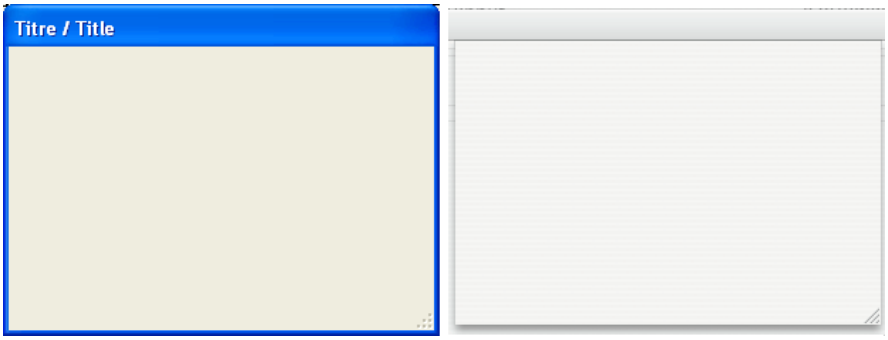
### Round corner window (16)



- Can have a title: Yes
- Can have a close box or equivalent: Yes
- Can be resized: No on Macintosh
- Can be minimized/maximized or zoomed: No
- Suitable for scroll bars: No on Macintosh
- Usage: Rare (obsolete)

### Sheet window (33) and Resizable sheet window (34)





Sheet windows are specific to Mac OS X. These windows “drop down” over the title bar of the main window using animation and are displayed above the main window. They are automatically centered in the main window. Their properties are comparable to those of the modal dialog boxes. They are generally used to perform an action directly relating to the action occurring in the primary window.

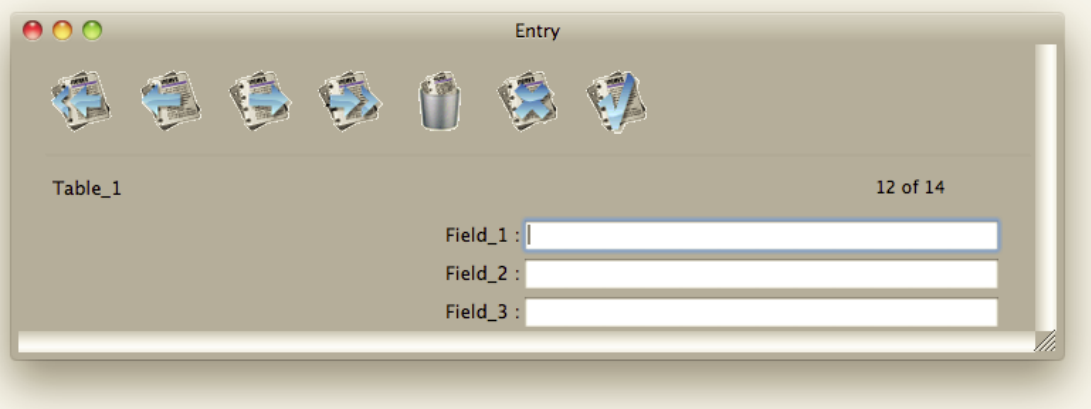
- You can only create a sheet window under Mac OS X if the last open window is visible and a document type (form).
- The command opens a type 1 (Modal dialog box) window instead of a type 33 window or type 8 (Plain) window instead of type 34:
  - if the last opened window is not visible or is not a document type,
  - under Windows.
- Since a sheet window must be drawn above a form, its display is pushed back in the On load event of the first form loaded in the window (see example 4 of the **Open window** command).
- Usage: **DIALOG**, **ADD RECORD** or equivalent, under Mac OS (not standard under Windows).

### Pop up window (32)

This type of window has the same basic characteristics of the Plain dialog box (2) type windows and features the following advanced specifics:

- The window is automatically closed and the "cancel" event is passed to the window when:
  - a click occurs outside the window;
  - the background window or the MDI (Multiple Document Interface) window is moved;
  - the user clicks the **Esc** key.
- This window is displayed in front of its "parent" window (it must not be used as the main window of the process). The background window is not disabled. However, it no longer receives events.
- You cannot resize or move the window using the mouse; however, when performing these actions programmatically, the redraw of background items is optimized.
- Usage: This type of window is primarily used to generate pop-up menus related to 3D “bevel” or “toolbar” type buttons.
- Limitations:
  - It is not possible to display pop-up menu objects inside this type of window.
  - Beginning with version 13 of 4D, this type of window does not permit the display of help tips under Mac OS.

### Texture appearance (2048)



Under Mac OS, it is possible to apply a texture appearance to windows. This type of look is found throughout the Macintosh interface. Under Windows, this property has no effect.

To apply a texture appearance to a window created by the **Open window** command, you can just add the Texture appearance constant to the window type set in the *type* parameter. For example:

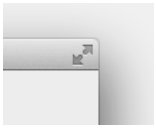
```
$win:=Open window(10;80;-1;-1;Plain window+Texture appearance;"")
```

This look can be associated with the following types of windows:

- Plain window
- Plain no zoom box window
- Plain fixed size window
- Movable dialog box
- Round corner window

### Has full screen mode Mac (65536)

The "full screen" option is available beginning with 4D v14 under OS X for document type windows. When this option is used, a "Full screen" button is displayed in the top right corner of the window:



When the user clicks on this icon, the window switches to full screen and 4D automatically hides the main tool bar.
To use this option, you just add the Has full screen mode Mac constant to the *type* parameter for the **Open window**, **Open form window** and **_o_Open external window** commands. For example, this code creates a form window with a full-screen button under OS X:

```
$win:=Open form window([Interface];"User_Choice";Plain form window+Form has full screen mode Mac)
DIALOG([Interface];"User_Choice")
```

**Note:** Under Windows, this option has no effect.

# CLOSE WINDOW

CLOSE WINDOW {{ window }}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |

## Description

**CLOSE WINDOW** closes the active window opened by the **Open window** or **Open form window** command in the current process. **CLOSE WINDOW** has no effect if a custom window is not open; it does not close system windows. **CLOSE WINDOW** also has no effect if called while a form is active in the window. You must call **CLOSE WINDOW** when you are done using a window opened by **Open window** or **Open form window**.

It is useless to pass a number to **CLOSE WINDOW** when closing a window previously opened by the **Open window** or **Open form window** function, since a call to **CLOSE WINDOW** will always close the last window created by one of these commands.

If you pass an external window reference number in the *Window* parameter, **CLOSE WINDOW** closes the specified external window. For more information about external windows, refer to the **_o_Open external window** function.

## Example

The following example opens a form window and adds new records with the **ADD RECORD** command. When the records have been added, the window is closed with **CLOSE WINDOW**:

```
FORM SET INPUT([Employees];"Entry")
$winRef:=Open form window([Employees];"Entry")
Repeat
   ADD RECORD([Employees]) //Add a new employee record
Until(OK=0) //Loop until the user cancels
CLOSE WINDOW //Close the window
```

# CONVERT COORDINATES

CONVERT COORDINATES ( xCoord ; yCoord ; from ; to )

| Parameter | Type | | Description |
|---|---|---|---|
| xCoord | Longint variable | ⇒ | Horizontal coordinate of a point (initial) |
| | | ⇐ | Horizontal coordinate of a point (converted) |
| yCoord | Longint variable | ⇒ | Vertical coordinate of a point (initial) |
| | | ⇐ | Vertical coordinate of a point (converted) |
| from | Longint | ⇒ | Coordinates system to convert from |
| to | Longint | ⇒ | Coordinates system to convert to |

## Description

The **CONVERT COORDINATES** command converts the (x;y) coordinates of a point from one coordinate system to another. The input and output coordinate systems supported are forms (and subforms), windows, and the screen. For example, you can use this command to get the coordinates in the main form of an object belonging to a subform. This makes it easy to create a context menu at any custom position.

In *xCoord* and *yCoord*, pass as variables the (x;y) coordinates of the point you want to convert. After the command is executed, these variables will contain the converted values.

In the *from* parameter, pass the initial coordinate system the input point is using, and in the *to* parameter, pass the coordinate system into which it must be converted. Both parameters can take one of the following constant values, added to the "**Windows**" theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| XY Current form | Longint | 1 | Origin is top left corner of current form |
| XY Current window | Longint | 2 | Origin is top left corner of current window |
| XY Main window | Longint | 4 | On Windows: origin is top left corner of main window; on OS X: same as XY Screen |
| XY Screen | Longint | 3 | Origin is top left corner of main screen (same as for **SCREEN COORDINATES** command) |

When this command is called from the method of a subform or a subform's object, and if one of the selectors is XY Current form, then the coordinates are relative to the subform itself, not to its parent form.

When converting from/to the position of a form window (for example when converting from the results of **GET WINDOW RECT**, or to values passed to **Open form window**), XY Main window must be used since it is the coordinate system used by window commands on Windows. It can also be used for this purpose on OS X, where it is equivalent to XY Screen.

When *from* is XY Current form and the point is in the body section of a list form, the result depends on the calling context of the command:

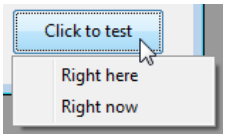
- If the command is called in the On Display Detail event, the resulting point is located in the display of the record being drawn on screen.
- If the command is called outside of an On Display Detail event but while a record is being edited, the resulting point is located in the display of the record being edited.
- Otherwise, the resulting point is located in the display of the first record.

## Example 1

You want to open a pop-up menu at the bottom left corner of the "MyObject" object.

```
// OBJECT GET COORDINATES works in the current form coordinate system
// Dynamic pop-up menu uses the current window coordinate system
// We need to convert the values
C_LONGINT($left;$top;$right;$bottom)
C_TEXT($menu)
OBJECT GET COORDINATES(*;"MyObject";$left;$top;$right;$bottom)
CONVERT COORDINATES($left;$bottom;XY Current form;XY Current window)
$menu:=Create menu
APPEND MENU ITEM($menu;"Right here")
```

```
APPEND MENU ITEM($menu;"Right now")
Dynamic pop up menu($menu;"";$left;$bottom)
RELEASE MENU($menu)
```



## Example 2

You want to open a pop-up window at the position of the mouse cursor. On Windows, you need to convert the coordinates since **GET MOUSE** (with the * parameter) returns values based on the position of the MDI window:

```
C_LONGINT($mouseX;$mouseY;$mouseButtons)
C_LONGINT($window)
GET MOUSE($mouseX;$mouseY;$mouseButtons)
CONVERT COORDINATES($mouseX;$mouseY;XY Current window;XY Main window)
$window:=Open form window("PopupWindowForm";Pop up form window;$mouseX;$mouseY)
DIALOG("PopupWindowForm")
CLOSE WINDOW($window)
```

# Current form window

Current form window -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | WinRef | | Current form window reference number |

## Description

The **Current form window** command returns the reference of the current form window. If no window has been set for the current form, the command returns 0.

The current form window can be generated automatically using a command such as **ADD RECORD**, following a user action or by using the **Open window** or **Open form window** commands.

# DRAG WINDOW

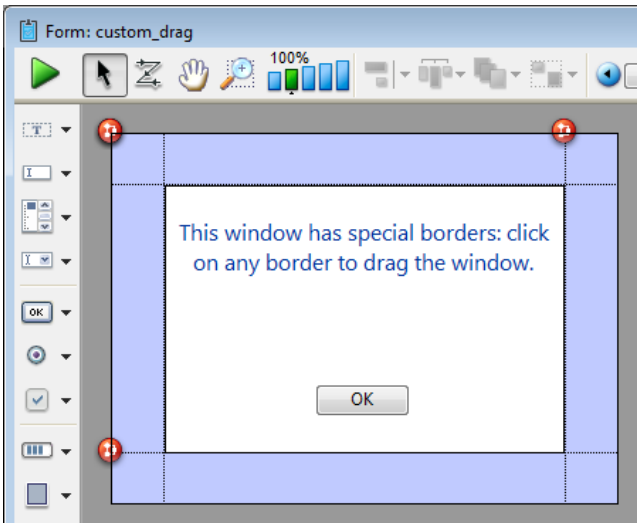
DRAG WINDOW
Does not require any parameters

## Description

The **DRAG WINDOW** command lets users drag the window on which they clicked following the movements of the mouse. Usually you call this command from within an object method of an object that can respond instantaneously to mouse clicks (i.e., invisible buttons).

## Example

The following form, shown here in the Form editor, contains a colored frame, above which are four invisible buttons for each side:



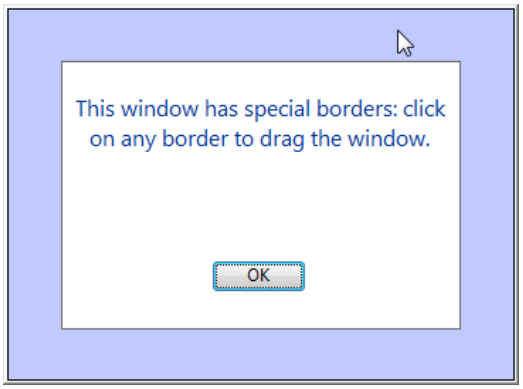
Each button has the following method:

```
DRAG WINDOW //Start dragging window when clicked
```

After executing the following project method:

```
$winRef:=Open form window("custom_drag";Modal form dialog box)
DIALOG("custom_drag")
CLOSE WINDOW
```

You obtain a window similar to this:



Then you can drag the window by clicking anywhere on the borders.

# ERASE WINDOW

ERASE WINDOW {( window )}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇨ | Window reference number, or Frontmost window of current process, if omitted |

## Description

The **ERASE WINDOW** command clears the contents of the window whose reference number is passed in *window*.

If you omit the *window* parameter, **ERASE WINDOW** clears the contents of the frontmost window for the current process.

Usually, you will use **ERASE WINDOW** in combination with **MESSAGE** and **GOTO XY**. In this case, **ERASE WINDOW** clears the contents of the window and moves the cursor to the upper-left corner of the window, the **GOTO XY**(0; 0) position.

Do not confuse **ERASE WINDOW**, which clears the contents of a window, with **CLOSE WINDOW**, which removes the window from the screen.

# Find window

Find window ( left ; top {; windowPart} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇒ | Global left coordinate |
| top | Longint | ⇒ | Global top coordinate |
| windowPart | Longint | ⇐ | 3 if window is "touched", 0 otherwise |
| Function result | WinRef | ⇔ | Window reference number |

## Description

The **Find window** command returns (if any) the reference number of the first window “touched” by the point whose coordinates passed in *left* and *top*.

The coordinates must be expressed relative to the top left corner of the contents area of the application window (Windows) or to the main screen (Macintosh).

The *windowPart* parameter returns 3 if the window is touched, and 0 otherwise. (**Compatibility note:** Starting with 4D v14, the constants of the **Find Window** theme are obsolete).

# Frontmost window

Frontmost window {( * )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| * | Operator | ⇒ | If specified, take floating windows into account If omitted, ignore floating windows |
| Function result | WinRef | ⇐ | Window reference number |

## Description

The **Frontmost window** command returns the window reference number of the frontmost window.

# GET WINDOW RECT

GET WINDOW RECT ( left ; top ; right ; bottom {; window} )

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇦ | Left coordinate of window's contents area |
| top | Longint | ⇦ | Top coordinate of window's contents area |
| right | Longint | ⇦ | Right coordinate of window's contents area |
| bottom | Longint | ⇦ | Bottom coordinate of window's contents area |
| window | WinRef | ⇨ | Window reference number, or Frontmost window of current process, if omitted or MDI window if -1 (Windows) |

## Description

The **GET WINDOW RECT** command returns the coordinates of the window whose reference number is passed in *window*. If the window does not exist, the variable parameters are left unchanged.

If you omit the *window* parameter, **GET WINDOW RECT** applies to the frontmost window for the current process.

The coordinates are expressed relative to the top left corner of the contents area of the application window (on Windows) or of the main screen (on Macintosh). The coordinates return the rectangle corresponding to the contents area of the window (excluding title bars and borders).

**Note:** Under Windows, if you pass -1 in *window*, **GET WINDOW RECT** returns the coordinates of the application window (MDI window). These coordinates correspond to the contents area of the window (excluding menu bars and borders).

## Example

See example for the **WINDOW LIST** command.

# Get window title

Get window title {( window )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |
| Function result | String | ⇐ | Window title |

## Description

The **Get window title** command returns the title of the window whose reference number is passed in *window*. If the window does not exist, an empty string is returned.

If you omit the *window* parameter, **Get window title** returns the title of the frontmost window for the current process.

## Example

See example for the **SET WINDOW TITLE** command.

# HIDE TOOL BAR

HIDE TOOL BAR
Does not require any parameters

## Description

The **HIDE TOOL BAR** command handles the display of custom toolbars created by the **Open form window** command for the current process.

If a toolbar window has been created by the **Open form window** command with the Toolbar form window option, the command hides this window. If the toolbar window was already hidden or if no window of this type has been created, the command does nothing.

## Example

On OS X, you have defined a custom toolbar and a standard window that has the Has full screen mode Mac option. When a standard window is maximized by a user while the toolbar window is displayed, you do not want the toolbar to overlap the maximized window.

To prevent this, in the On Resize form event of the standard window, you need to detect when the window has entered full screen mode and then call **HIDE TOOL BAR**:

```
Case of
   :(Form event=On Resize)
      GET WINDOW RECT($left;$top;$right;$bottom)
      If(Screen height=($bottom-$top))
         HIDE TOOL BAR
      Else
         SHOW TOOL BAR
      End if
End case
```

# HIDE WINDOW

HIDE WINDOW {( window )}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ➡ | Window reference number or Current process frontmost window, if omitted |

## Description

The **HIDE WINDOW** command hides the window whose number was passed in *window* or, if this parameter is omitted, the current process frontmost window. For example, this command lets you display only the active window in a process that consists of several processes.

The window disappears from the screen but remains open. You can still apply any changes supported by 4D windows programmatically.

To display a window that was previously hidden by the **HIDE WINDOW** command:

- Use the **SHOW WINDOW** command and pass the window reference ID.
- Use the **Process** page of the Runtime Explorer. Select the process in which the window is handled, then click on the **Show** button.

To hide all the windows of a process, use the **HIDE PROCESS** command.

## Example

This example corresponds to a method of a button located in an input form. This button opens a dialog box in a new window that belongs to the same process. In this example, the user wants to hide the other windows of the process (an entry form and a tool palette) while displaying the dialog box. Once the dialog box is validated, other process windows are displayed again.

```
  ` Object method for the "Information" button

HIDE WINDOW(Entry) ` Hide the entry window
HIDE WINDOW(Palette) ` Hide the palette
$Infos:=Open window(20;100;500;400;8) ` Create the information window
... ` Place here instructions that are dedicated to the dialog management
CLOSE WINDOW($Infos) ` Close the dialog
SHOW WINDOW(Entry)
SHOW WINDOW(Palette) ` Display the other windows
```

# MAXIMIZE WINDOW

MAXIMIZE WINDOW {{ window )}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number or if omitted, all current process frontmost windows (Windows) or current process frontmost window (Mac OS) |

## Description

The **MAXIMIZE WINDOW** command triggers the expansion of the window whose reference number was passed in *window*. If this parameter is omitted, the effect is the same but is applied to all the frontmost windows of the current process (Windows) or to the frontmost window of the current process (Mac OS).

This command has the same effect as a click on the zoom box of a 4D application window. Windows you want to maximize must have a zoom box. If the *window* type does not have a zoom box, the command does nothing (for more information about this point, refer to **Window Types** section).

A later click on the zoom box or a call to the **MINIMIZE WINDOW** command reduces the window to its initial size. On Windows, a call to **MINIMIZE WINDOW** without parameters sets the size of all application windows to their initial sizes.

If *window* is already maximized, the command does nothing.

### On Windows

The size of the window is increased to match the current size of the application window. The maximized window is set to be the frontmost window. If you do not pass the *window* parameter, the command is applied to all the application windows.

Windows zoom box

In cases where the command is applied to a window whose size is subject to constraints (for example, a form window):

- If no size constraint is in conflict with the target size, the window is "maximized" (i.e., it is restored to the size of the parent MDI ("Multiple Document Interface") window; its title bar and borders are hidden, and its control buttons - minimize, restore and close - are moved to the right of the application menu bar).
- If at least one size constraint is in conflict (for example, if the width of the MDI window is 100 and the form window's maximum width is set to 80), the window is not "maximized", but only restored to its maximum allowed size. This size is defined either by the MDI window, or by the constraint. This way, the interface remains consistent when windows with constraints are resized.

### On Mac OS

The size of the window is increased to match the size of its contents. If you do not pass the *window* parameter, the command is applied to the frontmost window of the current process.

Zoom box on Mac OS

- The zoom is based on the contents of the window; so, the command must be called in a context where the contents of the window are defined, for example in a form method. Otherwise, the command does nothing.
- The window is set to its "maximum" size. If the window is actually a form whose size was defined in the form properties, the window size is set to those values.

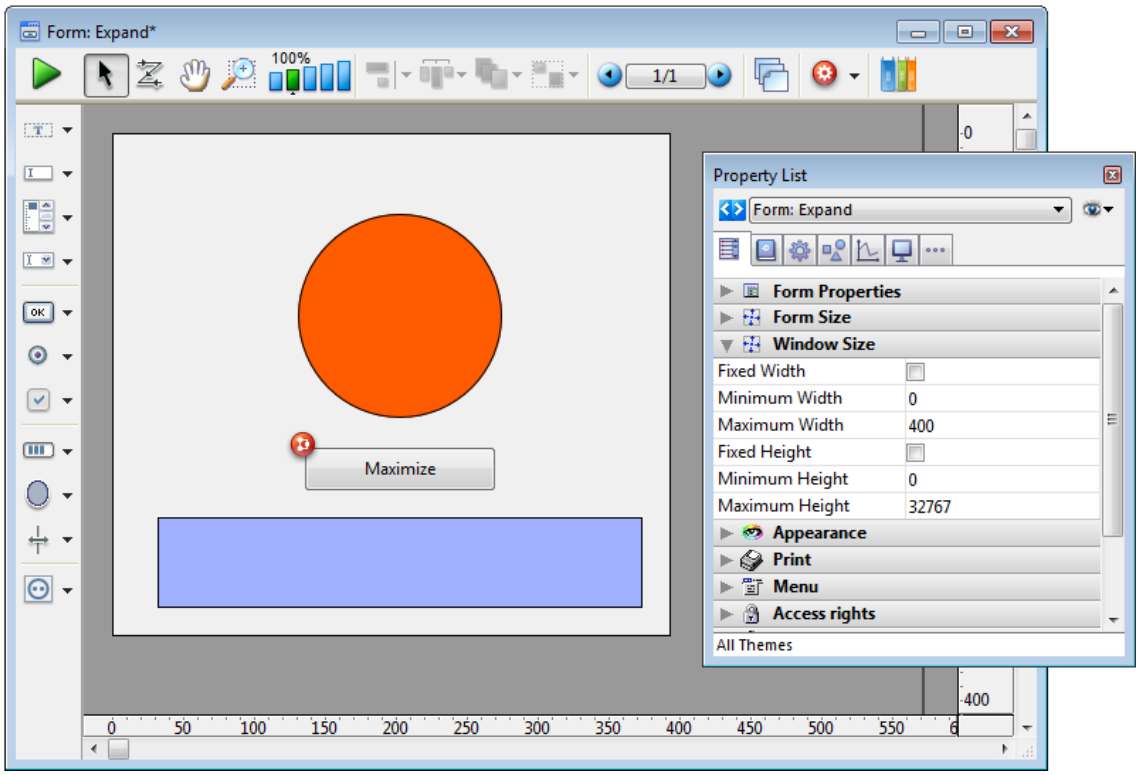
## Example 1

This example sets the window size of your form to full screen when it is opened. To achieve this, the following code is placed in the form method:

```
` In the Form method
MAXIMIZE WINDOW
```

## Example 2

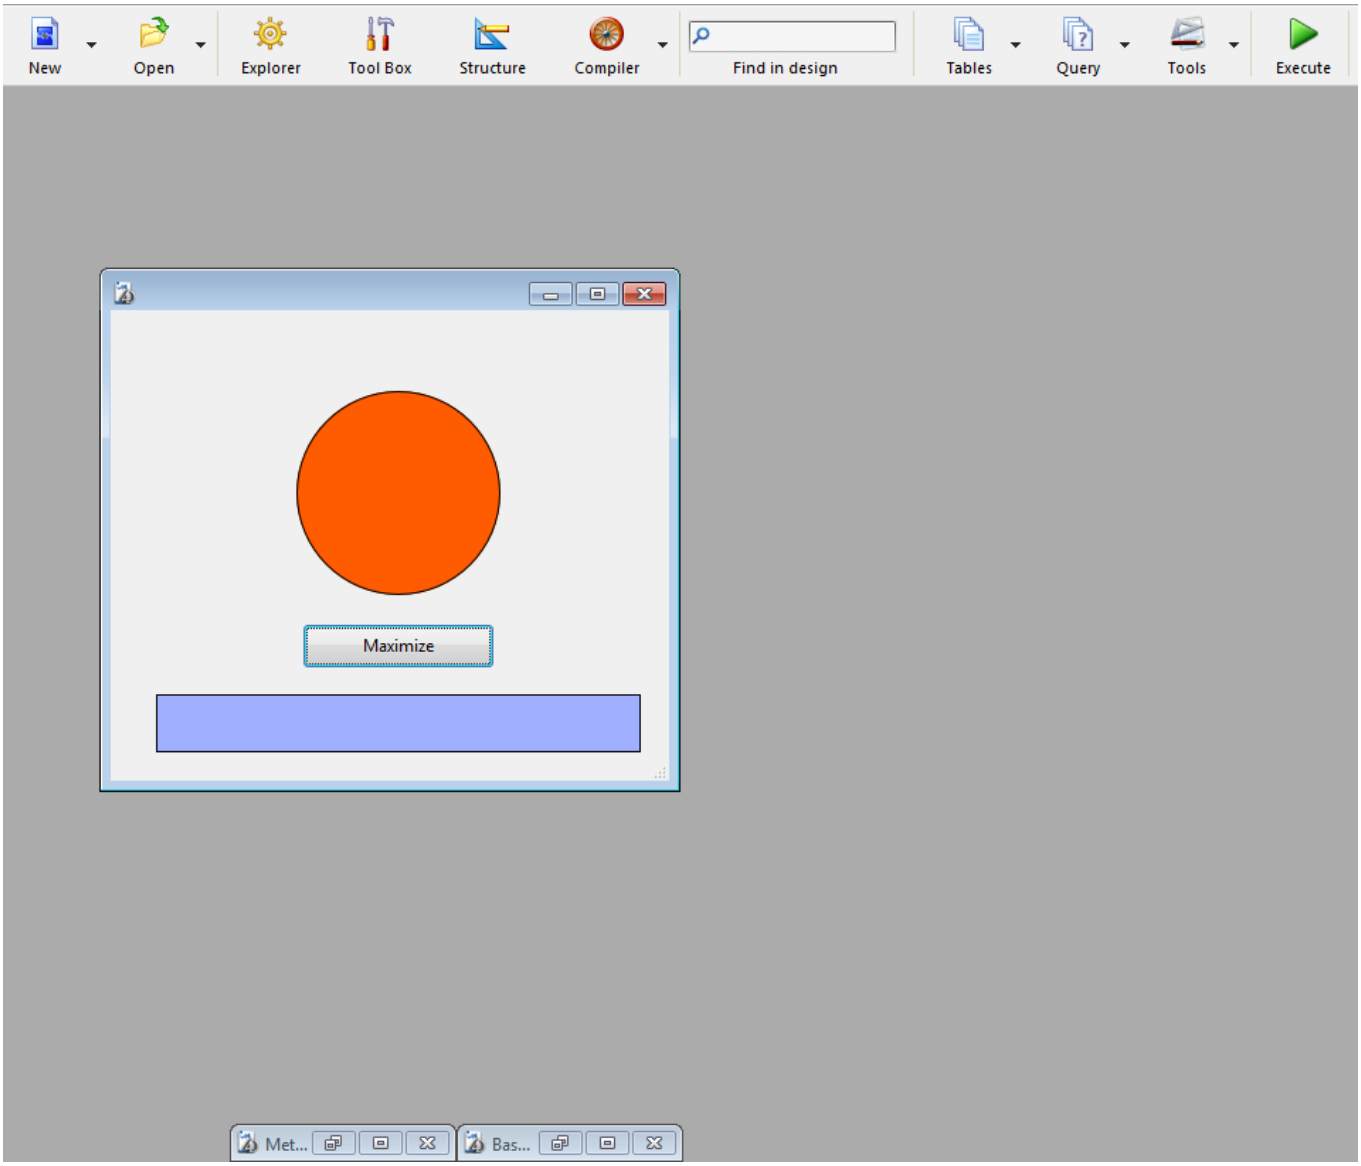
This example illustrates how size constraints are handled on Windows. The following form has a size constraint (maximum width=400):



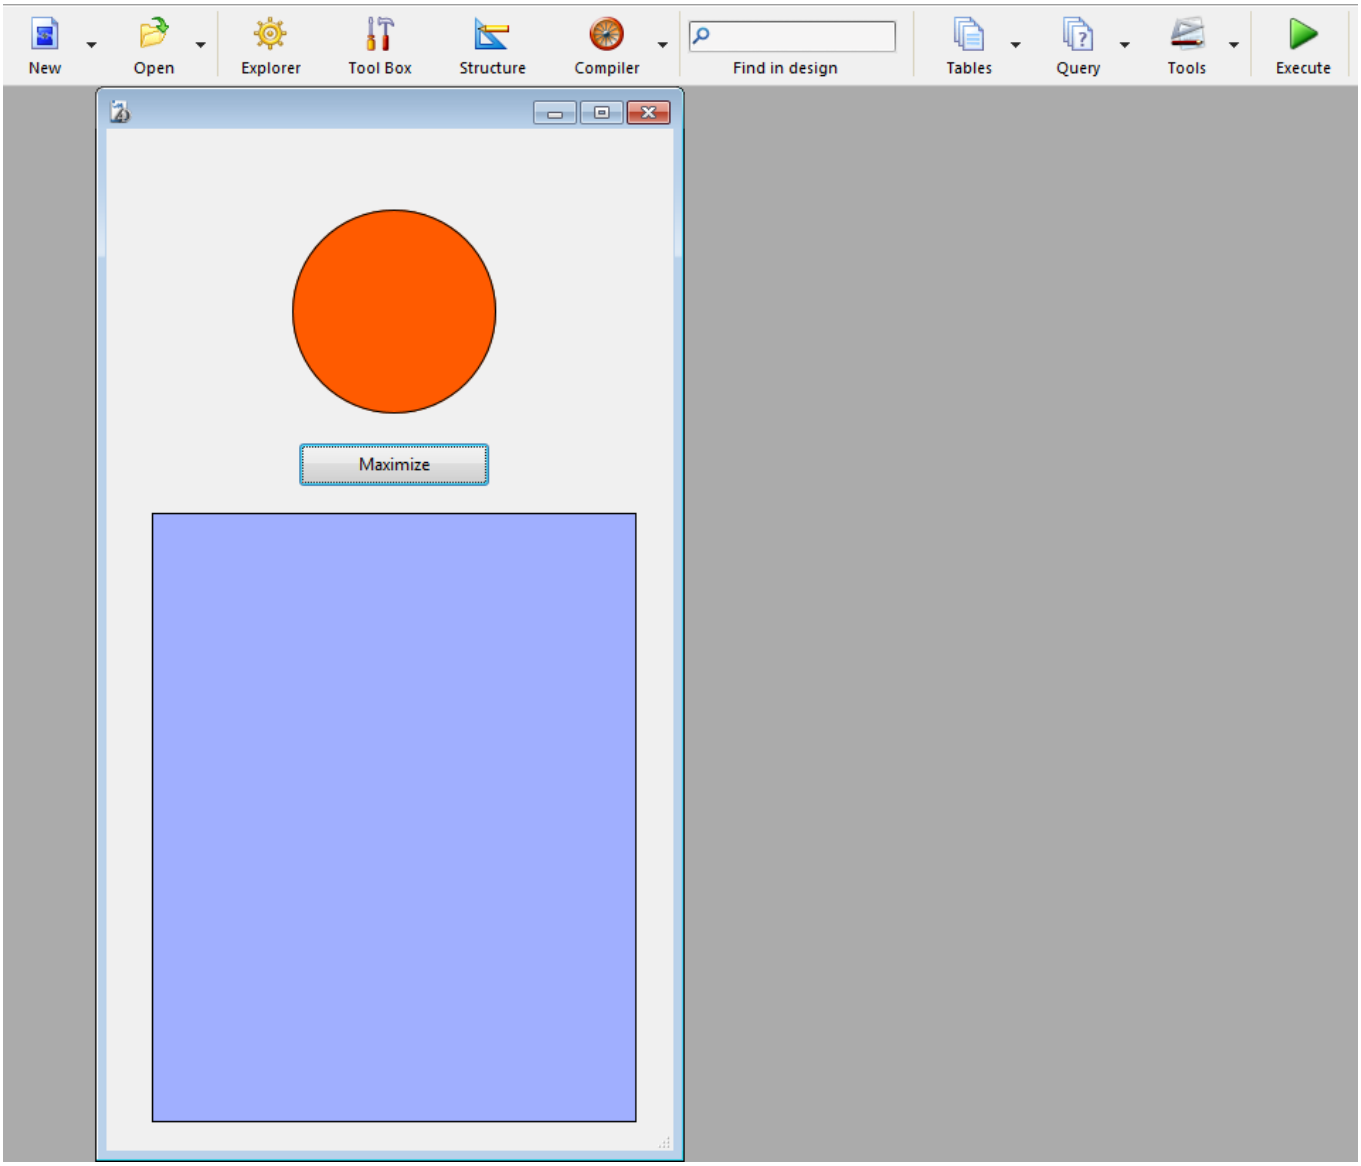
The method of the button contains simply:

```
MAXIMIZE WINDOW(Current form window)
```

In this context, when the user clicks on the button:



... the window is not "maximized"; only its height is increased:



New
Open
Explorer
Tool Box
Structure
Compiler
Find in design
Tables
Query
Tools
Execute
Maximize

# MINIMIZE WINDOW

MINIMIZE WINDOW {{ window }}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number or if omitted, all the current process frontmost windows (Windows) or current process frontmost window (Mac OS) |

## Description

The **MINIMIZE WINDOW** command sets the size of the window whose number is passed as *window* to the size it was before being maximized. If *window* is omitted, the command applies to each window of the application (Windows) or to the frontmost window of the process (on Mac OS).

This command has the same effect as one click on the reduction box of the 4D application:

### On Windows

The size of the window is set to its initial size, i.e., its size before being maximized. If the *window* parameter is omitted, all the application windows are set to their initial sizes.

Reduction box on Windows

### On Mac OS

The size of the window is set to its initial size (i.e. its size before being maximized). If the window parameter is omitted, the frontmost window of the current process is set to its initial size.

Reduction/zoom box on Mac OS

If the windows to which the command is applied were not previously maximized (manually or using **MAXIMIZE WINDOW**), or if the window type does not include a zoom box, the command has no effect. For more information on window types, refer to the **Window Types** section.

**Note:** This function is not to be confused with minimizing a window to a button (Windows) or in the Dock (Mac OS), which is triggered by a click on the button shown:

Windows

Mac OS

# Next window

Next window ( window ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number |
| Function result | WinRef | ⇒ | Window reference number |

## Description

The **Next window** command returns the window reference number of the window “behind” the window you pass in *window* (based on the front-to-back order of the windows).

# Open form window

Open form window ( {aTable ;} formName {; type {; hPos {; vPos {; *}}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| aTable | Table | ➡ | Table of the form or Default table, if omitted |
| formName | String | ➡ | Name of the form |
| type | Longint | ➡ | Window type |
| hPos | Longint | ➡ | Horizontal position of the window |
| vPos | Longint | ➡ | Vertical position of the window |
| * | Operator | ➡ | Save current position and size of the window |
| Function result | WinRef | ⬅ | Window reference number |

## Description

The **Open form window** command opens a new window using the size and resizing properties of the form *formName*.

Note that *formName* is not displayed in the window. If you want to display the form, you have to call a command which loads a form (**ADD RECORD** for example).

By default (if the *type* parameter is not passed), a standard window with a close box is opened. Unlike the **Open window** command, no method is associated to the window's close box. Clicking on this close box cancels and closes the window, except if the On Close Box form event has been activated for the form. In this case, the code associated with the On Close Box event will be executed.

If *formName* is resizable, the window opened will contain a zoom box as well as a grow box.

**Note:** To know the main properties of a form, use the **FORM GET PROPERTIES** command.

The optional *type* parameter allows you to specify a type for the window. You must pass one of the following predefined constants (placed in the **Open Form Window** theme):

| Constant | Type | Value |
|---|---|---|
| Form has full screen mode Mac | Longint | 65536 |
| Modal form dialog box | Longint | 1 |
| Movable form dialog box | Longint | 5 |
| Palette form window | Longint | 1984 |
| Plain form window | Longint | 8 |
| Pop up form window | Longint | 32 |
| Sheet form window | Longint | 33 |
| Toolbar form window | Longint | 35 |

**Notes:**

- The attributes (grow box, close box...) of the window created depend on the interface specifications of the operating system for the chosen *type*. It is therefore possible to obtain different results depending on the platform used.
- The Form has full screen mode Mac constant must be added to one of the other type constants.
- For more information about window types, refer to the **Window Types** section. Note that only the types listed in the **Open Form Window** theme can be used with the **Open form window** command.

When the Toolbar form window constant is passed, the window is created with the location, size and graphical properties of a toolbar, i.e.:

- The window will always be displayed just under the menu bar.
- The window's horizontal size will be automatically adjusted to fill all available horizontal space on the desktop (on OS X) or inside 4D's main window (on Windows). The window's vertical size is based on the form properties like all other form window types.
- The window has no border, cannot be moved and cannot be resized manually, and *hPos*, *vPos* and * parameters are ignored if present.
- It is not possible to create two different toolbar windows at the same time. If **Open form window** is called with the Toolbar form window *type* while a toolbar window already exists, an error -10613 ("Cannot create two form windows of type toolbar") is generated.

**Toolbar form windows and OS X full screen mode:** If your application displays both a toolbar window and standard windows that support full screen mode (Form has full screen mode Mac option), interface rules require that you hide the toolbar when a standard window enters full screen mode. To know if a window has switched to full screen mode, just test whether its vertical size is exactly the same as the screen's height (see the **HIDE TOOL BAR** command).

The optional parameter *hPos* allows you to define the horizontal position of the window. You can pass a defined position, expressed in points, to this parameter (refer to the **Open window** command) or one of the following predefined constants placed in the **Open Form Window** theme:

| Constant | Type | Value |
|---|---|---|
| Horizontally centered | Longint | 65536 |
| On the left | Longint | 131072 |
| On the right | Longint | 196608 |

The optional parameter *vPos* allows you to define the vertical position of the window. You can pass a defined position, expressed in points, to this parameter (refer to the **Open window** command) or one of the following predefined constants placed in the **Open Form Window** theme:

| Constant | Type | Value |
|---|---|---|
| At the bottom | Longint | 393216 |
| At the top | Longint | 327680 |
| Vertically centered | Longint | 262144 |

These parameters take into account the presence of the tool bar and menu bar as well as the current size of the application's window (on Windows).

If you pass the optional parameter *, the current position and size of the window are memorized when closed. When the window is reopened again, its previous position and size are respected. In this case, the *vPos* and *hPos* parameters are only used the first time the window is opened.

**Note:** To reopen a window at *vPos* and *hPos* initial coordinates when the * parameter is used, hold down the **Shift** key while the window is being opened.

## Example 1

The following statement opens a standard window with a close box and automatically adjusts it to be the same size as the "Input" form. Since the form has been defined as resizable, the window also has a grow and a zoom box:

```
$winRef :=Open form window([Table1];"Enter")
```

## Example 2

The following statement opens a floating palette in the upper left portion of the screen based on a project form named "Tools". This palette uses the last position it was in when the user closed it each time it is reopened:

```
$winRef :=Open form window("Tools";Palette form window;On the left;At the top;*)
```

# Open window

Open window ( left ; top ; right ; bottom {; type {; title {; controlMenuBox}}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇒ | Global left coordinate of window contents area |
| top | Longint | ⇒ | Global top coordinate of window contents area |
| right | Longint | ⇒ | Global right coordinate of window contents area, or -1 for using form default size |
| bottom | Longint | ⇒ | Global bottom coordinate of window contents area, or -1 for using form default size |
| type | Longint | ⇒ | Window type |
| title | String | ⇒ | Title of window or "" for using default form title |
| controlMenuBox | String | ⇒ | Method to call when the Control-menu box is double-clicked or the Close box is clicked |
| Function result | WinRef | ⇐ | Window reference number |

## Description

**Open window** opens a new window with the dimensions given by the first four parameters:

- *left* is the distance in pixels from the left edge of the application window to the left internal edge of the window.
- *top* is the distance in pixels from the top of the application window to the top internal edge of the window.
- *right* is the distance in pixels from the left edge of the application window to the right internal edge of the window.
- *bottom* is the distance in pixels from the top of the application window to the bottom internal edge of the window.

**Compatibility note: Open window** integrates various options which have evolved over the versions, and is now only kept for compatibility reasons. When you write new code for managing windows, we strongly recommended using the **Open form window** command, which is better suited to current interfaces.

If you pass -1 in both *right* and *bottom,* you instruct 4D to automatically size the window under the following conditions:

- You have designed a form and set its Sizing Options in the Design environment Form properties window
- Before calling **Open window**, you selected the form using the **FORM SET INPUT** command, to which you passed the optional * parameter.

**Important:** This automatic sizing of the window will occur only if you made a prior call to **FORM SET INPUT** for the form to be displayed, and if you passed the * optional parameter to **FORM SET INPUT**.

- The *type* parameter is optional. It represents the type of window you want to display, and corresponds to the different windows shown in the section **Window Types** (constants of the **Open Window** theme). If the window type is negative, the window created is a floating window. If the type is not specified, type 1 is used by default.
- The *title* parameter is the optional title for the window

If you pass an empty string ("") in *title,* you instruct 4D to use the Window Title set in the Design environment Form Properties window for the form to be displayed.

**Important:** The default form title will be set to the window only if you made a prior call to **FORM SET INPUT** for the form to be displayed, and if you passed the * optional parameter to **FORM SET INPUT**.

- The *controlMenuBox* parameter is the optional Control-menu box method for the window. If this parameter is specified, a Control-menu box (Windows) or a Close Box (Macintosh) is added to the window. When the user double-clicks the Control-menu box (Windows) or clicks on the Close Box (Macintosh), the method passed in *controlMenuBox* is called.

**Note:** You can also manage the closing of the window from within the form method of the form displayed in the window when an On Close Box event occurs. For more information, see the command **Form event**.

If more than one window is open for a process, the last window opened is the active (frontmost) window for that process. Only information within the active window can be modified. Any other windows can be viewed. When the user types, the active window will always come to the front, if it is not already there.

Forms are displayed inside an open window. Text from the **MESSAGE** command also appears in the window.

**Open window** returns a *WinRef* type window reference, which can be used by window management commands (see the "**WinRef**" section).

## Example 1

The following project method opens a window centered in the main window (Windows) or in the main screen (Macintosh). Note that it can accept two, three, or four parameters:

```
  ` OPEN CENTERED WINDOW project method
  ` $1 - Window width
  ` $2 - Window height
  ` $3 - Window type (optional)
  ` $4 - Window title (optional)
$SW:=Screen width¥2
$SH:=(Screen height¥2)
$WW:=$1¥2
$WH:=$2¥2
Case of
   :(Count parameters=2)
      Open window($SW-$WW;$SH-$WH;$SW+$WW;$SH+$WH)
   :(Count parameters=3)
      Open window($SW-$WW;$SH-$WH;$SW+$WW;$SH+$WH;$3)
   :(Count parameters=4)
      Open window($SW-$WW;$SH-$WH;$SW+$WW;$SH+$WH;$3;$4)
End case
```

After the project method is written, you can use it this way:

```
OPEN CENTERED WINDOW(400;250;Movable dialog box;"Update Archives")
DIALOG([Utility Table];"UPDATE OPTIONS")
CLOSE WINDOW
If(OK=1)
  ` ...
End if
```

## Example 2

The following example opens a floating window that has a Control-menu box (Windows) or Close Box (Macintosh) method. The window is opened in the upper right hand corner of the application window.

```
$myWindow:=Open window(Screen width-149;33;Screen width-4;178;-Palette window;"";"CloseColorPalette")
DIALOG([Dialogs];"Color Palette")
```

The ***CloseColorPalette*** method calls the **CANCEL** command:

```
CANCEL
```

## Example 3

The following example opens a window whose size and title come from the properties of the form displayed in the window:

```
FORM SET INPUT([Customers];"Add Records";*)
$myWindow:=Open window(10;80;-1;-1;Plain window;"")
Repeat
   ADD RECORD([Customers])
Until(OK=0)
```

**Reminder:** In order to have **Open window** automatically use the properties of the form, you must call **FORM SET INPUT** with the optional * parameter, and the properties of the form must have been set accordingly in the Design environment.

## Example 4

This example illustrates the “delay” mechanism for displaying sheet windows under Mac OS X:

```
$myWindow:=Open window(10;10;400;400;Sheet window)
  `For the moment, the window is created but remains hidden
DIALOG([Table];"dialForm")
  `The On Load event is generated then the sheet window is displayed: it "drops down" from the bottom
  `of the title bar
```

# REDRAW WINDOW

REDRAW WINDOW {( window )}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |

## Description

The **REDRAW WINDOW** command provokes a graphical update of the window whose reference number you pass in *window*.

If you omit the *window* parameter, **REDRAW WINDOW** applies to the frontmost window for the current process.

**Note:** 4D handles the graphical updates of the windows each time you move a window, resize it, or bring it to the front, as well as when you change the form and/or the values displayed in the window. You will rarely use this command.

# RESIZE FORM WINDOW

RESIZE FORM WINDOW ( width ; height )

| Parameter | Type | | Description |
|---|---|---|---|
| width | Longint | ⇒ | Pixels to add to or remove from the current form window width |
| height | Longint | ⇒ | Pixels to add to or remove from the current form window height |

## Description

The **RESIZE FORM WINDOW** command lets you change the size of the current form window.

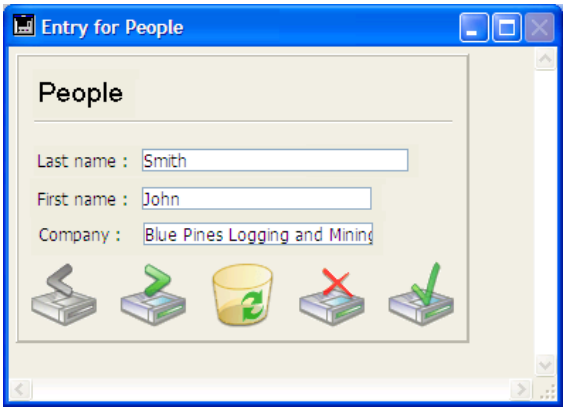
Pass the number of pixels that you would like to add to the current window size in the *width* and *height* parameters. Pass 0 in either parameter if you do not wish to change the current size. To reduce the size, pass a negative value in the *width* and *height* parameters.

This command produces the exact same result as a manual window resize using the resize box (if the window type allows it). As a result, the command takes into consideration resize properties for objects and size limitations defined in the form properties. If, for example, the command resizes a window to a size greater than what is allowed in the form, the command will have no effect.

Please note that this behavior is different than that of the **SET WINDOW RECT** command, which does not take form properties nor content into account when resizing the window. Also, note that this command does not necessarily modify the form size. To modify the size of a form by programming, please see the **FORM SET SIZE** command.

## Example

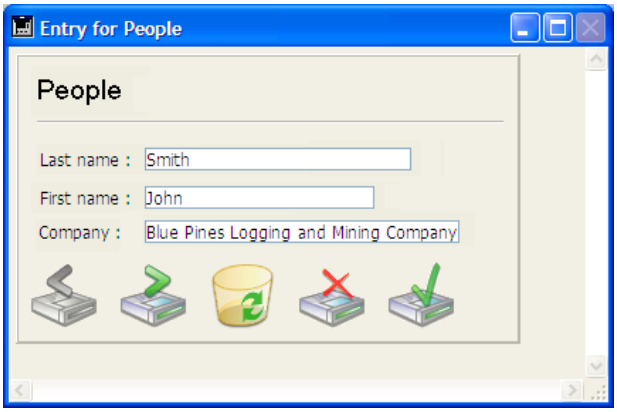
Given the following window (the fields and frame have the “Grow” property for horizontal resizing):



After execution of this line:

```
RESIZE FORM WINDOW(25;0)
```

... the window appears as follows:



# SET WINDOW RECT

SET WINDOW RECT ( left ; top ; right ; bottom {; window}{; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇒ | Global left coordinate of window's contents area |
| top | Longint | ⇒ | Global top coordinate of window's contents area |
| right | Longint | ⇒ | Global right coordinate of window's contents area |
| bottom | Longint | ⇒ | Global bottom coordinate of window's contents area |
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |
| * | Operator | ⇒ | If omitted (default) = change window to foreground<br>If passed = do not change the level of the window |

## Description

The **SET WINDOW RECT** command changes the global coordinates of the the window whose reference number is passed in *window*. If the window does not exist, the command does nothing.

If you omit the *window* parameter, **SET WINDOW RECT** applies to the frontmost window for the current process.

This command can resize and move the window, depending on the new coordinates passed.

The coordinates must be expressed relative to the top left corner of the contents area of the application window (on Windows) or to the main screen (on Macintosh). The coordinates indicate the rectangle corresponding to the contents area of the window (excluding title bars and borders).

**Warning:** Be aware that by using this command, you may move a window beyond the limits of the main window (on Windows) or of the screens (on Macintosh). To prevent this, use commands such as **Screen width** and **Screen height** to double-check the new coordinates of the window.

By default, executing this command automatically moves the window designated by the *window* parameter to the foreground (if this parameter is used). You can disable this by passing the * as the last parameter. In this case, the command no longer changes the original level ("z" coordinate) of the window.

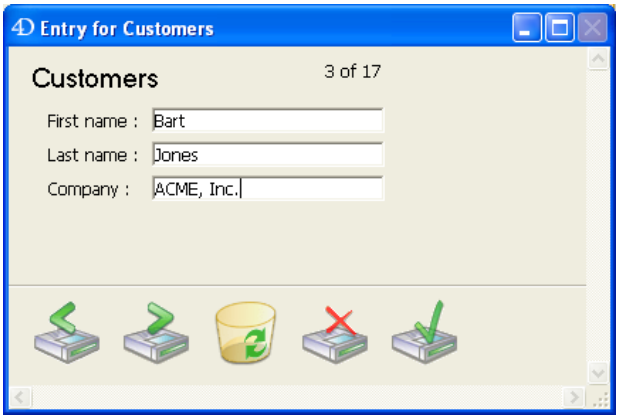
This command does not affect form objects. If the window contains a form, the form objects are not moved or resized by the command (regardless of their properties). Only the window is modified. In order to modify a form window while taking the resizing properties and the objects it contains into account, you must use the **RESIZE FORM WINDOW** command.

## Example 1

See example for the **WINDOW LIST** command.

## Example 2

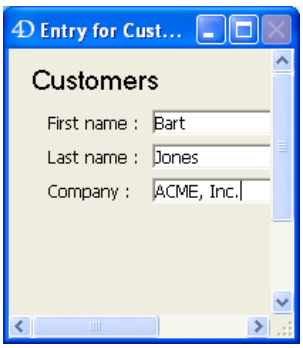
Given the following window:



After execution of the following line:

```
SET WINDOW RECT(100;100;300;300)
```

The window appears as follows:



Entry for Cust...
Customers
First name :
Bart
Last name :
Jones
Company :
ACME, Inc.

# SET WINDOW TITLE

SET WINDOW TITLE ( title {; window} )

| Parameter | Type | | Description |
|---|---|---|---|
| title | String | ⇒ | Window title |
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |

## Description

The **SET WINDOW TITLE** command changes the title of the window whose reference number is passed in *window* to the text passed in *title* (max. length 80 characters).

If the window does not exist, **SET WINDOW TITLE** does nothing.

If you omit the *window* parameter, **SET WINDOW TITLE** changes the title of the frontmost window for the current process.

**Note:** In the Design environment, 4D changes the window titles automatically —i.e., “Entry for Table” when you perform data entry. If you change a window title, 4D will probably override it. On the other hand, in the Application environment, 4D does not change the titles of the windows.

## Example

While performing data entry in a form, you click on a button that executes a lengthy operation (i.e., browsing programmatically related records shown in a subform). You keep informed about the progress of the operation using the title of the current window:

```
  ` bAnalysis button Object Method
Case of
   :(Form event=On Clicked)
  ` Save current window title in a local variable
      $vsCurTitle:=Get window title
  ` Start the lengthy operation
      FIRST RECORD([Invoice Line Items])
      For($vlRecord;1;Records in selection([Invoice Line Items]))
         DO SOMETHING
  ` Show progress information
         SET WINDOW TITLE("Processing Line Item #"+String($vlRecord))
      End for
  ` Restore original window title
      SET WINDOW TITLE($vsCurTitle)
End case
```

# SHOW TOOL BAR

SHOW TOOL BAR
Does not require any parameters

## Description

The **SHOW TOOL BAR** command handles the display of custom toolbars created by the **Open form window** command for the current process.

If a toolbar window has been created by the **Open form window** command with the Toolbar form window option, the command makes this window visible. If the toolbar window was already visible or if no window of this type has been created, the command does nothing.

## Example

Refer to the example of the **HIDE TOOL BAR** command.

# SHOW WINDOW

SHOW WINDOW {( window )}

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number or Current process frontmost window, if omitted |

## Description

The **SHOW WINDOW** command displays the window whose number was passed in *window*. If this parameter is omitted, the frontmost window of the current process will be displayed.

In order to use the **SHOW WINDOW** command, the window must have been hidden by using the **HIDE WINDOW** command. If the window is already displayed, the command does nothing.

## Example

Refer to the example of the **HIDE WINDOW** command.

# Tool bar height

Tool bar height -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| Function result | Longint | ➲ | Height (expressed in pixels) of tool bar or 0 if tool bar is hidden |

## Description

The **Tool bar height** command returns the height of the current visible tool bar, expressed in pixels. Depending on the context, it can be either the 4D Design mode toolbar, or a custom toolbar created with **Open form window** (the Design mode toolbar is automatically hidden when a custom toolbar is displayed).

If no tool bar is displayed, the command returns 0.

# Window kind

Window kind {( window )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number, or Frontmost window of current process, if omitted |
| Function result | Longint | ⇐ | Type of window |

## Description

The **Window kind** command returns the 4D type of the window whose reference number is passed in *window*. If the window does not exist, **Window kind** returns *0* (zero).

Otherwise, **Window kind** may return one of the following predefined constants found in the **Windows** theme:

| Constant | Type | Value |
|---|---|---|
| External window | Longint | 5 |
| Floating window | Longint | 14 |
| Modal dialog | Longint | 9 |
| Regular window | Longint | 8 |

If you omit the *window* parameter, **Window kind** returns the type of the frontmost window for the current process.

## Example

See example for the **WINDOW LIST** command.

# WINDOW LIST

WINDOW LIST ( windows {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| windows | Array | ⇐ | Array of window reference numbers |
| * | Operator | ⇒ | If specified, take floating windows into account If omitted, ignore floating windows |

## Description

The **WINDOW LIST** command populates the array *windows* with the window reference numbers of the windows currently open in all running processes (kernel or user processes).

If you do not pass the optional * parameter, floating windows are ignored.

## Example

The following project method tiles all the current open window, except floating windows and dialog boxes:

```
   ` TILE WINDOWS project method

WINDOW LIST($alWnd)
$vlLeft:=10
$vlTop:=80 ` Leave enough room for the Tool bar
For($vlWnd;1;Size of array($alWnd))
   If(Window kind($alWnd{$vlWnd})#Modal dialog)
      GET WINDOW RECT($vlWL;$vlWT;$vlWR;$vlWB;$alWnd{$vlWnd})
      $vlWR:=$vlLeft+($vlWR-$vlWL)
      $vlWB:=$vlTop+($vlWB-$vlWT)
      $vlWL:=$vlLeft
      $vlWT:=$vlTop
      SET WINDOW RECT($vlWL;$vlWT;$vlWR;$vlWB;$alWnd{$vlWnd})
      $vlLeft:=$vlLeft+10
      $vlTop:=$vlTop+25
   End if
End for
```

**Note:** This method could be improved by adding tests on the size of the main window (on Windows) or the size and location of the screens (on Macintosh).

# Window process

Window process {( window )} -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| window | WinRef | ⇒ | Window reference number |
| Function result | Longint | ⇐ | Process reference number |

## Description

The **Window process** command returns the process number that runs the window whose reference number is passed in *window*. If the window does not exist, 0 (zero) is returned.

If you omit the *window* parameter, **Window process** returns the process of the current frontmost window.

# _o_Open external window

_o_Open external window ( left ; top ; right ; bottom ; type ; title ; plugInArea ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| left | Longint | ⇒ | Global left coordinate of window contents area |
| top | Longint | ⇒ | Global top coordinate of window contents area |
| right | Longint | ⇒ | Global right coordinate of window contents area |
| bottom | Longint | ⇒ | Global bottom coordinate of window contents area |
| type | Longint | ⇒ | Window type |
| title | String | ⇒ | Title of window |
| plugInArea | String | ⇒ | External area command |
| Function result | WinRef | ⇐ | Reference number for window and external area |

## Compatibility note

The **_o_Open external window** command is declared obsolete in 4D beginning with version 16 and is only kept for compatibility reasons. Note that it is not supported in 64-bit versions of 4D.

# XML

- Overview of XML Utilities Commands
- XML DECODE
- XML GET ERROR
- XML GET OPTIONS
- XML SET OPTIONS
- *_o_XSLT APPLY TRANSFORMATION*
- *_o_XSLT GET ERROR*
- *_o_XSLT SET PARAMETER*

# Overview of XML Utilities Commands

This theme groups together the generic XML "utilities" commands of 4D. These are option- and error-management commands as well as commands specialized in XSL.

For general information about XML (overview, glossary) as well as the differences between DOM and SAX modes, please refer to the **Overview of XML DOM Commands** section.

## What is SVG?

SVG (Scalable Vector Graphics) is a file format used to describe vector graphics (extension .svg) in XML. The most common use of SVG is the publication of statistical or mapping data.

These files can be viewed in Web browsers either natively, or via plug-ins. 4D v11 includes an SVG rendering engine that lets you view SVG files in picture fields or variables. The **SVG EXPORT TO PICTURE** command can be used to generate a picture in 4D based on an SVG description. Also note that the **GRAPH** command can be used to take advantage of the integrated SVG engine of 4D.

For more information about this format, please refer to the following address: http://www.w3.org/Graphics/SVG/.

## About XSLT commands

Starting with 4D v14 R4, XSL transformation commands are declared obsolete and prefixed accordingly:

| Former name | 4D v14 R4 and higher |
|---|---|
| XSLT APPLY TRANSFORMATION | **_o_XSLT APPLY TRANSFORMATION** |
| XSLT GET ERROR | **_o_XSLT GET ERROR** |
| XSLT SET PARAMETER | **_o_XSLT SET PARAMETER** |

For compatibility, XSL transformations are still supported by 4D but their use is no longer recommended. In future versions of 4D, it will no longer be possible to use XSLT technology.

**Note for 4D Server 64-bit version for OS X:** XSLT is not included in the 64-bit version of 4D Server for OS X. As a result, executing one of these commands from this application generates an error 33, "Unimplemented command or function".

To replace XSLT technology in your databases, 4D provides two solutions:

- Using equivalent PHP functions available in the *libxslt* module, which is installed in 4D beginning with version 14.2. 4D provides a specific document to help you use PHP's XSL to replace 4D's XSLT commands: Download the "XSLT with PHP" document (PDF)
- Using the means provided by the **PROCESS 4D TAGS** command, whose capabilities have been expanded considerably starting with 4D v14 R4.

# XML DECODE

XML DECODE ( xmlValue ; 4Dobject )

| Parameter | Type | | Description |
|---|---|---|---|
| xmlValue | Text | ⇒ | Text type value coming from an XML structure |
| 4Dobject | Field, Variable | ⇐ | 4D variable or field receiving the converted XML value |

## Description

The **XML DECODE** command converts a value stored as an XML string into a 4D typed value. The conversion is carried out automatically according to the following rules:

| Value | Examples | Conversion on English system |
|---|---|---|
| number | <Price>8,5</Price><Price>8.5</Price> | Real: 8.5 |
| Boolean | <Double>1</Double> <Double>0</Double> or <Double>true</Double> <Double>false</Double> | Boolean: True/False |
| BLOB | | Base64 decoding |
| Picture | | Base64 decoding + BLOB to picture command |
| Dates | 2009-10-25T01:03:20+01:00 | Deletion of time part as well as time zone: !10/25/2009! |
| Time | 2009-10-25T01:03:20+01:00 | Deletion of date part as well as time zone: ?01:03:20? |

## Example

Importing data from an XML document in which values are stored as attributes.
Example of XML document:

```
<CD Date="2003-01-01T00:00:00Z"
Description="This double CD reissued by EMI in 1995 combines 4 Stabat mater hymns. One by Rossini interpreted by the Berlin Symphony Orchestra, directed by Karl Forster. Followed by a work of Verdi, by the Philharmonic Orchestra, directed by Carlo Maria Giulini. On the second CD, you will find Francis Poulenc interpreted by Régine Crespin. This compilation ends with a little-known version, that of the Polish composer Karol Szymanowski. Polish National Radio Symphony Orchestra directed by Antoni Wit"
Double="true"
Duration="7246"
Type="Sacred music"
CD_ID="5" Performer="Various"
Price="8.5"
Title="4 Stabat mater"/>
```

```
Repeat
   MyEvent:=SAX Get XML node(DocRef)

   Case of
      :(MyEvent=XML Start Element)
         ARRAY TEXT(arrAttrNames;0)
         ARRAY TEXT(arrAttrValues;0)
         SAX GET XML ELEMENT(DocRef;vName;vPrefix;arrAttrNames;arrAttrValues)
         If(vName="CD")
            CREATE RECORD([CD])
            For($i;1;Size of array(arrAttrNames))
               $attrName:=arrAttrNames{$i}
               Case of
                  :($attrName="CD_ID")
                     XML DECODE(arrAttrValues{$i};[CD]CD_ID)
                  :($attrName="Title")
```

```
                    [CD]Work:=arrAttrValues{$i}
                :($attrName="Price")
                    XML DECODE(arrAttrValues{$i};[CD]Price)
                :($attrName="Date")
                    XML DECODE(arrAttrValues{$i};[CD]Date entered)
                :($attrName="Duration")
                    XML DECODE(arrAttrValues{$i};[CD]Total_duration)
                :($attrName="Double")
                    XML DECODE(arrAttrValues{$i};[CD]Double_CD)
            End case
        End for
    End if
    ...
End case
Until(MyEvent=XML End Document)
```

# XML GET ERROR

XML GET ERROR ( elementRef ; errorText {; row {; column}} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇨ | XML element reference |
| errorText | Variable | ⇦ | Text of the error |
| row | Variable | ⇦ | Row number |
| column | Variable | ⇦ | Column number |

## Description

The **XML GET ERROR** command returns, in the *errorText* parameter, a description of the error encountered when processing the XML element designated by the *elementRef* parameter. The information returned is supplied by the Xerces.DLL library.

The optional *row* and *column* parameters indicate the location of the error: they retrieve, respectively, the row number and, in this row, the position of the first character of the expression at the origin of the error.

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# XML GET OPTIONS

XML GET OPTIONS ( elementRef | document ; selector ; value {; selector2 ; value2 ; ... ; selectorN ; valueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef \| document | Text, DocRef | ⇒ | XML root element reference or Reference of open document |
| selector | Longint | ⇒ | Option to get |
| value | Longint | ⇐ | Current value of option |

## Description

The XML GET OPTIONS command is used to get the current value of one or more XML parameters for the current session and the current user.

In selector, pass a constant of the "**XML**" theme indicating the option to get. The current value of the option is returned in the *value* parameter:

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| XML binary encoding | Longint | 5 | Specifies the way binary data will be converted.<br>**Possible values:**<br>• XML Base64 (default value): binary data are simply converted to Base64<br>• XML data URI scheme: binary data are converted to Base64 and the "data:;base64" header is added. This format mainly allows a browser to automatically decode a picture, and is also required for the insertion of pictures. For more information, see http://en.wikipedia.org/wiki/Data_URI_scheme. |
| XML date encoding | Longint | 2 | Specifies the way 4D dates will be converted. For example, !01/01/2003! in the Paris time zone.<br>**Possible values:**<br>• XML ISO (default value): use of the format xs:datetime without indication of time zone. Result: "2003-01-01". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML local: use of the format xs:date with indication of time zone. Result: "2003-01-01 +01:00". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime local: use of the format xs:dateTime (ISO 8601). Indication of time zone. This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00 +01:00</Date>".<br>• XML UTC: use of the format xs:date. Result: "2003-01-01Z". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime UTC: use of the format xs:dateTime (ISO 8601). This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00Z</Date>". |
| XML indentation | Longint | 4 | Specifies the indentation of the XML *document*.<br>**Possible values:**<br>• XML with indentation (default value): the document is indented.<br>• XML no indentation: the document is not indented; its contents are placed in a single line. |
| XML picture encoding | Longint | 6 | Specifies the way pictures must be converted (before encoding in Base64).<br>**Possible values:**<br>• XML convert to PNG (default value): pictures are converted to PNG before being encoded in Base64.<br>• XML native codec: pictures are converted in their first native storage CODEC before being encoded in Base64. You must use these options to encode SVG pictures (see example for the **XML SET OPTIONS** command). |
| XML string encoding | Longint | 1 | Specifies the way 4D strings are converted to element values. It does not concern the conversion to attributes for which XML imposes the use of escape characters.<br>**Possible values:**<br>• XML with escaping (default value): conversion of 4D strings to XML element values with replacement of characters. The Text type data are automatically parsed so that forbidden characters (<&>') are replaced by XML entities (&<>'").<br>• XML raw data: 4D strings are sent as raw data; 4D does not carry out encoding or parsing. 4D values are converted if possible to XML fragments and inserted as a child of the target element. If a value cannot be considered as an XML fragment, it is inserted as raw data into a new CDATA node. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| XML time encoding | Longint | 3 | Specifies the way 4D times are converted. For example, ?02/00/46? (Paris time). The encoding differs depending on whether you want to express a time or a duration.<br>**Possible values for times:**<br>• XML datetime UTC: time expressed in UTC (Universal Time Coordinated). Note that conversion to UTC is automatic. Result: "<Duration>0000-00-00T01:00:46Z</Duration>".<br>• XML datetime local: time expressed with the time difference of the machine of the 4D engine. Result: "<Duration>0000-00-00T02:00:46+01:00</Duration>".<br>• XML datetime local absolute (default value): time expressed without indication of time zone. No modification of the value. Result: "<Duration>0000-00-00T02:00:46</Duration>".<br>**Possible values for durations:**<br>• XML seconds: number of seconds since midnight; no modification of the value since it expresses a duration. Result: "<Duration>7246</Duration>".<br>• XML duration: duration expressed in compliance with XML Schema Part 2: Datatypes Second Edition. No modification of the value since it expresses a duration. Result: "<Duration>PT02H00M46S</Duration>". |

# XML SET OPTIONS

XML SET OPTIONS ( elementRef | document ; selector ; value {; selector2 ; value2 ; ... ; selectorN ; valueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef \| document | Text, DocRef | ⇒ | XML root element reference or Reference of open document |
| selector | Longint | ⇒ | Option to set |
| value | Longint | ⇒ | Value of option |

## Description

The **XML SET OPTIONS** command is used to modify the value of one or more XML options for the structure passed in the first parameter.

This command applies the XML structures of the "tree" type (DOM) or of the "document" type (SAX). In the first parameter, you can pass either a root element reference (*elementRef*), or the reference of an open SAX document (*document*).

The options set by this command are only used in the direction 4D to XML (it has no effect on the reading of XML values in 4D). The following commands use these options:

- **DOM SET XML ATTRIBUTE**
- **DOM SET XML ELEMENT VALUE**
- **SAX ADD XML ELEMENT VALUE**

Pass the option to be modified in *selector* and the new value of the option in *value*. You can pass as many *selector*/*value* pairs as you want.

You must use the constants described below, placed in the "**XML**" theme:

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| XML binary encoding | Longint | 5 | Specifies the way binary data will be converted.<br>**Possible values:**<br>• XML Base64 (default value): binary data are simply converted to Base64<br>• XML data URI scheme: binary data are converted to Base64 and the "data:;base64" header is added. This format mainly allows a browser to automatically decode a picture, and is also required for the insertion of pictures. For more information, see http://en.wikipedia.org/wiki/Data_URI_scheme. |
| XML date encoding | Longint | 2 | Specifies the way 4D dates will be converted. For example, !01/01/2003! in the Paris time zone.<br>**Possible values:**<br>• XML ISO (default value): use of the format xs:datetime without indication of time zone. Result: "2003-01-01". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML local: use of the format xs:date with indication of time zone. Result: "2003-01-01 +01:00". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime local: use of the format xs:dateTime (ISO 8601). Indication of time zone. This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00 +01:00</Date>".<br>• XML UTC: use of the format xs:date. Result: "2003-01-01Z". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime UTC: use of the format xs:dateTime (ISO 8601). This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00Z</Date>". |
| XML indentation | Longint | 4 | Specifies the indentation of the XML *document*.<br>**Possible values:**<br>• XML with indentation (default value): the document is indented.<br>• XML no indentation: the document is not indented; its contents are placed in a single line. |
| XML picture encoding | Longint | 6 | Specifies the way pictures must be converted (before encoding in Base64).<br>**Possible values:**<br>• XML convert to PNG (default value): pictures are converted to PNG before being encoded in Base64.<br>• XML native codec: pictures are converted in their first native storage CODEC before being encoded in Base64. You must use these options to encode SVG pictures (see example for the **XML SET OPTIONS** command). |
| XML string encoding | Longint | 1 | Specifies the way 4D strings are converted to element values. It does not concern the conversion to attributes for which XML imposes the use of escape characters.<br>**Possible values:**<br>• XML with escaping (default value): conversion of 4D strings to XML element values with replacement of characters. The Text type data are automatically parsed so that forbidden characters (<&>') are replaced by XML entities (&<>'").<br>• XML raw data: 4D strings are sent as raw data; 4D does not carry out encoding or parsing. 4D values are converted if possible to XML fragments and inserted as a child of the target element. If a value cannot be considered as an XML fragment, it is inserted as raw data into a new CDATA node. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| XML time encoding | Longint | 3 | Specifies the way 4D times are converted. For example, ?02/00/46? (Paris time). The encoding differs depending on whether you want to express a time or a duration.<br>**Possible values for times:**<br>• XML datetime UTC: time expressed in UTC (Universal Time Coordinated). Note that conversion to UTC is automatic. Result: "<Duration>0000-00-00T01:00:46Z</Duration>".<br>• XML datetime local: time expressed with the time difference of the machine of the 4D engine. Result: "<Duration>0000-00-00T02:00:46+01:00</Duration>".<br>• XML datetime local absolute (default value): time expressed without indication of time zone. No modification of the value. Result: "<Duration>0000-00-00T02:00:46</Duration>".<br>**Possible values for durations:**<br>• XML seconds: number of seconds since midnight; no modification of the value since it expresses a duration. Result: "<Duration>7246</Duration>".<br>• XML duration: duration expressed in compliance with XML Schema Part 2: Datatypes Second Edition. No modification of the value since it expresses a duration. Result: "<Duration>PT02H00M46S</Duration>". |

**Notes:**

- The XML local and XML datetime local values do not provide dates expressed in UTC (Universal Time Coordinated); they are converted without modification but indicating the time difference. These formats are useful in the case of successive and reciprocal conversions (round tripping).
- The XML UTC and XML datetime UTC values are equivalent to the previous from the formatting viewpoint, but are expressed in UTC. These formats should be given priority to ensure interoperability. The values are not modified.

## Example

Insertion of an SVG picture:

```
XML SET OPTIONS($pictElemRef;XML binary encoding;XML data URI scheme)
XML SET OPTIONS($pictElemRef;XML picture encoding;XML native codec)
DOM SET XML ATTRIBUTE($pictElemRef;"xlink:href";PictVar)
```

# _o_XSLT APPLY TRANSFORMATION

_o_XSLT APPLY TRANSFORMATION ( xmlSource ; xslSheet ; result {; compileSheet} )

| Parameter | Type | | Description |
|---|---|---|---|
| xmlSource | String, BLOB | ⇒ | Name or access path of XML source document, or BLOB containing the XML source |
| xslSheet | String, BLOB | ⇒ | Name or access path of document containing XSL stylesheet, or BLOB containing the XSL stylesheet |
| result | String, BLOB | ⇒ | Name or access path of the document receiving the result of the XSLT transformation, or BLOB receiving the result of the XSLT transformation |
| compileSheet | Boolean | ⇒ | True = Optimize XSLT transformation False or omitted = No optimization, remove the compiled XSL file (if any) |

## Compatibility note

*Starting with 4D v14 R4, XSL transformation commands are obsolete. For compatibility, they are still supported in 4D but we strongly recommend that you discontinue using them. In future versions of 4D, it will no longer be possible to use XSLT technology. For more information, please refer to the* **Overview of XML Utilities Commands***.*

# _o_XSLT GET ERROR

_o_XSLT GET ERROR ( errorText {; row {; column}} )

| Parameter | Type | | Description |
|---|---|---|---|
| errorText | Variable | ⇦ | Text of the error |
| row | Variable | ⇦ | Row number |
| column | Variable | ⇦ | Column number |

## Compatibility note

*Starting with 4D v14 R4, XSL transformation commands are obsolete. For compatibility, they are still supported in 4D but we strongly recommend that you discontinue using them. In future versions of 4D, it will no longer be possible to use XSLT technology. For more information, please refer to the* **Overview of XML Utilities Commands**.

# _o_XSLT SET PARAMETER

_o_XSLT SET PARAMETER ( paramName ; paramValue )

| Parameter | Type | | Description |
|---|---|---|---|
| paramName | String | ➡ | Name of the parameter to look for in the XSL sheet |
| paramValue | String | ➡ | Value of the parameter to use in the transformed document |

## Compatibility note

*Starting with 4D v14 R4, XSL transformation commands are obsolete. For compatibility, they are still supported in 4D but we strongly recommend that you discontinue using them. In future versions of 4D, it will no longer be possible to use XSLT technology. For more information, please refer to the* **Overview of XML Utilities Commands***.*

# Overview of XML DOM Commands

4D includes a set of commands used for parsing objects containing XML (eXtensible Markup Language) data.

**Note concerning preemptive mode:** XML references created by a preemptive process can only be used in that specific process. Conversely, XML references created by a cooperative process can be used by any other cooperative process, but cannot be used by any preemptive process.

## About the XML language

The XML language is a data exchange standard. It is based on the use of tags and enables precise description of the data exchanged as well as their structure. XML files are Text format files; their content is parsed by the applications importing the data. Many applications now support this format.

For more information about XML, refer, for instance, to the http://xml.org and http://www.w3.org sites.

For XML support, 4D uses a library named Xerces.dll developed by the Apache Foundation company. 4D supports XML version 1.0.

**Note**: 4D allows direct importing and exporting of data in XML format using the import/export editor.

## DOM and SAX

The commands of this theme are prefixed DOM. In fact, 4D offers two separate sets of XML commands, prefixed DOM and SAX: DOM (Document Object Model) and SAX (Simple API XML) are two different parsing modes for XML documents.

- The DOM mode parses an XML source and builds its structure (its “tree”) in memory. Because of this, access to each element of the source is extremely fast. However, since the entire tree structure is stored in memory, the processing of large XML documents may lead to the memory capacity being exceeded and thus provoke errors.
- The SAX mode does not build a tree structure in memory. In this mode, “events” (such as the start and end of an element) are generated when parsing the source. This mode lets you parse XML documents of any size, regardless of the amount of memory available. The SAX commands are grouped together in the "**XML SAX**" theme. For more information, please refer to the **Overview of XML SAX Commands** section.

For more information on XML standards, consult the following sites: http://www.saxproject.org/?selected=event and http://www.w3schools.com/xml/.

## Creating, opening and closing XML documents via DOM

Objects created, modified or parsed by the 4D DOM commands can be text, URLs, documents or BLOBs. The DOM commands used for opening XML objects in 4D are **DOM Parse XML source** and **DOM Parse XML variable**.

Many commands then let you read, parse and write the elements and attributes. Errors are recovered using the **DOM Parse XML variable** command (common to both XML standards).

The **XML GET ERROR** command lets you close the source in the end.

**Note about use of XML BLOB parameters:** XML structures are based on Text type data so it is recommended to use Text type fields or variables to work with them. For historical reasons, the XML commands of 4D (for example **DOM Parse XML variable**) accept BLOB type parameters. In previous versions of 4D, the size of Text type variables was limited to 32 KB. Starting with version 11 of 4D, Text fields and variables can contain up to 2 GB of data. Since the previous limitation was removed, it is now highly inadvisable to store text in BLOBs. The use of BLOBs is reserved for processing binary data. In conformity with XML specifications, beginning with 4D v12, binary data are automatically encoded in Base64, even when the BLOB contains text.

## Use of XPath notation (DOM)

Three XML DOM commands (**DOM Create XML element**, **DOM Find XML element** and **DOM SET XML ELEMENT VALUE**) accept XPath notation for accessing XML elements.
XPath notation comes from the XPath language, designed to navigate within XML structures. It allows the setting of elements directly within an XML structure via a "pathname" type syntax, without necessarily having to indicate the complete pathname in order to reach it. For example, given the following structure:

```
<RootElement>      <Elem1>          <Elem2>            <Elem3 Font=Verdana Size=10> </Elem3>          </Elem2>
   </Elem1>    </RootElement>
```

XPath notation allows you to access element 3 using the */RootElement/Elem1/Elem2/Elem3* syntax.

4D also accepts **indexed** XPath elements using the *Element[ElementNum]* syntax. For example, given the following structure:

```
<RootElement>      <Elem1>          <Elem2>aaa</Elem2>          <Elem2>bbb</Elem2>          <Elem2>ccc</Elem2>
   </Elem1>    </RootElement>
```

XPath notation allows you to access the “ccc” value using the */RootElement/Elem1/Elem2[3]* syntax.

For an illustration of XPath notation, please refer to the examples in the **DOM Create XML element** and **DOM Find XML element** commands.

## Character Sets

The following character sets are supported by the XML DOM and XML SAX commands of 4D:

- ASCII
- UTF-8
- UTF-16 (Big/Small Endian)
- UCS4 (Big/Small Endian)
- EBCDIC code pages IBM037, IBM1047 and IBM1140 encodings,
- ISO-8859-1 (or Latin1)
- Windows-1252.

## Terminology

The XML language uses a number of specific terms and acronyms. This non-exhaustive list details the main XML concepts used by the commands and functions of 4D.

**Attribute**: an XML sub-tag associated with an element. An attribute always contains a name and a value (see diagram below).

**Child**: In an XML structure, an element in a level directly below another.

**DTD**: Document Type Declaration The DTD records the set of specific rules and properties that the XML must follow. These rules define, more particularly, the name and content of each tag as well as its context. This formalization of the elements can be used to check whether an XML document is in compliance (in which case, it is declared “valid”).
The DTD may be included in the XML document (internal DTD) or in a separate document (external DTD). Note that the DTD is not mandatory.

**Element**: an XML tag. An element always contains a name and a value. Optionally, an element may contain attributes (see diagram).

**ElementRef**: XML reference used by the 4D XML commands to specify an XML structure. This reference is made up of 8 coded characters in hexadecimal form, which means that its length is either 16 or 32 characters depending on whether you use a 32- or 64-bit system. It is recommended to declare XML references using the **C_TEXT** directive.

**Parent**: In an XML structure, an element in a level directly above another.

**Parsing**, **parser**: The act of analyzing the contents of a structured object in order to extract useful information. The commands of the “XML” theme are used to parse the contents of any XML objects.

**Root**: An element located at the first level of an XML structure.

**Sibling**: In an XML structure, an element at the same level as another.

**Structure XML**: structured XML object. This object can be a document, a variable, or an element.

**Validation**: An XML document is “validated” by the parser when it is “well-formed” and in compliance with the DTD specifications. See also Well-formed.

**Well-formed**: An XML document is declared “well-formed” by the parser when it complies with the generic XML specifications. See also Validation.

**XML**: eXtensible Markup Language. A computerized data exchange standard enabling the transfer of data as well as their structure. The XML language is based on the use of tags and a specific syntax, in keeping with the HTML language. However, unlike the latter, the XML language allows the definition of customized tags.

**XSL**: eXtensible Stylesheet Language. A language permitting the definition of style sheets used to process and display the contents of an XSL document.

## Error Handling

Many functions in this theme return an XML element reference. If an error occurs during function execution (for example, if the root element reference is not valid), the OK variable is set to 0 and an error is generated.

In addition, the reference returned in this case is a sequence of zero "0" characters (16 characters in 32 bits, and 32 characters in 64 bits).

# DOM Append XML child node

DOM Append XML child node ( elementRef ; childType ; childValue ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | Text | ⇒ | XML element reference |
| childType | Longint | ⇒ | Type of child to append |
| childValue | Text, BLOB | ⇒ | Text or variable (Text or BLOB) whose value must be inserted as child node |
| Function result | Text | ⇐ | Reference of child XML element |

## Description

The **DOM Append XML child node** command is used to append the *childValue* value to the XML node designated by *elementRef*.

The type of node created is specified by the *childType* parameter. In this parameter you can pass one of the following constants, located in the "**XML**" theme:

| Constant | Type | Value |
|---|---|---|
| XML CDATA | Longint | 7 |
| XML comment | Longint | 2 |
| XML DATA | Longint | 6 |
| XML DOCTYPE | Longint | 10 |
| XML ELEMENT | Longint | 11 |
| XML processing instruction | Longint | 3 |

In *childValue*, pass the data to be inserted. You can pass a string or a 4D variable (string or BLOB). The contents of this parameter will always be converted into text.

**Note:** If the *elementRef* parameter designates the Document node (top level node), the command inserts a "Doctype" node before any other node. The same goes for processing instructions and comments, which are always inserted before the root node (but after the Doctype node).

## Example 1

Adding a text type node:

```
Reference:=DOM Create XML element(elementRef;"myElement")
DOM SET XML ELEMENT VALUE(Reference;"Hello")
temp:=DOM Create XML element(Reference;"br")
temp:=DOM Append XML child node(Reference;XML DATA;"New")
temp:=DOM Create XML element(Reference;"br")
temp:=DOM Append XML child node(Reference;XML DATA;"York")
```

Result:

```
<myElement>Hello<br/>New<br/>York</myElement>
```

## Example 2

Adding a processing instruction type node:

```
$Txt_instruction:="xml-stylesheet type = ¥"text/xsl¥" href=¥"style.xsl¥""
Reference:=DOM Append XML child node(elementRef;XML Processing Instruction;$Txt_instruction)
```

Result (inserted before first element):

```
<?xml-stylesheet type="text/xsl" href="style.xsl"?>
```

## Example 3

Adding a comment type node:

```
Reference:=DOM Append XML child node(elementRef;XML_Comment;"Hello world")
```

Result:

```
<!--Hello world-->
```

## Example 4

Adding a CDATA type node:

```
Reference:=DOM Append XML child node(elementRef;XML_CDATA;"12 < 18")
```

Result:

```
<element><![CDATA[12 < 18]]></element>
```

## Example 5

Adding or replacing a Doctype declaration type node:

```
Reference:=DOM Append XML child node(elementRef;XML_DOCTYPE;"Books SYSTEM ¥"Book.DTD¥"")
```

Result (inserted before first element):

```
<!DOCTYPE Books SYSTEM "Book.DTD">
```

## Example 6

Adding or replacing an Element type node.

- if the *childValue* parameter is an XML fragment, it is inserted as child nodes:

  ```
  Reference:=DOM Append XML child node(elementRef;XML_ELEMENT;"<child>simon</child><child>eva</child>")
  ```

  Result:

  ```
  <parent>    <child>simon</child>    <child>eva</child> </parent>
  ```

- otherwise, a new blank child element is appended:

  ```
  Reference:=DOM Append XML child node(elementRef;XML_ELEMENT;"tbreak")
  ```

  Result:

  ```
  <parent>    <tbreak/> </parent>
  ```

If the contents of *childValue* are not valid, an error is returned.

# DOM Append XML element

DOM Append XML element ( targetElementRef ; sourceElementRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| targetElementRef | Text | ⇒ | Reference of XML parent element |
| sourceElementRef | Text | ⇒ | Reference of XML element to append |
| Function result | Text | ⇐ | Reference of new XML element |

## Description

The **DOM Append XML element** command is used to add a new XML element to the children of the XML element whose reference is passed in the *targetElementRef* parameter.

In the *sourceElementRef* parameter, pass the element to be added. This element must be passed as the reference of an existing XML element in a DOM tree. It is added after the last existing child element of *targetElementRef*.

## Example

See the example of the **DOM Insert XML element** command.

# DOM CLOSE XML

DOM CLOSE XML ( elementRef )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇨ | XML root element reference |

## Description

The **DOM CLOSE XML** command frees up the memory occupied by the XML object designated by *elementRef*.
If *elementRef* is not an XML root object, an error is generated.

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM Count XML attributes

DOM Count XML attributes ( elementRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ➡ | XML element reference |
| Function result | Longint | ⮌ | Number of attributes |

## Description

The **DOM Count XML attributes** command returns the number of XML attributes present in the XML element designated by *elementRef*. For more information about XML attributes, refer to the **Overview of XML DOM Commands** section.

## Example

Before retrieving the values of elements in an array, you want to know the number of attributes in the following XML element:

```
<?xml version="1.0" ?>
- <LINES>
  <LINE N="1" Font="Verdana" size="10">this is a line</LINE>
  <LINE N="2" Font="charcoal" size="12">and another line</LINE>
  <LINE N="3" Font="Verdana" size="18">and we stop here</LINE>
</LINES>
```

```
C_BLOB(myBlobVar)
C_TEXT($xml_Parent_Ref;$xml_Child_Ref)
C_TEXT(myResult)
C_LONGINT($numAttributes)

$xml_Parent_Ref:=DOM Parse XML variable(myBlobVar)
$xml_Child_Ref:=DOM Get first child XML element($xml_Parent_Ref)

$numAttributes:=DOM Count XML attributes($xml_Child_Ref)
ARRAY TEXT(tAttrib;$numAttributes)
ARRAY TEXT(tValAttrib;$numAttributes)
For($i;1;$numAttributes)
   DOM GET XML ATTRIBUTE BY INDEX($xml_Child_Ref;$i;tAttrib{$i};tValAttrib{$i})
End for
```

In the above example, $numAttributes equals 3, tAttrib{1} contains “Font”, tAttrib{2} contains “N”, tAttrib{3} contains “size” and tValAttrib contains “Verdana”, “1” and “10”.

**Note:** The index number does not correspond to the location of the attribute in the XML file displayed in text form. In XML, the index of an attribute indicates its position among the attributes arranged in alphabetical order (according to their name).

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM Count XML elements

DOM Count XML elements ( elementRef ; elementName ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| elementName | String | ⇒ | Name of XML elements to count |
| Function result | Longint | ⇐ | Number of elements |

## Description

The **DOM Count XML elements** command returns the number of “child” elements dependent on the *elementRef* parent element and named *elementName*.

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM Create XML element

DOM Create XML element ( elementRef ; xPath {; attribName ; attrValue} {; attribName2 ; attrValue2 ; ... ; attribNameN ; attrValueN} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | Root XML element reference |
| xPath | Text | ⇒ | XPath path of the XML element to create |
| attribName | String | ⇒ | Attribute to set |
| attrValue | String, Boolean, Longint, Real, Time, Date | ⇒ | New attribute value |
| Function result | String | ⇐ | Reference of the created XML element |

## Description

The **DOM Create XML element** command creates a new element in the XML element *elementRef* in the path set by the *xPath* parameter and adds attributes to it if necessary.

Pass the root element reference in *elementRef* (created, for example, using the **DOM Create XML Ref** command).

In *xPath*, pass the access path in XPath notation of the element to create (see the “Use of XPath notation” paragraph in the **Overview of XML DOM Commands** section). If any path elements do not exist, they are created.

It is possible to pass a simple item name directly in the *xPath* parameter in order to create a sub-item from the current item (see example 3).

**Note:** If you have defined one or more namespaces for the tree set using *elementRef* (see the **DOM Create XML Ref** command), you must precede the *xPath* parameter with the namespace to be used (for example, “MyNameSpace:MyElement”).

You can pass attribute/attribute value pairs (in the form of variables, fields or literal values) in the optional *attrName* and *attrValue* parameters. You can pass as many pairs as you want.

The *attrValue* parameter can be of the text type or another type (Boolean, integer, real, date or time). If you pass a value other than text, 4D handles its conversion to text, according to the following principles:

| Type | Example of converted value |
|---|---|
| Boolean | "true" or "false" |
| Integer | "123456" |
| Real | "12.34" (the decimal separator is always ".") |
| Date | "2006-12-04T00:00:00Z" (RFC 3339 standard) |
| Time | "5233" (number of seconds) |

The command returns the XML reference of the element created as a result.

## Example 1

We want to create the following element:

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <RootElement>    <Elem1>        <Elem2>            <Elem3> </Elem3>
        <Elem3> </Elem3>        </Elem2>    </Elem1> </RootElement>
```

To do so, simply write:

```
C_TEXT(vRootRef;vElemRef)
vRootRef:=DOM Create XML Ref("RootElement")
vxPath:="/RootElement/Elem1/Elem2/Elem3"
vElemRef:=DOM Create XML element(vRootRef;vxPath)
vxPath:="/RootElement/Elem1/Elem2/Elem3[2]"
vElemRef:=DOM Create XML element(vRootRef;vxPath)
```

## Example 2

We want to create the following element (containing attributes):

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <RootElement>    <Elem1>       <Elem2>          <Elem3 Font=Verdana Size=10> </Elem3>       </Elem2>    </Elem1> </RootElement>
```

To do so, simply write:

```
C_TEXT(vRootRef;vElemRef)
C_TEXT($aAttrName1;$aAttrName2;$aAttrVal1;$aAttrVal2)
$aAttrName1:="Font"
$aAttrName2:="Size"
$aAttrVal1:="Verdana"
$aAttrVal2:="10"

vRootRef:=DOM Create XML Ref("RootElement")
vxPath:="/RootElement/Elem1/Elem2/Elem3"
vElemRef:=DOM Create XML element(vRootRef;vxPath;$aAttrName1;$aAttrVal1;$aAttrName2;$aAttrVal2)
```

## Example 3

We want to create and export the following structure:

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <Root>    <Elem1>Hello</Elem1> </Root>
```

We want to use the syntax based on a simple item name. To do this, simply write:

```
C_TEXT($root)
C_TEXT($ref1)

$root:=DOM Create XML Ref("Root")
$ref1:=DOM Create XML element($root;"Elem1")
DOM SET XML ELEMENT VALUE($ref1;"Hello")
DOM EXPORT TO FILE($root;"mydoc.xml")
DOM CLOSE XML($root)
```

## System variables and sets

If the command was executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

## Error management

An error is generated when:

- The root element reference is invalid.
- The name of the element to create is invalid (for example, if it starts with a number).

# DOM Create XML element arrays

DOM Create XML element arrays ( elementRef ; xPath {; attribNamesArray ; attribValuesArray} {; attribNamesArray2 ; attribValuesArray2 ; ... ; attribNamesArrayN ; attribValuesArrayN} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | Text | ⇒ | XML root element reference |
| xPath | Text | ⇒ | XPath path of the XML element to create |
| attribNamesArray | String array | ⇒ | Array of attribute names |
| attribValuesArray | String array | ⇒ | Array of attribute values |
| Function result | Text | ⇐ | Reference of created XML element |

## Description

The **DOM Create XML element arrays** command is used to add a new element in the *elementRef* XML element, as well as, optionally, attributes and their values in the form of arrays.

Apart from supporting arrays (see below), this command is identical to **DOM Create XML element**. Please refer to the description of this command for the details of its functioning.

Optionally, this command can be used to pass several pairs of attributes and attribute values as arrays in the *attribNamesArray* and *attribValuesArray* parameters. In *attribValuesArray*, you can pass arrays of the text, date, number, and picture type. 4D automatically carries out the necessary conversions; you can modify these conversions using the **XML SET OPTIONS** command.

The arrays must have been created beforehand and function by pairs. You can pass as many pairs of arrays and as many elements in each pair as you want.

## Example

We want to create the following element:

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <RootElement>    <Elem1>       <Elem2>          <Elem3
Font="Verdana" Size="10" Style="Bold"></Elem3>       </Elem2>    </Elem1> </RootElement>
```

For this, you can simply write:

```
ARRAY TEXT(arrAttNames;3)
ARRAY TEXT(arrAttValues;3)
arrAttNames{1}:="Font"
arrAttValues{1}:="Verdana"
arrAttNames{2}:="Size"
arrAttValues{2}:="10"
arrAttNames{3}:="Style"
arrAttValues{3}:="Bold"
vRootRef:=DOM Create XML Ref("RootElement")
vxPath:="/RootElement/Elem1/Elem2/Elem3"
vElementRef:=DOM Create XML element arrays(vRootRef;vxPath;arrAttNames;arrAttValues)
```

# DOM Create XML Ref

DOM Create XML Ref ( root {; nameSpace} {; nameSpaceName ; nameSpaceValue} {; nameSpaceName2 ; nameSpaceValue2 ; ... ; nameSpaceNameN ; nameSpaceValueN} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| root | String | ➡ | Name of root element |
| nameSpace | String | ➡ | Value of namespace |
| nameSpaceName | String | ➡ | Namespace name |
| nameSpaceValue | String | ➡ | Namespace value |
| Function result | String | ⬅ | Root XML element reference |

## Description

The **DOM Create XML Ref** command creates an empty XML tree in memory and returns its reference.

Pass the name of the XML tree root element in the *root* parameter.

Pass the declaration of the namespace value of the tree in the optional *nameSpace* parameter (for example, “http://www.4d.com”).
Note that you can prefix the *root* parameter with the namespace name followed by a colon *:* (for example “MyNameSpace:MyRoot”). In this case, the *nameSpace* parameter specifying the namespace value is mandatory.

**Note:** The namespace is a string that allows you to make sure the XML variable names are unique. In general, a URL like http://www.mysite.com/myurl is used. The URL does not necessarily have to be valid, but it does have to be unique.

You can declare one or more additional namespaces in the generated XML tree using *nameSpaceName/nameSpaceValue* pairs. You can pass as many namespace name/value pairs as you want.

**Important:** Remember to call the **DOM CLOSE XML** command in order to free up the memory when you have finished using the XML tree.

## Example 1

Creating a single XML tree:

```
C_TEXT(vElemRef)
vElemRef:=DOM Create XML Ref("MyRoot")
```

This code produces the following result:

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <MyRoot/>
```

## Example 2

Creating an XML tree with a single namespace:

```
C_TEXT(vElemRef)
$Root:="MyNameSpace:MyRoot"
$Namespace:="http://www.4D.com/tech/namespace"
vElemRef:=DOM Create XML Ref($Root;$Namespace)
```

This code produces the following result:

```
<MyNameSpace:MyRoot xmlns:MyNameSpace="http://www.4D.com/tech/namespace"/>
```

## Example 3

Creating an XML tree with several namespaces:

```
C_TEXT(vElemRef)
C_TEXT($aNSName1;$aNSName2;$aNSValue1;$aNSValue2)
$Root:="MyNameSpace:MyRoot"
$Namespace:="http://www.4D.com/tech/namespace"
$aNSName1:="NSName1"
$aNSName2:="NSName2"
$aNSValue1:="http://www.4D.com/Prod/namespace"
$aNSValue2:="http://www.4D.com/Mkt/namespace"
vElemRef:=DOM Create XML Ref($Root;$Namespace;$aNSName1;$aNSValue1;$aNSName2;$aNSValue2)
```

This code produces the following result:

```
<MyNameSpace:MyRoot xmlns:MyNameSpace="http://www.4D.com/tech/nameSpace" NSName1="http://www.4D.com/Prod/namespace"
NSName2="http://www.4D.com/Mkt/namespace"/>
```

## System variables and sets

If the command was executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# DOM EXPORT TO FILE

DOM EXPORT TO FILE ( elementRef ; filePath )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | Root XML element reference |
| filePath | Text | ⇒ | Full access path of the file |

## Description

The **DOM EXPORT TO FILE** command stores an XML tree in a file on disk.

Pass the root element reference to export in the *elementRef* parameter.

Pass the full access path to use or create of the export file in *filePath*. If the file does not already exist, it is created.

If you only pass a file name (without an access path), a search for the file will take place or it will be created next to the structure file.

If you pass an empty string (""), a standard open file and new file dialog box appears.

### Notes about processing end-of-line characters

In XML, line breaks are not significant regardless of whether they are within or between XML elements. Internally, XML uses standard LF characters as line separators.

During import and export operations, line break characters can be converted. During an import, the XML parser replaces CRLF characters (standard line breaks under Windows) with LF characters. During export, LF characters are replaced by CR characters.

If you want to keep carriage returns, you must include them in an XML CDATA element so that they will not be processed by the XML parser. Instead of CRLF characters, you can also use "<br/>" characters, which are explicit carriage returns that will not be processed by the parser.

## Example

This example stores the tree *vElemRef* in the file MyDoc.xml:

```
DOM EXPORT TO FILE(vElemRef;"C:¥¥folder¥MyDoc.xml")
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

## Error management

An error is generated when:

- The element reference is invalid,
- The specified access path is invalid,
- The storage volume returns an error (insufficient disk space, etc.).

# DOM EXPORT TO VAR

DOM EXPORT TO VAR ( elementRef ; vXmlVar )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | Root XML element reference |
| vXmlVar | Text, BLOB | ⇒ | Variable to receive XML tree |

## Description

The **DOM EXPORT TO VAR** command saves an XML tree in a text or BLOB variable.

Pass the root element reference to export in *elementRef*.

Pass the name of the variable that must contain the XML tree in *vXmlVar*. This variable must either be a Text or BLOB type. You can select the type depending on what you plan on doing next or the size that the tree can reach (remember that when not in Unicode mode, Text type variables are limited to 32 K of text, whereas in Unicode mode, this limit is 2 GB).

Keep in mind that if you use a Text variable to store *elementRef* when not in Unicode mode, , it will be encoded using the “current” Mac character set (i.e. Mac Roman on most Western systems). This means that the text returned will lose its original encoding (encoding="xxx"). In this case, the *vVarXml* variable allows you to view or store the code but NOT to generate a valid XML document (using the **SEND PACKET** command for example).

In Unicode mode, the original encoding is kept in the variable.

### Notes about processing end-of-line characters

In XML, line breaks are not significant regardless of whether they are within or between XML elements. Internally, XML uses standard LF characters as line separators.

During import and export operations, line break characters can be converted. During an import, the XML parser replaces CRLF characters (standard line breaks under Windows) with LF characters. During export, LF characters are replaced by CR characters.

If you want to keep carriage returns, you must include them in an XML CDATA element so that they will not be processed by the XML parser. Instead of CRLF characters, you can also use "<br/>" characters, which are explicit carriage returns that will not be processed by the parser.

## Example

This example stores the tree vElemRef in a text variable:

```
C_TEXT(vtMyText)
DOM EXPORT TO VAR(vElemRef;vtMyText)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated (for example, if the element reference is invalid).

# DOM Find XML element

DOM Find XML element ( elementRef ; xPath {; arrElementRefs} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| xPath | Text | ⇒ | XPath path of the element to look for |
| arrElementRefs | String array | ⇐ | List of element references found (if applicable) |
| Function result | String | ⇒ | Reference of the element found (if applicable) |

## Description

The **DOM Find XML element** command looks for specific XML elements in an XML structure. The search starts at the element designated by the *elementRef* parameter.

The XML node to seek is set expressed in XPath notation using the *xPath* parameter (see the "Use of XPath notation" parameter in the **Overview of XML DOM Commands** section). Indexed elements can be used.

**Note:** In conformity with the XML standard, searches will be case sensitive.

The command returns the XML reference of the element found.

When the *arrElementRefs* string array is passed, the command fills it with the list of XML references found. In this case, the command returns the first element of the *arrElementRefs* array as the result. This parameter is useful when several elements with the same name exist at the location specified by the *xPath* parameter.

## Example 1

This example lets you quickly look for an XML element and display its value:

```
vFound:=DOM Find XML element(vElemRef;"Items/Book[15]/Title")
DOM GET XML ELEMENT VALUE(vFound;value)
ALERT("The value of the element is: ¥""+value+"¥"")
```

The same search can also be done as follows:

```
vFound:=DOM Find XML element(vElemRef;"Items/Book[15]")
vFound:=DOM Find XML element(vFound;"Book/Title")
DOM GET XML ELEMENT VALUE(vFound;value)
ALERT("The value of the element is: ¥""+value+"¥"")
```

**Note:** As you can see in the above example, the XPath path must always begin with the name of the current element. This detail is important when you are handling relative XPath paths.

## Example 2

Given the following XML structure:

```
<Root>  <Elem1>  <Elem2>aaa</Elem2>  <Elem2>bbb</Elem2>  <Elem2>ccc</Elem2>  </Elem1> </Root>
```

The following code can be used to retrieve the reference of each Elem2 element in the arrAfound array:

```
ARRAY TEXT(arrAfound;0)
vFound:=DOM Find XML element(vElemRef;"/Root/Elem1/Elem2";arrAfound)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

## Error management

An error is generated when:

- The element reference is invalid
- The specified xPath path is invalid.

# DOM Find XML element by ID

DOM Find XML element by ID ( elementRef ; id ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| id | String | ⇒ | Value of ID attribute of element to look for |
| Function result | String | ⇐ | Reference of the element found (if applicable) |

## Description

The **DOM Find XML element by ID** command searches within an XML document for the element whose id attribute equals the value passed in the *id* parameter.

In *elementRef*, pass the reference of an element in the XML document where you want to perform the search. You can pass the reference of the root element or any other element; the search does not take the position of *elementRef* into account and always searches the whole document.

The command returns the XML reference of the element found as a result.

**Warning:** In XML, the id attribute associates a unique ID to each document element. The value of the id attribute must be a valid XML name and it must be unique among all the elements in the XML document (validity constraint). In order for the **DOM Find XML element by ID** command to work properly, this constraint must be complied with; otherwise, the result is random (the command returns the reference to the first element found in the document).

# DOM Get first child XML element

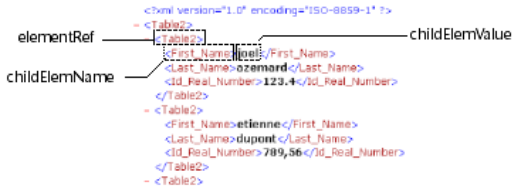
DOM Get first child XML element ( elementRef {; childElemName {; childElemValue}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| childElemName | String | ⇐ | Name of child XML element |
| childElemValue | String | ⇐ | Value of child XML element |
| Function result | String | ⇒ | Child XML element reference (16 characters) |

## Description

The **DOM Get first child XML element** command returns a reference to the first “child” of the XML element passed in *elementRef*. This reference can be used with other XML parsing commands.

The *childElemName* and *childElemValue* parameters, if they are passed, receive respectively the name and the value of the child element.



## Example 1

Retrieval of the reference of the first XML element of the parent root. The XML structure (C:¥¥import.xml) is first loaded into a BLOB:

```
C_BLOB(myBlobVar)
C_TEXT($xml_Parent_Ref;$xml_Child_Ref)

DOCUMENT TO BLOB("c:¥¥import.xml";myBlobVar)
$xml_Parent_Ref:=DOM Parse XML variable(myBlobVar)
$xml_Child_Ref:=DOM Get first child XML element($xml_Parent_Ref)
```

## Example 2

Retrieval of the reference, name and value of the first XML element of the parent root. The XML structure (C:¥¥import.xml) is first loaded into a BLOB:

```
C_BLOB(myBlobVar)
C_TEXT($xml_Parent_Ref;$xml_Child_Ref)
C_TEXT($childName;$childValue)

DOCUMENT TO BLOB("c:¥¥import.xml";myBlobVar)
$xml_Parent_Ref:=DOM Parse XML variable(myBlobVar)
$xml_Child_Ref:=DOM Get first child XML element($xml_Parent_Ref;$childName;$childValue)
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. Otherwise, it is set to 0.

# DOM Get last child XML element

DOM Get last child XML element ( elementRef {; childElemName {; childElemValue}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| childElemName | String | ⇐ | Name of child element |
| childElemValue | String | ⇐ | Value of child element |
| Function result | String | ⇒ | XML element reference (16 characters) |

## Description

The **DOM Get last child XML element** command returns an XML reference to the last “child” of the XML element passed as reference in *elementRef*. This reference may be used with the other XML parsing commands.

The optional *childElemName* and *childElemValue* parameters, when passed, receive respectively the name and value of the “child” element.

## Example

Recovery of the reference of the last XML element of the parent root. The XML structure (C:¥¥import.xml) is loaded into a BLOB beforehand:

```
C_BLOB(myBlobVar)
C_TEXT($ref_XML_Parent;$ref_XML_Child)
C_TEXT($childName;$childValue)

DOCUMENT TO BLOB("c:¥¥import.xml";myBlobVar)
$ref_XML_Parent:=DOM Parse XML variable(myBlobVar)
$ref_XML_Child:=DOM Get last child XML element($ref_XML_Parent;$childName;$childValue)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

# DOM Get next sibling XML element

DOM Get next sibling XML element ( elementRef {; siblingElemName {; siblingElemValue}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| siblingElemName | String | ⇐ | Name of sibling XML element |
| siblingElemValue | String | ⇐ | Value of sibling XML element |
| Function result | String | ⇐ | Sibling XML element reference (16 characters) |

## Description

The **DOM Get next sibling XML element** command returns a reference to the next “sibling” of the XML element passed as reference. This reference can be used with other XML parsing commands.

The *siblingElemName* and *siblingElemValue* parameters, if they are passed, receive respectively the name and the value of the “sibling” element.

This command is used to navigate among the “children” of the XML element.

After the last “sibling,” the system variable OK is set to 0.

## Example 1

Retrieval of the reference of the next sibling XML element following the element passed as parameter:

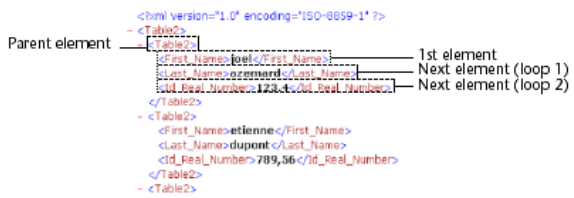
```
C_TEXT($xml_Parent_Ref;$next_XML_Ref)
$next_XML_Ref:=DOM Get next sibling XML element($xml_Parent_Ref)
```

## Example 2

Retrieval in a reference loop of all the child XML elements following the parent element passed as parameter, beginning with the first child:

```
C_TEXT($xml_Parent_Ref;$first_XML_Ref;$next_XML_Ref)

$first_XML_Ref:=DOM Get first child XML element($xml_Parent_Ref)
$next_XML_Ref:=$first_XML_Ref
While(OK=1)
   $next_XML_Ref:=DOM Get next sibling XML element($next_XML_Ref)
End while
```



## System variables and sets

If the command has been correctly executed and if the parsed element is not the last “sibling” of the referenced element, the system variable OK is set to 1. If an error occurs or if the parsed element is the last “sibling” of the referenced element, it is set to 0.

# DOM Get parent XML element

DOM Get parent XML element ( elementRef {; parentElemName {; parentElemValue}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| parentElemName | String | ⇐ | Name of parent XML element |
| parentElemValue | String | ⇐ | Value of parent XML element |
| Function result | String | ⇒ | Parent XML element reference (16 characters) |

## Description

The **DOM Get parent XML element** command returns an XML reference to the “parent” of the XML element passed as reference in *elementRef*. This reference may be used with the other XML parsing commands.

The optional *parentElemName* and *parentElemValue* parameters, when passed, receive respectively the name and value of the parent element.

When you pass a root element in *elementRef*, the command returns the "#document" reference. The document node is the parent of a root element.
If you use this command on a document node, the command returns a null reference ("0000000000000000") and the OK variable is set to 0.

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

# DOM Get previous sibling XML element

DOM Get previous sibling XML element ( elementRef {; siblingElemName {; siblingElemValue}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| siblingElemName | String | ⇐ | Name of sibling XML element |
| siblingElemValue | String | ⇐ | Value of sibling XML element |
| Function result | String | ⇒ | Sibling XML element reference (16 characters) |

## Description

The **DOM Get previous sibling XML element** command returns a reference to the previous “sibling” of the XML element passed as reference. This reference may be used with the other XML parsing commands.

The optional *siblingElemName* and *siblingElemValue* parameters, when passed, receive respectively the name and value of the previous “sibling” element.

This command can be used to navigate among the “children” of an XML element.

Before the first “sibling,” the system variable OK is set to 0.

## System variables and sets

If the command has been executed correctly and if the referenced element is not the first “child” of the structure, the system variable OK is set to 1. If an error occurs or if the element parsed is the first “child” of the structure, it is set to 0.

# DOM Get Root XML element

DOM Get Root XML element ( elementRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| Function result | String | ⇐ | Reference of root element (16 characters) or "" in case of error |

## Description

The **DOM Get Root XML element** command returns a reference to the root element of the document to which the XML element that is passed in the *elementRef* parameter belongs. This reference can be used with the other XML parsing commands.

# DOM GET XML ATTRIBUTE BY INDEX

DOM GET XML ATTRIBUTE BY INDEX ( elementRef ; attribIndex ; attribName ; attribValue )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| attribIndex | Longint | ⇒ | Attribute index number |
| attribName | Variable | ⇐ | Attribute name |
| attribValue | Variable | ⇐ | Attribute value |

## Description

The **DOM GET XML ATTRIBUTE BY INDEX** command gets the name of an attribute specified by its index number as well as its value.

Pass the reference of an XML element in *elementRef* and the index number of the attribute that you want to know the name of in *attribIndex*. The name is returned in the *attribName* parameter and its value is returned in the *attribValue*, parameter. 4D attempts to convert the value obtained into the same type as that of the variable passed as parameter.

**Note:** The index number does not correspond to the location of the attribute in the XML file displayed in text form. In XML, the index of an attribute indicates it position among the attributes when placed in alphabetical order (based on their names). For an illustration of this, refer to the example of the **DOM Count XML attributes** command.

If the value passed in *attribIndex* is greater than the number of attributes present in the XML element, an error is returned.

## Example

Refer to the example in the **DOM Count XML attributes** command.

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM GET XML ATTRIBUTE BY NAME

DOM GET XML ATTRIBUTE BY NAME ( elementRef ; attribName ; attribValue )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ➡ | XML element reference |
| attribName | String | ➡ | Attribute name |
| attribValue | Variable | ⬅ | Attribute value |

## Description

The **DOM GET XML ATTRIBUTE BY NAME** command gets the value of an attribute specified by name.

Pass the reference of an XML element in *elementRef* and the name of the attribute that you want to know the value of in *attribName*. The value is returned in the *attribValue* parameter. 4D attempts to convert the value obtained into the same type as that of the variable passed as parameter.

If no *attribName* attribute exists in the XML element, an error is returned. If several attributes of the XML element have the same name as that specified, only the value of the first attribute is returned.

## Example

This method is used to retrieve the value of an XML attribute using its name:

```
C_BLOB(myBlobVar)
C_TEXT($xml_Parent_Ref;$xml_Child_Ref)
C_LONGINT($LineNum)

$xml_Parent_Ref:=DOM Parse XML variable(myBlobVar)
$xml_Child_Ref:=DOM Get first child XML element($xml_Parent_Ref)
DOM GET XML ATTRIBUTE BY NAME($xml_Child_Ref;"N";$LineNum)
```

If this method is applied to the example below, $LineNum contains the value 1:

```
<?xml version="1.0" ?>
- <STANZA>
    <LINE N="1">I heard a thousand blended notes,</LINE>
    <LINE N="2">While in grove I sate reclined,</LINE>
    <LINE N="3">In that sweet mood when pleasant thoughts</LINE>
    <LINE N="4">Bring sad thoughts to the mind.</LINE>
  </STANZA>
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM GET XML CHILD NODES

DOM GET XML CHILD NODES ( elementRef ; childTypesArr ; nodeRefsArr )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | Text | ⇒ | XML element reference |
| childTypesArr | Longint array | ⇐ | Types of child nodes |
| nodeRefsArr | Text array | ⇐ | References or Values of child nodes |

## Description

The **DOM GET XML CHILD NODES** command returns the types and references or values of all the child nodes of the XML element designated by *elementRef*.

The types of child nodes are returned in the *childTypesArr* array. You can compare the values returned by the command with the following constants, found in the "**XML**" theme:

| Constant | Type | Value |
|---|---|---|
| XML comment | Longint | 2 |
| XML processing instruction | Longint | 3 |
| XML DATA | Longint | 6 |
| XML CDATA | Longint | 7 |
| XML DOCTYPE | Longint | 10 |
| XML ELEMENT | Longint | 11 |

For more information, please refer to the description of the **DOM Append XML child node** command.

The *nodeRefsArr* array receives the values or references of the elements according to their nature (contents or instructions).

## Example

Given the following XML structure:

```
<myElement>Hello<br/>New<br/>York</myElement>
```

After executing these instructions:

```
elementRef:=DOM Find XML element($root;"myElement")
DOM GET XML CHILD NODES(elementRef;$typeArr;$textArr)
```

... the $typeArr and $textArr arrays will contain the following values:

```
$typeArr{1}=6    $textArr{1} = "Hello"
$typeArr{2}=11   $textArr{2} = "AEF1233456878977" (element reference <Br/>)
$typeArr{3}=6    $textArr{3} = "New"
$typeArr{4}=11   $textArr{4} = "AEF1237897734568" (element reference <Br/>)
$typeArr{5}=6    $textArr{5} = "York"
```

# DOM Get XML document ref

DOM Get XML document ref ( elementRef ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | Text | ⇒ | Reference of existing element in DOM tree |
| Function result | Text | ⇐ | Reference of first element of a DOM tree (document node) |

## Description

The **DOM Get XML document ref** command is used to recover the reference of the "document" element of the DOM tree whose reference you have passed in *elementRef*. The document element is the first element of a DOM tree; it is the parent of the root element.

The reference of the document element lets you handle the "Doctype" and "Processing Instruction" nodes. It can only be used with the **DOM Append XML child node** and **DOM GET XML CHILD NODES** commands.

At this level, you can only append processing instructions and comments or replace the *Doctype* node. You cannot create *CDATA* or *Text* nodes there.

## Example

In this example, we want to find the DTD declaration of the XML document:

```
C_TEXT($rootRef)
$rootRef:=DOM Parse XML source("")
If(OK=1)
   C_TEXT($documentRef)
 // we are looking for the document node, since it is the node to which
 // the DOCTYPE node is attached before the root node
   $documentRef:=DOM Get XML document ref($rootRef)
   ARRAY TEXT($typeArr;0)
   ARRAY TEXT($valueArr;0)
 // on this node we look for the DOCTYPE type node among the
 // child nodes
   DOM GET XML CHILD NODES($refDocument;$typeArr;$valueArr)
   C_TEXT($text)
   $text:=""
   $pos:=Find in array($typeArr;XML DOCTYPE)
   If($pos>-1)
 // We retrieve the DTD declaration in $text
      $text:=$text+"Doctype: "+$valueArr{$pos}+Char(Carriage return)
   End if
   DOM CLOSE XML($rootRef)
End if
```

# DOM Get XML element

DOM Get XML element ( elementRef ; elementName ; index ; elementValue ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ➡ | XML element reference |
| elementName | String | ➡ | Name of element to get |
| index | Longint | ➡ | Index number of element to get |
| elementValue | Variable | ⬅ | Value of the element |
| Function result | String | ↩ | XML reference (16 characters) |

## Description

The **DOM Get XML element** command returns a reference to the “child” element dependent on the *elementName* and *index* parameters.

The value of the element is also returned in the *elementValue* parameter.

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM GET XML ELEMENT NAME

DOM GET XML ELEMENT NAME ( elementRef ; elementName )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| elementName | Variable | ⇐ | Name of the element |

## Description

The **DOM GET XML ELEMENT NAME** command returns, in the *elementName* parameter, the name of the XML element designated by *elementRef*. For more information on XML element names, refer to the **Overview of XML DOM Commands** section.

## Example

This method returns the name of the $xml_Element_Ref element:

```
C_TEXT($xml_Element_Ref)
C_TEXT($name)

DOM GET XML ELEMENT NAME($xml_Element_Ref;$name)
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM GET XML ELEMENT VALUE

DOM GET XML ELEMENT VALUE ( elementRef ; elementValue {; cDATA} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇨ | XML element reference |
| elementValue | Variable | ⇦ | Value of the element |
| cDATA | Variable | ⇦ | Contents of the CDATA section |

## Description

The **DOM GET XML ELEMENT VALUE** command returns, in the *elementValue* parameter, the value of the XML element designated by *elementRef*. 4D will attempt to convert the value obtained into the same type as that of the variable passed as parameter.

The optional *cDATA* parameter is used to retrieve the contents of the CDATA section(s) of the *elementRef* XML element. Like with the *elementValue* parameter, 4D will attempt to convert the value obtained into the same type as that of the variable passed as parameter.

**Note:** If the element designated by *elementRef* is a BLOB processed by the **DOM SET XML ELEMENT VALUE** command, it has been automatically encoded in base64. Therefore the command will automatically attempt to decode it in base64.

## Example

This method returns the value of the $xml_Element_Ref element:

```
C_TEXT($xml_Element_Ref)
C_REAL($value)

DOM GET XML ELEMENT VALUE($xml_Element_Ref;$value)
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. If an error occurs, it is set to 0.

# DOM Get XML information

DOM Get XML information ( elementRef ; xmlInfo ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇨ | XML root element reference |
| xmlInfo | Longint | ⇨ | Type of information to get |
| Function result | String | ⇦ | Value of the XML information |

## Description

The **DOM Get XML information** command retrieves diverse information about the XML element designated by *elementRef*.

In *xmlInfo*, pass a code indicating the type of information to be retrieved. You can use the following predefined constants, located in the **XML** theme:

| Constant | Type | Value | Comment |
|---|---|---|---|
| DOCTYPE Name | Longint | 3 | Name of the root element as defined in the DOCTYPE marker |
| Document URI | Longint | 6 | URI of the DTD |
| Encoding | Longint | 4 | Encoding used (UTF-8, ISO...) |
| PUBLIC ID | Longint | 1 | Public identifier (FPI) of the DTD to which the document conforms (if the DOCTYPE xxx PUBLIC tag is present). |
| SYSTEM ID | Longint | 2 | System identifier |
| Version | Longint | 5 | Accepted XML version |

# DOM Insert XML element

DOM Insert XML element ( targetElementRef ; sourceElementRef ; childIndex ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| targetElementRef | Text | ⇒ | Parent XML element reference |
| sourceElementRef | Text | ⇒ | XML element reference to insert |
| childIndex | Longint | ⇒ | Index of child of target element above which the new element must be inserted |
| Function result | Text | ⇐ | Reference of new XML element |

## Description

The **DOM Insert XML element** command can be used to insert a new XML element among the child elements of the XML element whose reference is passed in the *targetElementRef* parameter.

Pass the element to be inserted in *sourceElementRef*. This element must be passed as the reference of an existing XML element in a DOM tree.

The *childIndex* parameter can be used to designate the child of the parent element before which the new element must be inserted. Pass an index number in this parameter. If the value is not valid (for example, there is no child element having this index), the new element will be added before the first child of the parent element.

The command returns the reference of the XML element obtained.

## Example

In the following structure, we would like to invert the first and second book:

```
<?xml version="1.0" encoding="UTF-8" standalone="no" ?> <BookCatalog>   <Book>           <Title>Open Source Web
Services</Title>           <Author>Collective</Author>           <Date>2003</Date>           <ISBN>2-7440-1507-5</ISBN>
      <Publisher>Wrox</Publisher>     </Book> <Book>           <Title>Building XML Web services</Title>
<Author>Scott Short</Author>           <Date>2002</Date>           <ISBN>2-10-006476-2</ISBN>
<Publisher>Microsoft Press</Publisher>     </Book> </BookCatalog>
```

To do this, simply execute the following code:

```
C_TEXT($rootRef)
$rootRef:=DOM Parse XML source("") //selection of XML document
If(OK=1)
   C_TEXT($newStruct)
   $newStruct:=DOM Create XML Ref("BookCatalog")

   $bookRef:=DOM Find XML element($rootRef;"/BookCatalog/Book[1]")
   $newElementRef:=DOM Append XML element($newStruct;$bookRef)

   $bookRef:=DOM Find XML element($rootRef;"/BookCatalog/Book[2]")
   C_TEXT($newElementRef)
   $newElementRef:=DOM Insert XML element($newStruct;$bookRef;1)

   DOM CLOSE XML($newStruct)
   DOM CLOSE XML($rootRef)
End if
```

# DOM Parse XML source

DOM Parse XML source ( document {; validation {; dtd | schema}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | String | ⇒ | Document pathname |
| validation | Boolean | ⇒ | True = Validation False = No validation |
| dtd \| schema | String | ⇒ | Location of the DTD or XML schema |
| Function result | String | ⇐ | Reference of XML element (16 characters) |

## Description

The **DOM Parse XML source** command parses a document containing an XML structure and returns a reference for this document. The command can validate (or not) the document via a DTD or an XML schema (XML Schema Definition (XSD) document).
The document can be located on the disk or on the Internet/Intranet.

**Note:** Execution of the **DOM Parse XML source** command is synchronous.

In the *document* parameter, you can pass:

- either a standard complete pathname (of the type C:¥¥Folder¥¥File¥¥... under Windows and MacintoshHD:Folder:File under Mac OS),
- or a Unix path under Mac OS (which must start with /).
- or a network path of the type http://www.site.com/File or ftp://public.ftp.com...

The Boolean parameter *validation* indicates whether or not to validate the structure.

- If *validation* equals True, the structure is validated. In this case, the parser attempts to validate the XML structure of the document based either on the DTD or XSD reference included in the document, or via the DTD or XML schema designated by the third parameter when it is passed.
- If *validation* equals False, the structure is not validated.

If you pass True in *validation* and omit the third parameter, the command attempts to validate the XML structure via a DTD or XSD reference found in the structure itself. Validation can be indirect: if the structure contains a reference to a DTD file that itself contains a reference to an XSD file, the command attempts to carry out both validations.

The third parameter indicates a specific DTD or an XML schema for document parsing. If you use this parameter, the command does not take the DTD referred to in the XML document into account.

**Validation by DTD**
There are two ways to specify a DTD:

- As a reference. To do this, pass the complete pathname of the new DTD (“dtd” extension) in the *dtd* parameter. If the document indicated does not contain a valid DTD, the *dtd* parameter is ignored and an error is generated.
- Directly in a text. In this case, if the contents of the parameter begin with “<?xml”, 4D will consider that it is the DTD; otherwise, 4D will consider it as a pathname.

**Validation by schema**
To validate the document via an XML schema, you just need to pass a file or URL with an “xsd” extension instead of a “dtd” one in the third parameter. Validation by XML schema is considered to be more flexible and more powerful than validation by DTD. The language of XSD documents is based on XML language. More particularly, XML schemas support data types. For more information about XML schemas, please refer to the following address: *http://www.w3.org/XML/Schema*.

If validation cannot be performed (no DTD or XSD, incorrect URL, etc.), an error is generated. The Error system variable indicates the error number. You can intercept this error using a method installed by the **ON ERR CALL** command.

The command returns a 16-character string (ElementRef) making up the reference in the memory of the document virtual structure. This reference should be used with other XML parsing commands.

**Important:** Once you no longer have any need for it, remember to call the **DOM CLOSE XML** command with this reference in order to free up the memory.

## Example 1

Opening an XML document located on disk, without validation:

```
$xml_Struct_Ref:=DOM Parse XML source("C:¥¥import.xml")
```

## Example 2

Opening an XML document located next to the database structure file, without validation:

```
$xml_Struct_Ref:=DOM Parse XML source("import.xml")
```

## Example 3

Opening an XML document located on disk and validation using a DTD on the disk:

```
$xml_Struct_Ref:=DOM Parse XML source("C:¥¥import.xml";True;"C:¥¥import_dtd.xml")
```

## Example 4

Opening an XML document located at a specific URL, without validation:

```
$xml_Struct_Ref:=DOM Parse XML source("http://www.4D.com/xml/import.xml")
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. Otherwise, it is set to 0.

# DOM Parse XML variable

DOM Parse XML variable ( variable {; validation {; dtd | schema}} ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| variable | BLOB, Text | ➡ | Name of the variable |
| validation | Boolean | ➡ | True = Validation by the DTD, False = No validation |
| dtd \| schema | String | ➡ | Location of the DTD or XML schema |
| Function result | String | ⬅ | Reference of XML element (16 characters) |

## Description

The **DOM Parse XML variable** command parses a BLOB or Text type variable containing an XML structure and returns a reference for this variable. The command can validate (or not) the structure via a DTD or an XML schema (XML Schema Definition (XSD) document).

Pass the name of the BLOB or Text variable containing the XML object in the *variable* parameter.

The Boolean parameter *validation* indicates whether or not to validate the structure.

- If *validation* equals True, the structure is validated. In this case, the parser attempts to validate the XML structure of the document based either on the DTD or XSD reference included in the document, or via the DTD or XML schema designated by the third parameter when it is passed.
- If *validation* equals False, the structure is not validated.

If you pass True in *validation* and omit the third parameter, the command attempts to validate the XML structure via a DTD or XSD reference found in the structure itself. Validation can be indirect: if the structure contains a reference to a DTD file that itself contains a reference to an XSD file, the command attempts to carry out both validations.

The third parameter indicates a specific DTD or an XML schema for document parsing. If you use this parameter, the command does not take the DTD referred to in the XML document into account.

**Validation by DTD**

There are two ways to specify a DTD:

- As a reference. To do this, pass the complete pathname of the new DTD (“dtd” extension) in the *dtd* parameter. If the document indicated does not contain a valid DTD, the *dtd* parameter is ignored and an error is generated.
- Directly in a text. In this case, if the contents of the parameter begin with “<?xml”, 4D will consider that it is the DTD; otherwise, 4D will consider it as a pathname.

**Validation by schema**

To validate the document via an XML schema, you just need to pass a file or URL with an “xsd” extension instead of a “dtd” one in the third parameter. Validation by XML schema is considered to be more flexible and more powerful than validation by DTD. The language of XSD documents is based on XML language. More particularly, XML schemas support data types. For more information about XML schemas, please refer to the following address: *http://www.w3.org/XML/Schema*.

If validation cannot be performed (no DTD or XSD, incorrect URL, etc.), an error is generated. The Error system variable indicates the error number. You can intercept this error using a method installed by the **ON ERR CALL** command.

The command returns a character string (*ElementRef*) making up the reference in the memory of the document virtual structure. This reference should be used with other XML parsing commands.

**Important:** Once you no longer have any need for it, remember to call the **DOM CLOSE XML** command with this reference in order to free up the memory.

## Example 1

Opening an XML object located in a 4D Text variable, without validation:

```
C_TEXT(myTextVar)
C_TIME(vDoc)
C_TEXT($xml_Struct_Ref)

vDoc:=Open document("Document.xml")
If(OK=1)
```

```
   RECEIVE PACKET(vDoc;myTextVar;32000)
   CLOSE DOCUMENT(vDoc)
   $xml_Struct_Ref:=DOM Parse XML variable(myTextVar)
End if
```

## Example 2

Opening an XML document located in a 4D BLOB, without validation:

```
C_BLOB(myBlobVar)
C_TEXT($ref_XML_Struct)

DOCUMENT TO BLOB(c¥¥import.xml;myBlobVar)
$xml_Struct_Ref:=DOM Parse XML variable(myBlobVar)
```

## System variables and sets

If the command has been correctly executed, the system variable OK is set to 1. Otherwise, it is set to 0.

# DOM REMOVE XML ATTRIBUTE

DOM REMOVE XML ATTRIBUTE ( elementRef ; attribName )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | Text | ⇒ | XML element reference |
| attribName | Text | ⇒ | Attribute to be removed |

## Description

The **DOM REMOVE XML ATTRIBUTE** command removes, if it exists, the attribute designated by *attribName* from the XML element whose reference is passed in the *elementRef* parameter.

If the attribute has been correctly removed, the *OK* system variable is set to 1. If no attribute named *attribName* exists in *elementRef*, an error is returned and the *OK* system variable is set to 0.

## Example

Given the following structure:

```
<?xml version="1.0" ?>
- <STANZA>
    <LINE N="1">I heard a thousand blended notes,</LINE>
    <LINE N="2">While in grove I sate reclined,</LINE>
    <LINE N="3">In that sweet mood when pleasant thoughts</LINE>
    <LINE N="4">Bring sad thoughts to the mind.</LINE>
  </STANZA>
```

The following code can be used to remove the first attribute "N=1":

```
C_BLOB(myBlobVar)
C_TEXT($xml_Parent_Ref;$xml_Child_Ref)
C_LONGINT($LineNum)

$xml_Parent_Ref:=DOM Parse XML variable(myBlobVar)
$xml_Child_Ref:=DOM Get first child XML element($xml_Parent_Ref)
DOM REMOVE XML ATTRIBUTE($xml_Child_Ref;"N")
```

# DOM REMOVE XML ELEMENT

DOM REMOVE XML ELEMENT ( elementRef )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇨ | XML element reference |

## Description

The **DOM REMOVE XML ELEMENT** command removes the element designated by *elementRef*.

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.
An error is generated when the element reference is invalid.

# DOM SET XML ATTRIBUTE

DOM SET XML ATTRIBUTE ( elementRef ; attribName ; attrValue {; attribName2 ; attrValue2 ; ... ; attribNameN ; attrValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| attribName | String | ⇒ | Attribute to set |
| attrValue | String, Boolean, Longint, Real, Time, Date | ⇒ | New attribute value |

## Description

The **DOM SET XML ATTRIBUTE** command adds one or more attributes to the XML element whose reference is passed in the *elementRef* parameter. It also sets the value of each attribute defined.

Pass the attribute you want to set and its value respectively in the *attrName* and *attrValue* parameters (in the form of variables, fields or literal values). You can pass as many attribute/value pairs as you want.
The *attrValue* parameter can be of the text type or another type (Boolean, integer, real, date or time). If you pass a value other than text, 4D handles its conversion to text, according to the following principles:

| Type | Example of converted value |
|---|---|
| Boolean | "true" or "false" |
| Integer | "123456" |
| Real | "12.34" (the decimal separator is always ".") |
| Date | "2006-12-04T00:00:00Z" (RFC 3339 standard) |
| Time | "5233" (number of seconds) |

## Example

In the following XML source:

```
<Book>    <Title>The Best Seller</Title> </Book>
```

If the following code is executed:

```
vAttrName:="Font"
vAttrVal:="Verdana"
DOM SET XML ATTRIBUTE(vElemRef;vAttrName;vAttrVal)
```

We get:

```
<Book>    <Title Font=Verdana>The Best Seller</Title> </Book>
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# DOM SET XML DECLARATION

DOM SET XML DECLARATION ( elementRef ; encoding {; standalone {; indentation}} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| encoding | String | ⇒ | XML document character set |
| standalone | Boolean | ⇒ | True = document is standalone False (default) = document is not standalone |
| indentation | Boolean | ⇒ | *** Obsolete, do not use *** |

## Description

The **DOM SET XML DECLARATION** command allows you to define various options that are useful in creating the XML tree set using *elementRef*. These options concern the encoding and the standalone property of the tree:

- *encoding*: Indicates the character set used in the document. By default (if the command is not called), the UTF-8 character set (compressed Unicode) is used.
  **Note:** If you pass a character set that is not supported by 4D XML commands, UTF-8 will be used. Refer to **Character Sets** to see the list of character sets supported (UTF-8 is however recommended in most cases).
- *standalone*: Indicates whether the tree is standalone (**True**) or if it needs other files or external resources to operate (**False**). By default (if the command is not called or if the parameter is omitted), the tree is not standalone.

**Compatibility note:** The *indentation* parameter is kept for reasons of compatibility with previous versions of 4D but its use is not recommended in 4D v12. From now on, to specify the indentation of the document, it is strongly recommended to use the **XML SET OPTIONS** command.

## Example

The following example sets the encoding to use and the standalone option in the *elementRef* element:

```
DOM SET XML DECLARATION(elementRef;"UTF-16";True)
```

# DOM SET XML ELEMENT NAME

DOM SET XML ELEMENT NAME ( elementRef ; elementName )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| elementName | String | ⇒ | New name of element |

## Description

The **DOM SET XML ELEMENT NAME** command modifies the name of the element set by *elementRef*.

Pass the reference of the element to rename in *elementRef* and the new name of the element in *elementName*. The command also takes charge of updating the open and close tags of the element.

## Example

In the following XML source:

```
<Book>    <Title>The Best Seller</Title> </Book>
```

If the following code is executed, with *vElemRef* containing the reference to the 'Book' element:

```
DOM SET XML ELEMENT NAME(vElemRef;"BestSeller")
```

We get:

```
<BestSeller>    <Title>The Best Seller</Title> </BestSeller>
```

## System variables and sets

If the command was executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

## Error management

An error is generated when:

- The element reference is invalid
- The new name of the element to create is invalid (for example, if it starts with a number).

# DOM SET XML ELEMENT VALUE

DOM SET XML ELEMENT VALUE ( elementRef {; xPath}; elementValue {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| elementRef | String | ⇒ | XML element reference |
| xPath | Text | ⇒ | XPath path of the XML element |
| elementValue | String, Variable | ⇒ | New value of element |
| * | Operator | ⇒ | If passed: set the value in CDATA |

## Description

The **DOM SET XML ELEMENT VALUE** command modifies the value of the element set by *elementRef*.

If you pass the optional *xPath* parameter, you choose to use XPath notation to indicate the element to be modified (for more information about this notation, refer to the section **Use of XPath notation (DOM)**). In this case, you must pass the reference of a root XML element in *elementRef* and the XPath path of the element to be modified in *xPath* .

In *elementValue*, pass a string or a variable (or a field) containing the new value of the specified element:

- If you pass a string, the value is used “as is” in the XML structure.
- If you pass a variable or a field, 4D processes the value, depending on the type of *elementValue*. All data types can be used, except arrays, pictures and pointers.

When the optional asterisk (*) parameter is passed, this indicates that the value of the element must be set in the form of CDATA. The special CDATA form can be used to write raw text as is (see example 2).

**Note:** If the element designated by *elementRef* is a BLOB processed by this command, it is automatically encoded in base64. In this case, the **DOM GET XML ELEMENT VALUE** command does automatically the reverse operation.

## Example 1

In the following XML source:

```
<Book>    <Title>The Best Seller</Title> </Book>
```

If the following code is executed, with *vElemRef* containing the reference to the “Title” element:

```
DOM SET XML ELEMENT VALUE(vElemRef;"The Loser")
```

We get:

```
<Book>    <Title>The Loser</Title> </Book>
```

## Example 2

In the following XML source:

```
<Maths>    <Postulate>1+2=3</Postulate> </Maths>
```

We want to write the text “12<18” in the *<Postulate>* element. This string cannot be written as is in XML because the “<” character is not accepted. This character must therefore be changed into “<” or the CDATA form must be used. If *vElemRef* indicates the XML *<Postulate>* node:

```
` Normal form
DOM SET XML ELEMENT VALUE(vElemRef;"12<18")
```

We get:

```
<Maths>    <Postulate>12 < 18</Postulate> </Maths>
```

```
` CDATA form
DOM SET XML ELEMENT VALUE(vElemRef;"12<18";*)
```

We get:

```
<Maths>    <Postulate><![CDATA[12 < 18]]></Postulate> </Maths>
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated (for example, if the element reference is invalid).

# Overview of XML SAX Commands

This theme groups together the XML SAX commands of 4D.

For general information about XML (overview, character sets, glossary) as well as the differences between the DOM and SAX modes, please refer to the **Overview of XML DOM Commands** section.

**Note concerning preemptive mode:** XML references created by a preemptive process can only be used in that specific process. Conversely, XML references created by a cooperative process can be used by any other cooperative process but cannot be used by any preemptive process.

## Creating, opening and closing XML documents via SAX

The SAX commands work with the standard document references of 4D (*DocRef*, Time type reference). It is therefore possible to use these commands jointly with the 4D commands used to manage documents, such as **SEND PACKET** or **Append document**.

The creation and opening of XML documents by programming is carried out using the **Create document** and **Open document** commands. Subsequently, the use of an XML command with these documents will cause the automatic implementation of XML mechanisms such as encoding. For instance, the *<?xml version="1.0" encoding="··· encodage ···" standalone = "no "?>* header will be written automatically in the document.

**Note:** Documents read by SAX commands must be opened in read-only mode by the **Open document** command. This avoids any conflict between 4D and the Xerces library when you open “standard” and XML documents simultaneously. If you execute a SAX parsing command with a document open in read-write mode, an alert message is displayed and parsing is impossible.

Closing an XML document must be carried out using the **CLOSE DOCUMENT** command. If any XML elements were open, they will be closed automatically.

# SAX ADD PROCESSING INSTRUCTION

SAX ADD PROCESSING INSTRUCTION ( document ; statement )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| statement | Text | ⇒ | Statement to insert in the document |

## Description

In the XML document referenced by *document*, the **SAX ADD PROCESSING INSTRUCTION** command adds an XML processing *statement*.

A processing statement lets you indicate the application type and when necessary any additional parameters allowing you to process an unparsable external entity.

The command formats the data of the statement in conformity with XML. However, the statements themselves are not parsed and it is up to the developer to make sure that they are valid.

## Example

The following code:

```
vtInstruct:="xml-stylesheet type="+Char(Quote)+"text/xsl"+Char(Quote)+
"href="+Char(Quote)+"style.xsl"+Char(Quote)
SAX ADD PROCESSING INSTRUCTION($DocRef;vtInstruct)
```

... will write the following line in the document:

```
<?xml-stylesheet type="text/xsl"href="style.xsl"?>
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX ADD XML CDATA

SAX ADD XML CDATA ( document ; data )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| data | BLOB, Text | ⇒ | Text or BLOB to insert in the document between CData tags |

## Description

In the XML document referenced by *document*, the **SAX ADD XML CDATA** command adds *data* of the text or BLOB type. This *data* will be automatically framed between the *<![CDATA[* and *]]> tags.*

The text included in a CData section is ignored by the XML interpreter.

If you want to encode the contents of data, you must use the **BASE64 ENCODE** command. In this case, of course, you must pass a BLOB in *data*.

In order for this command to operate correctly, an element must be open. Otherwise, an error will be generated.

## Example

You want to insert the following lines in your XML document:

```
function matchwo(a,b) { if (a < b && a < 0) then       {       return 1       } else       {       return 0       } }
```

To do this, you just need to execute the following code:

```
C_TEXT(vtMytext)
... ` place the text in the vtMytext variable here
SAX ADD XML CDATA($DocRef;vtMytext)
```

The result will thus be:

```
<![CDATA[ function matchwo(a,b) { if (a < b && a < 0) then    {    return 1    } else    {    return 0    } } ]]>
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

# SAX ADD XML COMMENT

SAX ADD XML COMMENT ( document ; comment )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| comment | String | ⇒ | Comment to be added |

## Description

The **SAX ADD XML COMMENT** command adds a *comment* in the XML document referenced by *document*.

An XML comment is a text whose contents will not be parsed by the XML interpreter. XML comments must be enclosed between the <!-- and --> characters.

## Example

The following statement:

```
vComment:="Created by 4D"
SAX ADD XML COMMENT($DocRef;vComment)
```

... will write the following line in the document:

```
<!--Created by 4D-->
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

## Error management

In the event of an error, the command returns an error which can be intercepted using an error-handling method.

# SAX ADD XML DOCTYPE

SAX ADD XML DOCTYPE ( document ; docType )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| docType | String | ⇒ | DocType to be added |

## Description

The **SAX ADD XML DOCTYPE** command adds a DocType statement set by the *docType* parameter in the XML document referenced by *document*.

The DocType statement lets you indicate the type of XML in which the document has been written and to specify the Document Type Declaration (DTD) used. A DocType statement generally takes the following form: *<!DOCTYPE XML_type "DTD_address">*.

## Example

The following statement:

```
vDocType:="SYSTEM Books ¥"Book.DTD¥""
SAX ADD XML DOCTYPE($DocRef;vDocType)
```

... will write the following line in the document:

```
<!DOCTYPE SYSTEM Books"Book.DTD">
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0.

## Error management

In the event of an error, the the command returns an error which can be intercepted using an error-handling method.

# SAX ADD XML ELEMENT VALUE

SAX ADD XML ELEMENT VALUE ( document ; data {; *} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| data | Text, Variable | ⇒ | Text or variable to insert in the document |
| * | Operator | ⇒ | If passed: encoding of special characters If omitted: no encoding |

## Description

In the XML document referenced by *document*, the **SAX ADD XML ELEMENT VALUE** command adds *data* directly without converting them. This command is equivalent, for instance, to inserting an attachment in the body of an e-mail.

In *data*, you can either pass a character string directly, or a 4D variable. The variable contents will be converted into text before being included in the XML document.
If you want to encode the contents of *data*, you must use the **BASE64 ENCODE** command. In this case, of course, you must passs a BLOB in *data*.

By default, the command encodes special characters (< > " '...) contained in the *data* parameter unless you have disabled this mechanism for the current process using the **XML SET OPTIONS** command by passing the XML raw data value to the XML string encoding option. For example:

```
XML SET OPTIONS($docRef;XML string encoding;XML raw data)
```

In this context, to force the encoding of special parameters when calling **SAX ADD XML ELEMENT VALUE**, you must pass the optional * parameter.

In order for this command to operate correctly, an element must be open. Otherwise, an error will be generated.

## Example

This example inserts the *whitepaper.pdf* file into the open XML element:

```
C_BLOB(vBMyBLOB)
DOCUMENT TO BLOB("c:¥¥whitepaper.pdf";vBMyBLOB)
SAX ADD XML ELEMENT VALUE($DocRef;vBMyBLOB)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1; otherwise, it is set to 0 and an error is generated.

# SAX CLOSE XML ELEMENT

SAX CLOSE XML ELEMENT ( document )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ➡ | Reference of open document |

## Description

The **SAX CLOSE XML ELEMENT** command writes the statements necessary for closing the last element opened using the **SAX OPEN XML ELEMENT** command in the XML document referenced by *document*

The use of this command is optional. In fact, 4D will automatically add the necessary end tags for any unclosed elements when XML documents are closed.

## Example

If the last element opened is *<Book>*, the following statement:

```
SAX CLOSE XML ELEMENT($DocRef)
```

... will write the following line in the document:

```
</Book>
```

# SAX GET XML CDATA

SAX GET XML CDATA ( document ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ➡ | Reference of open document |
| value | Text, BLOB | ⬅ | Element value |

## Description

The **SAX GET XML CDATA** command gets the CDATA *value* of an XML element that exists in the XML document referenced in the *document* parameter. This command must be called with the XML CDATA SAX event. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

Pass a *value* variable of the Text type if you want to retrieve data having a size greater than 32 KB (the database must be running in Unicode mode).

**Compatibility note:** Starting with 4D v12, CDATA contents encoded in base64 are automatically decoded by the **SAX GET XML CDATA** command, so it is not necessary to call the **BASE64 DECODE** command.

## Example

Let's look at the following piece of XML code:

```
<RootElement>    <Child>MyText<![CDATA[MyCData]]</Child> </RootElement>
```

The following 4D code will return “MyCData” in *vTextData*:

```
C_BLOB(vData)
C_TEXT(vTextData)
SAX GET XML CDATA(DocRef;vData)
vTextData:=BLOB to text(vData;UTF8 C string)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML COMMENT

SAX GET XML COMMENT ( document ; comment )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇨ | Reference of open document |
| comment | String | ⇦ | XML comment |

## Description

The **SAX GET XML COMMENT** command returns a *comment* if an XML Comment SAX event is generated in the XML document referenced in the *document* parameter. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML DOCUMENT VALUES

SAX GET XML DOCUMENT VALUES ( document ; encoding ; version ; standalone )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| encoding | String | ⇐ | XML document character set |
| version | String | ⇐ | XML version |
| standalone | Boolean | ⇐ | True = document is standalone, otherwise False |

## Description

The **SAX GET XML DOCUMENT VALUES** command gets basic information from the XML header of the XML document referenced in the *document* parameter.

The command returns the type of encoding, version and the “standalone” property of the document respectively in the *encoding*, *version* and *standalone* parameters. This command must be used with the SAX event XML Start Document. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML ELEMENT

SAX GET XML ELEMENT ( document ; name ; prefix ; attrNames ; attrValues )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| name | String | ⇐ | Element name |
| prefix | String | ⇐ | Namespace |
| attrNames | String array | ⇐ | Attribute names |
| attrValues | String array | ⇐ | Attribute values |

## Description

The **SAX GET XML ELEMENT** command returns various information about the element *name* that is present in the XML document reference in the *document* parameter. This command must be called with the XML Start Element or XML End Element SAX events. In the specific case of XML End Element, the attribute parameters are not handled. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

The *name* parameter contains the name of the element.

The *prefix* parameter returns the namespace of the element. This parameter is empty if no namespace is linked to the element.

The command fills the *attrNames* array with the names of attributes of the target element. If necessary, the command creates and sizes the array automatically.

The command also fills the *attrValues* array with the values of attributes of the target element. If necessary, the command creates and sizes the array automatically.

## Example

Let's look at the following piece of XML code:

```
<RootElement>
<Child Att1="111"Att2="222"Att3="333">MyText</Child>
</RootElement>
```

Once the following statement has been executed:

```
SAX GET XML ELEMENT(DocRef;vName;vPrefix;tAttrNames;tAttrValues)
```

...*vName* will contain “Child”
*vPrefix* will contain “”
*tAttrNames{1}* will contain “Att1”, *tAttrNames{2}* will contain “Att2”, *tAttrNames{3}* will contain “Att3”
*tAttrValues{1}* will contain “111”, *tAttrValues{2}* will contain “222”, *tAttrValues{3}* will contain “333”

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML ELEMENT VALUE

SAX GET XML ELEMENT VALUE ( document ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇨ | Reference of open document |
| value | Text, BLOB | ⇦ | Element value |

## Description

The **SAX GET XML ELEMENT VALUE** command allows you to get the *value* of an XML element that exists in the XML document referenced in the *document* parameter. This command must be called with the XML DATA SAX event. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

Pass a Text or BLOB type variable in the *value* parameter. If you pass a BLOB, the command will automatically attempt to decode it into base64.

## Example

Let's look at the following piece of XML code:

```
<RootElement>    <Child Att1="111" Att2="222" Att3="333">MyText</Child> </RootElement>
```

The following instruction will return "MyText" in *vValue*:

```
SAX GET XML ELEMENT VALUE(DocRef;vValue)
```

## System variables and sets

If the command was executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML ENTITY

SAX GET XML ENTITY ( document ; name ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| name | String | ⇐ | Entity name |
| value | String | ⇐ | Entity value |

## Description

The **SAX GET XML ENTITY** command allows you to get the *name* and *value* of an XML entity that exists in the XML document referenced in the *document* parameter. This command must be called with the XML Entity SAX event. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

## Example

Let's look at the following piece of XML code:

```
<?xml version="1.0" encoding="UTF-8"?> <!DOCTYPE body [    <!ELEMENT body (element*)>    <!ELEMENT element (#PCDATA)>
   <!ENTITY name "Replacement"> ]> <body>    <element>Entity updated by &name;</element> </body>
```

The following instruction will return “name” in *vName* and “Replacement” in *vValue*.

```
SAX GET XML ENTITY(DocRef;vName;vValue)
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX Get XML node

SAX Get XML node ( document ) -> Function result

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ➡ | Reference of open document |
| Function result | Longint | ↩ | Event returned by function |

## Description

The **SAX Get XML node** command returns a long integer that indicates the type of SAX event returned while the XML document referenced in *document* is parsed.

Events that can be returned are available as "**XML**" theme constants:

| Constant | Type | Value |
|---|---|---|
| XML CDATA | Longint | 7 |
| XML Comment | Longint | 2 |
| XML DATA | Longint | 6 |
| XML End Document | Longint | 9 |
| XML End Element | Longint | 5 |
| XML Entity | Longint | 8 |
| XML Processing Instruction | Longint | 3 |
| XML Start Document | Longint | 1 |
| XML Start Element | Longint | 4 |

## Example

The following example processes an event:

```
DocRef:=Open document("";"xml";Read Mode)
If(OK=1)
   Repeat
      MyEvent:=SAX Get XML node(DocRef)
      Case of
         :(MyEvent=XML Start Document)
            DoSomething
         :(MyEvent=XML Comment)
            DoSomethingElse
      End case
   Until(MyEvent=XML End Document)
   CLOSE DOCUMENT(DocRef)
End if
```

## System variables and sets

If the command has been executed correctly, the system variable OK is set to 1. Otherwise, it is set to 0 and an error is generated.

# SAX GET XML PROCESSING INSTRUCTION

SAX GET XML PROCESSING INSTRUCTION ( document ; name ; value )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| name | String | ⇐ | Instruction name |
| value | String | ⇐ | Instruction value |

## Description

The **SAX GET XML PROCESSING INSTRUCTION** command returns the *name* and *value* of the XML instruction processed in the XML document referenced in the *document* parameter. This command must be called with the XML Processing Instruction event. For more information about SAX events, refer to the description of the **SAX Get XML node** command.

## Example

Let's look at the following piece of XML code:

```
<?xml version="1.0" encoding="UTF-8"?> <!-- Edited with XML Spy v3.0.7 NT (http://www.xmlspy.com) by Myself (4D SA)--> <?PI TextProcess?> <!DOCTYPE RootElement SYSTEM "ParseTest.dtd">
```

The following instruction will return “PI” in *vName* and “TextProcess” in *vValue*:

```
SAX GET XML PROCESSING INSTRUCTION($DocRef;vName;vValue)
```

# SAX OPEN XML ELEMENT

SAX OPEN XML ELEMENT ( document ; tag {; attribName ; attribValue} {; attribName2 ; attribValue2 ; ... ; attribNameN ; attribValueN} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| tag | String | ⇒ | Name of element to open |
| attribName | String | ⇒ | Attribute name |
| attribValue | String | ⇒ | Attribute value |

## Description

The **SAX OPEN XML ELEMENT** command adds a new element in the XML document referenced by *document* as well as, optionally, attributes and their values.

The added element is “open” in the document (the end tag is not added). To close an element created using this command, you must either:

- Use the **SAX CLOSE XML ELEMENT** command, or
- Close the XML document. In this case, 4D will automatically add the necessary XML end tags.

In *tag*, pass the name of the element to be created. This name may only contain letters, numbers and the characters “.”, “-”,”_” and “:”. If an invalid character is passed in *tag*, an error will be generated.

Optionally, the command can pass one or more attribute/value pairs (in the form of variables, fields or literal values) using the *attribName* and *attribValue* parameters. You can pass as many attribute/value pairs as you want.

## Example

The following statement:

```
vElement:="Book"
SAX OPEN XML ELEMENT($DocRef;vElement)
```

... writes the following line in the document:

```
<Book
```

## Error management

If an invalid character is passed in *tag*, an error is generated.

# SAX OPEN XML ELEMENT ARRAYS

SAX OPEN XML ELEMENT ARRAYS ( document ; tag {; attribNamesArray ; attribValuesArray} {; attribNamesArray2 ; attribValuesArray2 ; ... ; attribNamesArrayN ; attribValuesArrayN} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| tag | String | ⇒ | Name of element to open |
| attribNamesArray | String array | ⇒ | Array of attribute names |
| attribValuesArray | String array, Longint array, Date array, Real array, Picture array, Boolean array | ⇒ | Array of attribute values |

## Description

The **SAX OPEN XML ELEMENT ARRAYS** command is used to add a new element in the XML document whose reference is passed in *document* as well as, optionally, attributes and their values in the form of arrays.

Except for the support of arrays (see below), this command is identical to **SAX OPEN XML ELEMENT**. Please refer to the description of this command for more information about its operation.

**SAX OPEN XML ELEMENT ARRAYS** accepts arrays of the date, number, Boolean and picture type as *attribValuesArray* parameter(s). 4D automatically carries out the necessary conversions; you can configure these conversions using the **XML SET OPTIONS** command.

Optionally, the **SAX OPEN XML ELEMENT ARRAYS** command can be used to pass pairs of attributes and attribute values in the form of arrays in the *attribNamesArray* and *attribValuesArray* parameters.

The arrays must have been created previously and operate in attribute/attribute value pairs. You can pass as many pairs of arrays, and as many items in each pair, as you want.

## Example

The following method:

```
ARRAY STRING(80;tAttrNames;2)
ARRAY STRING(80;tAttrValues;2)
vElement:="Book"
tAttrNames{1}:="Font"
tAttrValues{1}:="Arial"
tAttrNames{2}:="Style"
tAttrValues{2}:="Bold"
SAX OPEN XML ELEMENT ARRAYS($DocRef;vElement;tAttrNames;tAttrValues)
```

... will write in the document:

```
<Book Font="Arial" Style="Bold">
```

# SAX SET XML DECLARATION

SAX SET XML DECLARATION ( document ; encoding {; standalone {; indentation}} )

| Parameter | Type | | Description |
|---|---|---|---|
| document | DocRef | ⇒ | Reference of open document |
| encoding | String | ⇒ | XML document character set |
| standalone | Boolean | ⇒ | True = the document is standalone False (default) = document is not standalone |
| indentation | Boolean | ⇒ | *** Obsolete, do not use *** |

## Description

The **SAX SET XML DECLARATION** command initializes the XML document referenced in *document* using the values passed in the parameter. These parameters allow determining the encoding, standalone attribute and document indentation.

- *encoding*: Indicates the character set used in the document. By default (if the command is not called), the UTF-8 character set (compressed Unicode) is used.
  **Note:** If you pass a character set that is not supported by 4D XML commands, UTF-8 will be used. Refer to **Character Sets** to see the list of character sets supported (UTF-8 is however recommended in most cases).
- *standalone*: Indicates whether the document is standalone (**True**) or if it needs other files or external resources to operate (**False**). By default (if the command is not called or if the parameter is omitted), the document is not standalone.

**Compatibility note:** The *indentation* parameter is kept for reasons of compatibility with previous versions of 4D but its use is not recommended beginning with 4D v12. From now on, to specify the indentation of the document, it is strongly recommended to use the **XML SET OPTIONS** command.

This command must be called one time per document and before the first XML set command in the document; otherwise, an error message will be generated.

## Example

The following code:

```
SAX SET XML DECLARATION($DocRef;"UTF-16";True)
```

... will write this line in the document:

```
<<?xml version="1.0" encoding="UTF-16" standalone="yes"?>
```

| 4D Remote mode | Longint | 4 | |
| 4D Server | Longint | 5 | |
| 4D Volume desktop | Longint | 1 | |
| 64 bit version | Longint | 1 | |
| Active 4D Folder | Longint | 0 | |
| Backup configuration file | Longint | 1 | Backup.xml file, stored in Preferences/Backup folder next to database structure file. |
| Current localization | Longint | 1 | Current language of the application: default language or language set via the **SET DATABASE LOCALIZATION** command. |
| Current resources folder | Longint | 6 | |
| Data folder | Longint | 9 | |
| Database folder | Longint | 4 | |
| Database folder Unix syntax | Longint | 5 | |
| Default localization | Longint | 0 | Language set automatically by 4D on startup according to the Resources folder and the system environment (not modifiable). |
| Demo version | Longint | 0 | |
| Full method text | Longint | 1 | |
| Highlighted method text | Longint | 2 | |
| HTML Root folder | Longint | 8 | |
| Internal 4D localization | Longint | 3 | Language used by 4D for sorts and text comparisons (set in the Preferences of the application). |
| Last backup file | Longint | 2 | Last backup file, named <databaseName>[bkpNum].4BK, stored at a custom location. |
| Licenses folder | Longint | 1 | |
| Logs folder | Longint | 7 | |
| Merged application | Longint | 2 | Version is an application merged with 4D Volume Desktop |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Structure settings | Longint | 0 | Access to "Structure settings" (default value if parameter omitted). In this mode, values used for *selector* are identical to those in standard mode. |
| User settings | Longint | 1 | Access to "User settings". In this mode, only certain keys can be used in the *selector* parameter |
| User settings file for data | Longint | 4 | settings.4DSettings file for current data file, stored in Preferences folder next to the data file. |
| User settings for data | Longint | 2 | Access to "User settings for data file", that is, user settings stored at the same level as the data file. In this mode, only certain keys can be used with the *selector* parameter (same subset as the User settings) |
| User structure settings file | Longint | 3 | settings.4DSettings file for all data files, stored in Preferences folder next to database structure file if enabled. |
| User system localization | Longint | 2 | Language set by the current user of the system. |

## 4D Write Pro

For more information, please refer to the **4D Write Pro Language** section.

| Constant | Type | Value | Comment |
|---|---|---|---|
| wk 4wp | Longint | 4 | The 4D Write Pro document is saved in a native archive format (zipped HTML and images saved in a separate folder). 4D specific tags are included and 4D expressions are not computed. This format is particularly suitable for saving and archiving 4D Write Pro documents on disk without any loss. |
| wk armenian | Longint | 19 | Traditional Armenian numbering style used (value for wk list style type) |
| wk author | String | author | **Used with:** Documents<br>**Default value:** none<br>**Possible values:** Custom string |
| wk auto | Longint | 0 | Value of property (constant) to which it is applied is adjusted automatically according to content or context of the element. |
| wk background clip | String | backgroundClip | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk border box<br>**Possible values:** wk border box / wk content box / wk padding box |
| wk background color | String | backgroundColor | **Used with:** Characters, Paragraphs, Documents, Pictures<br>**Default value:** wk transparent<br>**Description:** Background document is white by default(2) |
| wk background image | String | backgroundImage | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** none<br>**Description:** Image(3) |
| wk background origin | String | backgroundOrigin | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk padding box<br>**Possible values:** wk border box / wk content box / wk padding box |
| wk background position h | String | backgroundPositionH | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk left<br>**Possible values:** wk center / wk left / wk right |
| wk background position v | String | backgroundPositionV | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk top<br>**Possible values:** wk bottom / wk middle / wk top |
| wk background repeat | String | backgroundRepeat | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk repeat<br>**Possible values:** wk no repeat / wk repeat / wk repeat x / wk repeat y |
| wk background size h | String | backgroundSizeH | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk auto<br>**Possible values:** wk contain* / wk cover* / wk auto or Size(1)<br>*This value also affects wk background size v and modifies its value (CSS constraint). |
| wk background size v | String | backgroundSizeV | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk auto<br>**Possible values:** wk contain* / wk cover* / wk auto or Size(1)<br>*This value also affects wk background size h and modifies its value (CSS constraint). |
| wk bar | Longint | 4 | Inserts a vertical bar at tab position (value for wk tab stop types) |
| wk baseline | Longint | 4 | Aligns baseline of element with baseline of parent element (value for wk vertical align) |
| wk border box | Longint | 0 | Background is clipped to the border box (value for wk background clip) |
| wk border color | String | borderColor | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** black<br>**Description:** If there are multiple colors, **WP GET ATTRIBUTES** returns an empty string(2) |
| wk border color bottom | String | borderColorBottom | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** black<br>**Description:** Color(2) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| wk border color left | String | borderColorLeft | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** black<br>**Description:** Color(2) |
| wk border color right | String | borderColorRight | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** black<br>**Description:** Color(2) |
| wk border color top | String | borderColorTop | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** black<br>**Description:** Color(2) |
| wk border radius | String | borderRadius | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Integer(1), Radius in user unit |
| wk border style | String | borderStyle | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Possible values:** wk none / wk hidden / wk solid / wk dotted / wk dashed / wk double / wk groove / wk ridge / wk inset |
| wk border style bottom | String | borderStyleBottom | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Possible values:** wk none / wk hidden / wk solid / wk dotted / wk dashed / wk double / wk groove / wk ridge / wk inset |
| wk border style left | String | borderStyleLeft | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Possible values:** wk none / wk hidden / wk solid / wk dotted / wk dashed / wk double / wk groove / wk ridge / wk inset |
| wk border style right | String | borderStyleRight | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Possible values:** wk none / wk hidden / wk solid / wk dotted / wk dashed / wk double / wk groove / wk ridge / wk inset |
| wk border style top | String | borderStyleTop | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Possible values:** wk none / wk hidden / wk solid / wk dotted / wk dashed / wk double / wk groove / wk ridge / wk inset |
| wk border width | String | borderWidth | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** 2pt<br>**Description:** Integer(1) |
| wk border width bottom | String | borderWidthBottom | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** 2pt<br>**Description:** Integer(1) |
| wk border width left | String | borderWidthLeft | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** 2pt<br>**Description:** Integer(1) |
| wk border width right | String | borderWidthRight | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** 2pt<br>**Description:** Integer(1) |
| wk border width top | String | borderWidthTop | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** 2pt<br>**Description:** Integer(1) |
| wk bottom | Longint | 1 | Sets position of background image (value for wk background position v) or bottom of element aligned with lowest element on line (value for wk vertical align) |
| wk capitalize | Longint | 1 | Transforms first character of every word to uppercase (value for wk text transform) |
| wk center | Longint | 2 | Centers text or image (value for wk background position h, wk text align, and/or wk tab stop types) |
| wk circle | Longint | 11 | Circle-shaped glyph used (value for wk list style type) |
| wk cjk ideographic | Longint | 24 | Plain ideographic numbers used (value for wk list style type) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| wk club | Longint | 27 | Club-shaped glyph used (value for wk list style type) |
| wk company | String | company | **Used with:** Documents<br>**Default value:** none<br>**Description:** String |
| wk contain | Longint | -1 | Scales image to largest size such that its width and height fits inside content area (value for wk background size h and/or wk background size v) |
| wk content box | Longint | 2 | Background clipped to content box (value for wk background clip) or background image starts from upper left corner of content (value for wk background origin) |
| wk cover | Longint | -2 | Scales background image to largest size so that background area is completely covered by it (value for wk background size h and/or wk background size v) |
| wk custom | Longint | 29 | Custom marker used (value for wk list style type) |
| wk dashed | Longint | 3 | Dashed line used (value for wk text linethrough style and/or wk text underline style) |
| wk date creation | String | dateCreation | **Used with:** Documents<br>**Default value:** none<br>**Description:** Date *Value (dateCreation) is read-only and cannot be set |
| wk date modified | String | dateModified | **Used with:** Documents<br>**Default value:** none<br>**Description:** Date |
| wk decimal | Longint | 3 | Decimal alignment (value for wk tab stop types) or numbers used (value for wk list style type) |
| wk decimal greek | Longint | 28 | Greek numerals used (value for wk list style type) |
| wk decimal leading zero | Longint | 13 | Decimal numbers padded with initial zeros used (value for wk list style type) |
| wk default | Longint | -1 | Default value of property (constant) is used. |
| wk diamond | Longint | 26 | Diamond-shaped glyph used (value for wk list style type) |
| wk direction | String | direction | **Used with:** Paragraphs<br>**Default value:** wk left to right<br>**Possible values:** wk left to right / wk right to left |
| wk disc | Longint | 10 | Filled circle marker used (value for wk list style type) |
| wk dotted | Longint | 2 | Dotted line or border used (value for wk border style, wk text linethrough style and/or wk text underline style) |
| wk double | Longint | 4 | Double line or border used (value for wk border style, wk text linethrough style and/or wk text underline style) |
| wk dpi | String | dpi | **Used with:** Documents<br>**Default value:** none<br>**Description:** Integer, min: 72 - max: 1440 |
| wk end text | Longint | 0 | Sets end of document as end of text range |
| wk false | Longint | 0 | |
| wk font | String | font | **Used with:** Characters<br>**Default value:** Times<br>**Description:** Complete font name in string as given by the **FONT STYLE LIST** command. If the system does not recognize the font, it handles the substitution. If **WP SET ATTRIBUTES** does not recognize the font, it does nothing. |
| wk font bold | String | fontBold | **Used with:** Characters<br>**Default value:** wk false<br>**Description:** Abstract property which depends on the thickness of wk font. wk true if wk font has a font style whose weight is bold; wk false otherwise |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| wk font family | String | fontFamily | **Used with:** Characters<br>**Default value:** Times<br>**Description:** Font family as defined by wk font. Abstract property which modifies wk font. |
| wk font italic | String | fontItalic | **Used with:** Characters<br>**Default value:** wk false<br>**Description:** Abstract property which depends on the style of wk font. Value is wk true if wk font has a font style which is italic or oblique; wk false otherwise. |
| wk font size | String | fontSize | **Used with:** Characters<br>**Default value:** 12<br>**Description:** Size(1), only in points |
| wk georgian | Longint | 20 | Traditional Georgian numbering used (value for wk list style type) |
| wk groove | Longint | 6 | 3D grooved border used (value for wk border style) |
| wk hebrew | Longint | 21 | Traditional Hebrew numbering used (value for wk list style type) |
| wk height | String | height | **Used with:** Pictures<br>**Default value:** 0<br>**Description:** Size(1) or wk auto. Always automatic for document element (wk auto); the view handles the height. |
| wk hidden | Longint | 5 | No border used. Same as none (no border) except it takes precedence over all other conflicting borders (value for wk border style) |
| wk hiragana | Longint | 22 | Traditional Hiragana numbering used (value for wk list style type) |
| wk hollow square | Longint | 25 | Hollow square glyph used (value for wk list style type) |
| wk html debug | Longint | 1 | Formatted HTML code ("pretty print"), easier to debug |
| wk image | String | image | **Used with:** Pictures<br>**Default value:** none<br>**Description:** URL of image |
| wk image alternative text | String | imageAltText | **Used with:** Pictures<br>**Default value:** none<br>**Description:** HTML alternative text |
| wk inset | Longint | 8 | 3D inset border used (value for wk border style) |
| wk inside | String | Inside | **Used with:** Paragraphs<br>**Default value:** none<br>**Description:** For multi-paragraph ranges. To be added to a border, padding, or margin attribute to affect only the corresponding inter-paragraph property (not outside). |
| wk justify | Longint | 5 | Available for 4D Write Pro areas only |
| wk katakana | Longint | 23 | Traditional Katakana numbering used (value for wk list style type) |
| wk layout unit | String | userUnit | **Used with:** Documents<br>**Default value:** wk unit cm<br>**Possible values:** wk unit cm / wk unit pt / wk unit px / wk unit percent (only for line height and background size (h+v)) / wk unit mm / wk unit inch |
| wk left | Longint | 0 | Aligns text or tab to the left (value for wk text align or wk tab stop types) or sets starting position of background image (value for wk background position h) |
| wk left to right | Longint | 0 | Left-to-right text/writing direction used (value for wk direction) |
| wk line height | String | lineHeight | **Used with:** Paragraphs<br>**Default value:** wk normal<br>**Description:** Size(1) |
| wk linethrough | Longint | 2 | |

| Constant | Type | Value | Comment |
|---|---|---|---|
| wk list auto | Longint | 2147483647 | Restores/applies automatic list style values |
| wk list font | String | listFont | **Used with:** Paragraphs<br>**Default value:** Times<br>**Description:** Font name in string |
| wk list font family | String | listFontFamily | **Used with:** Paragraphs<br>**Default value:** Times<br>**Description:** Abstract property which depends on style of wk list font in string. |
| wk list start number | String | listStartNumber | **Used with:** Paragraphs<br>**Default value:** wk auto<br>**Possible values:** wk auto or an integer |
| wk list string format LTR | String | listStringFormatLtr | **Used with:** Paragraphs<br>**Default value:** # or string<br>**Description:** Bullet list direction if left-to-right (LTR) direction |
| wk list string format RTL | String | listStringFormatRtl | **Used with:** Paragraphs<br>**Default value:** # or string<br>**Description:** Bullet list direction if right-to-left (RTL) direction |
| wk list style image | String | listStyleImage | **Used with:** Paragraphs<br>**Default value:** wk none<br>**Description:** Image(3) |
| wk list style image height | String | listStyleImageHeight | **Used with:** Paragraphs<br>**Default value:** default<br>**Description:** Size(1) |
| wk list style type | String | listStyleType | **Used with:** Paragraphs<br>**Default value:** wk disc<br>**Description:** wk disc / wk circle / wk square / wk decimal(1 2 3) / wk decimal leading zero (01 02 03) / wk lower latin (a b c) / wk lower roman (i ii iii iv) / wk upper latin (A B C) / wk upper roman (I II III IV) / wk lower greek (alpha, beta, gamma, etc.) / wk armenian / wk georgian / wk hebrew / wk hiragana / wk katakana / wk cjk ideographic / wk hollow square / wk diamond / wk club / wk decimal greek / wk custom / wk none |
| wk lower greek | Longint | 18 | Lowercase classical Greek used (value for wk list style type) |
| wk lower latin | Longint | 14 | Lowercase ASCII letters used (value for wk list style type) |
| wk lower roman | Longint | 15 | Lowercase roman numerals used (value for wk list style type) |
| wk lowercase | Longint | 2 | Changes all characters to lowercase (value for wk text transform) |
| wk margin | String | margin | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk margin bottom | String | marginBottom | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk margin left | String | marginLeft | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk margin right | String | marginRight | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk margin top | String | marginTop | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk middle | Longint | 2 | Sets position of background image (value for wk background position v) or places element in middle of parent element (value for wk vertical align) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| wk mime html | Longint | 1 | 4D Write Pro document is saved as standard MIME HTML with HTML documents and images embedded as MIME parts (encoded in base64). Expressions are computed and 4D specific tags are removed. This format is particularly suitable for sending HTML emails with the **SMTP_QuickSend** command. |
| wk min height | String | minHeight | **Used with:** Paragraphs, Pictures<br>**Default value:** 0<br>**Description:** Size(1). Always automatic for document element; the view handles the height. |
| wk min width | String | minWidth | **Used with:** Paragraphs, Pictures<br>**Default value:** 0<br>**Description:** Size(1). Always automatic for document element; the view handles the width. |
| wk mixed | Longint | -2147483648 | |
| wk new line style sheet | String | newLineStyleSheet | **Used with:** Paragraphs<br>**Default value:** current style |
| wk no repeat | Longint | 3 | Background image will not be repeated (value for wk background repeat) |
| wk none | Longint | 0 | |
| wk normal | Longint | 0 | Standard HTML code |
| wk notes | String | notes | **Used with:** Documents<br>**Default value:** none<br>**Description:** String |
| wk outset | Longint | 9 | |
| wk outside | String | Outside | **Used with:** Paragraphs<br>**Default value:** none<br>**Description:** For multi-paragraph ranges. To be added to a border, padding, or margin attribute to affect only the corresponding outside paragraph property (not inside). |
| wk padding | String | padding | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk padding bottom | String | paddingBottom | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk padding box | Longint | 1 | Background clipped to padding box (value for wk background clip) or background image starts from upper left corner of padding edge (value for wk background origin) |
| wk padding left | String | paddingLeft | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk padding right | String | paddingRight | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk padding top | String | paddingTop | **Used with:** Paragraphs, Documents, Pictures<br>**Default value:** wk none<br>**Description:** Size(1) |
| wk range end | String | rangeEnd | (Read-only range attribute) |
| wk range owner | String | rangeOwner | (Read-only range attribute) |
| wk range start | String | rangeStart | (Read-only range attribute) |
| wk repeat | Longint | 0 | Background image repeated both vertically and horizontally (value for wk background repeat) |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| wk repeat x | Longint | 1 | Background image repeated only horizontally (value for wk background repeat) |
| wk repeat y | Longint | 2 | Background image repeated only vertically (value for wk background repeat) |
| wk ridge | Longint | 7 | 3D ridged border used (value for wk border style) |
| wk right | Longint | 1 | Aligns text or tab to the right (value for wk text align or wk tab stop types) or sets starting position of background image (value for wk background position h) |
| wk right to left | Longint | 1 | Right-to-left direction used (value for wk direction) |
| wk semi transparent | Longint | 5 | Semi-transparent line used (value for wk text linethrough style and/or wk text underline style) |
| wk small uppercase | Longint | 4 | Transforms all characters to small uppercase (value for wk text transform) |
| wk solid | Longint | 1 | Solid line or border used (value for wk border style, wk text linethrough style and/or wk text underline style) |
| wk square | Longint | 12 | Square marker used (value for wk list style type) |
| wk start text | Longint | 1 | Sets beginning of document as start of text range |
| wk style sheet | String | styleSheet | **Used with:** Paragraphs, Pictures<br>**Default value:** none<br>**Description:** Style sheet name in string |
| wk subject | String | subject | **Used with:** Documents<br>**Default value:** none<br>**Description:** String |
| wk subscript | Longint | 6 | Aligns element as subscript (value for wk vertical align) |
| wk superscript | Longint | 5 | Aligns element as superscript (value for wk vertical align) |
| wk tab stop offsets | String | tabStopOffsets | **Used with:** Paragraphs<br>**Default value:** 35.45pt<br>**Description:** Size(1) for array values in user unit. If not an array, SET will reset tab stops to a single default offset and GET will return last offset (which is the default relative offset for offsets beyond the last absolute offset). Max value: 10000pt(4) |
| wk tab stop types | String | tabStopTypes | **Used with:** Paragraphs<br>**Default value:** wk left<br>**Possible values:** wk left / wk right / wk center / wk decimal / wk bar or an array(4) |
| wk text align | String | textAlign | **Used with:** Paragraphs<br>**Default value:** wk left<br>**Possible values:** wk right / wk left / wk justify / wk center |
| wk text color | String | color | **Used with:** Characters<br>**Default value:** black<br>**Description:** Color(2) |
| wk text indent | String | textIndent | **Used with:** Paragraphs<br>**Default value:** 0<br>**Description:** Size(1) |
| wk text linethrough color | String | textLinethroughColor | **Used with:** Characters<br>**Default value:** textColor<br>**Description:** Color(2) |
| wk text linethrough style | String | textLinethroughStyle | **Used with:** Characters<br>**Default value:** wk none<br>**Possible values:** wk none / wk solid / wk dotted / wk dashed / wk double / wk semi transparent / wk word |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| wk text shadow color | String | textShadowColor | **Used with:** Characters<br>**Default value:** wk transparent<br>**Description:** Color(2) |
| wk text shadow offset | String | textShadowOffset | **Used with:** Characters<br>**Default value:** 1pt<br>**Description:** Size(1), only in points. |
| wk text transform | String | textTransform | **Used with:** Characters<br>**Default value:** wk none<br>**Description:** wk capitalize / wk lowercase / wk uppercase / wk small uppercase / wk none |
| wk text underline color | String | textUnderlineColor | **Used with:** Characters<br>**Default value:** textColor<br>**Description:** Color(2) |
| wk text underline style | String | textUnderlineStyle | **Used with:** Characters<br>**Default value:** wk none<br>**Possible values:** wk none / wk solid / wk dotted / wk dashed / wk double / wk semi transparent / wk word |
| wk title | String | title | **Used with:** Documents<br>**Default value:** New 4D Write Document<br>**Description:** String |
| wk top | Longint | 0 | Sets position of background image (value for wk background position v) or aligns element with top of tallest element on the line (value for wk vertical align) |
| wk transparent | Longint | -1 | Specifies color is transparent (value for wk background color or wk text shadow color) |
| wk true | Longint | 1 | |
| wk underline | Longint | 1 | |
| wk unit cm | String | cm | Unit used is centimeters (value for wk layout unit) |
| wk unit inch | String | in | Unit used is inches (value for wk layout unit) |
| wk unit mm | String | mm | Unit used is millimeters (value for wk layout unit) |
| wk unit percent | String | % | Unit used is a percentage (value for wk layout unit) |
| wk unit pt | String | pt | Unit used is points (value for wk layout unit) |
| wk unit px | String | px | Unit used is pixels (value for wk layout unit) |
| wk upper latin | Longint | 16 | Uppercase ASCII letters used (value for wk list style type) |
| wk upper roman | Longint | 17 | Uppercase roman numerals used (value for wk list style type) |
| wk uppercase | Longint | 3 | Changes all characters to uppercase (value for wk text transform) |
| wk value unit not percentage | Longint | -100000 | |
| wk value unit percentage | Longint | -100001 | |
| wk version | String | version | **Used with:** Documents<br>**Default value:** 1<br>**Description:** integer (from 1 to max). Get only; cannot be set. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| wk vertical align | String | verticalAlign | **Used with:** Characters, Paragraphs, Pictures<br>**Default value:** wk baseline<br>**Possible values:** wk top / wk bottom / wk middle / wk baseline / wk superscript / wk subscript. For characters, wk top and wk bottom have the same effect as wk baseline. For paragraphs, wk baseline, wk superscript and wk subscript have the same effect as wk top. |
| wk web page complete | Longint | 2 | .htm or .html extension. The document is saved as standard HTML and its resources are saved separately. 4D tags are removed and expressions are computed. This format is particularly suitable when you want to display a 4D Write Pro document in a web browser. |
| wk web page html 4D | Longint | 3 | 4D Write Pro document is saved as HTML and includes 4D specific tags; each expression is inserted as a non-breaking space. Since this format is lossless, it is appropriate for storing purposes in a text field. |
| wk width | String | width | **Default value:** 0<br>**Used with:** Paragraph, Picture<br>**Description:** Size(1) or wk auto. Always auto for document element; the view handles the width. |
| wk word | Longint | 6 | |

| Constant | Type | Value | Comment |

| US ASCII code | Longint | 31 | |
| VT ASCII code | Longint | 11 | |

## Backup and Restore

| Constant | Type | Value | Comment |
|---|---|---|---|
| Auto repair mode | Longint | 1 | Use flexible mode with auto-repair actions and fill the *errObject* parameter (if any) |
| Field attribute with name | Longint | 2 | Fields are identified by their name. Example: {"LastName":"Jones"} |
| Field attribute with number | Longint | 1 | Fields are identified by their number (default if omitted). Example: {"5":"Jones"}. |
| Last backup date | Longint | 0 | |
| Last backup status | Longint | 2 | |
| Last restore date | Longint | 0 | |
| Last restore status | Longint | 2 | |
| Next backup date | Longint | 4 | |
| Strict mode | Longint | 0 | Use strict integration mode (default) |

## BLOB

| Constant | Type | Value | Comment |
|---|---|---|---|
| Compact compression mode | Longint | 1 | Compressed as much as possible (at the expense of the speed of compression and decompression operations). Default method. |
| Extended real format | Longint | 1 | |
| Fast compression mode | Longint | 2 | Compressed as fast as possible (and will be decompressed as fast as possible), at the expense of the compression ratio (the compressed BLOB will be bigger). |
| GZIP best compression mode | Longint | -1 | Most compact GZIP compression |
| GZIP fast compression mode | Longint | -2 | Fastest GZIP compression |
| Is not compressed | Longint | 0 | No compression |
| Mac C string | Longint | 0 | |
| Mac Pascal string | Longint | 1 | |
| Mac text with length | Longint | 2 | |
| Mac text without length | Longint | 3 | |
| Macintosh byte ordering | Longint | 1 | |
| Macintosh double real format | Longint | 2 | |
| Native byte ordering | Longint | 0 | |
| Native real format | Longint | 0 | |
| PC byte ordering | Longint | 2 | |
| PC double real format | Longint | 3 | |
| UTF8 C string | Longint | 4 | |
| UTF8 text with length | Longint | 5 | |
| UTF8 text without length | Longint | 6 | |

## Colors

| Constant | Type | Value | Comment |
|---|---|---|---|
| Black | Longint | 15 | |
| Blue | Longint | 6 | |
| Brown | Longint | 13 | |
| Dark blue | Longint | 5 | |
| Dark brown | Longint | 10 | |
| Dark green | Longint | 9 | |
| Dark grey | Longint | 11 | |
| Green | Longint | 8 | |
| Grey | Longint | 14 | |
| Light blue | Longint | 7 | |
| Light grey | Longint | 12 | |
| Orange | Longint | 2 | |
| Purple | Longint | 4 | |
| Red | Longint | 3 | |
| White | Longint | 0 | |
| Yellow | Longint | 1 | |

## Communications

| Stop bits one and a half | Longint | -32768 | |
| Stop bits two | Longint | -16384 | |

## Data File Maintenance

| Constant | Type | Value | Comment |
|---|---|---|---|
| Compact address table | Longint | 131072 | Force the address table of the records to be rewritten (slows down compacting). Note that in this case, record numbers are rewritten. If you only pass this option, 4D automatically enables the 'Update records' option. |
| Create process | Longint | 32768 | When this option is passed, compacting will be asynchronous and you will need to manage the results using the callback method (see below). 4D will not display the progress bar (it is possible to do so using the callback method). The OK system variable is set to 1 if the process has been launched correctly and 0 in all other cases. When this option is not passed, the OK variable is set to 1 if the compacting takes place correctly and 0 otherwise. |
| Do not compact index | Longint | 2 | |
| Do not create log file | Longint | 16384 | Generally, this command creates a log file in XML format (refer to the end of the command description). With this option, no log file will be created. |
| Move to replaced files folder | Longint | 4 | |
| New file | Longint | 0 | |
| New file dialog | Longint | 1 | |
| Renumber records | Longint | 1 | |
| Timestamp log file name | Longint | 262144 | When this option is passed, the name of the log file generated will contain the date and time of its creation; as a result, it will not replace any log file already generated previously. By default, if this option is not passed, log file names are not timestamped and each new file generated replaces the previous one. |
| Update records | Longint | 65536 | Force all records to be rewritten according to current definition of the fields in the structure |
| Use default folder | Longint | 1 | The data of the field passed as parameter are saved in the default folder, named *databaseName*.ExternalData and placed next to the data file. In this mode, external data are managed by 4D as if they were inside the data file. |
| Use selected file | Longint | 2 | |
| Use structure definition | Longint | 0 | 4D uses the parameters set in the structure for field storage (see the *Design Reference* manual). If you change from external storage to internal storage, the external file is not deleted. |
| Verify all | Longint | 16 | |
| Verify indexes | Longint | 8 | This option checks the physical consistency of the indexes, without any link with the data. It signals invalid keys but does not permit you to detect duplicated keys (two indexes that point to the same record). This type of error can only be detected with the Verify All option. |
| Verify records | Longint | 4 | |

## Database Engine

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| New record | Longint | -3 | |
| No current record | Longint | -1 | |

## Database Events

| Constant | Type | Value | Comment |
|---|---|---|---|
| On after host database exit | Longint | 4 | The **On Exit database method** of the host database has just finished running |
| On after host database startup | Longint | 2 | The **On Startup database method** of the host database just finished running |
| On application background move | Longint | 1 | The 4D application moves to the background |
| On application foreground move | Longint | 2 | The 4D application moves to the foreground |
| On before host database exit | Longint | 3 | The host database is closing. The **On Exit database method** of the host database has not yet been called.<br>The **On Exit database method** of the host database is not called while the **On Host Database Event database method** of the component is running |
| On before host database startup | Longint | 1 | The host database has just been started. The **On Startup database method** method of the host database has not yet been called.<br>The On Startup database method of the host database is not called while the **On Host Database Event database method** of the component is running |

## Database Parameters

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Database cache size | Longint | 9 | **Scope**: 4D application<br>**Kept between two sessions**: -<br>**Description**: *Constant obsolete (kept for compatibility reasons only)*. We now recommend using the **Get cache size** command. |
| _o_Real display precision | Longint | 32 | **** *Selector disabled* **** |
| _o_Web conversion mode | Longint | 8 | **** *Selector disabled* **** |
| _o_Web Log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| 4D Local mode scheduler | Longint | 10 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |
| 4D Remote mode scheduler | Longint | 12 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: for selectors 10, 11 and 12, the *value* parameter is expressed in hexadecimal *0x00aabbcc* as follows:<br>*aa* = minimum number of ticks per call to the system (0 to 100 included).<br>*bb* = maximum number of ticks per call to the system (0 to 100 included).<br>*cc* = number of ticks between calls to the system (0 to 20 included).<br>If one of the values is out of range, 4D sets it to its maximum. You can pass one of the following preset standard values in the *value* parameter:<br>• *value* = -1: maximum priority allocated to 4D,<br>• *value* = -2: average priority allocated to 4D,<br>• *value* = -3: minimum priority allocated to 4D.<br>**Description**: This parameter allows you to dynamically set the 4D system internal calls. Depending on the Selector, the scheduler value will be set for:<br>• 4D local mode when the command is called from a 4D single-user application (*selector=10*).<br>• 4D Server when the command is called from 4D Server (*selector=11*).<br>• 4D remote mode when the command is called from a 4D connected to 4D Server (*selector=12*).<br>**Note:** The operation of selector 12 (4D Remote Mode Scheduler) differs according to whether the **SET DATABASE PARAMETER** command is executed on the server machine or on the client machine:<br>- If the command is executed on the server machine, the new value will be applied to all the client machines that connect to it subsequently.<br>- If the command is executed on the client machine, the new value is applied to the client machine immediately as well as to all the client machines that connect to the server subsequently.<br>You can use this operation to implement a dynamic and individualized management of priority for each client machine. This consists in executing the command initially on the client machine to be configured, then a second time on the server machine using the default value, which will then be used for the client machines that connect to it subsequently.<br>This operation is in effect in 4D starting with versions 6.8.6, 2003.3 and 2004.<br>**Warning**: Configuring these selectors inappropriately can cause serious degradation of application performance. It is recommended to only modify the default values with full knowledge of the facts. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| 4D Remote mode timeout | Longint | 14 | **Scope** (legacy network layer only): 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Description**: To be used in very specific cases. Value of the timeout granted by the remote 4D machine to the 4D Server machine. The default timeout value used by 4D in remote mode is set on the "Client-Server/Network options" page of the Database settings dialog box on the remote machine.<br>The 4D Remote mode timeout selector is only taken into account if you are using the legacy network. It is ignored when the *ServerNet* layer is activated: this setting is entirely managed by the 4D Server timeout (13) selector. |
| 4D Server log recording | Longint | 28 | **Scope**: 4D Server, 4D remote<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, added to the file name).<br>**Description**: Starts or stops the recording of standard requests received by 4D Server (excluding Web requests). By default, the value is 0 (requests not recorded).<br>4D Server lets you record each request received by the server machine in a log file. When this mechanism is enabled, two files are created in the Logs folder of the database, next to the database structure file.They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file of the same name already exists, it is replaced directly. You can set the starting number of the sequence using the *value* parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes. It can be imported, for example, into a spreadsheet software in order to be processed. |
| 4D Server scheduler | Longint | 11 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Description**: see selector 12 |
| 4D Server timeout | Longint | 13 | **Scope**: 4D application if *value* positive<br>**Kept between two sessions**: Yes if *value* positive<br>**Possible values**: 0 -> 32 767<br>**Description**: Value of the 4D Server timeout. The default 4D Server timeout value is defined on the "Client-Server/Network options" page of the Database settings dialog box on the server side.<br>The server timeout sets the maximum period "authorized" to wait for a client response, for example when it is executing a blocking operation. After this period, 4D Server disconnects the client. The 4D Server Timeout selector allows you to set, in the corresponding *value* parameter, a new timeout expressed in minutes. This feature is particularly useful to increase the timeout before executing a blocking and time-consuming operation on the client, such as printing a large number of pages, which can cause an unexpected timeout. You also have two options:<br>• If you pass a **positive** value in the *value* parameter, you set a global and permanent timeout: the new value is applied to all process and is stored in the preferences of the 4D application (equivalent to change in the Preferences dialog box).<br>• If you pass a **negative** value in the *value* parameter, you set a local and temporary timeout: The new value is applied to the calling process only (the other processes keep the default values) and is reset to default as soon as the server receives any signal of activity from the client — for example, when the operation is finished. This option is useful for managing long operations initiated by 4D plug-ins.<br>To set the "No timeout" option, pass 0 in *value*. See example 1. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Auto synchro resources folder | Longint | 48 | **Scope**: 4D remote machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 (no synchronization), 1 (auto synchronization) or 2 (ask).<br>**Description**: Dynamic synchronization mode for *Resources* folder of 4D client machine that executed the command with that of the server.<br>When the contents of the *Resources* folder on the server has been modified or a user has requested synchronization (for example via the resources explorer or following the execution of the **SET DATABASE LOCALIZATION** command), the server notifies the connected client machines.<br>Three synchronization modes are then possible on the client side. The Auto Synchro Resources Folder selector is used to specify the mode to be used by the client machine for the current session:<br>• 0 (default value): no dynamic synchronization (synchronization request is ignored)<br>• 1: automatic dynamic synchronization<br>• 2: display of a dialog box on the client machines, with the possibility of allowing or refusing synchronization.<br>The synchronization mode can also be set globally in the application Preferences. |
| Cache flush periodicity | Longint | 95 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: longint > 1 (seconds)<br>**Description**: Gets or sets the current cache flush periodicity, expressed in seconds.<br>Modifying this value overrides the **Flush Cache every X Seconds** option in the **Database/Memory page** of the Database settings for the session (it is not stored in the Database settings). |
| Cache unload minimum size | Longint | 66 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint > 1.<br>**Description**: Minimum size of memory to release from the database cache when the engine needs to make space in order to allocate an object to it (value in bytes).<br>The purpose of this selector is to reduce the number of times that data is released from the cache in order to obtain better performance. You can vary this setting according to the size of the cache and that of the blocks of data being handled in your database.<br>By default, if this selector is not used, 4D unloads at least 10% of the cache when space is needed. |
| Character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Circular log limitation | Longint | 90 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: No<br>**Possible values**: Any integer value, 0 = keep all logs<br>**Description**: Maximum number of files to keep in rotation for each type of log. By default, all files are kept. If you pass a value *X*, only the *X* most recent files are kept, with the oldest being erased automatically when a new one is created. This setting applies to each of the following log files: request logs (selectors 28 and 45), debug log (selector 34), events log (selector 79), as well as Web request logs and Web debug logs (selectors 29 and 84 of the **WEB SET OPTION** command). |
| Client character set | Longint | 24 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 17<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Client HTTPS port ID | Longint | 40 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector can be used to modify by programming the TCP port used by the Web servers of the client machines for secure connections via SSL (HTTPS protocol). By default, the value is 443 (standard value).<br>This selector operates exactly the same way as selector 39; however, it applies to all the 4D remote machines used as Web servers. If you only want to modify the value of certain specific client machines, use the Preferences dialog box of the remote 4D. |
| Client IP address to listen | Longint | 23 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 16<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client log recording | Longint | 45 | **Scope**: Remote 4D machine<br>**Kept between two sessions**: No<br>**Possible values**: 0 or from 1 to X (0 = do not record, 1 to X = sequential number, attached to file name).<br>**Description**: Starts or stops recording of standard requests carried out by the 4D client machine that executed the command (excluding Web requests). By default, the value is 0 (no recording of requests).<br>4D lets you record the log of requests carried out by the client machine. When this mechanism is activated, two files are created on the client machine, in the Logs subfolder of the local folder of the database. They are named 4DRequestsLog_X.txt and 4DRequestsLog_ProcessInfo_X.txt, where X is the sequential number of the log. Once the file 4DRequestsLog has reached a size of 10 MB, it is closed and a new one is generated, with an incremented sequential number. If a file with the same name already exists, it is directly replaced. You can set the starting number for the sequence using the value parameter.<br>These text files store various information concerning each request in a simple tabbed format: time, process number, size of request, processing duration, etc. This information is particularly useful during the development phase of the application or for statistical purposes |
| Client max concurrent Web proc | Longint | 25 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 18<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client Max Web requests size | Longint | 21 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 27<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client maximum Web process | Longint | 20 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 7<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Client minimum Web process | Longint | 19 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 6<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client port ID | Longint | 22 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: See selector 15<br>**Description**: Used to specify this parameter for all the remote 4D machines used as Web servers. The values defined using these selectors are applied to all the remote machines used as Web servers. If you want to define values only for certain remote machines, use the Preferences dialog box of 4D in remote mode. |
| Client Server port ID | Longint | 35 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 to 65535<br>**Description**: TCP port number where the 4D Server publishes the database (bound for 4D remote machines). By default, the value is 19813.<br>Customizing this value means that several 4D client-server applications can be used on the same machine with the TCP protocol; in this case, you must indicate a different port number for each application.<br>The value is stored in the database structure file. It can be set with 4D in local mode but is only taken into account in client-server configuration.<br>When you modify this value, it is necessary to restart the server machine in order for the new value to be taken into account. |
| Client Web log recording | Longint | 30 | **Scope**: All 4D remote machines<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br>**Description**: Starts or stops the recording of Web requests received by the Web servers of all the client machines. By default, the value is 0 (requests not recorded).<br>The operation of this selector is identical to that of selector 29; however, it applies to all the 4D remote machines used as Web servers. The "logweb.txt" file is, in this case, automatically placed in the Logs subfolder of the remote 4D database folder (cache folder).<br>If you only want to set values for certain client machines, use the Preferences dialog box of 4D in remote mode. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Debug log recording | Longint | 34 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Starts or stops the sequential recording of events occurring at the 4D programming level in the *4DDebugLog* file, which is automatically placed in the Logs subfolder of the database, next to the structure file. A new, more compact, tabbed text format is used in the event log file "4DDebugLog[_n].txt" starting with 4D v14 (where _n is the segment number of the file).<br>**Possible values**: Longint containing a bit field: value = bit1(1)+bit2(2)+bit3(4)+bit4(8)+…).<br>- Bit 1 (value 1) requests to enable the file (note that any other non-null value also enables it as well)<br>- Bit 2 (value 2) requests call parameters to methods and commands.<br>- Bit 3 (value 4) enables new tabbed format.<br>- Bit 4 (value 8) disables immediate writing of each operation on disk (enabled by default). Immediate writing is slower but more effective, for example for investigating causes of a crash. If you disable this mode, the file contents are more compact and are generated more quickly.<br>- Bit 5 (value 16) disables recording of plug-in calls (enabled by default).<br>In the (former) non-tabbed format, execution times are expressed in milliseconds and the "< ms" value is displayed when an operation lasts less than one millisecond.<br>In the new tabbed format, execution times are expressed in microseconds.<br>Examples:<br>SET DATABASE PARAMETER (34;1) // enables mode v13 file without parameters, with runtimes<br>SET DATABASE PARAMETER (34;2) // enables mode v13 file with parameters and runtimes<br>SET DATABASE PARAMETER (34;2+4) // enables file with v14 format, with parameters and runtimes<br>SET DATABASE PARAMETER (34;0) // disables file<br>To avoid having a file record too much information, you can restrict the 4D commands that are examined by using selector 80, Log Command list.<br>This option can be enabled for any type of 4D application (4D all modes, 4D Server, 4D Volume Desktop), in interpreted or compiled mode.<br>**Note:** This option is provided solely for the purpose of debugging and must not be put into production since it may lead to deterioration of the application performance and saturation of the hard disk. For more information about this format and on the use of the 4DDebugLog[_n].txt file, please contact the Technical Support of 4D Inc. |
| Diagnostic log recording | Longint | 79 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 or 1 (0 = do not record, 1 = record)<br>**Description**: Starts or stops recording of the 4D diagnostic file. By default, the value is 0 (do not record).<br>4D can continuously record a set of events related to the internal application operation into a diagnostic file. Information contained in this file is intended for the development of 4D applications and can be analyzed with the help of the 4D tech support. When you pass 1 in this selector, a diagnostic file, named *DatabaseName_X*.txt, is automatically created (or opened) in the database **Logs** folder. Once this file reaches a size of 10 MB, it is closed and a new file named *DatabaseName_X*.txt is generated, with an incremented sequence number X.<br>Note that you can include custom information in this file using the **LOG EVENT** command. |
| Direct2D disabled | Longint | 0 | See selector 69 (Direct2D Status) |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Direct2D get active status | Longint | 74 | **Note**: You can only use this selector with the **Get database parameter** command and its value cannot be set.<br>**Description**: Returns active implementation of Direct2D under Windows.<br>**Possible values**: 0, 1, 2, 3, 4 or 5 (see values of selector 69). The value returned depends on the availability of Direct2D, the hardware and the quality of Direct2D support by the operating system.<br>For example, if you execute:<br>`SET DATABASE PARAMETER(Direct2D status;Direct2D Hardware)`<br>`$mode:=Get database parameter(Direct2D get active status)`<br><br>- On Windows 7 and higher, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 3 (software context).<br>- On Windows Vista, *$mode* is set to 1 when the system detects hardware compatible with Direct2D; otherwise, *$mode* is set to 0 (disabling of Direct2D).<br>- On Windows XP, *$mode* is always set to 0 (not compatible with Direct2D). |
| Direct2D hardware | Longint | 1 | See selector 69 (Direct2D Status) |
| Direct2D software | Longint | 3 | See selector 69 (Direct2D Status) |
| Direct2D status | Longint | 69 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: Activation mode to implement Direct2D under Windows.<br>**Possible values**: One of the following constants (mode 3 by default):<br>Direct2D Disabled (0): Direct2D mode is not enabled and the database functions in the previous mode (GDI/GDIPlus).<br>Direct2D Hardware (1): Use Direct2D as graphics hardware context for entire 4D application. If this context is not available, use Direct2D graphics software context (except under Vista, in which case GDI/GDIPlus mode is used for better performance).<br>Direct2D Software (3) (Default mode): Beginning with Windows 7, use Direct2D graphics software context for entire 4D application. Under Vista, GDI/GDIPlus mode is used for better performance.<br>**Compatibility note:** Starting with 4D v14, hybrid modes are disabled and redirected to available modes (the former mode 2 is equivalent to 1; former modes 4 and 5 are equivalent to mode 3). |
| HTTP compression level | Longint | 50 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| HTTP compression threshold | Longint | 51 | **Scope**:4D application<br>**Kept between two sessions**: No<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| HTTPS Port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Idle connections timeout | Longint | 54 | **Scope**:4D application unless value is negative<br>**Kept between two sessions**: No<br>**Possible values**: Whole value expressing a duration in seconds. The value can be positive (new connections) or negative (existing connections). By default, the value is 20.<br>**Description**: Maximum period of inactivity (timeout) for connections to both the 4D database engine and the SQL engine, as well as, in *ServerNet* mode (new network layer), to the 4D application server. When an idle connection reaches this limit, it is automatically put on standby, which freezes the client/server session and closes the network socket. In the server administration window, the state of the user process is indicated as "Postponed". This functioning is completely transparent for the user: as soon as there is new activity on the connection which is on standby, the socket is automatically reopened and the client/server session is restored.<br>On the one hand, this setting lets you save resources on the server: connections on standby close the socket and free up a process on the server. On the other hand, it lets you avoid losing connections due to the closing of idle sockets by the firewall. For this, the timeout value for idle connections must be lower than that of the firewall in this case.<br>If you pass a positive value in *value*, it applies to all new connections in all the processes. If you pass a negative value, it applies to connections that are open in the current process. If you pass 0, idle connections are not subjected to a timeout.<br>This parameter can be set on both the server and client side. If you pass two different durations, the shorter one is taken into account. Usually, you do not need to change this value. |
| Invert objects | Longint | 37 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0, 1 or 2 (0 = mode disabled, 1 = automatic mode, 2 = mode enabled).<br>**Description**: Configuration of the "object inversion" mode which is used to invert forms, objects, menu bars, and so on, in Application mode when the database is displayed under Windows in a right-to-left language. This mode can also be configured on the Interface/Right-to-left languages page of the Database Settings.<br>• Value 0 indicates that the mode is never enabled, regardless of the system configuration (corresponds to the Never value in the Database Settings).<br>• Value 1 indicates that the mode is enabled or disabled depending on the system configuration (corresponds to the Automatic value in the Database Settings).<br>• Value 2 indicates that the mode is enabled, regardless of the system configuration (corresponds to the Always value in the Database Settings).<br>For more information, refer to the *Design Reference* manual of 4D. |
| IP Address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| JSON use local time | Longint | 85 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 = ignore local time zone, 1 (default) = take time zone into account.<br>**Description**: By default, 4D dates converted to JSON format take the local time zone into account. For example, converting the date !23/08/2013! gives you "2013-08-22T22:00:00Z" in JSON format when the operation is performed in France during Daylight Savings Time (GMT+2). This principle conforms to the standard operation of JavaScript. This can be a source of errors when you want to send JSON date values to someone in a different time zone. This is the case, for example, when you export a table using **Selection to JSON** in France that is meant to be reimported in the US using **JSON TO SELECTION**. By default, since dates are re-interpreted in each time zone, the values stored in the database will be different. In this case, you can modify the conversion mode for dates so that they do not take the time zone into account by passing 0 in this selector. Converting the date !23/08/2013! will then give you "2013-08-23T00:00:00Z" in all cases. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Log command list | String | 80 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: String containing a list of 4D command numbers to record (separated by semi-colons) or "all" to record all the commands or "" (empty string) to record none of them.<br>**Description**: List of 4D commands to record in the debugging file (see selector 34, Debug Log Recording). By default, all 4D commands are recorded.<br>This selector restricts the quantity of information saved in the debugging file by limiting the 4D commands whose execution you want to record. For example, you can write:<br>`SET DATABASE PARAMETER(Log command list;"277;341") //Record only the QUERY and QUERY SELECTION commands` |
| Max concurrent Web processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |
| Maximum temporary memory size | Longint | 61 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Maximum size of temporary memory that 4D can allocate to each process, expressed in MB. By default, the value is 0 (no maximum size). 4D uses a special temporary memory dedicated to indexing and sorting operations. This memory is intended to preserve the "standard" cache memory during massive operations. It is activated only when needed. By default, the size of the temporary memory is limited only by the resources available (according to the system memory configuration).<br>This mechanism is suitable for most applications. However, in certain specific contexts, more particularly when a client-server application simultaneously carries out a large number of sequential sorts, the size of the temporary memory can increase critically, to the point where it can render the system unstable. In this context, setting a maximum size for the temporary memory allows you to preserve proper functioning of the application. In return, the running speed might be affected: when the maximum size is reached for a process, 4D uses disk files which may slow down processing. For specific needs such as those described above, a maximum size of around 50 MB is generally a good compromise. However, the ideal value will need to be determined according to the specificities of the application and will generally be the result of real-time volumetric testing. |
| Maximum Web process | Longint | 7 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Maximum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 10.<br>In non-contextual mode, for the Web server to be reactive, 4D delays the Web processes for 5 seconds and reuses them to execute any possible future HTTP queries. In terms of performance, this is actually more advantageous than creating a new process for each query. Once a Web process is reused, it is delayed again for 5 seconds. When the maximum number of Web processes has been reached, the web process is then aborted. If no query has been attributed to a Web process within the 5 second delay, the process is aborted, except if the minimum number of Web processes has been reached (in which case the process is delayed again).<br>These parameters allow you to adjust how your Web server operates in relation to the number of requests and the memory available as well as other parameters. |
| Maximum Web requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: *Constant obsolete (kept for compatibility reasons only).* We now recommend using the **WEB SET OPTION** and **WEB GET OPTION** commands for configuring the HTTP server. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Minimum Web process | Longint | 6 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 -> 32 767<br>**Description**: Minimum number of Web processes to maintain in non-contextual mode with 4D in local mode and 4D Server. By default, the value is 0 (see below). |
| Number of formulas in cache | Longint | 92 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Positive longints<br>**Default value**: 0 (no cache)<br>**Description**: Sets or gets the maximum number of formulas to be kept in the cache of formulas, which is used by the **EXECUTE FORMULA** command. This limit is applied to all processes, but each process has its own formula cache. Caching formulas accelerates the **EXECUTE FORMULA** command execution in compiled mode since each cached formula is tokenized only once in this case. When you change the cache value, existing contents are reset even if the new size is larger than the previous one. Once the maximum number of formulas in the cache is reached, a new executed formula will erase the oldest one in the cache (FIFO mode). This parameter is only taken into account in compiled databases or compiled components. |
| Order by formula on server | Longint | 47 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description** : Execution location of **ORDER BY FORMULA** command for the table passed in the parameter.<br>When using a database in client-server mode, this command can be executed either on the server or on the client machine. This selector can be used to specify the execution location of this command (server or client). This mode can also be set in the database preferences. For more information, please refer to the description of selector 46, Query By Formula On Server.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |
| PHP interpreter IP address | Longint | 55 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Formatted string of the type "nnn.nnn.nnn.nnn" (for example "127.0.0.1").<br>**Description**:  IP address used locally by 4D to communicate with the PHP interpreter via FastCGI. By default, the value is "127.0.0.1". This address must correspond to the machine where 4D is located. This parameter can also be set globally for all the machines via the Database Settings.<br>For more information about the PHP interpreter, please refer to the *Design Reference* manual. |
| PHP interpreter port | Longint | 56 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 8002.<br>**Description**: Number of the TCP port used by the PHP interpreter of 4D. This parameter can also be modified globally for all the machines via the Database Settings. For more information about the PHP interpreter, please refer to the *Design Reference* manual. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| PHP max requests | Longint | 58 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 500.<br>**Description**: Maximum number of requests accepted by the PHP interpreter. When this maximum number is reached, the interpreter returns errors of the "server busy" type. For security or performance reasons, you can modify this value. This parameter can also be modified globally for all the machines via the Database Settings. For more information about this parameter, please refer to the FastCGI-PHP documentation.<br>**Note:** On the 4D side, these parameters are applied dynamically; it is not necessary to exit 4D in order for them to be taken into account. On the other hand, if the PHP interpreter is already launched, it will be necessary to exit and relaunch it in order for these modifications to be taken into account. |
| PHP number of children | Longint | 57 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values**: Positive long integer type value. By default, the value is 5.<br>**Description**: Number of child processes to be created and maintained locally by the PHP interpreter of 4D. For optimization reasons, the PHP interpreter creates and uses a set (pool) of system processes called "child processes" for processing script execution requests. You can vary the number of child processes according to the needs of your application. This parameter can also be modified globally for all the machines via the Database Settings. For more information about the PHP interpreter, please refer to the *Design Reference* manual.<br>**Note:** Under Mac OS, all the child processes share the same port. Under Windows, each child process uses a specific port number. The first number is the one set for the PHP interpreter; the other child processes increment the first one. For example, if the default port is 8002 and you launch 5 child processes, they will use ports 8002 to 8006. |
| PHP use external interpreter | Longint | 60 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Values** : 0 = use internal interpreter, 1 = use external interpreter<br>**Description**: Value indicating whether PHP requests in 4D are sent to the internal interpreter provided by 4D or to an external interpreter. By default the value is 0 (use of interpreter provided by 4D). If you want to use your own PHP interpreter, for example in order to use additional modules or a specific configuration, pass 1 in *value*. In this case, 4D does not launch its internal interpreter in the case of PHP requests.<br>The custom PHP interpreter must have been compiled in FastCGI and be located on the same machine as the 4D engine. Note that in this case, you must manage the interpreter entirely; it will not be started nor stopped by 4D. This parameter can also be modified globally for all the machines via the Database Settings. |
| Port ID | Longint | 15 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: No<br>**Description**: TCP port ID used by the 4D Web server with 4D in local mode and 4D Server. The default value, which can be set on the "Web/Configuration" page of the Preferences dialog box, is 80. You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>The Port ID selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode). For more information about the TCP port ID, refer to the **Web Server Settings** section. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Query by formula joins | Longint | 49 | **Scope**: Current process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (always use automatic relations) or 2 (use SQL joins if possible).<br>**Description**: Operating mode of the **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands relating to the use of "SQL joins."<br>In databases created starting with version 11.2 of 4D v11 SQL, these commands carry out joins based on the SQL joins model. This mechanism can be used to modify the selection of a table according to a query carried out on another table without these tables being connected by an automatic relation (necessary condition in previous versions of 4D).<br>The QUERY BY FORMULA Joins selector lets you specify the operating mode of the query by formula commands for the current process:<br>• 0: Uses the current settings of the database (default value). In databases created starting with version 11.2 of 4D v11 SQL, "SQL joins" are always activated for queries by formula. In converted databases, this mechanism is not activated by default for compatibility reasons but can be implemented via a preference.<br>• 1: Always use automatic relations (= functioning of previous versions of 4D). In this mode, a relation is necessary in order to set the selection of a table according to queries carried out on another table. 4D does not do "SQL joins."<br>• 2: Use SQL joins if possible (= default operation of databases created in version 11.2 and higher of 4D v11 SQL ). In this mode, 4D establishes "SQL joins" for queries by formula when the formula is suited for it (with two notable exceptions, see the description of the **QUERY BY FORMULA** or **QUERY SELECTION BY FORMULA** command).<br>**Note:** With 4D in remote mode, "SQL joins" can only be used if the formulas are executed on the server (they must have access to the records). To configure where formulas are to be executed, please refer to selectors 46 and 47. |
| Query by formula on server | Longint | 46 | **Scope**: Current table and process<br>**Kept between two sessions**: No<br>**Possible values**: 0 (use database configuration), 1 (execute on client) or 2 (execute on server)<br>**Description**: Execution location of **QUERY BY FORMULA** and **QUERY SELECTION BY FORMULA** commands for the *table* passed in the parameter.<br>When using a database in client-server mode, the query "by formula" commands can be executed either on the server or on the client machine:<br>• In databases created with 4D v11 SQL, these commands are executed on the server.<br>• In converted databases, these commands are executed on the client machine, as in previous versions of 4D.<br>• In converted databases, a specific preference (Application/Compatibility page) can be used to globally modify the execution location of these commands.<br>This difference in execution location influences not only application performance (execution on the server is usually faster) but also programming. In fact, the value of the components of the formula (in particular variables called via a method) differ according to the execution context. You can use this selector to punctually adapt the operation of your application.<br>If you pass 0 in the *value* l'parameter, the execution location of query "by formula" commands will depend on the database configuration: in databases created with 4D v11 SQL, these commands will be executed on the server. In converted databases, they will be executed on the client machine or the server according to the database preferences. Pass 1 or 2 in *value* to "force" the execution of these commands, respectively, on the client or on the server machine.<br>Refer to example 4.<br>**Note:** If you want to be able to enable "SQL type" joins (see the QUERY BY FORMULA Joins selector), you must always execute formulas on the server so that they have access to the records. Be careful, in this context, the formula must not contain any calls to a method, otherwise it will automatically be switched to the remote machine. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| QuickTime support | Longint | 82 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (default) = QuickTime disabled, 1 = QuickTime enabled.<br>**Description**: In 4D starting with v14, by default QuickTime codecs are no longer supported. For compatibility, you can use this selector to re-enable them in your database. Modification of this option requires that the database be restarted. Nevertheless, you should note that in future versions of 4D, QuickTime support is permanently removed. |
| Server base process stack size | Longint | 53 | **Scope**: 4D Server<br>**Kept between two sessions**: No<br>**Possible values**: Positive longint.<br>**Description**: Size of the stack allocated to each preemptive system process on the server, expressed in bytes. The default size is determined by the system.<br>Preemptive system processes (processes of the 4D client base process type) are loaded to control the main 4D client processes. The size allocated by default to the stack of each preemptive process allows a good ease of execution but may prove to be consequential when very large numbers of processes (several hundred) are created.<br>For optimization purposes, this size can be reduced considerably if the operations carried out by the database allow for it (for example if the database does not carry out sorts of large quantities of records). Values of 512 or even 256 KB are possible. Be careful, under-sizing the stack is critical and can be harmful to the operation of 4D Server. Setting this parameter should be done with caution and must take the database conditions of use into account (number of records, type of operations, etc.).<br>In order to be taken into account, this parameter must be executed on the server machine (for example in the **On Server Startup Database Method**). |
| Spellchecker | Longint | 81 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: 0 (default) = native OS X spellchecker (Hunspell disabled), 1 = Hunspell spellcheck enabled.<br>**Description**: Enables the Hunspell spellcheck under OS X. By default, the native spellchecker is enabled on this platform. You may prefer to use the Hunspell spellcheck, for example, in order to unify the interface for your cross-platform applications (under Windows, only the Hunspell spellcheck is available). For more information, refer to **Support of Hunspell dictionaries**. |
| SQL Autocommit | Longint | 43 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (deactivation) or 1 (activation)<br>**Description**: Activation or deactivation of the SQL auto-commit mode. By default, the value is 0 (deactivated mode)<br>The auto-commit mode is used to strengthen the referential integrity of the database. When this mode is active, all **SELECT**, **INSERT**, **UPDATE** and **DELETE** (SIUD) queries are automatically included in ad hoc transactions when they are not already executed within a transaction. This mode can also be set in the Preferences of the database. |
| SQL Engine case sensitivity | Longint | 44 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (case not taken into account) or 1 (case-sensitive)<br>**Description**: Activation or deactivation of case-sensitivity for string comparisons carried out by the SQL engine.<br>By default, the value is 1 (case-sensitive): the SQL engine differentiates between upper and lower case and between accented characters when comparing strings (sorts and queries). For example “ABC”= “ABC” but “ABC” # “Abc” and "abc" # "âbc." In certain cases, for example so as to align the functioning of the SQL engine with that of the 4D engine, you may wish for string comparisons to not be case-sensitive (“ABC”=“Abc"="âbc").<br>This option can also be set on the **SQL page** of the Database settings. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| SQL Server Port ID | Longint | 88 | **Scope**: 4D local, 4D Server.<br>**Kept between two sessions**: Yes<br>**Description**: Gets or sets the TCP port number used by the integrated SQL server of 4D in local mode or 4D Server. By default, the value is 19812. When this selector is set, the database setting is updated. You can also set the TCP port number on the "SQL" page of the Database Settings dialog box.<br>**Possible values**: 0 to 65535.<br>**Default value**: 19812 |
| SSL cipher list | String | 64 | **Scope**: 4D application<br>**Kept between two sessions**: No<br>**Possible values**: Sequence of strings separated by colons (for example "RC4-MD5:RC4-64-MD5:....")<br>**Description:** Cipher list used by 4D for the secure protocol. This list modifies the priority of ciphering algorithms implemented by 4D. For example, you can pass the following string in the *value* parameter: "AES:ALL:!aNULL:!eNULL:+RC4:@STRENGTH". For a complete description of the syntax for the ciphers list, refer to the ciphers page of the OpenSSL site. This setting applies to the entire 4D application (it concerns the HTTP server, SQL server, client/server connections, as well as the HTTP client and all the 4D commands that make use of the secure protocol) but it is temporary (it is not maintained between sessions). When the cipher list has been modified, you will need to restart the server concerned in order for the new settings to be taken into account.<br>To reset the cipher list to its default value (stored permanently in the SLI file), call the **SET DATABASE PARAMETER** command and pass an empty string ("") in the *value* parameter.<br>**Note:** With the **Get database parameter** command, the cipher list is returned in the optional *stringValue* parameter and the return parameter is always 0. |
| Table sequence number | Longint | 31 | **Scope**: 4D application<br>**Kept between two sessions**: Yes<br>**Possible values**: Any longint value.<br>**Description**: This selector is used to modify or get the current unique number for records of the table passed as parameter. "Current number" means "last number used": if you modify this value using **SET DATABASE PARAMETER**, the next record will be created with a number that consists of the value passed + 1. This new number is the one returned by the **Sequence number** command as well in any field of the table to which the "Autoincrement" property has been assigned in the Structure editor or via SQL.<br>By default, this unique number is set by 4D and corresponds to the order of record creation. For additional information, refer to the documentation of the **Sequence number** command. |
| Unicode mode | Longint | 41 | **Scope**: Database<br>**Kept between two sessions**: Yes<br>**Possible values**: 0 (compatibility mode) or 1 (Unicode mode)<br>**Description**: Current database operating mode, with regards to the character set. 4D supports the Unicode character set but can function in “compatibility” mode (based on the Mac ASCII character set). By default, converted databases are executed in compatibility mode (0) and databases created with version 11 or higher are executed in Unicode mode. The execution mode can be controlled via an option in the Preferences and can also be read or (for testing purposes) modified via this selector. Modifying this option requires the database to be restarted in order for it to be taken into account. Note that within a component it is not possible to modify this value, but only to read it. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Use legacy network layer | Longint | 87 | **Scope**: 4D in local mode, 4D Server<br>**Kept between two sessions**: Yes<br>**Description:** Sets or gets the current status of the legacy network layer for client/server connections. The legacy network layer is obsolete beginning with 4D v14 R5 and should be replaced progressively in your applications with the *ServerNet* network layer. *ServerNet* will be required in upcoming 4D releases in order to benefit from future network evolutions. For compatibility reasons, the legacy network layer is still supported to allow a smooth transition for existing applications; (it is used by default in applications converted from a release prior to v14 R5). Pass 1 in this parameter to use the legacy network layer (and disable *ServerNet*) for your client/server connections, and pass 0 to disable the legacy network (and use the *ServerNet*).<br>This property can also be set by means of the "Use legacy network layer" option found on the **Compatibility page** of the Database Settings (see **Network and Client-Server options**). In this section, you will also find a discussion about migration strategy. We recommend that you activate the *ServerNet* as soon as possible.<br>You will need to restart the application in order for this parameter to be taken into account. It is not available in 4D Server v14 R5 64-bit version for OS X, which only supports the *ServetNet*; (it always returns 0).<br>**Possible values:** 0 or 1 (0 = do not use legacy layer, 1 = use legacy layer)<br>**Default value:** 0 in databases created with 4D v14 R5 or higher, 1 in databases converted from 4D v14 R4 or earlier. |

## Date Display Formats

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null date | Longint | 100 | "" instead of 0 |
| Date RFC 1123 | Longint | 10 | Fri, 10 Sep 2010 13:07:20 GMT |
| Internal date abbreviated | Longint | 6 | Dec 29, 2006 |
| Internal date long | Longint | 5 | December 29, 2006 |
| Internal date short | Longint | 7 | 12/29/2006 |
| Internal date short special | Longint | 4 | 12/29/06 (but 12/29/1896 or 12/29/2096) |
| ISO Date | Longint | 8 | 2006-12-29T00:00:00 (deprecated) |
| ISO Date GMT | Longint | 9 | 2010-09-13T16:11:53Z |
| System date abbreviated | Longint | 2 | Sun, Dec 29, 2006 |
| System date long | Longint | 3 | Sunday, December 29, 2006 |
| System date short | Longint | 1 | 12/29/2006 |

## Days and Months

| Constant | Type | Value | Comment |
|---|---|---|---|
| April | Longint | 4 | |
| August | Longint | 8 | |
| December | Longint | 12 | |
| February | Longint | 2 | |
| Friday | Longint | 6 | |
| January | Longint | 1 | |
| July | Longint | 7 | |
| June | Longint | 6 | |
| March | Longint | 3 | |
| May | Longint | 5 | |
| Monday | Longint | 2 | |
| November | Longint | 11 | |

| Wednesday | Longint | 4 | |

## Design Object Access

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute executed on server | Longint | 8 | Corresponds to the "Execute on server" option |
| Attribute folder name | Longint | 1024 | Name of folder for the method ("folder" attribute). When you pass this constant, you must pass a folder name in *attribValue*:<br>• if this name corresponds to a valid folder, the method is placed in this parent folder,<br>• if the folder does not exist, the command does not change anything at the parent folder level,<br>• if you pass an empty string, the method is placed at the root level. |
| Attribute invisible | Longint | 1 | Corresponds to the "Invisible" option |
| Attribute published SOAP | Longint | 3 | Corresponds to the "Offered as a Web Service" option |
| Attribute published SQL | Longint | 7 | Corresponds to the "Available through SQL" option |
| Attribute published Web | Longint | 2 | Corresponds to the "Available through 4D HTML tags and URLs (4DACTION...)" option |
| Attribute published WSDL | Longint | 4 | Corresponds to the "Published in WSDL" option |
| Attribute shared | Longint | 5 | Corresponds to the "Shared by components and host database" option |
| Code with tokens | Longint | 1 | Include tokens in exported code |
| On object locked abort | Longint | 0 | Loading of object is aborted (default functioning) |
| On object locked confirm | Longint | 2 | 4D displays a dialog box so that you can choose to try again or to abort. In remote mode, this option is not supported (loading is aborted) |
| On object locked retry | Longint | 1 | 4D keeps attempting to load the object until it has been released |
| Path all objects | Longint | 31 | Paths of all the methods of the database |
| Path database method | Longint | 2 | Path of database methods specified (English name). List of these methods:<br>*[databaseMethod]/onStartup*<br>*[databaseMethod]/onExit*<br>*[databaseMethod]/onDrop*<br>*[databaseMethod]/onBackupStartup*<br>*[databaseMethod]/onBackupShutdown*<br>*[databaseMethod]/onWebConnection*<br>*[databaseMethod]/onWebAuthentication*<br>*[databaseMethod]/onWebSessionSuspend*<br>*[databaseMethod]/onServerStartup*<br>*[databaseMethod]/onServerShutdown*<br>*[databaseMethod]/onServerOpenConnexion*<br>*[databaseMethod]/onServerCloseConnection*<br>*[databaseMethod]/onSystemEvent*<br>*[databaseMethod]/onSqlAuthentication* |
| Path project form | Longint | 4 | Path of project form methods and all their object methods. Examples:<br>*[projectForm]/myForm/{formMethod}*<br>*[projectForm]/myForm/button1*<br>*[projectForm]/myForm/my%2list*<br>*[projectForm]/myForm/button1* |
| Path project method | Longint | 1 | Name of method.<br>Example: *MyProjectMethod* |
| Path table form | Longint | 16 | Path of table form methods and all their object methods. Example:<br>*[tableForm]/table_1/Form1/{formMethod}*<br>*[tableForm]/table_1/Form1/button1*<br>*[tableForm]/table_1/Form1/my%2list*<br>*[tableForm]/table_2/Form1/my%2list* |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Path trigger | Longint | 8 | Path of database triggers. Example:<br>*[trigger]/table_1*<br>*[trigger]/table_2* |

## Dictionaries

**Compatibility note:** These constants correspond to numbers for "Cordial" dictionaries, which are no longer supported in 4D starting with version 14. These constants are kept for reasons of compatibility (an equivalent Hunspell dictionary is used internally).

| Constant | Type | Value | Comment |
|---|---|---|---|
| English dictionary | Longint | 69632 | |
| French dictionary | Longint | 262144 | |
| German dictionary | Longint | 131584 | |
| Norwegian dictionary | Longint | 589824 | |
| Spanish dictionary | Longint | 196608 | |

## Digest Type

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D digest | Longint | 2 | Use internal algorithm of 4D |
| MD5 digest | Longint | 0 | Use the MD5 algorithm |
| SHA1 digest | Longint | 1 | Use the SHA-1algorithm |

## Euro Currencies

| Constant | Type | Value | Comment |
|---|---|---|---|
| Austrian Schilling | String | ATS | |
| Belgian Franc | String | BEF | |
| Deutsche Mark | String | DEM | |
| Euro | String | EUR | |
| Finnish Markka | String | FIM | |
| French Franc | String | FRF | |
| Greek Drachma | String | GRD | |
| Irish Pound | String | IEP | |
| Italian Lira | String | ITL | |
| Luxembourg Franc | String | LUF | |
| Netherlands Guilder | String | NLG | |
| Portuguese Escudo | String | PTE | |
| Spanish Peseta | String | ESP | |

## Events (Modifiers)

| Constant | Type | Value | Comment |
|---|---|---|---|
| Activate window bit | Longint | 0 | |
| Activate window mask | Longint | 1 | |
| Caps lock key bit | Longint | 10 | Windows and OS X |
| Caps lock key mask | Longint | 1024 | Windows and OS X |
| Command key bit | Longint | 8 | Ctrl key under Windows, Command key under OS X |
| Command key mask | Longint | 256 | Ctrl key under Windows, Command key under OS X |
| Control key bit | Longint | 12 | Ctrl key under OS X, or right click under Windows and OS X |
| Control key mask | Longint | 4096 | Ctrl key under OS X, or right click under Windows and OS X |
| Mouse button bit | Longint | 7 | |
| Mouse button mask | Longint | 128 | |
| Option key bit | Longint | 11 | Alt key (also called Option under OS X) |
| Option key mask | Longint | 2048 | Alt key (also called Option under OS X) |
| Right control key bit | Longint | 15 | |
| Right control key mask | Longint | 32768 | |
| Right option key bit | Longint | 14 | |
| Right option key mask | Longint | 16384 | |
| Right shift key bit | Longint | 13 | |
| Right shift key mask | Longint | 8192 | |
| Shift key bit | Longint | 9 | Windows and OS X |
| Shift key mask | Longint | 512 | Windows and OS X |

| Time array | Longint | 32 | |

## Find Window

| Constant | Type | Value | Comment |
|---|---|---|---|
| In contents | Longint | 3 | Platform: Mac OS and Windows |
| In drag | Longint | 4 | Platform: Mac OS only (obsolete beginning with 4D v14) |
| In go away | Longint | 6 | Platform: Mac OS only (obsolete beginning with 4D v14) |
| In grow | Longint | 5 | Platform: Mac OS only (obsolete beginning with 4D v14) |
| In menu bar | Longint | 1 | Platform: Mac OS only (obsolete beginning with 4D v14) |
| In system window | Longint | 2 | Platform: Mac OS only (obsolete beginning with 4D v14) |
| In zoom box | Longint | 8 | Platform: Mac OS only (obsolete beginning with 4D v14) |

## Font Styles

Constants prefixed with _O_ are obsolete and must no longer be used.

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Condensed | Longint | 32 | |
| _o_Extended | Longint | 64 | |
| _o_Outline | Longint | 8 | |
| _o_Shadow | Longint | 16 | |
| Automatic style sheet | String | __automatic__ | Used by default for all objects |
| Automatic style sheet_additional | String | __automatic_additional_text__ | Supported by static text, fields and variables only. Used for additional text in dialog boxes. |
| Automatic style sheet_main | String | __automatic_main_text__ | Supported by static text, fields and variables only. Used for main text in dialog boxes. |
| Bold | Longint | 1 | |
| Bold and Italic | Longint | 3 | |
| Bold and Underline | Longint | 5 | |
| Italic | Longint | 2 | |
| Italic and Underline | Longint | 6 | |
| Plain | Longint | 0 | |
| Underline | Longint | 4 | |

## Font Type List

| Constant | Type | Value | Comment |
|---|---|---|---|
| Favorite fonts | Longint | 1 | *fonts* contains the list of favorite fonts.<br>- Under Windows: list of active font family names.<br>- Under OS X: list of font family names found in the control panel, entitled "Favorites" in English, "Favoris" in French, "Favoriten" in German, and so on . This collection may be blank if the user has not added any favorite fonts. |
| Recent fonts | Longint | 2 | *fonts* contains the list of recent fonts (the ones used during the 4D session). This list is used in particular by multi-style text areas. |
| System fonts | Longint | 0 | *fonts* contains the list of all the system fonts. Default option when *listType* is omitted. |

## Form Area

| Constant | Type | Value | Comment |
|---|---|---|---|
| Form break0 | Longint | 300 | |
| Form break1 | Longint | 301 | |
| Form break2 | Longint | 302 | |
| Form break3 | Longint | 303 | |
| Form break4 | Longint | 304 | |
| Form break5 | Longint | 305 | |
| Form break6 | Longint | 306 | |
| Form break7 | Longint | 307 | |
| Form break8 | Longint | 308 | |
| Form break9 | Longint | 309 | |
| Form detail | Longint | 0 | |
| Form footer | Longint | 100 | |
| Form header | Longint | 200 | |
| Form header1 | Longint | 201 | |
| Form header10 | Longint | 210 | |
| Form header2 | Longint | 202 | |
| Form header3 | Longint | 203 | |
| Form header4 | Longint | 204 | |
| Form header5 | Longint | 205 | |
| Form header6 | Longint | 206 | |
| Form header7 | Longint | 207 | |
| Form header8 | Longint | 208 | |
| Form header9 | Longint | 209 | |

## Form Events

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_On Mac toolbar button | Longint | 55 | *** Obsolete constant *** |
| On Activate | Longint | 11 | The form’s window becomes the frontmost window |
| On After Edit | Longint | 45 | The contents of the enterable object that has the focus has just been modified |
| On After Keystroke | Longint | 28 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text including this character. |
| On After Sort | Longint | 30 | (*List box only*) A standard sort has just been carried out in a list box column |
| On Alternative Click | Longint | 38 | • *3D buttons*: The “arrow” area of a 3D button is clicked<br>• *List boxes*: In a column of an object array, an ellipsis button ("alternateButton" attribute) is clicked<br>**Note**: Ellipsis buttons are only available for versions v15 or higher. |
| On Before Data Entry | Longint | 41 | (*List box only*) A list box cell is about to change to editing mode |
| On Before Keystroke | Longint | 17 | A character is about to be entered in the object that has the focus. **Get edited text** returns the object's text without this character. |
| On Begin Drag Over | Longint | 46 | An object is being dragged |
| On Begin URL Loading | Longint | 47 | (*Web areas only*) A new URL is loaded in the Web area |
| On bound variable change | Longint | 54 | The variable bound to a subform is modified. |
| On Clicked | Longint | 4 | A click occurred on an object |
| On Close Box | Longint | 22 | The window’s close box has been clicked |
| On Close Detail | Longint | 26 | You left the detail form and are going back to the output form |
| On Collapse | Longint | 44 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been collapsed using a click or a keystroke |
| On Column Moved | Longint | 32 | (*List box only*) A list box column is moved by the user via drag and drop |
| On Column Resize | Longint | 33 | (*List box only*) The width of a list box column is modified by a user with the mouse |
| On Data Change | Longint | 20 | Object data has been modified |
| On Deactivate | Longint | 12 | The form’s window ceases to be the frontmost window |
| On Delete Action | Longint | 58 | (*Hierarchical lists and List boxes*) The user attempts to delete an item |
| On Display Detail | Longint | 8 | A record is about to be displayed in a list or a row is about to be displayed in a list box. |
| On Double Clicked | Longint | 13 | A double click occurred on an object |
| On Drag Over | Longint | 21 | Data could be dropped onto an object |
| On Drop | Longint | 16 | Data has been dropped onto an object |
| On End URL Loading | Longint | 49 | (*Web areas only*) All the resources of the URL have been loaded |
| On Expand | Longint | 43 | (*Hierarchical lists and hierarchical list boxes*) An element of the hierarchical list or hierarchical list box has been expanded using a click or a keystroke |

| Constant | Type | Value | Comment |
|---|---|---|---|
| On Footer Click | Longint | 57 | (*List boxes only*) A click occurs in the footer of a list box or a list box column |
| On Getting Focus | Longint | 15 | A form object is getting the focus |
| On Header | Longint | 5 | The form's header area is about to be printed or displayed |
| On Header Click | Longint | 42 | (*List box only*) A click occurs in a column header of the list box |
| On Load | Longint | 1 | The form is about to be displayed or printed |
| On Load Record | Longint | 40 | During entry in list, a record is loaded during modification (the user clicks on a record line and a field changes to editing mode) |
| On Long Click | Longint | 39 | (*3D buttons only*) A 3D button is clicked and the mouse button remains pushed for a certain lapse of time |
| On Losing Focus | Longint | 14 | A form object is losing the focus |
| On Menu Selected | Longint | 18 | A menu item has been chosen |
| On Mouse Enter | Longint | 35 | The mouse cursor enters the graphic area of an object |
| On Mouse Leave | Longint | 36 | The mouse cursor leaves the graphic area of an object |
| On Mouse Move | Longint | 37 | The mouse cursor moves at least one pixel OR a modifier key (Shift, Alt, Shift Lock) was pressed. If the event is checked for an object only, it is generated only when the cursor is within the graphic area of the object |
| On Mouse Up | Longint | 2 | (*Pictures only*) The user has just released the left mouse button in a Picture object |
| On Open Detail | Longint | 25 | The detail form associated with the output form or with the listbox is about to be opened |
| On Open External Link | Longint | 52 | (*Web areas only*) An external URL has been opened in the browser |
| On Outside Call | Longint | 10 | The form received a **CALL PROCESS** call |
| On Page Change | Longint | 56 | The current page of the form is changed |
| On Plug in Area | Longint | 19 | An external object requested its object method to be executed |
| On Printing Break | Longint | 6 | One of the form's break areas is about to be printed |
| On Printing Detail | Longint | 23 | The form's detail area is about to be printed |
| On Printing Footer | Longint | 7 | The form's footer area is about to be printed |
| On Resize | Longint | 29 | The form window is resized |
| On Row Moved | Longint | 34 | (*List box only*) A list box row is moved by the user via drag and drop |
| On Scroll | Longint | 59 | The user scrolls the contents of a picture field or variable using the mouse or keyboard. |
| On Selection Change | Longint | 31 | • *List box*: The current selection of rows or columns is modified<br>• *Records in list*: The current record or the current selection of rows is modified in a list form or subform<br>• *Hierarchical list*: The selection in the list is modified following a click or a keystroke<br>• *Enterable field or variable*: The text selection or the position of the cursor in the area is modified following a click or a keystroke |
| On Timer | Longint | 27 | The number of ticks defined by the **SET TIMER** command has passed |
| On Unload | Longint | 24 | The form is about to be exited and released |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| On URL Filtering | Longint | 51 | (*Web areas only*) A URL was blocked by the Web area |
| On URL Loading Error | Longint | 50 | (*Web areas only*) An error occurred when the URL was loading |
| On URL Resource Loading | Longint | 48 | (*Web areas only*) A new resource is loaded in the Web area |
| On Validate | Longint | 3 | The record data entry has been validated |
| On Window Opening Denied | Longint | 53 | (*Web areas only*) A pop-up window has been blocked |

## Form Object Types

| Constant | Type | Value | Comment |
|---|---|---|---|
| Object type 3D button | Longint | 16 | |
| Object type 3D checkbox | Longint | 26 | |
| Object type 3D radio button | Longint | 23 | |
| Object type button grid | Longint | 20 | |
| Object type checkbox | Longint | 25 | |
| Object type combobox | Longint | 11 | |
| Object type dial | Longint | 28 | |
| Object type group | Longint | 21 | |
| Object type groupbox | Longint | 30 | |
| Object type hierarchical list | Longint | 6 | |
| Object type hierarchical popup menu | Longint | 13 | |
| Object type highlight button | Longint | 17 | |
| Object type invisible button | Longint | 18 | |
| Object type line | Longint | 32 | |
| Object type listbox | Longint | 7 | |
| Object type listbox column | Longint | 9 | |
| Object type listbox footer | Longint | 10 | |
| Object type listbox header | Longint | 8 | |
| Object type matrix | Longint | 35 | |
| Object type oval | Longint | 34 | |
| Object type picture button | Longint | 19 | |
| Object type picture input | Longint | 4 | |
| Object type picture popup menu | Longint | 14 | |
| Object type picture radio button | Longint | 24 | |
| Object type plugin area | Longint | 38 | |
| Object type popup dropdown list | Longint | 12 | |
| Object type progress indicator | Longint | 27 | |
| Object type push button | Longint | 15 | |
| Object type radio button | Longint | 22 | |
| Object type radio button field | Longint | 5 | |
| Object type rectangle | Longint | 31 | |
| Object type rounded rectangle | Longint | 33 | |
| Object type ruler | Longint | 29 | |
| Object type splitter | Longint | 36 | |
| Object type static picture | Longint | 2 | |
| Object type static text | Longint | 1 | |
| Object type subform | Longint | 39 | |
| Object type tab control | Longint | 37 | |
| Object type text input | Longint | 3 | |
| Object type unknown | Longint | 0 | |
| Object type web area | Longint | 40 | |
| Object type write pro area | Longint | 41 | |

## Form Objects (Access)

| Constant | Type | Value | Comment |
|---|---|---|---|
| Form all pages | Longint | 2 | Returns all objects of all the pages, excluding inherited objects |
| Form current page | Longint | 1 | Returns all objects of the current page, including page 0 but excluding inherited objects |
| Form inherited | Longint | 4 | Returns inherited objects only |
| Object current | Longint | 0 | |
| Object first in entry order | String | ;FirstObject | |
| Object named | Longint | 3 | |
| Object subform container | Longint | 2 | |
| Object with focus | Longint | 1 | |

## Form Objects (Properties)

| Constant | Type | Value | Comment |
|---|---|---|---|
| Align bottom | Longint | 4 | |
| Align center | Longint | 3 | |
| Align default | Longint | 1 | |
| Align left | Longint | 2 | |
| Align right | Longint | 4 | |
| Align top | Longint | 2 | |
| Asynchronous progress bar | Longint | 3 | Circular indicator displaying continuous animation |
| Barber shop | Longint | 2 | Bar displaying continuous animation |
| Border Dotted | Longint | 2 | Objects appear framed with a dotted 1-pt. border line |
| Border Double | Longint | 5 | Objects appear framed with a double line, i.e., two continuous 1-pt. lines separated by a pixel |
| Border None | Longint | 0 | Objects appear with no border |
| Border Plain | Longint | 1 | Objects appear framed with a continuous 1-pt. border line |
| Border Raised | Longint | 3 | Objects appear framed with a 3D effect (raised) |
| Border Sunken | Longint | 4 | Objects appear framed with a sunken 3D effect |
| Border System | Longint | 6 | The border line is drawn based on the graphic specifications of the system |
| Choice list | Longint | 0 | Simple list of values to choose from ("Choice List" option in the Property List) (default) |
| Disable events others unchanged | Longint | 2 | All the events listed in the *arrEvents* array are disabled; the status of other events remain unchanged |
| Enable events disable others | Longint | 0 | All the events listed in the *arrEvents* array are enabled; all the other events are disabled |
| Enable events others unchanged | Longint | 1 | All the events listed in the *arrEvents* array are enabled; the status of other events remain unchanged |
| Excluded list | Longint | 2 | Lists values not accepted for entry ("Excluded List" option in the Property List) |
| Multiline Auto | Longint | 0 | In single-line areas, words located at the end of lines are truncated and there are no line returns.<br>In multiline areas, 4D carries out automatic line returns. |
| Multiline No | Longint | 2 | There are never line returns: the text is always displayed on a single row. If the Alpha or Text field or variable contains carriage returns, the text located after the first carriage return is removed as soon as the area is modified. |
| Multiline Yes | Longint | 1 | In single-line areas, the text is displayed up to the first carriage return or until the last word that can be displayed entirely. 4D inserts line returns; it is possible to scroll the contents of the area by pressing the down arrow key.<br>In multiline areas, 4D carries out automatic line returns. |
| Orientation 0° | Longint | 0 | No rotation (default value) |
| Orientation 180° | Longint | 180 | Orientation of text to 180° clockwise |
| Orientation 90° left | Longint | 270 | Orientation of text to 90° counter-clockwise |
| Orientation 90° right | Longint | 90 | Orientation of text to 90° clockwise |
| Print Frame fixed with multiple records | Longint | 2 | The frame remains the same size, but 4D prints the form several times to include all the records. |
| Print Frame fixed with truncation | Longint | 1 | 4D prints only the records that fit into the area of the subform. The form is printed only once and those records that are not printed are ignored. |
| Progress bar | Longint | 1 | Standard progress bar |
| Required list | Longint | 1 | Lists only values accepted for entry ("Required List" option in the Property List) |
| Resize horizontal grow | Longint | 1 | If the window grows by 50% in width, the object is expanded by 50% to the right. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Resize horizontal move | Longint | 2 | If the window grows by 100 pixels in width, the object is moved 100 pixels to the right. |
| Resize horizontal none | Longint | 0 | If the window is expanded in width, neither the width nor the position of the object changes. |
| Resize vertical grow | Longint | 1 | If the window grows by 50% in height, the object is lengthened by 50% towards the bottom. |
| Resize vertical move | Longint | 2 | If the window grows by 100 pixels in height, the object is moved 100 pixels towards the bottom. |
| Resize vertical none | Longint | 0 | If the window is expanded in height, neither the height nor the position of the object changes. |

## Form Parameters

| Constant | Type | Value | Comment |
|---|---|---|---|
| Multiple selection | Longint | 2 | The user can select several records at once. To select adjacent records, click on the first record to be selected, then press the **Shift** key before clicking on the last record you want to include in the selection. To select non-adjacent records, click on each record separately while holding down the **Ctrl** (under Windows) or **Command** (under Mac OS) key. |
| No selection | Longint | 0 | It is not be possible to select a record in the list |
| NonInverted objects | Longint | 0 | |
| Single selection | Longint | 1 | Only one record can be selected at a time |

## Function Keys

| Constant | Type | Value | Comment |
|---|---|---|---|
| Backspace key | Longint | 8 | |
| Down arrow key | Longint | 31 | |
| End key | Longint | 4 | |
| Enter key | Longint | 3 | |
| Escape key | Longint | 27 | |
| F1 key | Longint | -122 | |
| F10 key | Longint | -109 | |
| F11 key | Longint | -103 | |
| F12 key | Longint | -111 | |
| F13 key | Longint | -105 | |
| F14 key | Longint | -107 | |
| F15 key | Longint | -113 | |
| F2 key | Longint | -120 | |
| F3 key | Longint | -99 | |
| F4 key | Longint | -118 | |
| F5 key | Longint | -96 | |
| F6 key | Longint | -97 | |
| F7 key | Longint | -98 | |
| F8 key | Longint | -100 | |
| F9 key | Longint | -101 | |
| Help key | Longint | 5 | |
| Home key | Longint | 1 | |
| Left arrow key | Longint | 28 | |
| Page down key | Longint | 12 | |
| Page up key | Longint | 11 | |
| Return key | Longint | 13 | |
| Right arrow key | Longint | 29 | |
| Tab key | Longint | 9 | |
| Up arrow key | Longint | 30 | |

## Graph Parameters

| Constant | Type | Value | Comment |
|---|---|---|---|
| Graph background color | String | graphBackgroundColor | **Possible values:** SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph background opacity | String | graphBackgroundOpacity | **Possible values**: Integers, range 0-100<br>**Default value**: 100 |
| Graph background shadow color | String | graphBackgroundShadowColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph bottom margin | String | bottomMargin | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph colors | String | colors | **Possible values**: Text array. Colors for each graph series.<br>**Default values**: Blue-green (#19BAC9), Yellow (#FFC338), Purple (#573E82), Green (#4FA839), Orange (#D95700), Blue (#1D9DF2), Yellow-green (#B5CF32), Red (#D43A26) |
| Graph column gap | String | columnGap | **Possible value**s: Longints<br>**Default value**: 12<br>Sets spacing between bars |
| Graph column width max | String | columnWidthMax | **Possible values**: Real numbers<br>**Default value**: 200 |
| Graph column width min | String | columnWidthMin | **Possible values**: Real numbers<br>**Default value**: 10 |
| Graph default height | String | defaultHeight | **Possible values**: Real numbers<br>**Default value**: 400. If graphType=7 (Pie), then default value = 600 |
| Graph default width | String | defaultWidth | **Possible values**: Real numbers<br>**Default value**: 600. If graphType=7 (Pie), then default value = 800 |
| Graph display legend | String | displayLegend | **Possible value**s: Boolean<br>**Default value**: True |
| Graph document background color | String | documentBackgroundColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414". When a graph saved as an SVG picture is opened elsewhere, the document background color is only displayed if the SVG rendering engine supports the *SVG tiny 1.2* norm (supported on IE, Firefox, but not on Chrome). |
| Graph document background opacity | String | documentBackgroundOpacity | **Possible values**: Integer, range 0-100 (default value: 100). When a graph saved as an SVG picture is opened elsewhere, the document background opacity is only displayed if the SVG rendering engine supports the *SVG tiny 1.2* norm (supported on IE, Firefox, but not on Chrome). |
| Graph font color | String | fontColor | **Possible values:** SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph font size | String | fontSize | **Possible values**: Longints<br>**Default value**: 12. If graphType=7 (Pie), see Graph pie font size |
| Graph left margin | String | leftMargin | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph legend font color | String | legendFontColor | **Possible values**: SVG compliant color expression (text), for example "#7F8E00", "Pink", or "#0a1414" |
| Graph legend icon gap | String | legendIconGap | **Possible values**: Real numbers<br>**Default value**: Graph legend icon height/2 |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Graph legend icon height | String | legendIconHeight | **Possible values**: Real numbers<br>**Default value**: 20 |
| Graph legend icon width | String | legendIconWidth | **Possible values**: Real numbers<br>**Default value**: 20 |
| Graph legend labels | String | legendLabels | **Possible values**: Text array. If missing, 4D displays icons without text. |
| Graph line width | String | lineWidth | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph pie font size | String | pieFontSize | **Possible values**: Real numbers<br>**Default value**: 16 |
| Graph pie shift | String | pieShift | **Possible values**: Real numbers<br>**Default value**: 8 |
| Graph plot height | String | plotHeight | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph plot radius | String | plotRadius | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph plot width | String | plotWidth | **Possible values**: Real numbers<br>**Default value**: 12 |
| Graph right margin | String | rightMargin | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph top margin | String | topMargin | **Possible values**: Real numbers<br>**Default value**: 2 |
| Graph type | String | graphType | **Possible values**: Longints [1 to 8] where 1 = bars, 2 = proportional, 3 = stacked, 4 = lines, 5 = surfaces, 6 = scatter, 7 = pie, 8 = pictures.<br>**Default value**: 1<br>If null, the graph is not drawn and no error message is displayed. If out of range, the graph is not drawn and an error message is displayed.<br>If you want to modify picture type graphs (value=8), you must copy the 4D/Resources/GraphTemplates/Graph_8_Pictures/ folder into the Resources folder of your database and perform the necessary modifications. Local picture files will be used instead of 4D files. There is no pattern for picture names; 4D sorts the files contained in the folder and assigns the first file to the first graph. These files can be of the SVG or image type. |
| Graph xGrid | String | xGrid | **Possible values**: Boolean<br>**Default value**: True.<br>Used only with proportional types 4 and 6. |
| Graph xMax | String | xMax | **Possible values**: Number, Date, Time (same type as *xLabels* parameter).<br>Only values lower than xMax are displayed on the graph. xMax is used only for graph types 4, 5, or 6 if xProp=true and if *xLabels* type is a number, date, or time. If missing or if xMin>xMax, 4D automatically calculates the xMax value. |
| Graph xMin | String | xMin | **Possible values**: Number, Date, Time (same type as *xLabels* parameter).<br>Only values higher than xMin are displayed on the graph. xMin is used only for graph types 4, 5, or 6 if xProp=true and if *xLabels* type is a number, date, or time. If missing or if xMin>xMax, 4D automatically calculates the xMin value. |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Graph xProp | String | xProp | **Possible values**: Boolean<br>**Default value**: False<br>True for proportional x-axis; False for normal x-axis. xProp is used only for graph types 4, 5, or 6 |
| Graph yGrid | String | yGrid | **Possible values**: Boolean<br>**Default value**: True |
| Graph yMax | String | yMax | **Possible value**s: Numbers<br>If missing, 4D automatically calculates the yMax value. |
| Graph yMin | String | yMin | **Possible values**: Numbers<br>If missing, 4D automatically calculates the yMin value. |

## Hierarchical Lists

| Constant | Type | Value | Comment |
|---|---|---|---|
| Additional text | String | 4D_additional_text | |
| Ala Macintosh | Longint | 1 | |
| Ala Windows | Longint | 2 | |
| Macintosh node | Longint | 860 | |
| Use PicRef | Longint | 131072 | |
| Use PICT resource | Longint | 65536 | |
| Windows node | Longint | 138 | |

## HTTP Client

| Constant | Type | Value | Comment |
|---|---|---|---|
| HTTP basic | Longint | 1 | Use BASIC authentication method |
| HTTP compression | Longint | 6 | *value* = 0 (do not compress) or 1 (compress). Default value: 0<br>This option enables or disables the compression mechanism intended to accelerate exchanges for requests between the client and server. When this mechanism is enabled, the HTTP client uses deflate or gzip compression depending on the server response. |
| HTTP DELETE method | String | DELETE | See RFC 2616 |
| HTTP digest | Longint | 2 | Use DIGEST authentication method |
| HTTP display auth dial | Longint | 4 | *value* = 0 (do not display dialogue box) or 1 (display dialogue box). Default value: 0<br>This option displays the authentication dialog box when the **HTTP Get** or **HTTP Request** command is executed. By default, this command never displays the dialog box and you must normally use the **HTTP AUTHENTICATE** command. However, if you want an authentication dialog box to appear so that users can enter their identifiers, then pass 1 in value. The dialog box only appears when the request requires authentication. |
| HTTP follow redirect | Longint | 2 | *value* = 0 (do not accept redirections) or 1 (accept redirections).<br>Default value = 1 |
| HTTP GET method | String | GET | See RFC 2616. Same as using **HTTP Get** command. |
| HTTP HEAD method | String | HEAD | See RFC 2616 |
| HTTP max redirect | Longint | 3 | *value* = Maximum number of redirections accepted<br>Default value = 2 |
| HTTP OPTIONS method | String | OPTIONS | See RFC 2616 |
| HTTP POST method | String | POST | See RFC 2616 |
| HTTP PUT method | String | PUT | See RFC 2616 |
| HTTP reset auth settings | Longint | 5 | *value* = 0 (do not delete information) or 1 (delete information). Default value: 0<br>This option indicates to 4D to reset the authentication information of the user (user name, password, method) after each execution of the **HTTP Get** or **HTTP Request** command in the same process. By default, this information is kept and reused for each request. Pass 1 in *value* to delete this information after each call. Note that regardless of the setting, this information is deleted when the process is killed. |
| HTTP timeout | Longint | 1 | *value* = timeout of client request, expressed in seconds. This timeout sets how long the HTTP client waits for the server to respond. After this period of time has passed, the client closes the session and the request is lost.<br>By default, this timeout is 120 seconds. It can be changed because of specific characteristics (network state, request characteristics, etc.). |
| HTTP TRACE method | String | TRACE | See RFC 2616 |

## Index Type

| Constant | Type | Value | Comment |
|---|---|---|---|
| Cluster BTree index | Longint | 3 | B-Tree type index using clusters. This type of index is optimized when the index contains few keywords, i.e. when the same values occur frequently in the data. |
| Default index type | Longint | 0 | 4D specifies the index type (excluding keywords indexes) that is the most optimized according to the contents of the field. |
| Keywords index | Longint | -1 | Permits word-by-word indexing of field contents. This type of index can only be used with fields of the Text, Alpha or Picture type. Warning: Keywords indexes cannot be composite. |
| Standard BTree index | Longint | 1 | Standard B-Tree type index. This multi-purpose index type is used in previous versions of 4D |

## Is License Available

| Constant | Type | Value | Comment |
|---|---|---|---|
| 4D Client SOAP license | Longint | 808465465 | |
| 4D Client Web license | Longint | 808465209 | |
| 4D Draw license | Longint | 808464694 | |
| 4D for ADO license | Longint | 808465714 | |
| 4D for MySQL license | Longint | 808465712 | |
| 4D for OCI license | Longint | 808465208 | |
| 4D for PostgreSQL license | Longint | 808465713 | |
| 4D for Sybase license | Longint | 808465715 | |

## LDAP

| Constant | Type | Value | Comment |
|---|---|---|---|
| LDAP all levels | String | sub | Search in the root entry level defined by *dnRootEntry* and in all subsequent entries |
| LDAP password MD5 | Longint | 0 | (Default) Send password encrypted in MD5 |
| LDAP password plain text | Longint | 1 | Send password with no encryption (TLS connection recommended) |
| LDAP root and next | String | one | Search in the root entry level defined by *dnRootEntry* and in the directly subsequent entries on one level |
| LDAP root only | String | base | Search only in the root entry level defined by *dnRootEntry* (default if omitted) |

## List Box

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| lk add to selection | Longint | 1 | The row selected is added to the existing selection. If the row specified already belongs to the existing selection, the command does nothing. |
| lk all | Longint | 0 | The command affects all sub-levels (default value, used when parameter is omitted). |
| lk background color | Longint | 1 | |
| lk background color array | Longint | 1 | |
| lk break row | Longint | 2 | The command affects the sub-level to which the "cell" designated by the *row* and *column* parameters belongs. Note that these parameters represent the row and column numbers in the list box in standard mode and not in its hierarchical representation. If the *row* and *column* parameters are omitted, the command does nothing. |
| lk control array | Longint | 3 | |
| lk display footer | Longint | 8 | **Display Footers** property<br>Applies to: List box<br>Possible values:<br>• lk no (0): hidden<br>• lk yes (1): shown |
| lk display header | Longint | 0 | **Display Headers** property<br>Applies to: List box<br>Possible values:<br>• lk no (0): hidden<br>• lk yes (1): shown |
| lk display hor scrollbar | Longint | 2 | 0=hidden, 1=shown |
| lk display ver scrollbar | Longint | 4 | 0=hidden, 1=shown |
| lk font color | Longint | 0 | |
| lk font color array | Longint | 0 | |
| lk footer height | Longint | 9 | Height in pixels |
| lk header height | Longint | 1 | Height in pixels |
| lk hor scrollbar height | Longint | 3 | Height in pixels |
| lk hor scrollbar position | Longint | 6 | Position of the cursor in pixels |
| lk inherited | Longint | -255 | |
| lk last printed row number | Longint | 0 | Returns in *info* the number of the last row printed. Lets you find out the number of the next row to be printed.<br>The number returned may be greater than the number of rows actually printed if the list box contains invisible rows or if the **OBJECT SET SCROLL POSITION** command has been called. For example, if rows 1, 18 and 20 have been printed, *info* is 20. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| lk level | Longint | 3 | The command affects all the break rows corresponding to the *level* column. This parameter designates a column number in the list box in standard mode and not in its hierarchical representation. If the *level* parameter is omitted, the command does nothing. |
| lk lines | Longint | 1 | Height designates a number of lines. 4D calculates the height of a line according to the font |
| lk pixels | Longint | 0 | Height is a number of pixels (default). |
| lk printed height | Longint | 3 | Returns in *info* the height in pixels of the object actually printed (including headers, lines, etc.). Remember that if the number of rows to print is less than the "capacity" of the list box, its height is automatically reduced. |
| lk printed rows | Longint | 1 | Returns in *info* the number of rows actually printed during the last call to the **Print object** command. This number includes any break rows added in the case of a hierarchical list box. For example, *info* is 10 if the list box contains 20 rows and the odd-numbered rows were hidden. |
| lk printing is over | Longint | 2 | Returns in *info* a Boolean indicating whether the last (visible) row of the list box has actually been printed. True = row has been printed; Otherwise, False. |
| lk remove from selection | Longint | 2 | The row selected is removed from the existing selection. If the row specified does not belong to the existing selection, the command does nothing. |
| lk replace selection | Longint | 0 | The row selected becomes the new selection and replaces the existing selection. The command has the same effect as a user click on a row (however, the On Clicked event is not generated). This is the default action (if the *action* parameter is omitted). |
| lk row height array | Longint | 4 | (4D View Pro license required) |
| lk row is disabled | Longint | 2 | The corresponding row is disabled. The text and controls such as check boxes are dimmed or grayed out. Enterable text input areas are no longer enterable. Default value: Enabled |
| lk row is hidden | Longint | 1 | The corresponding row is hidden. Hiding rows only affects the display of the list box. The hidden rows are still present in the arrays and can be managed by programming. The language commands, more particularly **LISTBOX Get number of rows** or **LISTBOX GET CELL POSITION**, do not take the displayed/hidden status of rows into account. For example, in a list box with 10 rows where the first 9 rows are hidden, **LISTBOX Get number of rows** returns 10. From the user's point of view, the presence of hidden rows in a list box is not visibly discernible. Only visible rows can be selected (for example using the Select All command). Default value: Visible |
| lk row is not selectable | Longint | 4 | The corresponding row is not selectable (highlighting is not possible). Enterable text input areas are no longer enterable unless the "Single-Click Edit" option is enabled. Controls such as check boxes and lists are still functional however. This setting is ignored if the list box selection mode is "None". Default value: Selectable |
| lk selection | Longint | 1 | The command affects selected sub-levels. |
| lk style array | Longint | 2 | |
| lk ver scrollbar position | Longint | 7 | Position of the cursor in pixels |
| lk ver scrollbar width | Longint | 5 | Width in pixels |

## Listbox Footer Calculation

| Constant | Type | Value | Comment |
|---|---|---|---|
| Listbox footer std deviation | Longint | 7 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |
| lk footer average | Longint | 6 | Used with number or time type columns<br>Default type of the result: Real |
| lk footer count | Longint | 5 | Used with number, text, date, time, Boolean or picture type columns<br>Default type of the result: Longint |
| lk footer custom | Longint | 1 | No calculation performed by 4D. The footer variable must be calculated by programming.<br>Default type of the result: Footer variable type |
| lk footer max | Longint | 3 | Used with number, date, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer min | Longint | 2 | Used with number, date, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer sum | Longint | 4 | Used with number, time or Boolean type columns<br>Default type of the result: Column array or field type |
| lk footer sum squares | Longint | 9 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |
| lk footer variance | Longint | 8 | Used with number or time type columns (only for array type list boxes)<br>Default type of the result: Real |

## Log Events

| Constant | Type | Value | Comment |
|---|---|---|---|
| Error message | Longint | 2 | |
| Information message | Longint | 0 | |
| Into 4D commands log | Longint | 3 | Indicates to 4D to record the *message* in the 4D commands log file, if this file has been activated. The 4D commands log file can be enabled using the **SET DATABASE PARAMETER** command (selector 34).<br>**Note:** 4D log files are grouped together in the **Logs** folder, which is created next to the database structure file (see the **Get 4D folder** command). |
| Into 4D debug message | Longint | 1 | Indicates to 4D to send the *message* to the system debugging environment. The result depends on the platform:<br>• Under Mac OS: the command sends the message to the Console<br>• Under Windows: the command sends the message as a debug message. To be able to read this message, you must have Microsoft Visual Studio or the DebugView utility for Windows (http://technet.microsoft.com/en-us/sysinternals/bb896647.aspx) |
| Into 4D diagnostic log | Longint | 5 | Indicates to 4D to record the *message* in the 4D diagnostic file, if this file has been enabled. The diagnostic log file can be enabled using the **SET DATABASE PARAMETER** command (selector 79). |
| Into 4D request log | Longint | 2 | Indicates to 4D to record the *message* in the 4D requests log, if this file has been activated |
| Into Windows log events | Longint | 0 | Indicates to 4D to send the *message* to the “Log events” of Windows. This log receives and stores messages coming from running applications. In this case, you can attribute a level of importance to *message* via the optional *importance* parameter (see below).<br>**Notes:**<br>• For this feature to be available, the Windows Log Events service must be running.<br>• Under Mac OS, the command does nothing with this output type |
| Warning message | Longint | 1 | |

## Math

| Constant | Type | Value | Comment |
|---|---|---|---|
| Degree | Real | 0.0174532925199432958 | |
| e number | Real | 2.71828182845904524 | |
| Pi | Real | 3.141592653589793239 | |
| Radian | Real | 57.29577951308232088 | |

## Menu Item Properties

| Constant | Type | Value | Comment |
|---|---|---|---|
| Access privileges | String | 4D_access_group | Assign an access group to the command<br>0 = All Groups<br>>0 = Group ID |
| Associated standard action | String | 4D_standard_action | Associate a standard action with a menu item<br>See the constants of the **Value for Associated Standard Action** theme |
| Start a new process | String | 4D_start_new_process | Activate the "Start New Process" option<br>0 = No, 1 = Yes |

## Multistyle Text

| Constant | Type | Value | Comment |
|---|---|---|---|
| ST 4D Expressions as sources | Longint | 2 | The original string of 4D expression references is returned |
| ST 4D Expressions as values | Longint | 1 | 4D expression references are returned in their evaluated form (default functioning in forms) |
| ST End highlight | Longint | -1001 | Designates last character of current text selection in object (*) |
| ST End text | Longint | 0 | Designates last character of text contained in object |
| ST Expression type | Longint | 2 | Selection contains only an expression reference |
| ST Expressions display mode | Longint | 1 | The *value* parameter can contain ST Values or ST References |
| ST Mixed type | Longint | 3 | Selection contains at least two different types of contents |
| ST Picture type | Longint | 6 | Selection contains only a picture (4D Write Pro areas only) |
| ST Plain type | Longint | 0 | Selection contains text and no references |
| ST References | Longint | 1 | Display source strings of expressions |
| ST References as spaces | Longint | 0 | Each reference is returned as a non-breaking space character (default operation, used by other commands) |
| ST Start highlight | Longint | -1000 | Designates first character of current text selection in object (*) |
| ST Start text | Longint | 1 | Designates first character of text contained in object |
| ST Tags as plain text | Longint | 64 | The label of the tag is returned in plain text. For example for the tag '<img src="test.jpg" alt="picture">my picture</img>', the plain text is "my picture" (default functioning in forms) |
| ST Tags as XML code | Longint | 128 | The XML code of the tag is returned in plain text. For example for the tag '<img src="test.jpg" alt="picture">my picture</img>', the plain text is '<img src="test.jpg" alt="picture">my picture</img>' |
| ST Text displayed with 4D Expression sources | Longint | 86 | Returns the text as it is shown in the forms with the original string of the 4D expressions.<br>Corresponds a predefined combination of constants 2+4+16+64. |
| ST Text displayed with 4D Expression values | Longint | 85 | Returns the text as it is shown in the forms with the 4D expressions in their evaluated form.<br>Corresponds to a predefined combination of constants 1+4+16+64. |
| ST Unknown tag type | Longint | 4 | Selection contains only an unknown tag type |
| ST URL as labels | Longint | 4 | The visible label of URLs is returned, for example "Visit our Web site" (default functioning in forms) |
| ST URL as links | Longint | 8 | The link is returned, for example "http://www.4d.com" |
| ST URL type | Longint | 1 | Selection contains only a URL reference |
| ST User links as labels | Longint | 16 | The visible label of the user link is returned (default functioning in forms) |
| ST User links as links | Longint | 32 | The contents of the user link is returned |
| ST User type | Longint | 5 | Selection contains only a custom reference |
| ST Values | Longint | 0 | Display computed values of expressions |

## Multistyle Text Attributes

| Constant | Type | Value | Comment |
|---|---|---|---|
| Attribute background color | Longint | 8 | *attribValue*=Hexadecimal values or HTML color names (Windows only) |
| Attribute bold style | Longint | 1 | *attribValue*=0: remove bold attribute from selection<br>*attribValue*=1: apply bold attribute to selection |
| Attribute font name | Longint | 5 | *attribValue*=Font family name (string) |
| Attribute italic style | Longint | 2 | *attribValue*=0: remove italic attribute from selection<br>*attribValue*=1: apply italic attribute to selection |
| Attribute strikethrough style | Longint | 3 | *attribValue*=0: remove strikethrough attribute from selection<br>*attribValue*=1: apply strikethrough attribute to selection |
| Attribute text color | Longint | 7 | *attribValue*=Hexadecimal values or HTML color names |
| Attribute text size | Longint | 6 | *attribValue*=Number of points (number) |
| Attribute underline style | Longint | 4 | *attribValue*=0: remove underline attribute from selection<br>*attribValue*=1: apply underline attribute to selection |

## Open Form Window

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Compositing mode form | Longint | 4096 | *** Obsolete constant *** |
| _o_Has toolbar button Mac OS | Longint | 8192 | *** Obsolete constant *** |
| At the bottom | Longint | 393216 | |
| At the top | Longint | 327680 | |
| Form has full screen mode Mac | Longint | 65536 | |
| Horizontally centered | Longint | 65536 | |
| Modal form dialog box | Longint | 1 | |
| Movable form dialog box | Longint | 5 | |
| On the left | Longint | 131072 | |
| On the right | Longint | 196608 | |
| Palette form window | Longint | 1984 | |
| Plain form window | Longint | 8 | |
| Pop up form window | Longint | 32 | |
| Sheet form window | Longint | 33 | |
| Toolbar form window | Longint | 35 | |
| Vertically centered | Longint | 262144 | |

## Open Window

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Compositing Mode | Longint | 4096 | *** Obsolete constant *** |
| _o_Has toolbar button Mac | Longint | 8192 | *** Obsolete constant *** |
| Alternate dialog box | Longint | 3 | Can be a floating window |
| Has full screen mode Mac | Longint | 65536 | |
| Has grow box | Longint | 4 | |
| Has highlight | Longint | 1 | |
| Has window title | Longint | 2 | |
| Has zoom box | Longint | 8 | |
| Modal dialog box | Longint | 1 | |
| Movable dialog box | Longint | 5 | Can be a floating window |
| Palette window | Longint | 1984 | Can be a floating window |
| Plain dialog box | Longint | 2 | Can be a floating window |
| Plain fixed size window | Longint | 4 | |
| Plain no zoom box window | Longint | 0 | |
| Plain window | Longint | 8 | |
| Pop up window | Longint | 32 | |
| Resizable sheet window | Longint | 34 | |
| Round corner window | Longint | 16 | |
| Sheet window | Longint | 33 | |
| Texture appearance | Longint | 2048 | |

## Pasteboard

| Constant | Type | Value | Comment |
|---|---|---|---|
| No such data in pasteboard | Longint | -102 | |
| Picture data | String | PICT | |
| Text data | String | TEXT | |

## PHP

| Constant | Type | Value | Comment |
|---|---|---|---|
| PHP privileges | Longint | 1 | Definition of specific user privileges relating to the execution of the script.<br>**Possible value(s)**: String in the form "User:Password". For example: "root:jd51254d" |
| PHP raw result | Longint | 2 | Definition of processing mode for HTTP headers returned by PHP in the execution result when this result is of the Text type (when the result is of the BLOB type, headers are always kept).<br>**Possible value(s)**: Boolean. False (default value = remove HTTP headers from result. True = keep HTTP headers. |

## Picture Compression

| Constant | Type | Value | Comment |
|---|---|---|---|
| QT animation compressor | String | rle | |
| QT compact video compressor | String | cdvc | |
| QT graphics compressor | String | smc | |
| QT photo compressor | String | jpeg | |
| QT raw compressor | String | raw | |
| QT video compressor | String | rpza | |

## Picture Display Formats

| Constant | Type | Value | Comment |
|---|---|---|---|
| On background | Longint | 3 | |
| Replicated | Longint | 7 | |
| Scaled to fit | Longint | 2 | |
| Scaled to fit prop centered | Longint | 6 | |
| Scaled to fit proportional | Longint | 5 | |
| Truncated centered | Longint | 1 | |
| Truncated non centered | Longint | 4 | |

## Picture Metadata Names

| Constant | Type | Value | Comment |
|---|---|---|---|
| EXIF aperture value | String | EXIF/ApertureValue | Possible values: Real (APEX value) |
| EXIF brightness value | String | EXIF/BrightnessValue | Possible values: Real (APEX value) |
| EXIF color space | String | EXIF/ColorSpace | Possible values: EXIF Adobe RGB, EXIF s RGB, EXIF Uncalibrated<br>(read only) |
| EXIF components configuration | String | EXIF/ComponentsConfiguration | Possible values: EXIF B, EXIF Cb, EXIF Cr, EXIF G, EXIF R, EXIF Unused, EXIF Y |
| EXIF compressed bits per pixel | String | EXIF/CompressedBitsPerPixel | Possible values: Real |
| EXIF contrast | String | EXIF/Contrast | Possible values: EXIF High, EXIF Low, EXIF Normal |
| EXIF custom rendered | String | EXIF/CustomRendered | Possible values: EXIF Normal, EXIF Custom |
| EXIF date time digitized | String | EXIF/DateTimeDigitized | Possible values: Date or Text (XML Datetime) |
| EXIF date time original | String | EXIF/DateTimeOriginal | Possible values: Date or Text (XML Datetime) |
| EXIF digital zoom ratio | String | EXIF/DigitalZoomRatio | Possible values: Real |
| EXIF EXIF version | String | EXIF/ExifVersion | Possible values: Integer array (4 values) |
| EXIF exposure bias value | String | EXIF/ExposureBiasValue | Possible values: Real |
| EXIF exposure index | String | EXIF/ExposureIndex | Possible values: Real |
| EXIF exposure mode | String | EXIF/ExposureModus | Possible values: EXIF Auto, EXIF Auto Bracket, EXIF Manual |
| EXIF exposure program | String | EXIF/ExposureProgram | Possible values: EXIF Manual, EXIF Action, EXIF Aperture Priority AE, EXIF Creative, EXIF Landscape, EXIF Exposure Portrait, EXIF Program AE, EXIF Shutter Speed Priority AE |
| EXIF exposure time | String | EXIF/ExposureTime | Possible values: Real |
| EXIF F number | String | EXIF/FNumber | Possible values: Real |
| EXIF file source | String | EXIF/FileSource | Possible values: EXIF Digital Camera, EXIF Film Scanner, EXIF Reflection Print Scanner |
| EXIF flash | String | EXIF/Flash | Possible values: EXIF Auto Mode, EXIF Compulsory Flash Firing, EXIF Compulsory Flash Suppression, EXIF Unknown, EXIF Detected, EXIF No Detection Function, EXIF Not Detected, EXIF Reserved |
| EXIF flash energy | String | EXIF/FlashEnergy | Possible values: Real |
| EXIF flash fired | String | EXIF/Flash/Fired | Possible values: Boolean |
| EXIF flash function present | String | EXIF/Flash/FunctionPresent | Possible values: Boolean |

| Constant | Type | Value | Comment |
|---|---|---|---|
| EXIF flash mode | String | EXIF/Flash/Mode | Possible values: EXIF Auto Mode, EXIF Compulsory Flash Firing, EXIF Compulsory Flash Suppression, EXIF Unknown |
| EXIF flash pix version | String | EXIF/FlashPixVersion | Possible values: Integer array (4 values) |
| EXIF flash red eye reduction | String | EXIF/Flash/RedEyeReduction | Possible values: Boolean |
| EXIF flash return light | String | EXIF/Flash/ReturnLight | Possible values: EXIF Detected, EXIF No Detection Function, EXIF Not Detected, EXIF Reserved |
| EXIF focal len in 35 mm film | String | EXIF/FocalLenIn35mmFilm | Possible values: Longint |
| EXIF focal length | String | EXIF/FocalLength | Possible values: Real |
| EXIF focal plane resolution unit | String | EXIF/FocalPlaneResolutionUnit | Possible values: Longint |
| EXIF focal plane X resolution | String | EXIF/FocalPlaneXResolution | Possible values: Real |
| EXIF focal plane Y resolution | String | EXIF/FocalPlaneYResolution | Possible values: Real |
| EXIF gain control | String | EXIF/GainControl | Possible values: EXIF High Gain Down, EXIF High Gain Up, EXIF Low Gain Down, EXIF Low Gain Up, EXIF None |
| EXIF gamma | String | EXIF/Gamma | Possible values: Real |
| EXIF image unique ID | String | EXIF/ImageUniqueID | Possible values: Text |
| EXIF ISO speed ratings | String | EXIF/ISOSpeedRatings | Possible values: Longint or Longint array |
| EXIF light source | String | EXIF/LightSource | Possible values: EXIF Unknown, EXIF Cloudy, EXIF Cool White Fluorescent, EXIF D50, EXIF D55, EXIF D65, EXIF D75, EXIF Daylight, EXIF Daylight Fluorescent, EXIF Day White Fluorescent, EXIF Fine Weather, EXIF Flash, EXIF Light Fluorescent, EXIF ISOStudio Tungsten, EXIF Other, EXIF Shade, EXIF Standard Light A, EXIF Standard Light B, EXIF Standard Light C, EXIF Tungsten, EXIF White Fluorescent |
| EXIF maker note | String | EXIF/MakerNote | Possible values: Text |
| EXIF max aperture value | String | EXIF/MaxApertureValue | Possible values: Real |
| EXIF metering mode | String | EXIF/MeteringMode | Possible values: EXIF Other, EXIF Average, EXIF Center Weighted Average, EXIF Multi Segment, EXIF Multi Spot, EXIF Partial, EXIF Spot |
| EXIF pixel X dimension | String | EXIF/PixelXDimension | Possible values: Longint<br>(read only) |
| EXIF pixel Y dimension | String | EXIF/PixelYDimension | Possible values: Longint<br>(read only) |
| EXIF related sound file | String | EXIF/RelatedSoundFile | Possible values: Text |
| EXIF saturation | String | EXIF/Saturation | Possible values: EXIF High, EXIF Low, EXIF Normal |
| EXIF scene capture type | String | EXIF/SceneCaptureType | Possible values: EXIF Scene Landscape, EXIF Night, EXIF Scene Portrait, EXIF Standard |

| Constant | Type | Value | Comment |

| Mac theme | Longint | 4 | |
| Windows 3.11, NT 3.51 | Longint | 1 | |
| Windows 9x | Longint | 2 | |

## Platform Properties

Constants prefixed with _o_ are obsolete and cannot be returned by the command. They are only kept for compatibility.

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_INTEL 386 | Longint | 386 | |
| _o_INTEL 486 | Longint | 486 | |
| _o_Macintosh 68K | Longint | 1 | |
| _o_PowerPC 601 | Longint | 601 | |
| _o_PowerPC 603 | Longint | 603 | |
| _o_PowerPC 604 | Longint | 604 | |
| _o_PowerPC G3 | Longint | 510 | |
| Intel compatible | Longint | 586 | |
| Mac OS | Longint | 2 | |
| Power PC | Longint | 406 | |
| Windows | Longint | 3 | |

## Print Options

| Constant | Type | Value | Comment |
|---|---|---|---|
| Color option | Longint | 8 | (Windows only) *value1* only: code specifying the mode for handling color: 1=Black and white (monochrome), 2=Color.<br>**64-bit versions**: This option is not supported in 4D 64-bit versions (obsolete) |
| Destination option | Longint | 9 | *value1*: code specifying the type of print destination: 1=Printer, 2=(PC)/PS File (Mac), 3=PDF file, 5=Screen (OS X driver option).<br>If *value1* is different from 1 or 5, *value2* contains pathname for resulting document. This path will be used until another path is specified. If a file with the same name already exists at the destination location, it will be replaced. With **GET PRINT OPTION**, if the current value is not in the predefined list, *value1* contains -1 and the system variable OK is set to 1. If an error occurs, *value1* and the system variable OK are set to 0.<br>**Note**: Under Windows, you can set the printing destination to 3 (PDF File) when the PDF Creator driver has been installed. When the *(9;3;path)* values are passed, 4D automatically starts a "silent" PDF printing which takes into account any option codes that are passed (note that if you pass an empty string in *value2* or omit this parameter, a file saving dialog appears at the time of printing.) After printing, the current settings are restored. This simplifies control of printing PDFs for 4D and lets you write multi-platform code. When the *(9;3;path)* values are not passed, printing is not controlled by 4D and any PDF Creator option codes that were passed are ignored. |
| Double sided option | Longint | 11 | (Windows only) *value1*: 0=Single-sided or standard, 1=Double-sided. If *value1*=1, *value2* contains the binding: 0=Left binding (default value), 1=Top binding.<br>**Note:** This option can only be used under Windows. |
| Generic PDF driver | String | _4d_pdf_printer | **Note:** This function is not available in 32-bit versions of 4D.<br>• On OS X, sets the current printer to the default driver. This driver is invisible; it is not found in the list returned by **PRINTERS LIST**. Note that a PDF document path must have been set using **SET PRINT OPTION**, otherwise error 3107 is returned.<br>• On Windows, sets the current printer to the Windows PDF driver (named "Microsoft Print to PDF"). This constant is only available in Windows 10 with the PDF option installed. In other Windows versions, or if no PDF driver is available, the command does nothing and the *OK* variable is set to 0. |
| Hide printing progress option | Longint | 14 | *value1* only: 1=hide progress windows, 0=display progress windows (default). This option is particularly useful in the case of PDF printing under OS X.<br>**Note:** There is already a Printing progress option found in the Database Settings dialog box (Interface page). However, it is applied globally to the application and does not hide all the windows under OS X. |
| Legacy printing layer option | Longint | 16 | (4D 64-bit versions for Windows only) *value1* only: 1=select the GDI-based legacy printing layer for the subsequent printing jobs. 0=select the D2D printing layer (default).<br>**64-bit versions:** This selector is only supported on 4D 64-bit single-user applications on Windows; it is ignored on other platforms. It is mainly intended to allow legacy plug-ins to print inside 4D jobs in 4D 64-bit applications. |
| Mac spool file format option | Longint | 13 | (Mac only) *value1* only: 0=print job in PDF mode (default value) 1=print job in PostScript mode.<br>**Notes:**<br>- This option has no effect under Windows.<br>- Under OS X, printing is done as a PDF by default. However, the PDF print driver does not support PICT pictures with encapsulated PostScript information — these pictures are generated, more particularly, by vectorial drawing software. To avoid this problem, this option lets you modify the print mode to use under OS X for the current session. Keep in mind that printing in PostScript mode can lead to undesired side effects.<br>**64-bit versions:** This option is not supported; it is replaced by the Generic PDF driver option of the **SET CURRENT PRINTER** command. |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Number of copies option | Longint | 4 | *value1* only: number of copies to be printed. |
| Orientation option | Longint | 2 | *value1* only: 1=Portrait, 2=Landscape. If a different orientation option is used, **GET PRINT OPTION** returns 0 in *value1*.<br>**64-bit versions**: This option can be called within a print job, which means that you can switch from portrait to landscape, or vice versa, during the same print job. |
| Page range option | Longint | 15 | *value1*=first page to print (default value is 1) and (optional) *value2*=number of the last page to print (default value -1 = end of document). |
| Page setup dialog | Longint | 1 | Display the Page setup dialog box |
| Paper option | Longint | 1 | If you use only *value1*, it contains the name of the paper. If you use both parameters, *value1* contains the paper width and *value2* contains the paper height. The width and height are expressed in screen pixels. Use the **PRINT OPTION VALUES** command to get the name, height and width of all the paper formats offered by the printer. |
| Paper source option | Longint | 5 | (Windows only) *value1* only: number corresponding to the index, in the array of trays returned by the **PRINT OPTION VALUES** command, of the paper tray to be used. This option can only be used under Windows. |
| PDFCreator Printer name | String | PDFCreator | |
| Print dialog | Longint | 2 | Display the Print dialog box |
| Scale option | Longint | 3 | *value1* only: scale value in percentage. Be careful, some printers do not allow you to modify the scale. If you pass an invalid value, the property is reset to 100% at the time of printing. |
| Spooler document name option | Longint | 12 | *value1* only: name of the current print document, which appears in the list of spooler documents. The name defined by this statement will be used for all the print documents of the session for as long as a new name or an empty string is not passed. To use or restore standard operation (using the method name in the case of a method, the table name for a record, etc.), pass an empty string in *value1*. |

## Process State

| Constant | Type | Value | Comment |
|---|---|---|---|
| Aborted | Longint | -1 | |

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr printing dialog | Longint | 1 | Display of the print dialog box:<br>• If value = 0, the print dialog is not displayed prior to printing.<br>• If value = 1, the print dialog is displayed prior to printing (default value). |
| qr unit | Longint | 2 | Document unit:<br>• If value = 0, the document unit is points.<br>• If value = 1, the document unit is centimeters.<br>• If value = 2, the document unit is inches. |

## QR Operators

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| qr average | Longint | 2 | |
| qr count | Longint | 16 | |
| qr max | Longint | 8 | |
| qr min | Longint | 4 | |
| qr standard deviation | Longint | 32 | |
| qr sum | Longint | 1 | |

## QR Output Destination

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr 4D Chart area | Longint | 4 | *** Obsolete constant *** |
| qr 4D View area | Longint | 3 | *specifics*: N.A. |
| qr HTML file | Longint | 5 | *specifics*: Pathname to the file. |
| qr printer | Longint | 1 | *specifics*: "*" to remove the print dialog boxes |
| qr text file | Longint | 2 | *specifics*: Pathname to the file. |

## QR Report Types

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| qr cross report | Longint | 2 | |
| qr list report | Longint | 1 | |

## QR Rows for Properties

| Constant | Type | Value | Comment |
|---|---|---|---|
| qr detail | Longint | -2 | Detail area of report |
| qr footer | Longint | -5 | Page footer |
| qr grand total | Longint | -3 | Grand total area |
| qr header | Longint | -4 | Page header |
| qr title | Longint | -1 | Title of report |

## QR Text Properties

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_qr font | Longint | 1 | Obsolete since 4D v14R3 (use qr font name) |
| qr alternate background color | Longint | 9 | Alternate background color number |
| qr background color | Longint | 8 | Background color number |
| qr bold | Longint | 3 | Bold style attribute (0 or 1) |
| qr font name | Longint | 10 | Name of font as returned for example by the **FONT LIST** command |
| qr font size | Longint | 2 | Font size expressed in points (9 to 255) |
| qr italic | Longint | 4 | Italic style attribute (0 or 1) |
| qr justification | Longint | 7 | Justification attribute (0 for default, 1 for left, 2 for center or 3 for right) |
| qr text color | Longint | 6 | Color number attribute (Longint) |
| qr underline | Longint | 5 | Underline style attribute (0 or 1) |

## Queries

| Constant | Type | Value | Comment |
|---|---|---|---|
| Description in text format | Longint | 0 | |
| Description in XML format | Longint | 1 | |
| Into current selection | Longint | 0 | |
| Into named selection | Longint | 2 | |
| Into set | Longint | 1 | |
| Into variable | Longint | 3 | |

## Relations

| Constant | Type | Value | Comment |
|---|---|---|---|
| Automatic | Longint | 3 | |
| Do not modify | Longint | 0 | |
| Manual | Longint | 2 | |
| No relation | Longint | 0 | |
| Structure configuration | Longint | 1 | |

## Resources Properties

| Constant | Type | Value | Comment |
|---|---|---|---|
| Changed resource bit | Longint | 1 | |
| Changed resource mask | Longint | 2 | |
| Locked resource bit | Longint | 4 | |
| Locked resource mask | Longint | 16 | |
| Preloaded resource bit | Longint | 2 | |
| Preloaded resource mask | Longint | 4 | |
| Protected resource bit | Longint | 3 | |
| Protected resource mask | Longint | 8 | |
| Purgeable resource bit | Longint | 5 | |
| Purgeable resource mask | Longint | 32 | |
| System heap resource bit | Longint | 6 | |
| System heap resource mask | Longint | 64 | |

## SCREEN DEPTH

| Constant | Type | Value | Comment |
|---|---|---|---|
| Black and white | Longint | 0 | |
| Four colors | Longint | 2 | |
| Is color | Longint | 1 | |
| Is gray scale | Longint | 0 | |
| Millions of colors 24 bit | Longint | 24 | |
| Millions of colors 32 bit | Longint | 32 | |
| Sixteen colors | Longint | 4 | |
| Thousands of colors | Longint | 16 | |
| Two fifty six colors | Longint | 8 | |

## SET RGB COLORS

| Constant | Type | Value | Comment |
|---|---|---|---|
| Background color | Longint | -2 | |
| Background color none | Longint | -16 | This constant can only be used with the *backgroundColor* and *altBackgrndColor* parameters. |
| Dark shadow color | Longint | -3 | |
| Disable highlight item color | Longint | -11 | |
| Foreground color | Longint | -1 | |
| Highlight menu background color | Longint | -9 | |
| Highlight menu text color | Longint | -10 | |
| Highlight text background color | Longint | -7 | |
| Highlight text color | Longint | -8 | |
| Light shadow color | Longint | -4 | |

## Shortcut and Associated Keys

| Constant | Type | Value | Comment |
|---|---|---|---|
| Shortcut with Backspace | String | [backspace] | |
| Shortcut with Carriage Return | String | [return] | |
| Shortcut with Delete | String | [del] | |
| Shortcut with Down arrow | String | [down arrow] | |
| Shortcut with End | String | [end] | |
| Shortcut with Enter | String | [enter] | |
| Shortcut with Escape | String | [esc] | |
| Shortcut with F1 | String | [F1] | |
| Shortcut with F10 | String | [F10] | |
| Shortcut with F11 | String | [F11] | |
| Shortcut with F12 | String | [F12] | |
| Shortcut with F13 | String | [F13] | |
| Shortcut with F14 | String | [F14] | |
| Shortcut with F15 | String | [F15] | |
| Shortcut with F2 | String | [F2] | |
| Shortcut with F3 | String | [F3] | |
| Shortcut with F4 | String | [F4] | |
| Shortcut with F5 | String | [F5] | |
| Shortcut with F6 | String | [F6] | |
| Shortcut with F7 | String | [F7] | |
| Shortcut with F8 | String | [F8] | |
| Shortcut with F9 | String | [F9] | |
| Shortcut with Help | String | [help] | |
| Shortcut with Home | String | [home] | |
| Shortcut with Left arrow | String | [left arrow] | |
| Shortcut with Page down | String | [page down] | |
| Shortcut with Page up | String | [page up] | |
| Shortcut with Right arrow | String | [right arrow] | |
| Shortcut with Tabulation | String | [tab] | |
| Shortcut with Up arrow | String | [up arrow] | |

## SQL

| Constant | Type | Value | Comment |
|---|---|---|---|
| SQL all records | Longint | -1 | |
| SQL asynchronous | Longint | 1 | 0 = Synchronous connection (default value), 1 (or value other than 0) = Asynchronous connection |
| SQL charset | Longint | 100 | Text encoding used for requests sent to external sources (via the SQL pass-through). The modification is carried out for the current process and the current connection.<br>Possible values: MIBEnum identifier (see note 2) or value -2 (see note 3)<br>By default: 106 (UTF-8) |
| SQL connection timeout | Longint | 5 | Maximum timeout awaiting response when executing the **SQL LOGIN** command. This value must be set before opening the connection in order to be taken into account<br>Possible values: time in seconds<br>By default: no timeout |
| SQL max data length | Longint | 3 | Maximum length of data returned |
| SQL max rows | Longint | 2 | Maximum number of rows in resulting group (used for previews) |
| SQL On error abort | Longint | 1 | In the event of an error, 4D immediately stops script execution. |
| SQL On error confirm | Longint | 2 | In the event of an error, 4D displays a dialog box describing the error and allowing the user to interrupt or continue script execution. |
| SQL On error continue | Longint | 3 | In the event of an error, 4D ignores it and continues script execution. |
| SQL param in | Longint | 1 | |
| SQL param in out | Longint | 2 | Usable only in the context of an SQL stored procedure (in-out parameter defined in the stored procedure) |
| SQL param out | Longint | 4 | Usable only in the context of an SQL stored procedure (out parameter defined in the stored procedure) |
| SQL query timeout | Longint | 4 | Maximum timeout awaiting response when executing the **SQL EXECUTE** command.<br>Values: time in seconds<br>By default: no timeout |
| SQL use access rights | String | SQL_Use_Access_Rights | Used to restrict the access rights to be applied during execution of the SQL commands of the script. When you use this attribute, you must pass 0 or 1 in *attribValue*:<br>• *attribValue* = 1: 4D uses the access rights of the current 4D user.<br>• *attribValue* = 0 (or attribute not specified): 4D does not restrict access, the Designer rights are used. |
| SQL_INTERNAL | String | ;DB4D_SQL_LOCAL; | |
| System data source | Longint | 2 | |
| User data source | Longint | 1 | |

## Standard System Signatures

The Standard System Signatures are 4-character strings designated standard file types, resource types, standard data types stored into the Clipboard and so on.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Picture document | String | PICT | |
| Text document | String | TEXT | |
| Windows MIDI document | String | MID | |
| Windows sound document | String | WAV | |
| Windows video document | String | AVI | |

System Documents

| Constant | Type | Value | Comment |
|---|---|---|---|
| Absolute path | Longint | 2 | The *documents* array contains absolute pathnames |
| Alias selection | Longint | 8 | Authorizes the selection of shortcuts (Windows) or aliases (Mac OS) as document. By default, if this constant is not used, when an alias or shortcut is selected, the command will return the access path of the targeted element. When you pass the constant, the command returns the path of the alias or shortcut itself. |
| Delete only if empty | Longint | 0 | Deletes folder only when it is empty |
| Delete with contents | Longint | 1 | Deletes folder along with everything it contains |
| Document unchanged | Longint | 0 | No processing |
| Document with CR | Longint | 3 | Line breaks are converted to OS X format: CR (carriage return) |
| Document with CRLF | Longint | 2 | Line breaks are converted to Windows format: CRLF (carriage return + line feed) |
| Document with LF | Longint | 4 | Line breaks are converted to Unix format: LF (line feed) |
| Document with native format | Longint | 1 | (Default) Line breaks are converted to the native format of the operating system: CR (carriage return) under OS X, CRLF (carriage return + line feed) under Windows |
| File name entry | Longint | 32 | Allows user to enter a file name in a 'Save as' dialog box. No file is saved and it is up to the developer to create a file in response to this action (the Document system variable is updated). In this context, the *directory* parameter may contain the path to a file instead of a directory. The file name will be used as the suggested file name in the Save as text field. The parent directory will be used as default path. |
| Folder separator | String | Windows="¥" Mac OS=":" | This constant has a different value depending on the operating system from which it is called. It can be used to build valid pathnames without taking the operating platform into account.<br>**Note:** This constant is only used for 4D applications executed in Unicode mode (it is not supported in non-Unicode compatibility mode). |
| Get pathname | Longint | 3 | |
| Ignore invisible | Longint | 8 | Invisible documents are not listed |
| Is a document | Longint | 1 | |
| Is a folder | Longint | 0 | |
| Multiple files | Longint | 1 | Authorizes the simultaneous selection of several files using the key combinations **Shift+click** (adjacent selection) and **Ctrl+click** (Windows) or **Command+click** (Mac OS). In this case, the *selected* parameter, if passed, contains the list of all selected files. By default, if this constant is not used, the command will not allow the selection of multiple files. |
| Package open | Longint | 2 | (Mac OS only): Authorizes the opening of packages as folders and thus the viewing /selection of their contents. By default, if this constant is not used, the command will not allow the opening of packages. |
| Package selection | Longint | 4 | (Mac OS only): Authorizes the selection of packages as entities. By default, if this constant is not used, the command will not allow the selection of software packages as such. |
| Posix path | Longint | 4 | The *documents* array contains Posix format pathnames |
| Read and write | Longint | 0 | Default mode |
| Read mode | Longint | 2 | |
| Recursive parsing | Longint | 1 | The *documents* array contains all files and subfolders of the specified folder |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Use sheet window | Longint | 16 | (Mac OS only): Displays the selection dialog box in the form of a sheet window (this option is ignored under Windows).<br>Sheet windows are specific to the Mac OS X interface which have graphic animation (for more information, refer to the **Window Types** section). By default, if this constant is not used, the command will display a standard dialog box. |
| Write mode | Longint | 1 | |

## System Folder

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_Mac control panels | Longint | 11 | |
| _o_Mac extensions | Longint | 10 | |
| _o_Mac shutdown items_all | Longint | 6 | |
| _o_Mac shutdown items_user | Longint | 7 | |
| Applications or program files | Longint | 16 | |
| Desktop | Longint | 15 | |
| Documents folder | Longint | 17 | "Documents" folder of user |
| Favorites Win | Longint | 14 | |
| Fonts | Longint | 1 | |
| Start menu Win_all | Longint | 8 | |
| Start menu Win_user | Longint | 9 | |
| Startup Win_all | Longint | 4 | |
| Startup Win_user | Longint | 5 | |
| System | Longint | 0 | |
| System Win | Longint | 12 | |
| System32 Win | Longint | 13 | |
| User preferences_all | Longint | 2 | |
| User preferences_user | Longint | 3 | |

## System Format

| Constant | Type | Value | Comment |
|---|---|---|---|
| Currency symbol | Longint | 2 | Currency symbol (e.g.: “$”) |
| Date separator | Longint | 13 | Separator used in date formats (e.g.: “/”) |
| Decimal separator | Longint | 0 | Decimal separator (e.g.: “.”) |
| Short date day position | Longint | 15 | Position of the day in the short date format: “1” = left, “2” = middle, “3” = right |
| Short date month position | Longint | 16 | Position of the month in the short date format: “1” = left, “2” = middle, “3” = right |
| Short date year position | Longint | 17 | Position of the year in the short date format: “1” = left, “2” = middle, “3” = right |
| System date long pattern | Longint | 8 | Long date display format in the form “dddd MMMM yyyy” |
| System date medium pattern | Longint | 7 | Medium date display format in the form “dddd MMMM yyyy” |
| System date short pattern | Longint | 6 | Short date display format in the form “dddd MMMM yyyy” |
| System time AM label | Longint | 18 | Additional label for a time before noon in 12-hour formats (e.g.: “Morning”) |
| System time long pattern | Longint | 5 | Long time display format in the form “HH:MM:SS” |
| System time medium pattern | Longint | 4 | Medium time display format in the form “HH:MM:SS” |
| System time PM label | Longint | 19 | Additional label for a time after noon in 12-hour formats (e.g.: “Afternoon”) |
| System time short pattern | Longint | 3 | Short time display format in the form “HH:MM:SS” |
| Thousand separator | Longint | 1 | Thousand separator (e.g.: “,”) |
| Time separator | Longint | 14 | Separator used in time formats (e.g.: “:”) |

## TCP Port Numbers

| Constant | Type | Value | Comment |
|---|---|---|---|
| TCP Authentication | Longint | 113 | |
| TCP DNS | Longint | 53 | |
| TCP Finger | Longint | 79 | |
| TCP FTP Control | Longint | 21 | |
| TCP FTP Data | Longint | 20 | |
| TCP Gopher | Longint | 70 | |
| TCP HTTP WWW | Longint | 80 | |
| TCP IMAP3 | Longint | 220 | |
| TCP Kerberos | Longint | 88 | |
| TCP KLogin | Longint | 543 | |
| TCP Nickname | Longint | 43 | |
| TCP NNTP | Longint | 119 | |
| TCP NTalk | Longint | 518 | |
| TCP NTP | Longint | 123 | |
| TCP PMCP | Longint | 1643 | |
| TCP PMD | Longint | 1642 | |
| TCP POP3 | Longint | 110 | |
| TCP Printer | Longint | 515 | |
| TCP RADACCT | Longint | 1646 | |
| TCP RADIUS | Longint | 1645 | |
| TCP Remote Cmd | Longint | 514 | |
| TCP Remote Exec | Longint | 512 | |
| TCP Remote Login | Longint | 513 | |
| TCP Router | Longint | 520 | |
| TCP SMTP | Longint | 25 | |
| TCP SNMP | Longint | 161 | |
| TCP SNMPTRAP | Longint | 162 | |
| TCP SUN RPC | Longint | 111 | |
| TCP Talk | Longint | 517 | |
| TCP Telnet | Longint | 23 | |
| TCP TFTP | Longint | 69 | |
| TCP UUCP | Longint | 540 | |
| TCP UUCP RLOGIN | Longint | 541 | |

## Text Values for Associated Standard Action

| Constant | Type | Value | Comment |
|---|---|---|---|
| Object Accept action | String | 2 | |
| Object Add subrecord action | String | 14 | |
| Object Automatic splitter action | String | 16 | |
| Object Cancel action | String | 1 | |
| Object Clear action | String | 21 | |
| Object Copy action | String | 19 | |
| Object Cut action | String | 18 | |
| Object Database Settings action | String | 32 | |
| Object Delete record action | String | 7 | |
| Object Delete subrecord action | String | 13 | |
| Object Edit subrecord action | String | 12 | |
| Object First page action | String | 10 | |
| Object First record action | String | 5 | |
| Object Goto page action | String | 15 | |
| Object Last page action | String | 11 | |
| Object Last record action | String | 6 | |
| Object MSC action | String | 36 | |
| Object Next page action | String | 8 | |
| Object Next record action | String | 3 | |
| Object No standard action | String | 0 | |
| Object Open back URL action | String | 37 | |
| Object Open next URL action | String | 38 | |
| Object Paste action | String | 20 | |
| Object Previous page action | String | 9 | |
| Object Previous record action | String | 4 | |
| Object Quit action | String | 27 | |
| Object Redo action | String | 31 | |
| Object Refresh current URL action | String | 39 | |
| Object Return to Design mode action | String | 35 | |
| Object Select all action | String | 22 | |
| Object Show Clipboard action | String | 23 | |
| Object Stop loading URL action | String | 40 | |
| Object Test Application action | String | 26 | |
| Object Undo action | String | 17 | |

## Time Display Formats

| Constant | Type | Value | Comment |
|---|---|---|---|
| Blank if null time | Longint | 100 | "" instead of 0 |
| HH MM | Longint | 2 | 01:02 |
| HH MM AM PM | Longint | 5 | 1:02 AM |
| HH MM SS | Longint | 1 | 01:02:03 |
| Hour min | Longint | 4 | 1 hour 2 minutes |
| Hour min sec | Longint | 3 | 1 hour 2 minutes 3 seconds |
| ISO time | Longint | 8 | 0000-00-00T01:02:03 |
| Min sec | Longint | 7 | 62 minutes 3 seconds |
| MM SS | Longint | 6 | 62:03 |
| System time long | Longint | 11 | 1:02:03 AM HNEC (Mac only) |
| System time long abbreviated | Longint | 10 | 1•02•03 AM (Mac only) |
| System time short | Longint | 9 | 01:02:03 |

## Trigger Events

| Constant | Type | Value | Comment |
|---|---|---|---|
| _o_On Loading Record Event | Longint | 4 | |
| On Deleting Record Event | Longint | 3 | |
| On Saving Existing Record Event | Longint | 2 | |
| On Saving New Record Event | Longint | 1 | |

## Value for Associated Standard Action

All constants in this theme are deprecated starting with 4D v16 R3. You should use text constants from the **Text Values for Associated Standard Action** theme.

| Constant | Type | Value | Comment |
|---|---|---|---|
| Accept action | Longint | 2 | |
| Add subrecord action | Longint | 14 | |
| Cancel action | Longint | 1 | |
| Clear action | Longint | 21 | |
| Copy action | Longint | 19 | |
| Cut action | Longint | 18 | |
| Database settings action | Longint | 32 | |
| Delete record action | Longint | 7 | |
| Delete subrecord action | Longint | 13 | |
| Edit subrecord action | Longint | 12 | |
| First page action | Longint | 10 | |
| First record action | Longint | 5 | |
| Last page action | Longint | 11 | |
| Last record action | Longint | 6 | |
| MSC action | Longint | 36 | |
| Next page action | Longint | 8 | |
| Next record action | Longint | 3 | |
| No action | Longint | 0 | |
| Paste action | Longint | 20 | |
| Previous page action | Longint | 9 | |
| Previous record action | Longint | 4 | |
| Quit action | Longint | 27 | |
| Redo action | Longint | 31 | |
| Return to Design mode | Longint | 35 | |
| Select all action | Longint | 22 | |
| Show clipboard action | Longint | 23 | |
| Test application action | Longint | 26 | |
| Undo action | Longint | 17 | |

## Web Area

| Constant | Type | Value | Comment |
|---|---|---|---|
| WA enable contextual menu | Longint | 4 | Allow the display of a standard contextual menu in the Web area |
| WA enable Java applets | Longint | 1 | Allow the execution of Java applets in the Web area. |
| WA enable JavaScript | Longint | 2 | Allow the execution of JavaScript code in the Web area |
| WA enable plugins | Longint | 3 | Allow the installation of plug-ins in the Web area |
| WA enable URL drop | Longint | 101 | Allow dropping of URLs or files in the Web area (default = False) |
| WA enable Web inspector | Longint | 100 | Allow the display of the Web inspector in the area |
| WA next URLs | Longint | 1 | |
| WA previous URLs | Longint | 0 | |

## Web Server

| Constant | Type | Value | Comment |
|---|---|---|---|
| wdl disable | Longint | 0 | Web HTTP debug log is disabled |
| wdl enable with all body parts | Longint | 7 | Web HTTP debug log is enabled with body parts in response and request |
| wdl enable with request body | Longint | 5 | Web HTTP debug log is enabled with body part in request only |
| wdl enable with response body | Longint | 3 | Web HTTP debug log is enabled with body part in response only |
| wdl enable without body | Longint | 1 | Web HTTP debug log is enabled without body parts (body size is provided in this case) |
| Web character set | Longint | 17 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Character set that the 4D Web Server (with 4D in local mode and 4D Server) should use to communicate with browsers connecting to the database. The default value actually depends on the language of the operating system. This parameter is set in the Database settings.<br>**Possible values**: The possible values depend on the operating mode of the database relating to the character set.<br>• *Unicode Mode*: When the application is operating in Unicode mode, the values to pass for this parameter are character set identifiers (*MIBEnum* longint or *Name* string, identifiers defined by IANA, see the following address: http://www.iana.org/assignments/character-sets). Here is the list of identifiers corresponding to the character sets supported by the 4D Web server:<br>4=ISO-8859-1<br>12=ISO-8859-9<br>13=ISO-8859-10<br>17=Shift-JIS<br>2024=Windows-31J<br>2026=Big5<br>38=euc-kr<br>106=UTF-8<br>2250=Windows-1250<br>2251=Windows-1251<br>2253=Windows-1253<br>2255=Windows-1255<br>2256=Windows-1256<br>• *ASCII compatibility mode*:<br>Western European<br>1: Japanese<br>2: Chinese<br>3: Korean<br>4: User-defined<br>5: Reserved<br>6: Central European<br>7: Cyrillic<br>8: Arabic<br>9: Greek<br>10: Hebrew<br>11: Turkish<br>12: Baltic |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web debug log | Longint | 84 | **Scope:** Local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted (a new log file is used in this case)<br>**Description:** Allows you to get or set the status of the HTTP request log file of the 4D Web server. When enabled, this file, named "**HTTPDebugLog_*nn*.txt**", is stored in the "Logs" folder of the application (*nn* is the file number). It is useful for debugging issues related to the Web server. It records each request and each response in raw mode. Whole requests, including headers, are logged; optionally, body parts can be logged as well.<br>**Values**: One of the constants prefixed with "wdl" (refer to the descriptions of these constants in this theme).<br>**Default value**: 0 (not enabled) |
| Web HTTP compression level | Longint | 50 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Compression level for all compressed HTTP exchanges for the 4D HTTP server (client requests or server replies, Web and Web Service). This selector lets you optimize exchanges by either privileging speed of execution (less compression) or the amount of compression (less speed). The choice of a value depends on the size and type of data exchanged. Pass 1 to 9 in the *value* parameter where 1 is the fastest compression and 9 the highest. You can also pass -1 to get a compromise between speed and rate of compression. By default, the compression level is 1 (faster compression).<br>**Possible values**: 1 to 9 (1 = faster, 9 = more compressed) or -1 = best compromise. |
| Web HTTP compression threshold | Longint | 51 | **Scope**: Local HTTP server<br>**Kept between two sessions**: No<br>**Description**: In the framework of optimized HTTP exchanges, size threshold for requests below which exchanges should not be compressed. This setting is useful in order to avoid losing machine time by compressing small exchanges.<br>**Possible values**: Any Longint type value. Pass the size expressed in bytes in *vaue*. By default, the compression threshold is set to 1024 bytes |
| Web HTTP TRACE | Longint | 85 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Allows you to disable or enable the HTTP TRACE method in the 4D Web server. For security reasons, starting with 4D v15 R2, by default the 4D Web server rejects HTTP TRACE requests with an error 405 (see HTTP TRACE disabled). If necessary, you can enable the HTTP TRACE method for the session by passing this constant with value 1. When this option is enabled, the 4D Web server replies to HTTP TRACE requests with the request line, header, and body.<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 0 (disabled) |
| Web HTTPS port ID | Longint | 39 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: TCP port number used by the Web server of 4D in local mode and of 4D Server for secure connections via SSL (HTTPS protocol). The HTTPS port number is set on the “Web/Configuration” page of the Database settings dialog box.<br>By default, the value is 443 (standard value). You can use the constants of the **TCP Port Numbers** theme for the *value* parameter.<br>**Possible values**: 0 to 65535 |
| Web inactive process timeout | Longint | 78 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Modifies the life duration of the inactive processes associated with sessions. At the end of the timeout, the process is killed on the server, the **On Web Close Process database method** is called then the session context is destroyed.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |
| Web inactive session timeout | Longint | 72 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Modifies the life duration of inactive sessions (duration set in cookie). At the end of this period, the session cookie expires and is no longer sent by the HTTP client.<br>**Possible values**: Longint (minutes)<br>**Default value**: 480 minutes (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web IP address to listen | Longint | 16 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: IP address on which the 4D Web server will receive HTTP requests with 4D in local mode and 4D Server. By default, no specific address is defined (*value* = 0). This parameter can be set in the Database settings. The *Web IP Address to listen* selector is useful for 4D Web Servers compiled and merged with 4D Desktop (in which there is no access to the Design mode).<br>You pass a hexadecimal IP address in the *value* parameter. In other words, to designate a IP address such as "a.b.c.d", you should write:<br>`C_LONGINT($addr)`<br>`$addr:=($a<<24)\|($b<<16)\|($c<<8)\|$d`<br>`WEB SET OPTION(Web IP address to listen;$addr)` |
| Web keep session | Longint | 70 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Enables or disables the session management mode (described in the **Web Sessions Management** section)<br>**Possible values**: 1 (enable mode) or 0 (disable mode)<br>**Default value**: 1 for databases created in v13, 0 for converted databases. Note that this mode also enables the mechanism for reusing temporary contexts in remote mode. For more information about this mechanism, refer to the description of this option in the **Web Server Settings** section. |
| Web log recording | Longint | 29 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Starts or stops the recording of Web requests received by the Web server of 4D in local mode or 4D Server. By default, the value is 0 (requests not recorded).<br>The log of Web requests is stored as a text file named "logweb.txt" that is automatically placed in the Logs folder of the database, next to the structure file. The format of this file is determined by the value that you pass. For more information about Web log file formats, please refer to the **Information about the Web Site** section.<br>This file can also be activated on the "Web/Log" page of the Database settings.<br>**Possible values**: 0 = Do not record (default), 1 = Record in CLF format, 2 = Record in DLF format, 3 = Record in ELF format, 4 = Record in WLF format.<br><br>**Warning**: Formats 3 and 4 are custom formats whose contents must be set beforehand in the Database settings. If you use one of these formats without any of its fields having been selected on this page, the log file will not be generated. |
| Web max concurrent processes | Longint | 18 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Strictly upper limit of concurrent Web processes of any type supported by the 4D Web Server with 4D in local mode and 4D Server. When this number (minus one) is reached, 4D will not create any other processes and returns the HTTP status 503 - Service Unavailable to all new requests.<br>This parameter can prevent the 4D Web Server from saturation, which can occur when an exceedingly large number of concurrent requests are sent, or when too many context creations are requested. This parameter can also be set in the Database settings.<br>In theory, the maximum number of Web processes is the result of the following formula: Available memory/Web process stack size. Another solution is to view the information on Web processes displayed in the Runtime Explorer: the current number of Web processes and the maximum number reached since the Web server boot are indicated.<br>**Possible values**: Any value between 10 and 32 000. The default value is 100. |
| Web max sessions | Longint | 71 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description**: Limits the number of simultaneous sessions. When you reach the limit set, the oldest session is closed (and **On Web Close Process database method** is called) if the Web server needs to create a new one.<br>**Possible values**: Longint. The number of simultaneous sessions cannot exceed the total number of Web processes (Web Max Concurrent Processes option, 100 by default)<br>**Default value**: 100 (pass 0 to restore the default value) |

| Constant | Type | Value | Comment |
|---|---|---|---|
| Web maximum requests size | Longint | 27 | **Scope**: 4D local, 4D Server<br>**Kept between two sessions**: Yes<br>**Description**: Maximum size (in bytes) of incoming HTTP requests (POST) that the Web server is authorized to process. By default, the value is 2 000 000, i.e. a little less than 2 MB. Passing the maximum value (2 147 483 648) means that, in practice, no limit is set.<br>This limit is used to avoid Web server saturation due to incoming requests that are too large. When a request reaches this limit, the 4D Web server refuses it.<br>**Possible values**: 500 000 to 2 147 483 648. |
| Web port ID | Longint | 15 | **Scope**: 4D in local mode and 4D Server.<br>**Kept between two sessions:** No<br>**Description:** Sets or gets the number of the TCP port used by the 4D Web server with 4D in local mode and 4D Server. By default, the value is 80. The TCP port number is set on the "Web/Configuration" page of the Database Settings dialog box. You can use one of the constants in the **TCP Port Numbers** theme for the *value* parameter. This selector is useful within the framework of 4D Web servers that are compiled and merged using 4D Desktop (no access to the Design environment).<br>**Possible values:** For more information about the TCP port number, refer to the **Web Server Settings** section.<br>**Default value:** 80 |
| Web session cookie domain | Longint | 81 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "domain" field of the session cookie. This selector (as well as selector 82) is useful for controlling the scope of the session cookies: If you set, for example, the value "/*.4d.fr" for this selector, the client will only send a cookie when the request is addressed to the domain ".4d.fr", which excludes servers hosting external static data.<br>**Possible values:** Text |
| Web session cookie name | Longint | 73 | **Scope**: Local Web server<br>**Kept between two sessions**: No, but remains valid even if the HTTP server is restarted<br>**Description:** Sets the name of the cookie used for saving the session ID.<br>**Possible values:** Text<br>**Default value:** "4DSID" (pass an empty string to restore the default value) |
| Web session cookie path | Longint | 82 | **Scope:** local Web server<br>**Kept between two sessions:** No, but remains valid even if the HTTP server is restarted.<br>**Description:** Sets or gets the value of the "path" field of the session cookie. This selector (as well as selector 81) is useful for controlling the scope of the session cookies: If you set, for example, the value "/4DACTION" for this selector, the client will only send a cookie for dynamic requests beginning with 4DACTION, and not for pictures, static pages, etc.<br>**Possible values:** Text |
| Web session enable IP address validation | Longint | 83 | **Scope**: Local Web server<br>**Kept between two sessions**: No<br>**Description**: Enables or disables IP address validation for session cookies. For security reasons, by default the 4D Web server checks the IP address of each request containing a session cookie and rejects it if this address does not match the IP address used to create the cookie. In some specific applications, you may want to disable this validation and accept session cookies, even when their IP addresses do not match. For example when mobile devices switch between Wifi and 3G/4G networks, their IP address will change. In this case, you must pass 0 in this option to allow clients to be able to continue using their Web sessions even when the IP addresses change. Note that this setting lowers the security level of your application.<br>When it is modified, this setting is effective immediately (you do not need to restart the HTTP server).<br>**Possible values**: 0 (disabled) or 1 (enabled)<br>**Default value**: 1 (IP addresses are checked) |

Web Services (Client)

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web Service compression | Longint | 1 | |
| Web Service detailed message | Longint | 1 | Detailed message describing the error. The type of message differs according to the main error type.<br>- If the main error = 9910 (Soap fault): the cause of the SOAP fault is returned (e.g.: “the remote method does not exist”).<br>- If the main error = 9911 (Parser fault): the location of the error in the XML document is returned.<br>- If the main error = 9912 (HTTP fault):<br>- if the HTTP error is located in the interval [300-400] (problems linked to the location of the requested document), the new location of the requested URL is returned.<br>- for any other HTTP error code, the <body> is returned.<br>- If the main error = 9913 (Network fault): the cause of the network fault is returned (e.g.: “ServerAddress: DNS lookup failure”)<br>- If the main error = 9914 (Internal fault): the cause of the internal fault is returned |
| Web Service display auth dialog | Longint | 4 | *value* = 0 (do not display dialog box) or 1 (display dialog box)<br>This option manages the display of the authentication dialog box during execution of the **WEB SERVICE CALL** command. By default, this command never displays the dialog box; normally, you have to use the **WEB SERVICE AUTHENTICATE** command to do so. However, if you want the authentication dialog box to appear in order for the user to enter their identifiers, you will need to use this option: pass 1 in *value* to display the dialog box and 0 otherwise. The dialog box only appears if the Web service requires authentication |
| Web Service dynamic | Longint | 0 | |
| Web Service error code | Longint | 0 | Main error code (defined by 4D). This code is also returned in the Error system variable.<br>List of codes that may be returned:<br>9910: Soap fault (see also Web Service Fault Actor)<br>9911: Parser fault<br>9912: HTTP fault (see also Web Service HTTP Error code)<br>9913: Network fault<br>9914: Internal fault. |
| Web Service fault actor | Longint | 3 | Cause of the error (returned by the SOAP protocol — to be used in the case of main error 9910).<br>- Version Mismatch<br>- Must Understand (the server was unable to interpret a parameter defined as mandatory)<br>- Sender Fault<br>- Receiver Fault<br>- Encoding Unknown |
| Web Service HTTP compression | Longint | 6 | *value* = Web Service Compression<br>This option is used to enable an internal compression mechanism for SOAP requests in order to accelerate inter-4D application exchanges. When you execute the statement **WEB SERVICE SET OPTION**(Web Service HTTP Compression; Web Service Compression) on the 4D client of the Web Service, the data of the next SOAP request sent by the client will be compressed using a standard HTTP mechanism ("gzip" or "deflate", depending on the request contents) before being sent to the 4D SOAP server. The server will decompress and parse the request, then will reply automatically using the same mechanism. Only the request that follows the call to the **WEB SERVICE SET OPTION** command is affected. You must therefore call this command each time you want to use compression. By default, 4D does not compress Web Service HTTP requests.<br>**Note:** This mechanism cannot be used for requests sent to a 4D SOAP server whose version is earlier than 11.3. So that you can further optimize this functioning, additional options configure the threshold and compression rate of the requests. These options can be accessed via the **SET DATABASE PARAMETER** command |
| Web Service HTTP error code | Longint | 2 | HTTP error code (to be used in case of main error 9912). |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| Web Service HTTP timeout | Longint | 1 | *value* = timeout of the client portion expressed in seconds.<br>The timeout of the client portion is the wait period of the Web Service client in case the server does not respond. After this period, the client closes the session and the request is lost.<br>This timeout is 180 seconds by default. It can be modified for specific reasons (network status, Web Service specifics, etc.). |
| Web Service manual | Longint | 3 | |
| Web Service manual in | Longint | 1 | |
| Web Service manual out | Longint | 2 | |
| Web Service reset auth settings | Longint | 5 | *value* = 0 (do not erase information) or 1 (erase information)<br>This option lets you indicate to 4D whether to memorize the authentication information of the user (user name, password, method, etc.), in order to reuse it subsequently. By default, this information is erased after each execution of the **WEB SERVICE CALL** command. Pass 0 in value to store the information and 1 to erase it. Note that when you pass 0, the information is kept during the session but is not stored. |
| Web Service SOAP header | Longint | 2 | *value* = XML root element reference to insert as a header in the SOAP request.<br>This option allows you to insert a header in a SOAP request generated using the **WEB SERVICE CALL** command. SOAP requests do not contain a specific header by default. However, certain Web Services require a header, for example when managing identification parameters |
| Web Service SOAP version | Longint | 3 | *value* = Web Service SOAP_1_1 or Web Service SOAP_1_2<br>This option lets you specify the SOAP protocol version used in the request. Pass the Web Service SOAP_1_1 constant in value to indicate version 1.1 and Web Service SOAP_1_2 to indicate version 1.2. |
| Web Service SOAP_1_1 | Longint | 0 | |
| Web Service SOAP_1_2 | Longint | 1 | |

## Web Services (Server)

| Constant | Type | Value | Comment |
|---|---|---|---|
| Is DOM reference | Longint | 37 | |
| Is XML | Longint | 36 | |
| SOAP client fault | Longint | 1 | |
| SOAP input | Longint | 1 | |
| SOAP method name | Longint | 1 | Name of the Web Service method about to be executed |
| SOAP output | Longint | 2 | |
| SOAP server fault | Longint | 2 | |
| SOAP service name | Longint | 2 | Name of the Web Service to which the method belongs |

## Windows

| Constant | Type | Value | Comment |
|---|---|---|---|
| External window | Longint | 5 | |
| Floating window | Longint | 14 | |
| Modal dialog | Longint | 9 | |
| Regular window | Longint | 8 | |
| XY Current form | Longint | 1 | Origin is top left corner of current form |
| XY Current window | Longint | 2 | Origin is top left corner of current window |
| XY Main window | Longint | 4 | On Windows: origin is top left corner of main window; on OS X: same as XY Screen |
| XY Screen | Longint | 3 | Origin is top left corner of main screen (same as for **SCREEN COORDINATES** command) |

XML

| Constant | Type | Value | Comment |
|---|---|---|---|
| Copy XML data source | Longint | 1 | 4D keeps a copy of the DOM tree with the picture, which means the picture can be saved in a picture field of the database and then redisplayed or exported at any time. |
| DOCTYPE Name | Longint | 3 | Name of the root element as defined in the DOCTYPE marker |
| Document URI | Longint | 6 | URI of the DTD |
| Encoding | Longint | 4 | Encoding used (UTF-8, ISO...) |
| Get XML data source | Longint | 0 | 4D only reads the XML data source; it is not kept with the picture. This noticeably increases command execution speed; however, because the DOM tree is not kept, it is not possible to store or export the picture. |
| Own XML data source | Longint | 2 | 4D exports the DOM tree with the picture. The picture can be stored or exported and command execution is fast. However, the *elementRef* XML reference can then no longer be used by other 4D commands. This is the default mode for exporting when the *exportType* parameter is omitted. |
| PUBLIC ID | Longint | 1 | Public identifier (FPI) of the DTD to which the document conforms (if the DOCTYPE xxx PUBLIC tag is present). |
| SYSTEM ID | Longint | 2 | System identifier |
| Version | Longint | 5 | Accepted XML version |
| XML Base64 | Longint | 1 | |
| XML binary encoding | Longint | 5 | Specifies the way binary data will be converted.<br>**Possible values:**<br>• XML Base64 (default value): binary data are simply converted to Base64<br>• XML data URI scheme: binary data are converted to Base64 and the "data:;base64" header is added. This format mainly allows a browser to automatically decode a picture, and is also required for the insertion of pictures. For more information, see http://en.wikipedia.org/wiki/Data_URI_scheme. |
| XML CDATA | Longint | 7 | |
| XML comment | Longint | 2 | |
| XML convert to PNG | Longint | 1 | |
| XML DATA | Longint | 6 | |
| XML data URI scheme | Longint | 2 | |
| XML date encoding | Longint | 2 | Specifies the way 4D dates will be converted. For example, !01/01/2003! in the Paris time zone.<br>**Possible values:**<br>• XML ISO (default value): use of the format xs:datetime without indication of time zone. Result: "2003-01-01". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML local: use of the format xs:date with indication of time zone. Result: "2003-01-01 +01:00". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime local: use of the format xs:dateTime (ISO 8601). Indication of time zone. This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00 +01:00</Date>".<br>• XML UTC: use of the format xs:date. Result: "2003-01-01Z". The time part, if it is present in the 4D value (via SQL) is lost.<br>• XML datetime UTC: use of the format xs:dateTime (ISO 8601). This format allows the time part to be kept, if it is present in the 4D value (via SQL). Result: "<Date>2003-01-01T00:00:00Z</Date>". |

| Constant | Type | Value | Comment |
|---|---|---|---|
| XML datetime local | Longint | 3 | |
| XML datetime local absolute | Longint | 1 | |
| XML datetime UTC | Longint | 5 | |
| XML DOCTYPE | Longint | 10 | |
| XML duration | Longint | 2 | |
| XML ELEMENT | Longint | 11 | |
| XML end document | Longint | 9 | |
| XML end element | Longint | 5 | |
| XML entity | Longint | 8 | |
| XML indentation | Longint | 4 | Specifies the indentation of the XML *document*.<br>**Possible values:**<br>• XML with indentation (default value): the document is indented.<br>• XML no indentation: the document is not indented; its contents are placed in a single line. |
| XML ISO | Longint | 1 | |
| XML local | Longint | 2 | |
| XML native codec | Longint | 2 | |
| XML no indentation | Longint | 2 | |
| XML picture encoding | Longint | 6 | Specifies the way pictures must be converted (before encoding in Base64).<br>**Possible values:**<br>• XML convert to PNG (default value): pictures are converted to PNG before being encoded in Base64.<br>• XML native codec: pictures are converted in their first native storage CODEC before being encoded in Base64. You must use these options to encode SVG pictures (see example for the **XML SET OPTIONS** command). |
| XML processing instruction | Longint | 3 | |
| XML raw data | Longint | 2 | |
| XML seconds | Longint | 4 | |
| XML start document | Longint | 1 | |
| XML start element | Longint | 4 | |

| Constant | Type | Value | Comment |
| --- | --- | --- | --- |
| XML string encoding | Longint | 1 | Specifies the way 4D strings are converted to element values. It does not concern the conversion to attributes for which XML imposes the use of escape characters.<br>**Possible values:**<br>• XML with escaping (default value): conversion of 4D strings to XML element values with replacement of characters. The Text type data are automatically parsed so that forbidden characters (<&>') are replaced by XML entities (&<> '").<br>• XML raw data: 4D strings are sent as raw data; 4D does not carry out encoding or parsing. 4D values are converted if possible to XML fragments and inserted as a child of the target element. If a value cannot be considered as an XML fragment, it is inserted as raw data into a new CDATA node. |
| XML time encoding | Longint | 3 | Specifies the way 4D times are converted. For example, ?02/00/46? (Paris time). The encoding differs depending on whether you want to express a time or a duration.<br>**Possible values for times:**<br>• XML datetime UTC: time expressed in UTC (Universal Time Coordinated). Note that conversion to UTC is automatic. Result: "<Duration>0000-00-00T01:00:46Z</Duration>".<br>• XML datetime local: time expressed with the time difference of the machine of the 4D engine. Result: "<Duration>0000-00-00T02:00:46+01:00</Duration>".<br>• XML datetime local absolute (default value): time expressed without indication of time zone. No modification of the value. Result: "<Duration>0000-00-00T02:00:46</Duration>".<br>**Possible values for durations:**<br>• XML seconds: number of seconds since midnight; no modification of the value since it expresses a duration. Result: "<Duration>7246</Duration>".<br>• XML duration: duration expressed in compliance with XML Schema Part 2: Datatypes Second Edition. No modification of the value since it expresses a duration. Result: "<Duration>PT02H00M46S</Duration>". |
| XML UTC | Longint | 4 | |
| XML with escaping | Longint | 1 | |
| XML with indentation | Longint | 1 | |

# Error Codes

- Syntax Errors (1 -> 81)
- Database Engine Errors (-10602 -> 4004)
- SQL Engine Errors (1001 -> 3018)
- Network Errors (-10051 -> -10001)
- Backup Manager Errors (1401 -> 1421)
- Client Update Errors (-10650 -> -10655)
- Updater Errors (-10603 -> -10613)
- OS File Manager Errors (-124 -> -33)
- OS Memory Manager Errors (-117 -> -108)
- OS Printing Manager Errors (-8192 -> -1)
- OS Resource Manager Errors (-196 -> -1)
- SANE NaN Errors (1 -> 255)
- OS Sound Manager Errors (-209 -> -203)
- OS Serial Ports Manager Errors (-28)
- Mac OS System Errors (4 -> 28)
- Miscellaneous Errors (-10700)

## Syntax Errors (1 -> 81)

---

The following table lists the syntax error codes for errors that may occur during code execution in the Design or Application environment. Some of these errors may occur in interpreted mode only, some in compiled mode only, some in both modes. You can intercept these errors using an error interruption method installed using **ON ERR CALL**.

| Code | Description |
|---|---|
| 1 | A “(” was expected. |
| 2 | A field was expected. |
| 3 | The command may be executed only on a field in a subtable. |
| 4 | Parameters in the list must all be of the same type. |
| 5 | There is no table to which to apply the command. |
| 6 | The command may only be executed on a Subtable type field. |
| 7 | A Numeric argument was expected. |
| 8 | An Alphanumeric argument was expected. |
| 9 | The result of a conditional test was expected. |
| 10 | The command cannot be applied to this field type. |
| 11 | The command cannot be applied between two conditional tests. |
| 12 | The command cannot be applied between two Numeric arguments. |
| 13 | The command cannot be applied between two Alphanumeric arguments. |
| 14 | The command cannot be applied between two Date arguments. |
| 15 | The operation is not compatible with the two arguments. |
| 16 | The field has no relation. |
| 17 | A table was expected. |
| 18 | Field types are incompatible. |
| 19 | The field is not indexed. |
| 20 | An “=” was expected. |
| 21 | The method does not exist. |
| 22 | The fields must belong to the same table or subtable for a sort or graph. |
| 23 | A “<” or “>” was expected. |
| 24 | A “;” was expected. |
| 25 | There are too many fields for a sort. |
| 26 | The field type cannot be Text, Picture, Blob or Subtable. |
| 27 | The field must be prefixed by the name of its table. |
| 28 | The field type must be Numeric. |
| 29 | The value must be 1 or 0. |
| 30 | A variable was expected. |
| 31 | There is no menu bar with this number. |
| 32 | A date was expected. |
| 33 | Unimplemented command or function. |
| 34 | Accounting files are not open. |
| 35 | The sets are from different tables. |
| 36 | Invalid table name. |
| 37 | A “:=” was expected. |
| 38 | This is a function, not a procedure. |
| 39 | The set does not exist. |
| 40 | This is a procedure, not a function. |
| 41 | A variable or field belonging to a subtable was expected. |
| 42 | The record cannot be pushed onto the stack. |
| 43 | The function cannot be found. |
| 44 | The method cannot be found. |
| 45 | Field or variable expected. |
| 46 | A Numeric or Alphanumeric argument was expected. |
| 47 | The field type must be Alphanumeric. |
| 48 | Syntax error. |
| 49 | This operator cannot be used here. |
| 50 | These operators cannot be used together. |
| 51 | Module not implemented. |

| | |
|---|---|
| 52 | An array was expected. |
| 53 | Indice out of range. |
| 54 | Argument types are incompatible. |
| 55 | A Boolean argument was expected. |
| 56 | Field, variable, or table expected. |
| 57 | An operator was expected. |
| 58 | A “)” was expected. |
| 59 | This kind of argument was not expected here. |
| 60 | A parameter or a local variable cannot be used in an *EXECUTE* statement in a compiled database. |
| 61 | The type of an array cannot be modified in a compiled database. |
| 62 | The command cannot be applied to a subtable. |
| 63 | The field is not indexed. |
| 64 | A picture field or variable was expected. |
| 65 | The value should contain 4 characters. |
| 66 | The value should not contain more than 3 characters. |
| 67 | This command cannot be executed on 4D Server. |
| 68 | A list was expected. |
| 69 | An external window reference was expected. |
| 70 | The command cannot be applied between two Picture arguments. |
| 71 | The **SET PRINT MARKER** command can only be called in the header of a form being printed. |
| 72 | A pointer array was expected. |
| 73 | A numeric array was expected. |
| 74 | The size of arrays does not match. |
| 75 | No pointer on local arrays. |
| 76 | Bad array type. |
| 77 | Bad variable name. |
| 78 | Invalid sort parameter. |
| 79 | This command cannot be executed during the draw of a list. |
| 80 | Too many query arguments. |
| 81 | The form was not found. |

## Tips

Some of these error codes denote plain syntax errors due to mistyping. For example, you get an error *#37* if you execute the statement *v=0* when you actually meant *v:=0*. You can eliminate the error by fixing your code in the Method editor.

Some of these error codes are due to simple programming errors. For example, you get an error *#5* if you execute an **ADD RECORD** command, when you have not first set the default table (using the **DEFAULT TABLE** command), and do not pass the table parameter. In this case, there is no table to which to apply the command. You eliminate the error by checking to see if you forgot to set the default table or if you forgot to pass the table parameter to the command for this occurrence.

Some of these error codes denote errors due to a flaw in the design. For example, you get an error *#16* if you apply **RELATE ONE** to a field that is not related to any other field. You eliminate the error by checking to see if your code is actually wrong or if you simply forgot to create the relation starting from the field.

Some errors, when they occur, are not always located exactly where your code breaks. For example, if in a subroutine you get an error *#53* (indice out of range) on the line *vpFld:=Field($1;$2)*, the error is due to a wrong table and/or field number that has been passed to the subroutine as a parameter. Therefore, the error is located in the caller method and not where the error actually occurs. In this case, trace your code in the Debugger window to determine which line of code is the real culprit, then fix it in the Method editor.

## Database Engine Errors (-10602 -> 4004)

---

This table lists the error codes generated by the 4D Database Engine. These codes cover errors that occur at a low level of the database engine, such as user interruption, privilege errors, and damaged objects.

| Code | Description |
|---|---|
| -10602 | Can't execute the given command because there is no open print job. |
| -10601 | The **OBJECT DUPLICATE** command does not work during printing operations. |
| -10600 | This BLOB could not be read. It may be damaged. |
| -10532 | Cannot call error handling project method 'methodName. |
| -10526 | Can't create database {database_name}. |
| -10525 | Can't delete existing database {database_name}. |
| -10524 | Can't open database {database_name}: current data file not found at last known location: '{datafile_path}'. |
| -10523 | Can't open database {database_name}: current data file is not defined. |
| -10522 | Can't load component {database_name} because it's not in Unicode mode. |
| -10521 | Can't open database {database_name} because it's not in Unicode mode. |
| -10520 | Unauthorized user: Only an Administrator or Designer can execute this command. |
| -10519 | Bad url: {url} |
| -10518 | Assert failed: {assertion} |
| -10517 | Failed to synchronize {folder_name} folder. |
| -10516 | The server is running a maintenance operation, please reconnect later. |
| -10515 | Your attempt to connect to 4D Server has been denied |
| -10514 | The maximum number of concurrent users for your license has been reached |
| -10513 | Can't call {command_name} command from a remote 4D Developer. |
| -10512 | The encoding is not supported |
| -10511 | Can't call command "{command_name}" from a component. |
| -10510 | Can't load component "{component_name}". |
| -10509 | Can't open database "{database_name}". |
| -10508 | Project method not found. |
| -10507 | This version does not allow a compiled database to be opened. |
| -10506 | Limit of the Standard Edition version. |
| -10505 | Client and server have version numbers that are incompatible. |
| -10504 | Index page # is out of range (index needs to be repaired). |
| -10503 | Record # is out of range (during **GOTO RECORD**, or data file needs to be repaired). (see note 3) |
| -10502 | Invalid record structure (data file needs to be repaired). |
| -10501 | Invalid index page (index needs to be repaired). |
| -10500 | Invalid record address (database needs to be repaired). |
| -9999 | No more room to save the record. (see note 4) |
| -9998 | Duplicated key. |
| -9997 | Maximum number of records has been reached. |
| -9996 | Stack is full (too much recursion or nested calls). |
| -9995 | Demo limit has been reached. |
| -9994 | Serial communication interrupted by the user—user pressed Ctrl-Alt-Shift (Windows) or Command-Option-Shift (Mac OS). |
| -9993 | Menu bar is damaged (database needs to be repaired). |
| -9992 | Wrong password. |
| -9991 | Privileges error. |
| -9990 | Time-out error. |
| -9989 | Invalid structure (database needs to be repaired). |
| -9988 | The form cannot be loaded. Either the form or the structure is damaged. |
| -9987 | Some other records are already related to this record. |
| -9986 | Record locked during an automatic deletion action. |
| -9985 | Recursive integrity. |
| -9984 | Transaction has been cancelled because of a duplicated index key error. |
| -9983 | The same external package is installed twice. |
| -9982 | The record was not loaded because it is not in the selection on the workstation. |
| -9981 | Invalid field name/field number definition table sent by the workstation. |
| -9980 | The file cannot be created because the structure is locked. |

| | |
|---|---|
| -9979 | Unknown user. |
| -9978 | Bad user password. |
| -9977 | The selection does not exist. |
| -9976 | Backup in progress; no modification allowed. |
| -9975 | Transaction index page could not be loaded. |
| -9974 | Record has already been deleted. |
| -9973 | The TRIC resources are not the same. |
| -9972 | Table number is out of range requested by workstation. |
| -9971 | Field number is out of range requested by workstation. |
| -9970 | Field is not indexed. |
| -9969 | Invalid field type requested by workstation. |
| -9968 | Invalid selected record number requested by workstation. |
| -9967 | The record could not be modified because it could not be loaded. |
| -9966 | Invalid type requested by a workstation. |
| -9965 | Bad search definition table sent by a workstation. |
| -9964 | Bad sort definition table sent by a workstation. |
| -9963 | Invalid record number requested by a workstation. |
| -9962 | The backup cannot be run because the server is shutting down. |
| -9961 | The backup process is not currently running. |
| -9960 | 4D Backup is not installed on the server. |
| -9959 | The backup process has already been started by another user or process. |
| -9958 | The process could not be started. |
| -9957 | The choice list is locked. |
| -9956 | Versions of 4D Client and 4D Server are different. |
| -9955 | QuickTime is not installed. |
| -9954 | There is no current record. |
| -9953 | There is no Log file. |
| -9952 | Invalid data segment header. |
| -9951 | This field has no relation. |
| -9950 | Invalid data segment number. |
| -9949 | License or privilege error. |
| -9948 | A modal dialog is activated. |
| -9947 | The “Allow 4D Open connections” check box has not been selected. |
| -9946 | Unable to clear the named selection because it does not exist. |
| -9945 | CD-ROM 4D Runtime error; writing operations are not allowed. |
| -9944 | The user does not belong to the 4D Open access group. |
| -9943 | 4D Connectivity Plug-ins version error. |
| -9942 | 4D Client licensing scheme is incompatible with this version of 4D Server. |
| -9941 | Unknown EX_GESTALT selector. |
| -9940 | 4D Extension initialization failed. |
| -9939 | External routine not found. |
| -9938 | The current record has been changed from within the trigger. |
| -9937 | Password System is locked by another user. |
| -9936 | External password code does not match to the database one |
| -9935 | The XML file is not valid or is not well-formed. |
| -9934 | The XML file is not well-formed. |
| -9933 | The XML file is not valid. |
| -9932 | The XML DLL is not loaded. |
| -9931 | The index for this attribute is invalid. |
| -9930 | There is no attribute with this name for this element. |
| -9929 | The index for this element is invalid. |
| -9928 | The name of the element is unknown. |

-9927 The referenced element is not the “root”.
-9926 The referenced element is invalid.
-9925 The referenced element is null.
-9924 The file must be opened in read only
-9923 The attribute name is not valid
-9922 Missing the parameter value in the attributes definition
-9921 Attempt to write a XML Prolog on a non-empty document
-9920 The type of the node is invalid
-9919 This encoding is not supported.
-9918 The name of the element is invalid.
-9917 The type of the array passed in parameter is invalid.
-9916 The element is not open.
-9915 The document's reference is invalid.
-9914 Internal fault.
-9913 Network fault.
-9912 HTTP fault.
-9911 Parser fault.
-9910 Soap fault.
-9909 No window available to run the form.
-9855 Invalid parameter number 5.
-9854 Invalid parameter number 4.
-9853 Invalid parameter number 3.
-9852 Invalid parameter number 2.
-9851 Invalid parameter number 1.
-9850 Invalid area parameter passed to an external command.
-9803 Unnamed object found in the form "{form}".
-9802 Object path not unique: {path}. Verify the application with the MSC.
-9801 Unable to open the method: {path}
-9800 One of the processes modified the access rights.
-9799 Error during preview initialization.
-9778 An error occurred while loading the dictionary
-9777 The method language does not match the application localization: {path}
-9776 Unable to create method: {path}
-9775 Unable to write method code: {path}
-9774 Unable to read method code: {path}
-9773 Unable to write method comments: {path}
-9772 Unable to read method comments: {path}
-9771 Unable to write method properties: {path}
-9770 Unable to read method properties: {path}
-9769 Invalid method property: {path}
-9768 Invalid object path: {path}
-9767 Cannot update methods. One or more resources are locked.
-9766 The method is currently being edited.
-9765 One or more comments are currently being edited.
-9764 The comment is currently being edited.
-9763 The command cannot be executed in a component.
-9762 The command cannot be executed in a compiled database.
-9761 Invalid object type.
-9760 It is not possible to move or copy the XML node to the specified position.
-9759 The Object Library could not be opened.
-9758 The user form already exists.
-9757 The user form does not exist.

| | |
|---|---|
| -9756 | There is no user structure file. |
| -9755 | The user form does not have a name. |
| -9754 | This command cannot be used from a dialog window. |
| -9753 | The source form does not exist. |
| -9752 | The user form cannot be created. |
| -9751 | The source form is not accessible by the user. |
| -9750 | The source form is not editable. |
| -1 | Invalid table number requested by a Plug-In |
| 1001 | No column to import in table {TableName} |
| 1002 | Wrong table to import |
| 1003 | No column to export in table {TableName} |
| 1004 | Wrong table to export |
| 1006 | Program interrupted by user—user pressed Alt-click (Windows) or Option-click (Mac OS) |
| 1006 | Cannot save structure of database {BaseName} |
| 1007 | Cannot create data file of database: {BaseName} |
| 1008 | Wrong data segment in database {BaseName} |
| 1009 | Memory is full |
| 1010 | Cannot load a table definition of database {BaseName} |
| 1011 | Cannot open data file of database {BaseName} |
| 1012 | Data segment is full in database: {BaseName} |
| 1013 | Cannot save data segment in database {BaseName} |
| 1014 | Cannot read data segment of database {BaseName} |
| 1015 | Wrong database header in database {BaseName} |
| 1016 | Cannot create table in database {BaseName} |
| 1017 | Cannot read index list of database {BaseName} |
| 1018 | Cannot write index list of database {BaseName} |
| 1019 | Wrong table reference in database {BaseName} |
| 1020 | Wrong field reference in database {BaseName} |
| 1021 | Invalid index type in database {BaseName} |
| 1022 | Invalid field name in table {TableName} of database {BaseName} |
| 1023 | Invalid database name |
| 1024 | Cannot open structure of database {BaseName} |
| 1025 | Cannot create structure of database {BaseName} |
| 1026 | Cannot load bit selection of database {BaseName} |
| 1027 | Cannot load set of database {BaseName} |
| 1028 | Cannot modify set of database {BaseName} |
| 1029 | Cannot save set of database {BaseName} |
| 1030 | Cannot save BLOB {BlobNum} in table {TableName} of database {BaseName} |
| 1031 | Cannot load BLOB {BlobNum} in table {TableName} of database {BaseName} |
| 1032 | Cannot allocate BLOB {BlobNum} in table {TableName} of database {BaseName} |
| 1033 | Cannot load data bit table of database {BaseName} |
| 1034 | Cannot save data bit table of database {BaseName} |
| 1035 | Cannot load table of data bit tables of database {BaseName} |
| 1036 | Cannot save table of data bit tables in database {BaseName} |
| 1037 | Cannot close data segment of database {BaseName} |
| 1038 | Cannot delete data segment of database {BaseName} |
| 1039 | Cannot open data segment of database {BaseName} |
| 1040 | Cannot create data segment of database {BaseName} |
| 1041 | Cannot allocate space in data segment |
| 1042 | Cannot free space in data segment of database {BaseName} |
| 1043 | File is write protected |
| 1044 | Cannot access field in record {RecNum} in table {TableName} of database {BaseName} |

1045 Field definition code is missing in record {RecNum} in table {TableName} of database {BaseName}
1046 Cannot save record {RecNum} in table {TableName} of database {BaseName}
1047 Cannot load record {RecNum} in table {TableName} of database {BaseName}
1048 Cannot allocate record in table {TableName} of database {BaseName}
1049 Cannot update record {RecNum} in table {TableName} of database {BaseName}
1050 Wrong header for record {RecNum} in table {TableName} of database {BaseName}
1051 Cannot save definition of table {TableName} of database {BaseName}
1052 Cannot update definition of table {TableName} of database {BaseName}
1053 Field name already exists
1055 Cannot update index values while saving a record in table {TableName} of database {BaseName}
1056 Cannot update BLOBs while saving a record in table {TableName} of database {BaseName}
1057 Cannot delete BLOBs while saving or deleting a record in table {TableName} of database {BaseName}
1058 Cannot add field in table {TableName} of database {BaseName}
1059 Cannot allocate table in memory
1061 Cannot allocate record in memory
1062 Cannot completely delete table {TableName} of database {BaseName}
1063 Cannot lock record {RecNum} in table {TableName} of database {BaseName}
1064 Cannot unlock record {RecNum} in table {TableName} of database {BaseName}
1065 Cannot delete record {RecNum} in table {TableName} of database {BaseName}
1066 Record {RecNum} is locked in table {TableName} of database {BaseName}
1067 Sequential search could not be completed in table {TableName} of database {BaseName}<
1068 Cannot save header for table {TableName} of database {BaseName}<
1069 Cannot import data in table {TableName} of database {BaseName}
1070 Cannot load index header of database {BaseName}
1071 Cannot save header for index {IndexName} of database {BaseName}
1072 Cannot get page address for index {IndexName} of database {BaseName}
1073 Cannot set page address for index {IndexName} of database {BaseName}
1074 Cannot drop index {IndexName} of database {BaseName}
1075 Cannot sort index {IndexName} of database {BaseName}
1076 Cannot load page for index {IndexName} of database {BaseName}
1077 Cannot save page for index {IndexName} of database {BaseName}
1078 Cannot insert key into index {IndexName} of database {BaseName}
1079 Cannot delete key from index {IndexName} of database {BaseName}
1080 Cannot completely delete index {IndexName} of database {BaseName}
1081 Cannot complete scan on index {IndexName} of database {BaseName}
1082 Cannot complete sort of index {IndexName} of database {BaseName}
1083 Cannot insert key into page of index {IndexName} of database {BaseName}
1084 Cannot delete key from page of index {IndexName} of database {BaseName}
1085 Cannot load index cluster of database {BaseName}
1086 Cannot add to index cluster of database {BaseName}
1087 Cannot delete from index cluster of database {BaseName}
1088 Index {IndexName} is invalid
1089 SQL syntax error (Obsolete)
1090 SQL token not found (Obsolete)
1091 Not implemented
1092 Cannot register code
1093 Operation in progress cancelled by user
1094 Transaction conflict
1095 Invalid table name in database {BaseName}
1096 Table {TableName} is locked in database {BaseName}
1097 Database {BaseName} is locked
1098 Data address is invalid in database {BaseName}

| | |
|---|---|
| 1099 | Record is empty |
| 1100 | Wrong source field |
| 1101 | Wrong destination field |
| 1102 | Invalid relation name |
| 1103 | Field types do not match |
| 1104 | Relation is empty< |
| 1105 | Cannot load relations list from database {BaseName} |
| 1106 | Cannot save relations list into database {BaseName} |
| 1107 | Query and lock not completed; at least one record locked somewhere else |
| 1108 | Invalid record |
| 1109 | Wrong record ID |
| 1110 | Relation already exists in database {BaseName} |
| 1111 | Index already exists in database {BaseName} |
| 1112 | Wrong comparison operator |
| 1113 | End of data buffer |
| 1114 | Wrong DB4D version number |
| 1115 | Duplicated key |
| 1116 | Mandatory field is Null in record {RecNum} in table {TableName} |
| 1117 | Cannot set field to mandatory for table {TableName} |
| 1118 | Cannot get exclusive access to table {TableName} |
| 1119 | Cannot check referential integrity of table {TableName} |
| 1120 | Reference integrity: some foreign keys still exist matching primary key on record {RecNum} in table {TableName} |
| 1121 | Cannot delete all records in selection of table {TableName} |
| 1122 | BLOB is Null |
| 1123 | Invalid database context |
| 1124 | Invalid relation reference |
| 1125 | Invalid record name in table {TableName} |
| 1126 | Wrong field type |
| 1127 | Cannot load extra properties |
| 1128 | Cannot save extra properties |
| 1129 | Subrecord ID is out of range |
| 1130 | Duplicate name for index {IndexName} in database {BaseName} |
| 1131 | Invalid name for index {IndexName} in database {BaseName} |
| 1132 | Wrong key value on index {IndexName} |
| 1133 | Wrong type for index {IndexName} |
| 1134 | Invalid accessor |
| 1135 | Accessor is read only |
| 1136 | Null value not accepted |
| 1137 | THIS is Null |
| 1138 | Selection is Null |
| 1139 | Database {BaseName} is write protected |
| 1140 | Database {BaseName} is closing |
| 1141 | Invalid transaction |
| 1142 | Array limit is exceeded |
| 1143 | Creator of array values is missing |
| 1144 | Cannot build selection of table {TableName} |
| 1145 | Busy object |
| 1146 | Data file does not match structure file |
| 1147 | Cannot start listener |
| 1148 | Cannot start server |
| 1149 | No listener |
| 1150 | Task is dying |

| | |
|---|---|
| 1151 | Invalid request tag |
| 1152 | Invalid context ID |
| 1153 | Not enough temporary space on disk |
| 1154 | Data set is Null |
| 1155 | No primary key matching the foreign key |
| 1156 | Type of field {FieldName} of table {TableName} does not support being set to Unique |
| 1157 | Type of field {FieldName} of table {TableName} does not support being set to NEVER NULL |
| 1158 | Cannot alter primary key definition of table {TableName} |
| 1159 | Maximum number of records has been reached for table {TableName} |
| 1160 | Maximum number of BLOBs has been reached for table {TableName} |
| 1161 | Indice is out of range |
| 1162 | Query is invalid |
| 1163 | Record is NULL |
| 1164 | Object is NULL |
| 1165 | Wrong owner for this object |
| 1166 | Object was not locked |
| 1167 | Object is locked by another context |
| 1168 | Internal error on remote connection |
| 1169 | Invalid table number |
| 1170 | Invalid field number |
| 1171 | Invalid Database ID |
| 1172 | Invalid Parameter |
| 1173 | Cache Flushing did not complete |
| 1174 | Data Flushing did not complete |
| 1175 | Structure Flushing did not complete |
| 1176 | Log file is invalid for database {BaseName} |
| 1177 | Log file cannot be found for database {BaseName} |
| 1178 | Last operation in log file doest not match the one in database {BaseName} |
| 1179 | Log file does not match database {BaseName} |
| 1180 | Data Table has been deleted |
| 1181 | Keys are not unique in index {IndexName} |
| 1182 | Cannot create log file for database {DataBase} |
| 1183 | Cannot write into log file of database {DataBase} |
| 1184 | Cannot drop table {TableName} in database {DataBase} |
| 1185 | Remote database cannot be opened< |
| 1186 | Log file cannot be integrated into database {DataBase} |
| 1187 | Internal Computation on Set cannot be completed |
| 1188 | Array cannot be saved |
| 1189 | Array cannot be loaded |
| 1190 | Sequence number header cannot be loaded |
| 1191 | Cannot select record |
| 1192 | Record cannot be created |
| 1193 | Cannot complete selection to array in table {TableName} of database {BaseName} |
| 1194 | Cannot complete array to selection in table {TableName} of database {BaseName} |
| 1195 | Cannot complete sequential sort |
| 1196 | Selection cannot be locked |
| 1197 | Index key cannot be loaded |
| 1198 | Index key cannot be saved |
| 1199 | Index key cannot be built |
| 1200 | Query cannot be completed |
| 1201 | Query cannot be analyzed |
| 1202 | Formula could not be processed on this column |

| | |
|---|---|
| 1203 | Query could not be completed |
| 1204 | Query could not be analyzed |
| 1205 | Could not get all distinct values of table {TableName} of database {BaseName} |
| 1206 | Cannot build array of values in table {TableName} of database {BaseName} |
| 1207 | Selection cannot be loaded |
| 1208 | Cannot send data |
| 1209 | Cannot receive request reply |
| 1210 | Cannot send request |
| 1211 | Cannot create connection |
| 1212 | Index {IndexName} cannot be quickly created in database {BaseName} |
| 1213 | Cannot build distinct index keys |
| 1214 | Selection cannot be sorted in table {TableName} of database {BaseName} |
| 1215 | Address table cannot loaded |
| 1216 | Address table cannot modified |
| 1217 | Cannot allocate new entry into address table |
| 1218 | Cannot allocate free entry from address table |
| 1219 | Transaction temporary record cannot be saved |
| 1220 | Transaction temporary blob cannot be saved |
| 1221 | Transaction temporary record cannot be loaded |
| 1222 | Transaction temporary blob cannot be loaded |
| 1223 | Transaction cannot be started |
| 1224 | Transaction cannot be committed |
| 1225 | Cannot get extra property |
| 1226 | Cannot set extra property |
| 1227 | Table name is already used |
| 1228 | Cannot get list of NULL keys from index {IndexName} |
| 1229 | Cannot modify list of NULL keys of index {IndexName} |
| 1230 | Invalid key for index {IndexName} |
| 1231 | Cannot set log file |
| 1232 | Context is NULL |
| 1233 | Database {BaseName} cannot be locked |
| 1234 | Wrong field reference in record# {RecNum} of table: {TableName} of database: {BaseName} |
| 1235 | Wrong field reference in table: {TableName} of database: {BaseName} |
| 1236 | Cannot read data from temporary transaction file |
| 1237 | Cartesian Product failed |
| 1238 | Cannot merge selections |
| 1239 | The format of the {BaseName} database cannot be upgraded in read only mode |
| 1240 | Wrong Header |
| 1241 | Wrong CheckSum |
| 1243 | Cannot load data tables of database: {BaseName} |
| 1244 | The list of foreign key constraints is not empty for table: {TableName} of database: {BaseName} |
| 1245 | Address entry is not empty |
| 1246 | Cannot pre-allocate address |
| 1247 | Cannot update new record in table {TableName} of database {BaseName} |
| 1248 | Cannot save new record in table {TableName} of database {BaseName} |
| 1249 | Cannot save subrecord |
| 1250 | Cannot save record |
| 1251 | Cannot lock structure object definition |
| 1252 | Cannot unlock structure object definition |
| 1253 | Invalid relation number |
| 1254 | Circular Reference in records address table of table {TableName} of database {BaseName} |
| 1255 | Circular Reference in blobs address table of table {TableName} of database {BaseName} |

| | |
|---|---|
| 1256 | Duplicated Schema Name in database {BaseName} |
| 1257 | Schema cannot be saved in database {BaseName} |
| 1258 | Schema cannot be deleted in database {BaseName} |
| 1259 | Schema cannot be renamed in database {BaseName} |
| 1260 | Selected log file is too recent for database {BaseName} |
| 1261 | Selected log file is too old for database {BaseName} |
| 1262 | Some DataTables do not have matching table definitions for database {BaseName} |
| 1263 | Given stamp does not match current one for record# {RecNum} of table {TableName} |
| 1264 | A primary key is needed and missing in table {TableName} |
| 1265 | Invalid field |
| 1266 | Unknown field type (this version of 4D is perhaps too old) |
| 1267 | Stack Overflow |
| 1268 | DataTable cannot be rebuilt for database {BaseName} |
| 1269 | DataTable cannot be found |
| 1270 | Missing structure could not be rebuilt |
| 1271 | Invalid REST request handler |
| 1272 | Some records are still locked in table {tableName} in database {BaseName} |
| 1273 | Cannot drop table {TableName} in database {BaseName} |
| 1274 | The current journal file of database {BaseName} is not available. For data security reasons, write operations are stopped. Please contact your administrator as soon as possible. |
| 1275 | "(" is missing at the beginning of the Javascript statement in this query. |
| 1276 | Datastream has an invalid header. |
| 1277 | The database journal integration failed at entry# {p1}. |
| 1278 | Javascript code not allowed in the query. |
| 1300 | Invalid Selection Type |
| 1301 | Array is too big |
| 1302 | Array size does not match |
| 1303 | Invalid Selection ID |
| 1304 | Invalid Selection Part |
| 4001 | Invalid table number requested by a Plug-In |
| 4002 | Invalid record number requested by a Plug-In |
| 4003 | Invalid field number requested by a Plug-In |
| 4004 | Access to a table's current record requested by a Plug-in while there is no current record |

**Notes**

1. While some of the errors listed reflect serious problems, i.e., *-10502 Invalid record structure (data file needs to be repaired)*, other errors may occur on a regular basis and can be managed using an **ON ERR CALL** project method. For example, it is common to handle the error *–9998 Duplicated key* if your application offers opportunities to create duplicated values for a table that includes an indexed field whose Unique property is set.
2. Some of the errors listed never occur at the 4D language level. They can occur and be handled at a low level by database engine routines or when using 4D Backup or 4D Open.
3. The error *-10503 Record # is out of range* generally means that your code (for example, the **GOTO RECORD** command) is attempting to access a record that no longer exists (or has never existed). In certain more unusual cases, this error may mean that the database needs repairing.
4. The error *-9999 No more room to save the record* occurs when the data file of your database is full or located on a full volume. This error can also be generated if the data file is locked or located on a locked volume.

# SQL Engine Errors (1001 -> 3018)

The SQL engine of 4D returns specific errors which are listed below. These errors can be intercepted using an error-handling method installed by the **ON ERR CALL** command and analyzed using the **GET LAST ERROR STACK** command.

## Generic errors

| | |
|---|---|
| 1001 | INVALID ARGUMENT |
| 1002 | INVALID INTERNAL STATE |
| 1003 | SQL SERVER IS NOT RUNNING |
| 1004 | Access denied |
| 1005 | FAILED TO LOCK SYNCHRONIZATION PRIMITIVE |
| 1006 | FAILED TO UNLOCK SYNCHRONIZATION PRIMITIVE |
| 1007 | SQL SERVER IS NOT AVAILABLE |
| 1008 | COMPONENT BRIDGE IS NOT AVAILABLE |
| 1009 | REMOTE SQL SERVER IS NOT AVAILABLE |
| 1010 | EXECUTION INTERRUPTED BY USER |

## Semantic errors

| | |
|---|---|
| 1101 | Table '{key1}' does not exist in the database. |
| 1102 | Column '{key1}' does not exist. |
| 1103 | Table '{key1}' is not declared in the FROM clause. |
| 1104 | Column name reference '{key1}' is ambiguous. |
| 1105 | Table alias '{key1}' is the same as table name. |
| 1106 | Duplicate table alias - '{key1}'. |
| 1107 | Duplicate table in the FROM clause - '{key1}'. |
| 1108 | Operation {key1} {key2} {key3} is not type safe. |
| 1109 | Invalid ORDER BY index - {key1}. |
| 1110 | Function {key1} expects one parameter, not {key2}. |
| 1111 | Parameter {key1} of type {key2} in function call {key3} is not implicitly convertible to {key4}. |
| 1112 | Unknown function - {key1}. |
| 1113 | Division by zero. |
| 1114 | Sorting by indexed item in the SELECT list is not allowed - ORDER BY item {key1}. |
| 1115 | DISTINCT NOT ALLOWED |
| 1116 | Nested aggregate functions are not allowed in the aggregate function {key1}. |
| 1117 | Column function is not allowed. |
| 1118 | Cannot mix column and scalar operations. |
| 1119 | Invalid GROUP BY index - {key1}. |
| 1120 | GROUP BY index is not allowed. |
| 1121 | GROUP BY is not allowed with 'SELECT * FROM ...'. |
| 1122 | HAVING is not an aggregate expression. |
| 1123 | Column '{key1}' is not a grouping column and cannot be used in the ORDER BY clause. |
| 1124 | Cannot mix {key1} and {key2} types in the IN predicate. |
| 1125 | Escape sequence '{key1}' in the LIKE predicate is too long. It must be exactly one character. |
| 1126 | Bad escape character - '{key1}'. |
| 1127 | Unknown escape sequence - '{key1}'. |
| 1128 | Column references from more than one query in aggregate function {key1} are not allowed. |
| 1129 | Scalar item in the SELECT list is not allowed when GROUP BY clause is present. |
| 1130 | Sub-query produces more than one column. |
| 1131 | Subquery must return one row at the most but instead it returns {key1}. |
| 1132 | INSERT value count {key1} does not match column count {key2}. |
| 1133 | Duplicate column reference in the INSERT list - '{key1}'. |
| 1134 | Column '{key1}' does not allow NULL values. |
| 1135 | Duplicate column reference in the UPDATE list - '{key1}'. |
| 1136 | Table '{key1}' already exists. |
| 1137 | Duplicate column '{key1}' in the CREATE TABLE command. |
| 1138 | DUPLICATE COLUMN IN COLUMN LIST |
| 1139 | More than one primary key is not allowed. |
| 1140 | Ambiguous foreign key name - '{key1}'. |
| 1141 | Column count {key1} in the child table does not match column count {key2} in the parent table of the foreign key definition. |
| 1142 | Column type mismatch in the foreign key definition. Cannot relate {key1} in child table to {key2} in parent table. |
| 1143 | Failed to find matching column in parent table for '{key1}' column in child table. |
| 1144 | UPDATE and DELETE constraints must be the same. |
| 1145 | FOREIGN KEY DOES NOT EXIST |
| 1146 | Invalid LIMIT value in SELECT command - {key1}. |
| 1147 | Invalid OFFSET value in SELECT command - {key1}. |
| 1148 | Primary key does not exist in table '{key1}'. |
| 1149 | FAILED TO CREATE FOREIGN KEY |
| 1150 | Column '{key1}' is not part of a primary key. |
| 1151 | FIELD IS NOT UPDATEABLE |
| 1152 | FOUND VIEW COLUMN |

| | |
|---|---|
| 1153 | Bad data type length '{key1}'. |
| 1154 | EXPECTED EXECUTE IMMEDIATE COMMAND |
| 1155 | INDEX ALREADY EXISTS |
| 1156 | Auto-increment option is not allowed for column '{key1}' of type {key2}. |
| 1157 | SCHEMA ALREADY EXISTS |
| 1158 | SCHEMA DOES NOT EXIST |
| 1159 | Cannot drop system schema |
| 1160 | CHARACTER ENCODING NOT ALLOWED |

### Implementation errors

| | |
|---|---|
| 1203 | FUNCTIONALITY IS NOT IMPLEMENTED |
| 1204 | Failed to create record {key1}. |
| 1205 | Failed to update field '{key1}'. |
| 1206 | Failed to delete record '{key1}'. |
| 1207 | NO MORE JOIN SEEDS POSSIBLE |
| 1208 | FAILED TO CREATE TABLE |
| 1209 | FAILED TO DROP TABLE |
| 1210 | CANT BUILD BTREE FOR ZERO RECORDS |
| 1211 | COMMAND COUNT GREATER THAN ALLOWED |
| 1212 | FAILED TO CREATE DATABASE |
| 1213 | FAILED TO DROP COLUMN |
| 1214 | VALUE IS OUT OF BOUNDS |
| 1215 | FAILED TO STOP SQL_SERVER |
| 1216 | FAILED TO LOCALIZE |
| 1217 | Failed to lock table for reading. |
| 1218 | FAILED TO LOCK TABLE FOR WRITING |
| 1219 | TABLE STRUCTURE STAMP CHANGED |
| 1220 | FAILED TO LOAD RECORD |
| 1221 | FAILED TO LOCK RECORD FOR WRITING |
| 1222 | FAILED TO PUT SQL LOCK ON A TABLE |
| 1223 | FAILED TO RETAIN COOPERATIVE TASK |
| 1224 | FAILED TO LOAD INFILE |

### Parsing error

| | |
|---|---|
| 1301 | PARSING FAILED |

### Runtime language access errors

| | |
|---|---|
| 1401 | COMMAND NOT SPECIFIED |
| 1402 | ALREADY LOGGED IN |
| 1403 | SESSION DOES NOT EXIST |
| 1404 | UNKNOWN BIND ENTITY |
| 1405 | INCOMPATIBLE BIND ENTITIES |
| 1406 | REQUEST RESULT NOT AVAILABLE |
| 1407 | BINDING LOAD FAILED |
| 1408 | COULD NOT RECOVER FROM PREVIOUS ERRORS |
| 1409 | NO OPEN STATEMENT |
| 1410 | RESULT EOF |
| 1411 | BOUND VALUE IS NULL |
| 1412 | STATEMENT ALREADY OPENED |
| 1413 | FAILED TO GET PARAMETER VALUE |
| 1414 | INCOMPATIBLE PARAMETER ENTITIES |
| 1415 | Query parameter is either not allowed or was not provided. |
| 1416 | COLUMN REFERENCE PARAMETERS FROM DIFFERENT TABLES |
| 1417 | EMPTY STATEMENT |
| 1418 | FAILED TO UPDATE VARIABLE |
| 1419 | FAILED TO GET TABLE REFERENCE |
| 1420 | FAILED TO GET TABLE CONTEXT |
| 1421 | COLUMNS NOT ALLOWED |
| 1422 | INVALID COMMAND COUNT |
| 1423 | INTO CLAUSE NOT ALLOWED |
| 1424 | EXECUTE IMMEDIATE NOT ALLOWED |
| 1425 | ARRAY NOT ALLOWED IN EXECUTE IMMEDIATE |
| 1426 | COLUMN NOT ALLOWED IN EXECUTE IMMEDIATE |
| 1427 | NESTED BEGIN END SQL NOT ALLOWED |
| 1428 | RESULT IS NOT A SELECTION |
| 1429 | INTO ITEM IS NOT A VARIABLE |
| 1430 | VARIABLE WAS NOT FOUND |
| 1431 | PTR OF PTR NOT ALLOWED |
| 1432 | POINTER OF UNKNOWN TYPE |

### Date formatting errors

| | |
|---|---|
| 1501 | SEPARATOR_EXPECTED |
| 1502 | FAILED TO PARSE DAY OF MONTH |
| 1503 | FAILED TO PARSE MONTH |
| 1504 | FAILED TO PARSE YEAR |
| 1505 | FAILED TO PARSE HOUR |
| 1506 | FAILED TO PARSE MINUTE |
| 1507 | FAILED TO PARSE SECOND |
| 1508 | FAILED TO PARSE MILLISECOND |
| 1509 | INVALID AM PM USAGE |
| 1510 | FAILED TO PARSE TIME ZONE |
| 1511 | UNEXPECTED CHARACTER |
| 1512 | Failed to parse timestamp. |
| 1513 | Failed to parse duration. |
| 1551 | FAILED TO PARSE DATE FORMAT |

### Lexer errors

| | |
|---|---|
| 1601 | NULL INPUT STRING |
| 1602 | NON TERMINATED STRING |
| 1603 | NON TERMINATED COMMENT |
| 1604 | INVALID NUMBER |
| 1605 | UNKNOWN START OF TOKEN |
| 1606 | NON TERMINATED NAME/* closing ']' is missing |
| 1607 | NO VALID TOKENS |

### Validation errors for error stack - state errors that follow direct errors

| | |
|---|---|
| 1701 | Failed to validate table '{key1}'. |
| 1702 | Failed to validate FROM clause. |
| 1703 | Failed to validate GROUP BY clause. |
| 1704 | Failed to validate SELECT list. |
| 1705 | Failed to validate WHERE clause. |
| 1706 | Failed to validate ORDER BY clause. |
| 1707 | Failed to validate HAVING clause. |
| 1708 | Failed to validate COMPARISON predicate. |
| 1709 | Failed to validate BETWEEN predicate. |
| 1710 | Failed to validate IN predicate. |
| 1711 | Failed to validate LIKE predicate. |
| 1712 | Failed to validate ALL ANY predicate. |
| 1713 | Failed to validate EXISTS predicate. |
| 1714 | Failed to validate IS NULL predicate. |
| 1715 | Failed to validate subquery. |
| 1716 | Failed to validate SELECT item {key1}. |
| 1717 | Failed to validate column '{key1}'. |
| 1718 | Failed to validate function '{key1}'. |
| 1719 | Failed to validate CASE expression. |
| 1720 | Failed to validate command parameter. |
| 1721 | Failed to validate function parameter {key1}. |
| 1722 | Failed to validate INSERT item {key1}. |
| 1723 | Failed to validate UPDATE item {key1}. |
| 1724 | Failed to validate column list. |
| 1725 | Failed to validate foreign key. |
| 1726 | Failed to validate SELECT command. |
| 1727 | Failed to validate INSERT command. |
| 1728 | Failed to validate DELETE command. |
| 1729 | Failed to validate UPDATE command. |
| 1730 | Failed to validate CREATE TABLE command. |
| 1731 | Failed to validate DROP TABLE command. |
| 1732 | Failed to validate ALTER TABLE command. |
| 1733 | Failed to validate CREATE INDEX command. |
| 1734 | Failed to validate LOCK TABLE command. |
| 1735 | Failed to calculate LIKE predicate pattern. |

### Execution errors for error stack - state errors that follow direct errors

| | |
|---|---|
| 1801 | Failed to execute SELECT command. |
| 1802 | Failed to execute INSERT command. |
| 1803 | Failed to execute DELETE command. |
| 1804 | Failed to execute UPDATE command. |
| 1805 | Failed to execute CREATE TABLE command. |
| 1806 | Failed to execute DROP TABLE command. |
| 1807 | Failed to execute CREATE DATABASE command. |
| 1808 | Failed to execute ALTER TABLE command. |
| 1809 | Failed to execute CREATE INDEX command. |
| 1810 | Failed to execute DROP INDEX command. |
| 1811 | Failed to execute LOCK TABLE command. |
| 1812 | Failed to execute TRANSACTION command. |
| 1813 | Failed to execute WHERE clause. |
| 1814 | Failed to execute GROUP BY clause. |
| 1815 | Failed to execute HAVING clause. |
| 1816 | Failed to aggregate. |
| 1817 | Failed to execute DISTINCT. |
| 1818 | Failed to execute ORDER BY clause. |
| 1819 | Failed to build DB4D query. |
| 1820 | Failed to calculate comparison predicate. |
| 1821 | Failed to execute subquery. |
| 1822 | Failed to calculate BETWEEN predicate. |
| 1823 | Failed to calculate IN predicate. |
| 1824 | Failed to calculate ALL/ANY predicate. |
| 1825 | Failed to calculate LIKE predicate. |
| 1826 | Failed to calculate EXISTS predicate. |
| 1827 | Failed to calculate NULL predicate. |
| 1828 | Failed to perform arithmetic operation. |
| 1829 | Failed to calculate function call '{key1}'. |
| 1830 | Failed to calculate case expression. |
| 1831 | Failed to calculate function parameter '{key1}'. |
| 1832 | Failed to calculate 4D function call. |
| 1833 | Failed to sort while executing ORDER BY clause. |
| 1834 | Failed to calculate record hash. |
| 1835 | Failed to compare records. |
| 1836 | Failed to calculate INSERT value {key1}. |
| 1837 | DB4D QUERY FAILED |
| 1838 | FAILED TO EXECUTE ALTER SCHEMA COMMAND |
| 1839 | FAILED TO EXECUTE GRANT COMMAND |

### Cacheable errors

| | |
|---|---|
| 2000 | CACHEABLE NOT INITIALIZED |
| 2001 | VALUE ALREADY CACHED |
| 2002 | CACHED VALUE NOT FOUND |
| 2003 | CACHE IS FULL |
| 2004 | CACHING IS NOT POSSIBLE |

### Protocol errors

| | |
|---|---|
| 3000 | HEADER NOT FOUND |
| 3001 | UNKNOWN COMMAND |
| 3002 | ALREADY LOGGED IN |
| 3003 | NOT LOGGED IN |
| 3004 | UNKNOWN OUTPUT MODE |
| 3005 | INVALID STATEMENT ID |
| 3006 | UNKNOWN DATA TYPE |
| 3007 | STILL LOGGED IN |
| 3008 | SOCKET READ ERROR |
| 3009 | SOCKET WRITE ERROR |
| 3010 | BASE64 DECODING ERROR |
| 3011 | SESSION TIMEOUT |
| 3012 | FETCH TIMESTAMP ALREADY EXISTS |
| 3013 | BASE64 ENCODING ERROR |
| 3014 | INVALID HEADER TERMINATOR |
| 3015 | INVALID SESSION TICKET |
| 3016 | HEADER TOO LONG |
| 3017 | INVALID AGENT SIGNATURE |
| 3018 | UNEXPECTED HEADER VALUE |

## Network Errors (-10051 -> -10001)

---

The following table describes the errors that can occur with a network connection.

| Code | Description |
|---|---|
| -10051 | Incorrect value for network component option. |
| -10050 | Unknown network component option. |
| -10033 | Incorrect data size during read cycle. |
| -10031 | Desynchronization has occurred during the read cycle. |
| -10030 | Desynchronization has occurred during the write cycle. |
| -10021 | No server was found. |
| -10020 | No server was selected. |
| -10003 | Bad connection parameters. |
| -10002 | The connection for this process has been disrupted or the connection couldn't be established. |
| -10001 | The current connection to the database has been disrupted. |

## Backup Manager Errors (1401 -> 1421)

---

The following table lists the specific error codes generated by the backup and restore module of 4D.
You can retrieve these errors using a method installed via the **ON ERR CALL** command.

| Code | Description |
|---|---|
| 1401 | The maximum number of backup attempts has been reached; automatic backup is temporarily disabled. |
| 1403 | No log file. |
| 1404 | A transaction is opened in this process. |
| 1405 | The maximum timeout for transactions to end in a concurrent process has been reached. |
| 1406 | Backup canceled by user. |
| 1407 | Destination folder is not valid. |
| 1408 | Error during log file backup. |
| 1409 | Error during backup. |
| 1410 | Cannot find the backup file to be checked. |
| 1411 | Error during backup file check. |
| 1412 | Cannot find the log backup file to be checked. |
| 1413 | Error during log backup file check. |
| 1414 | This command can only be executed on 4D Server. |
| 1415 | Cannot back up log file; a critical operation is in progress. |
| 1416 | This log file does not correspond to the database opened. |
| 1417 | A log integration operation is already running. The backup cannot be launched. |
| 1420 | Integration aborted due to detection of locked records. |
| 1421 | This command cannot be used in a client/server environment. |

- Errors 1408 and 1409 generally come from a read error for files to be backed up or a write error during file backup.
- Errors 1411 and 1413 occur during checking of archives.
  When these errors occur, it may be prudent to first check the space remaining on the disk and the read-write access privileges.

## Client Update Errors (-10650 -> -10655)

---

The following table describes errors that may occur in the context of a client update:

| Code | Description |
|---|---|
| -10650 | Cannot download client update |
| -10651 | Cannot expand client update |
| -10652 | Update information not available ({path}) |
| -10653 | Cannot download update '{path}' |
| -10654 | Update information invalid |
| -10655 | Client update is not available |

## Updater Errors (-10603 -> -10613)

---

The following table describes updater errors that may occur:

| Code | Description |
|---|---|
| -10603 | Updater installation failed |
| -10604 | Cannot identify updater package {path} |
| -10605 | Error while copying updater package files |
| -10606 | Cannot disable current updater version |
| -10607 | Cannot create new updater install folder |
| -10608 | Cannot find folder containing software update {path} |
| -10609 | Cannot start software updater |
| -10611 | Cannot start software updater (invalid install) |
| -10612 | The running application cannot be updated with itself |
| -10613 | Cannot create two form windows of type toolbar |

## OS File Manager Errors (-124 -> -33)

---

The following table lists codes returned by the Operating System File Manager. These codes can be returned when you are using, for example, the System Documents commands (see the **System Documents** chapter). In this list, the word “file” indicates a document on disk and not a file in your database structure.

| Code | Description |
|---|---|
| -124 | Tried to access a disconnected shared volume. |
| -121 | An access path could not be created. |
| -120 | Tried to access a file by using a pathname that specifies a non existing directory. |
| -84 | There is a hardware problem with the disk (bad installation, incorrect formatting,...). |
| -64 | There is a hardware problem with the disk (bad installation, incorrect formatting,...). |
| -61 | Read/write permission doesn’t allow writing. |
| -60 | Bad master directory block. Your disk is damaged. |
| -58 | Error in the external file system. |
| -57 | Tried to work with a non-Macintosh disk. |
| -54 | Attempt to open locked file for writing. |
| -53 | Volume not on line. |
| -52 | Internal file manager error (position of file marker is lost). |
| -51 | Tried to access a document with an invalid document reference number. |
| -49 | Tried to open a file already open with write permission. |
| -48 | Tried to rename a file with the name of an already deleted file. |
| -47 | The file is already open, or the folder is not empty. |
| -46 | Volume is locked by an application. |
| -45 | The file is locked, or the pathname is not correct. |
| -44 | Volume is locked by a hardware setting. |
| -43 | File not found. |
| -42 | Too many files open at the same time. |
| -41 | Not enough memory to open a new file on the disk. |
| -40 | Attempt to position before start of file. |
| -39 | Logical end-of-file reached during read operation. |
| -38 | Tried to read or write to a file that is not open. |
| -37 | Bad filename or volume name. |
| -36 | I/O error. There is probably a bad block on the disk. |
| -35 | Specified volume doesn’t exist. |
| -34 | Disk is full. There is no more room available on the disk. |
| -33 | File directory full. You cannot create new files on disk. |

## OS Memory Manager Errors (-117 -> -108)

---

The following table lists the error codes returned by the Operating System Memory Manager.

| Code | Description |
|---|---|
| -117 | Internal Memory problem. Memory is probably logically corrupted.<br>Exit as soon as possible. Restart your machine and reopen the database. |
| -111 | Internal Memory problem. Memory is probably logically corrupted.<br>Exit as soon as possible. Restart your machine and reopen the database. (*) |
| -109 | Internal Memory problem. Memory is probably logically corrupted.<br>Exit as soon as possible. Restart your machine and reopen the database. |
| -108 | Not enough memory to perform an operation.<br>Give more memory to your 4D application. |

**Tip**: When allocating and working with large arrays, BLOBs, pictures, as well as sets (objects that can hold large amount of data), use an **ON ERR CALL**. project method to test the error -108.

(*) Error -111 can also occur when you attempt to read a value from a BLOB with an offset out of range. In this case, the error is minor and you do not need to terminate the working session. Just fix the offset you pass to the BLOB command.

## OS Printing Manager Errors (-8192 -> -1)

---

The following table lists the error codes returned by the Operating System Printing Manager. These codes can be returned during printing.

| Code | Description |
|---|---|
| -8192 | LaserWriter time-out |
| -8151 | The printer has been initialized with a different driver version |
| -8150 | A LaserWriter is not selected |
| -4101 | Printer busy or not connected |
| -4100 | Printer connection has been interrupted |
| -193 | Resource file not found |
| -128 | Printing interrupted by the user |
| -27 | Problem opening or closing connection with printer |
| -1 | Problem saving file to be printed |

## OS Resource Manager Errors (-196 -> -1)

---

The following table lists the error codes returned by the Operating System Resource Manager.

| Code | Description |
|---|---|
| -196 | Resource could not be deleted |
| -194 | Resource could not be added |
| -193 | Resource map is damaged (file needs to be repaired) |
| -192 | Resource not found |
| -1 | Resource file could not be opened |

## SANE NaN Errors (1 -> 255)

---

The following table lists the NaN codes returned by the Operating System. NaN is a Standard Apple Numeric Environment (SANE) representation which means “Not a Number.” NaN appears when an operation produces a result that is beyond SANE’s scope.

| Code | Description |
|---|---|
| 1 | Invalid square root |
| 2 | Invalid addition |
| 4 | Invalid division |
| 8 | Invalid multiplication |
| 9 | Invalid remainder |
| 17 | Converting an invalid ASCII string |
| 20 | Converting a Comp type number to floating-point |
| 21 | Creating a NaN with a zero code |
| 33 | Invalid argument to a trig function |
| 34 | Invalid argument to an inverse trig function |
| 36 | Invalid argument to a log function |
| 37 | Invalid argument to an xi or xy function |
| 38 | Invalid argument to a financial function |
| 255 | Uninitialized storage |

## OS Sound Manager Errors (-209 -> -203)

---

The following table lists the codes returned by the Operating System Sound Manager.

| Code | Description |
|---|---|
| -209 | The sound channel is busy |
| -207 | Not enough memory to perform the sound |
| -206 | The format of the sound resource is wrong |
| -205 | The sound channel is logically corrupted |
| -204 | The sound resource cannot be loaded |
| -203 | Too many sound commands |

## OS Serial Ports Manager Errors (-28)

---

The following table lists error codes returned by the Operating System Serial Ports Manager.

| Code | Description |
|---|---|
| -28 | There is no open serial port |

## Mac OS System Errors (4 -> 28)

---

The following table lists some of the Mac OS system errors. It is usually not possible to recover from these errors.

| Code | Description |
|---|---|
| 4 | Zero divide |
| 15 | Segment Loader Error: 4D failed in loading one of its own code segments.<br>You must allocate more memory to 4D. |
| 17 to 24 | A system package is missing. Check if your system directory has been correctly installed |

## Miscellaneous Errors (-10700)

---

The following table describes miscellaneous errors that may occur:

| Code | Description |
| --- | --- |
| -10700 | Port must be in the 0 to 65535 range. |

# Character Codes

- Unicode Codes
- Function Key Codes

## Unicode Codes

---

In databases created with version 11 of 4D, the language as well as the database engine store and work natively with Unicode characters.

This facilitates the internationalization of 4D applications. Unicode is a standard unified character set that can handle practically every common language of the world. A character set is a character/number value correspondence table, for example “a”->1, “b”->2, “5”->15, “oe”->662, and so on. Whereas with ASCII, the basic number value is typically included between 1 and 127, with Unicode the upper limit exceeds 65,000, which means that nearly every character for all languages can be represented.

There are several ways to code the Unicode number values: UTF-16 codes them on 16-bit integers, UTF-32 uses 32-bit integers and UTF-8 uses 8-bit integers. 4D mainly uses UTF-16 (like Windows and Mac OS).

Sometimes, essentially for specific needs related to the Internet, 4D uses UTF-8 which has the advantage of being more compact and having better readability for common characters (a-z,0-9).

For more information about the Unicode standard, please refer, for example, to the following page:
http://en.wikipedia.org/wiki/Unicode

A list of Unicode codes:
http://en.wikipedia.org/wiki/List_of_Unicode_characters

**Warning:** In Unicode in 4D v11, the following character codes are reserved and must never be included in a text:
0
65534 (FFFE)
65535 (FFFF)

**Compatibility Note:** Databases created with a version of 4D prior to version 11 can function in ASCII compatibility mode. For more information, please refer to the **EXPORT TEXT** section.

## Function Key Codes

4D returns values for Function keys in the *KeyCode* system variable, which is used within project methods installed by the **ON EVENT CALL** command. These project methods are used to catch events.

The values for Function keys are not based on ASCII Codes. They are:

| Function key | KeyCode |
|---|---|
| F1 | -122 |
| F2 | -120 |
| F3 | -99 |
| F4 | -118 |
| F5 | -96 |
| F6 | -97 |
| F7 | -98 |
| F8 | -100 |
| F9 | -101 |
| F10 | -109 |
| F11 | -103 |
| F12 | -111 |
| F13 | -105 |
| F14 | -107 |
| F15 | -113 |

**Reminder**

The *KeyCode* system variable is to be used in a project method installed using **ON EVENT CALL**.

In addition to the function keys, the following table lists the values returned in *KeyCode* when you press one of the common keys, such as **Return** or **Enter**.

| Key | Code |
|---|---|
| Enter | 3 |
| Return | 13 |
| Backspace | 8 |
| Tab | 9 |
| Escape | 27 |
| Del | 127 |
| Help | 5 |
| Home | 1 |
| End | 4 |
| Page Up | 11 |
| Page Down | 12 |
